**Research Question 1:
The Relationship Between Profitability and IT Investment**

The data needed for this section was gathered from financial returns provided by the organisations. Figure 2 illustrates a profile of both, the turnover and operating expenses for the organisations in the sample (2001/2002). Turnover exceeds the operating expenses in 2001 as can be seen from Figure 2. However, in 2002, the effects of a low growth rate in South Africa manifests in the turnover slumping to a low. One organisation spent additional resources to expand their operations affecting the overall picture.

Operating Expense Ratio (OPEX)³ and information technology expense ratio (ITEX)⁴ were the two ratios used in this instance. These were calculated and presented in Table 1.

These ratios were calculated and averaged over the period under investigation to negate the effects of seasonal and abnormal influences as indicated. Finally, the organisations were sorted in ascending order using the OPEX ratio as a primary key in

and grouped in quartiles (Table 2). This was done partly to disguise the data and to neutralise the effect of seasonal and other influences.

As stated before, Table 2 is the result of sorting the organisations (OPEX as the primary key) in ascending order and grouped together in quartiles; the first three companies were used for quartile I, the second three for quartile II, etc. Although all the previously mentioned operations were used to negate the effects of seasonal and economic fluctuations, the results of a loss by one organisation could be seen in the second quartile. There is a negative correlation of 0.5425 between the Operating expense ratio and the IT ratio. This provides evidence that there is a link between the two ratios and supports statements by authors such as Weill et al. (1989) and Lubbe et al. (2002).

**Research Question 2:
The Relationship Between Profitability and Computerisation Index**

Table 3 compares the operating expense ratio, IT expense ratio, and CI⁵. The CI indicates and supports the second research question noting that there is a link between computerisation and organisational performance. The better an organisation performs, the higher the CI. From a statistical point of view, the Spearman ranking indicates a high negative correlation of 0.8842

Figure 2. Turnover vs. operating expense

The Impact of IT Investment in South African E-Commerce SME Organizations

Table 1. Operating expense ratios (OPEX) and IT expense ratios (ITEX)

Co	2001		2002	
	OPEX	ITEX	OPEX	ITEX
1	0.152	0.119	0.157	0.128
2	0.128	0.037	0.148	0.053
3	0.162	0.117	0.180	0.145
4	0.257	0.160	0.427	0.180
5	0.172	0.483	0.252	0.820
6	0.422	0.139	0.374	0.232
7	0.783	0.118	0.718	0.099
8	0.916	0.002	0.933	0.003
9	0.991	0.002	0.963	0.001
10	0.987	0.003	0.980	0.003
11	1.009	0.062	0.860	0.082
12	0.093	0.001	0.963	0.000

Table 2. Quartile groupings for organisations (2001/2002)

Quartile	OPEX	ITEX
I	0.155	0.100
II	0.317	0.336
III	0.734	0.037
IV	0.965	0.076

between the CI and the OPEX, while only a positive correlation of 0.4126 was measured between the OPEX and ITEX ratios. CI is therefore a better measure for the intensity of computerisation in an organisation. Lubbe et al. (1992) indicated that the CI applies to other industries as well and this further supports this finding.

Further statistical analysis indicates an F-Ratio of 3.89 and squared mean deviation of 0.384485 between the CI, OPEX, and ITEX ratios. The correlation matrix used to estimate

the coefficients produced a correlation-coefficient of -0.8778 between the CI and OPEX ratio and a correlation-coefficient of -0.675 between the CI and ITEX ratio. The correlation was in both instances negative and high. There was also a weak correlation between the CI (the constant, level of computerisation) and the ITEX and OPEX ratios (the variables). It thus helps to answer the second question by delivering proof that there is a relationship between profitability and computerisation. Figure 3 illustrates the link between CI and OPEX clearly.

Table 3. Relationship between CI and operating and IT ratios

C	CI	OPEX	ITEX
1	73	0.155	0.124

12	6	0.528	0.000

Figure 3. CI vs. OPEX ratio

**Research Question 3:
The Relationship Between Profitability and IT/E-Commerce Strategic Management Integration with Organisational Strategic Management**

A positive correlation of 0.54 was calculated, which led the researcher to accept the fact that there is a relationship between profitability and IT/e-commerce strategic management integration at the 95% level. A problem that all the respondents mentioned is that they still get the same amount

of funding but that top management expects more from them. In real terms, this means that top management expects e-Commerce to stem naturally from the IT department. All the responding organisations placed e-Commerce as part of the IT department.

DISCUSSION AND CONCLUSION

The relative high correlation that is evident from Figure 3 may be attributed to the strategy employed

with IT investment decisions and is supported by Dykman (2003). The strategic importance of IT investment should be emphasized and the importance of IT investment decisions needs to be considered by business managers. The reason being stated is that it may affect their e-commerce and other commercial operations. Organisations also need to ensure that e-commerce is not part of the IT department but a department on its own with an own strategy.

It is important to note that the more integrated IT and e-commerce investment decisions become the better chance for full alignment with the overall organisational strategy. This will help businesses in the long run. Although the study does not conclusively deliver proof of a positive or negative correlation in one instance, it shows that in the sample used, a strong tendency exists that:

- Organisational performance is correlated with IT investment intensity.
- IT investments will be correlated to IT and e-commerce intensive organisations with their profitability.

It should be noted that to find organisations just embarking on e-commerce is extremely difficult and explains the reason for the small sample size.

ENDNOTES

¹ Information technology (IT) and information systems (IS) will be used alternatively and for the purpose of this article will be interpreted as meaning the same whilst discussing the investment of IT.

² Computerisation index was discussed in detail in a previous paper of Lubbe, Hoard, and Parker (1995): The profit impact of IT investment. *Journal of Information Technology (JIT)*, 1(10), 44-51.

³ OPEX = non-interest operating expenses to income.

⁴ ITEX = IT expenses to non-interest operating expenses.

⁵ CI means the extent and sophistication of computerization. Ten variables (for example years using computers, management activity level, etc.) were selected to collectively represent the computerization process.

Chapter 6.17

Organizational Performance and IT Investment Intensity of South African Companies

Johan Nel

Brisbane Solution Centre, Australia

ABSTRACT

This chapter considers if a link exists between company performance and information technology (IT) investment intensity in selected South African companies. The study, which covered the period 1989–1991, was based on the hypotheses viz: that in top performing companies (1) IT costs as proportions of operating costs were higher; (2) IT costs as a proportion of turnover was lower, than in weak performing companies; and (3) that a positive correlation exists between the computerization index and operating cost efficiency ratio. Evidence is presented that company performance was linked to the level of IT investment intensity in a sample of organizations in the RSA. Findings of later case study research supporting this are also presented.

INTRODUCTION

Getting business value from information technology (IT) investments is probably one of the most common business concerns of the chief executives in organisations today. IT is one of the growing areas of investments for most organizations; many organizations would not be able to function without IT. The role of IT has changed from being a tool for processing transactions to a “strategic weapon” that can affect a company’s competitive position (Benjamin, 1984; Cash & Konynski, 1985; Weill & Oson, 1989). More recently however, there have been reports of real business and human benefits delivered by IT falling short of expectations (Beck, 2000; Du Plooy, 1993; Earl, 1994; Lee & Barua, 1999; Mahmood, 1994; Thorp & Leadership, 1998).

From its research findings, Butler Cox Foundation (1990) observed that managers of organizations are concerned about whether their organization is getting value from IT investments. Weill et al. (1989) noted that the product portfolio and profit impact of marketing strategy (PIMS) established average IT expenditure in 1983 as 2% of revenues. The Diebold Group survey in 1984 revealed that centralized management information systems expenditures on average accounted for 1.4% of revenues. Shoval and Lugasi (1988) postulated that the selection of alternative computer systems must consider the relative importance of the benefit and cost factors. Kwong and Mohamed (1985), in a case study of petroleum-producing companies in Malaysia, adduced that the computerization index (CI) measures the extent and sophistication of computerization.

In an empirical study among insurance companies in the USA, Harris and Katz (1988) established a relationship between an organization's profitability and their IT capital intensity. They concluded that the most profitable firms, or top performers, are more likely to spend a significantly higher proportion of their non-interest operating expense on IT. They observed further that the least profitable firms are more likely to spend a significantly smaller proportion of their non-interest operating expense on IT. Sippel (1989) stated that life insurance, like most of the financial services sector, is an "information intensive" industry. Lubbe et al. (1992) conjectured that the ratios used by Harris and Katz, and the CI model of Kwong et al. (1985) are applicable in the South African long term insurance industry.

Ward (1987) observed that a trend towards decreasing IT costs and increasing IT capabilities will make the use of IT both economically and technically feasible in the next decade. Bender (1986) examined the relationship between the ratio of information processing expense to operating expense and the ratio of operating expense to premium income in life insurance companies. The correlation between the two

ratios was negative, indicating that higher values of the ratio of information processing expense to operating expense were associated with better performance.

Allen (1987), in a literature study on methods to make information systems (IS) pay its way, postulated that companies gain a competitive advantage if IT is run as a profit centre. Surveys done (Choudhury, 1986; Drury, 1980) in both charge-back and non-charge-back environments showed that MIS managers are in favour of using charge-back to control the use of scarce information resources.

Nel (1991) in an empirical study conjectured that the amount of IT expenditure is larger in some industry sectors than others. In addition, that rates of increase in expenditure are also significant. Industry sectors for which information is a key asset, (often referred to as "information intensive" or "strategically dependent on IT" industries), rely heavily on IT to support their organizations and their expenditure is relatively high. In the South African financial sector, IT budgets can easily account for 40% of operating expenditure.

Strassmann (1991) found little or no correlation between the proportion of corporate revenue spent on IT, return on assets or shareholder's investments.

THE HYPOTHESES AND RESEARCH METHODOLOGY

The Hypotheses

Relationship Between Profitability and IT Investment

Harris and Katz (1988, 1991) studied the relationship between profitability and information technology expenditures in American insurance companies. Turner (1985) noted no relationship between an organization's performance and the

relative portion of resources allocated to IS. He observed that the measure of performance will not capture all factors that contribute to high performance. Using case studies, Weill et al. (1989) noted the importance of converting IT investment into productive inputs with different levels of effectiveness, depending on the organization. There is empirical evidence that the use of IT can result in lower labour costs (Harris & Katz, 1997).

Thus, the first hypothesis, based on the hypotheses of Harris et al. (1991), can be formulated as:

- **H1:** IT investments will be negatively correlated, in IT intense companies, with their operating expense ratio.

Relationship Between Profitability and Computerization Index

Weill et al. (1989) identified two key factors, which are: (1) that determining the return on investments in IT is difficult and (2) that investment in IT alone is not sufficient. Kwong et al. (1985), in a case study of the profit impact of computerization, suggested that IT investment reduces the cost of revenue generation. Harris et al. (1991) observed that evidence indicates that firm performance was linked to the level of information technology investment intensity.

The second hypothesis can thus be conjectured, based on the hypothesis of Kwong et al. (1985):

- **H2:** Organizational performance is positively correlated with information technology investment intensity.

Relationship Between Profitability and IT Strategic Management Integration with Corporate Strategic Management

The third hypothesis was formulated as:

- **H3:** IT investments will be positively correlated, in IT intense companies, with their strategic management of IT.

Research Methodology

In order to gather the data needed to calculate all statistical and other indicators, a structured questionnaire was used. The population consisted of listed companies on the JSE and other companies in South Africa. All the identified companies were sent a questionnaire with a request to include financial statements for the period covered.

The completed questionnaires were analyzed to extract the data. The CI was calculated from data collected by the questionnaire. The financial ratios were calculated using data from the statements and the questionnaire. Data showing the relationships between the CI and the measures of financial performance were plotted on graphs using Quattro Pro Version 4.0. Additionally to the graphs, it was decided to perform statistical analysis. Stat graphics was used for regression analysis and the Spearman Rank Correlation Test.

PILOT STUDY

In order to test for aspects of the questionnaire, which respondents may have had difficulty in understanding, a pilot study was completed using some companies in the sample. This was to ensure that it was possible to collect all data required for the ratios. Ambiguities were removed in order to reflect a concise research instrument.

DATA COLLECTION INSTRUMENT RELIABILITY

It was assumed that the company's figures were accurate and complete. In addition, it was assumed that the respondent completing the ques-

Table 1. Operating expense ratios and IT expense ratios

12	0.093	0.001	0.963	0.000

Figure 1. Operating expense ratio vs. IT expense ratio (1990-1991)

tionnaire did so accurately. Some data given by the respondent in the questionnaire could not be verified. The study also did not check the method of accounting and it is therefore acknowledged that it could influence results obtained.

RESULTS

Hypothesis 1

The data needed for this section was gathered from financial returns provided by the companies. Figure 3 illustrates a profile of both the turnover and operating expense for the companies in the

Table 2. Quartile groupings for companies (1990-1991)

QUARTILE	OPEX	ITEX
I	0.155	0.100
II	0.317	0.336
III	0.734	0.037
IV	0.965	0.076

Figure 2. Turnover vs. operating expense (1990-1991)

sample from 1990 to 1991. As it can be observed from the figure, turnover normally exceeds the operating expenses. However, in 1991, the effects of the economy could be seen as turnover slumped to a low. One of the companies did spend more money on expansion of their operations and this does affect the picture as painted.

Table 1 shows the calculated operating expense (OPEX) ratio and information technology expense (ITEX) ratio, the ratios were averaged over the period under investigation to negate the effects of seasonal and abnormal influences as seen in Figure 1. Finally, the companies were sorted in

ascending order of the OPEX ratio and grouped in quartiles as shown in Table 2. This was done partly to disguise the data and to neutralize the effect of seasonal and other influences.

In Table 2, the first three companies being used as quartile I, the second three as quartile II, and so forth. Figure 2 shows the average OPEX ratio vs. the average ITEX ratio.

Although all the previously mentioned operations were used to negate the effects of seasonal and economical fluctuations, the result of a loss could still be seen in the second quartile. The overall effect, however, supports the first hypothesis.

Table 3. Relationship between CI and operating and IT ratios

C	CI	OPEX	ITEX
C1	73	0.152	0.119
C2	47	0.128	0.037
C3	13	0.162	0.117
C4	10	0.257	0.160
C5	7	0.172	0.483
C6	6	0.422	0.139
C7	5	0.783	0.118
C8	5	0.916	0.002
C9	5	0.991	0.002
C10	5	0.987	0.003
C11	8	1.009	0.062
C12	6	0.093	0.001

Figure 3. CI vs. operating expense ratio

Using Statgraphics, there seems to be a negative correlation of 52.45% between the operating expense ratio and the information technology ratio. This further supports the first hypothesis.

Hypothesis 2

Table 3 compares the OPEX ratio, ITEX ratio, and the CI. The figures in this table support the second hypothesis that the better a company performs, the higher the computerization index. Statistically, the Spearman correlation indicates

a high negative correlation of 88.42% between the CI and the OPEX while a positive correlation of 41.26 was discovered between the OPEX and ITEX ratios. This indicates that the CI is a good measure of the intensity of computerization in any company. It also supports the assertion made in a previous study by Lubbe et al. (1992) that the CI applies to other industries and thus.

Further, statistical analysis indicates an F-ratio of 3.89 and a squared mean deviation of 0.34485 between the CI and the OPEX and ITEX ratios. The correlation matrix used to estimate

the coefficients produced a correlation coefficient of $-.8778$ between the CI and OPEX ratio and a correlation coefficient of $-.675$ between the CI and the ITEX ratio. A positive correlation coefficient of 0.4894 was calculated between the OPEX and ITEX ratios. These results produced a high degree of correlation between the CI (the constant) and the ratios of ITEX and OPEX (the variables). Thus, it further supports the second hypothesis and leads to the acceptance of this hypothesis. Figure 3 supports these findings.

Hypothesis 3

A positive correlation of $.54$ was discovered which led to the acceptance of Hypothesis 3. This was at the 95% level.

Following a pilot case study, case analysis of five South African Banks done by Nel (2004) using the following sources of information, as well as a case study protocol with personal interviews:

- Annual reports
- Monthly reports
- All classified minutes of all management committees (the author was an assistant to the inter-company secretary to all the South African banks studied)
- Strategy documents (author facilitated the strategic management process in ABSA BANK)
- Personal interviews with most general managers, at least twice a year
- Brief interviews with the managing directors
- User satisfaction surveys (author conducted these)
- Competitor analysis reports
- Independent expert's reports

It can be concluded that the top two financial performing banks had a high degree of alignment and integration between the business- and IT strategic management of the organisation.

CONCLUSION

The relative high correlation that is evident from Figure 5 may be attributed to the strategy employed with IT investment decisions and is supported by the studies of Nel (1991) and Nel (2004). The strategic importance of IT investment's needs to be emphasized and the importance of IT investment decision's needs to be considered by business managers, as it may affect their company's profitability in the long run.

Although the study does not conclusively prove a positive correlation for all organizations in the Republic of South Africa, it shows that in the sample a strong tendency exists that:

- Organizational performance is positively correlated with information technology investment intensity.
- IT investments (strategic management of IT) will be positively correlated, in IT intense companies, with their profitability.

Chapter 6.18

Government Procurement ICT's Impact on the Sustainability of SMEs and Regional Communities

Peter Demediuk
Victoria University, Australia

INTRODUCTION

SMEs (small and medium sized enterprises) are a dynamic force for sustainable economic growth and job creation within developed and developing communities (MFT, 2001; NOIE, 2003; BRTF, 2003). SMEs stimulate private ownership and entrepreneurial skills; they are flexible and can adapt quickly to changing market demand and supply conditions; they generate employment, help diversify economic activities and make significant contributions to export and trade. An economy's overall economic health and well-being can be measured by the growth of SMEs-so it is vital to enhance the capacity of SMEs to compete domestically, nationally, and internationally (APPC, 1999).

The sustainability of SMEs is compromised by their struggle to gain a significant share of the government procurement pie, and this impacts

on the economic, social and cultural capital of countries and communities and the distribution of wealth. So governments need to foster an appropriate business and policy environment to improve the growth prospects of SMEs (Loudon, 2003). In particular, the implementation of Information and Communication Technologies (ICT) can provide an enabling environment for SME access to government procurement markets (Calarco, 2003).

BACKGROUND: SMES AND GOVERNMENT PROCUREMENT MARKETS

Definitions of SMEs differ from economy to economy, and are based on specific criteria such as the number of employees, level of assets or turnover. However the economic, social and cultural

contributions of SMEs that are common across economies are their ability to (MFT, 2001):

- create jobs with low capital costs;
- create conditions for development and introduction of new technologies;
- function as subcontractors for large corporations;
- adapt faster to the demands and fluctuations of the market place;
- fill marginal areas of the market, which are not targeted by large corporations;
- decentralise business activity and help foster faster development of regions, small towns and rural communities; and
- alleviate the negative impact of structural changes.

By opening up the public sector procurement market to SMEs, governments in Australia, the USA, the UK, New Zealand, and the developing economies are attempting to use their buying power to build the business capabilities of SMEs, foster economic growth, and get “value for money” in public spending (Breen & Demediuk, 2003; BRTF, 2003). Whilst the opportunity space for SMEs in the government procurement market is currently limited in developing countries (Wittig, 1999) and in developed nations (BRTF, 2003; DCITA, 2002), globalisation, the acceleration of technological change and innovation create expanded opportunities for SMEs (OECD, 2000). In particular, the use of ICT is a major driver for improving SME access to local and international government procurement (Calarco, 2003).

IMPACT OF ICTS ON GOVERNMENT PROCUREMENT SYSTEMS

ICTs facilitate the development of purchaser-supplier systems that have been termed e-procure-

ment or e-tendering. In practice, systems can be as simple as providing orders via an e-mail message or as complex as integrated supply chain ordering, delivery and payment systems (Calarco, 2003). E-procurement functionality is about the business not just the technology. The major functions of such electronic systems can range across registration of suppliers; notification of tenders; issuing and downloading of tender documents; receiving and responding to enquiries; submission of tender offers; notification of contract award; and ongoing supply management (Calarco, 2003). The use of ICT in E-procurement can involve (Wittig, 2002, p. 7):

- procurement planning & budget control;
- tracking supply needs (including demand forecasting, inventory management, etc.);
- preparing catalogues of approved items (e.g., for common use items, framework contracts) and providing information on the buyer's procurement catalogue;
- communicating the buyer's procurement program (e.g., yearly, quarterly) and advertising previous contract awards;
- tracking the solicitation approval process, advertising the buyer's solicitation notices, providing suppliers' access to the buyer's solicitation documents, and buyer/supplier communications on technical and other clarifications regarding solicitation;
- sharing of information in networks of public procurement agencies on topics like: membership, news, public procurement events, common texts on public procurement laws and regulations, regulation guidelines, standard procurement documents and contracts, and standard management and record-keeping forms;
- managing supplier data, like expressions of interest, suppliers' registration and pre-qualification, suppliers' submission of bids, quotations and proposals;

- buyer processing and evaluation of bids, quotations, proposals and buyer communication of award to supplier;
- communications as needed between buyer & supplier prior to closing the contract;
- communications between buyer & supplier on supply management (delivery and progress of awarded contracts, including tracking supplier delivery schedules), and invoicing & payment; and
- data archiving for purposes of audit trail and security.

ICT may improve the functionality of government procurement marketplaces through e-procurement systems that facilitate transparency, accountability and access through an open system; reduce the transaction costs to all parties of doing business by minimising non-valued added activities (telephoning, printing, postage, re-keying, etc.); reduce process cycle times; and provide a platform for competitiveness and growth (Calarco, 2003). While such ICT-based reforms benefit all firms, it should have a more significant impact on SMEs since "... SMEs have fewer resources, (and) anything that makes the process easier and lowers the cost of involvement will have a greater relative result for them" (Holden & Dade, 1998, p. 2).

Governments can provide a more level playing field in information access that not only assists SMEs to find and respond to market opportunities, but also acts as an incubator for the uptake of new technologies that can improve businesses generally. In one region the state-of-the-art technology may be the general introduction of e-mail capacity, whereas in another more developed community it may be the ability to make a binding contract over the Internet (Wittig, 2002).

The goal of relative improvement in SME access to government procurement markets requires technology solutions such as aggregated, simplified or standardised access portals, along

with good help-desk options and technology and training support (BRTF, 2003). What is also required is a revision of the processes to which the technology is to be applied. If ICT innovations simply embed into an electronic form some existing procurement policies and procedures that inhibit SME access, the problems for SMEs may become relatively worse. For example, the use of larger contracts in government procurement is often driven by the need for greater efficiency. These larger contracts require less staff to manage them and there is a single point of contact for dealing with problems. However the contracts generally result in a reduced number of larger suppliers, effectively ruling out smaller firms and the advantages they potentially bring in agility and focused solutions. Where tender evaluation criteria are geared towards lowest tender price, the perceived innovation, flexibility and quality advantages of SMEs are discarded, as the potential for wider societal and economic community development is lost. SMEs are also disadvantaged where small-scale tenders are left off generally advertised lists, or SME tenderers are required to provide unlimited liability or reach unrealistic experiential or financial pre-qualification hurdles (Breen & Demediuk, 2003).

FUTURE TRENDS

Given the limited success of many ICT-based government procurement initiatives (Breen & Demediuk, 2003; OGC, 2002), in the future full account must be taken of SME perspectives when government agencies are designing new ICT-based policies, processes or initiatives. There also needs to be greater awareness among SMEs of the benefits of the ICT and the "Information Society" and of integrating Internet use and electronic commerce in their business strategies. Awareness, interest and capability of SMEs in relation to ICT-based procurement systems can be fostered by resource

and demonstration centres, training initiatives, pilot projects and encouraging the development of effective and user-friendly frameworks for certification, authentication, transaction security, and preservation of intellectual property rights (IPRs). These imperatives provide a rich source for future research studies into the operationalisation of ICT in an SME context.

CONCLUSION

Where ICT drives improved SME access to government procurement markets through greater transparency and access, they can have a positive impact on the development of economic, social and cultural capital. However SMEs can be further disadvantaged and the sustainability of regional communities compromised where ICT merely embed existing inhibitors of SME access to government business into more efficient electronic forms.

KEY TERMS

E-Procurement: E-procurement is the business-to-business (B2B) or government-to-business (G2B) purchase and sale of supplies and services that is facilitated by the Internet and is sometimes referred to by other terms such as e-tendering or supplier exchange.

E-Tendering: Another term for e-procurement.

Help Desk: A section that can respond to technical queries by users.

Information and Communication Technologies (ICTS) In E-Procurement: Portals and electronic systems that facilitate registration of suppliers; notification of tenders; issue and downloading of tender documents; receiving and responding to enquiries; submission of tender offers; notification of contract award; and supply administration.

Information Society: A context in which people interact with technology as an important part of life and social organization to exchange information.

Intellectual Property Rights (IPRS): Treats certain intangible products of the human mind as

belonging to the creator or holder in legal form such as patents, trademarks or copyright.

Portals (Web Portals): Web sites that give access to a broad array of resources and services such as: e-mail; discussion forums; search engines; and business information.

Small and Medium-Sized Enterprise (SMEs): Small and medium-sized enterprises are socially and economically important, since they represent 99% of all enterprises worldwide and contribute to entrepreneurship, innovation and economic, social and cultural development. Precise definitions that separate SMEs from large enterprises differ between countries and rely on variables such as headcount, turnover and balance sheet size.

Chapter 6.19

Women Entrepreneurs in Finnish ICT Industry

Tarja Pietiläinen

Life Works Consulting Ltd., Finland

Hanna Lehtimäki

Life Works Consulting Ltd. & University of Tampere, Finland

Heidi Keso

Life Works Consulting Ltd. & University of Tampere, Finland

INTRODUCTION

The Nordic countries—Finland, Denmark, Norway, and Sweden—offer interesting material to investigate gendering processes. In these societies, gender equality policy has long traditions and many propagated goals have been researched: women and men participate in paid work almost to the same extent; women make a significant contribution to family income, because it rests on a dual income model; public, low cost day-care is available to all children over one year of age; women's level of education is exceeding that of men's. Yet, the labour market is notoriously segregated both horizontally, meaning that men and women work in different occupations, and vertically meaning that men hold high ranking positions in public and private organisations. The

focal phenomenon of this article, entrepreneurship shows even more profound segregation with women and men enterprising in different lines of business and within the same lines of business in different branches (Kovalainen, 1995; Spilling & Berg, 2000).

Nordic experience shows that gaining access to men-only spaces does not bring the same prestige, make women equally influential, and powerful as men. Thus, the question remains what are the processes which hinder women entrepreneurs from achieving a significant position? The article offers one possible answer by reporting a study by Pietiläinen (2002) who set out to investigate what kinds of spaces for entrepreneurial action women business owners are offered in the Finnish information and communication technology (ICT) industry.

BACKGROUND

Since the early 1980s, academic interest in women entrepreneurs has increased steadily due to the increasing impact businesses owned by women have on society and the economy. Presently female entrepreneurship research is a subfield of entrepreneurship studies (Carter, Anderson, & Shaw 2001). In this field, scholars are united in their view that women's unequal access to economic power needs to be changed.

Within the field, researchers differ in their views about the sources of gender inequality and the means to analyse and battle it. This, of course, is based on the presumption that inequality is undesirable. In Pietiläinen's study the different views were categorised into three broad empowerment agendas in female entrepreneurship literature. Table 1 displays the three feminist lines of inquiry. The first two lines of inquiry provided the study with analytical concepts which aided the interpretation of gendering processes in the empirical material. The third approach "doing gender," was followed throughout the research process.

Gender Equality

The overwhelming majority of research is inspired by "gender equality." Researchers following this line of inquiry believe that overt discrimination prevents women from realising their full entrepreneurial potential (Fischer, Reuber, & Dyke, 1993). Over the years they have devoted much research into identifying what kinds of barriers women have to overcome before, during, and after a business start up. Results point to gender differences and cultural prejudices. The latter have been identified as the biggest obstacle for entrepreneurial women. Repeatedly, they encounter gender-based stereotyping and suffer from lack of credibility and support (e.g., Carter & Kolvereid, 1998; Fabowale & Orser, 1995; Kolvereid, Shane, & Westhead, 1993).

Voice to Women

Researchers who are interested in investigating women entrepreneurs' "own voice" and experiences start from the assumption that the source of inequality is women's lifetime experiences of subjugation. These studies represent the second empowerment agenda. Socialization into a woman's position results in uniquely female worldview, and consequently, in different entrepreneurial behaviours than men's (Ahl, 2002). This research has excelled in revealing that women's entrepreneurial choices are greatly shaped by the overall pattern of women's labour market behaviour, life style, and stage of life (e.g., Brush, 1992; Goffee & Scase, 1985; Green & Cohen, 1995; Sundin & Holmquist, 1989).

Doing Gender

Recently, a growing number of European researchers claim that inequality in entrepreneurship is a result of gendering processes which privilege male-typical behaviours and values. Their proposition is to make use of the concept "doing gender" (West & Zimmerman, 1991). These scholars suggest that researchers of female entrepreneurship need to take a critical look at their own empowerment agendas to move forward. Critical assessment of research inspired by "gender equality" thinking shows that gender equality, in fact, diverts attention away from deeply masculine connotations of entrepreneurship. "Voice to women," in turn, suffers from searching for unique female behaviours, which does more to mystify female experience than to give space for real life women entrepreneurs with their differing aspirations, possibilities, and life strategies. The proponents of "doing gender" approach suggest that effort should be put into exposing the gendered power relations at work in entrepreneurship (Kovalainen, 1995), and move toward change in gendered social and symbolic arrangements governing entrepreneurial activity (Ahl, 2002).

Table 1. Three lines of feminist inquiry in female entrepreneurship literature

LINE OF INQUIRY	SOURCE OF INEQUALITY	ANALYTICAL CONCEPTS	EMPOWERMENT AGENDA	EXAMPLES OF RESEARCH
Gender equality	Overt discrimination of women	Gender stereotyping; gender differences	Removal of obstacles; incentives to women; change of attitudes	Kolvereid, Shane, & Westhead, 1993
Voice to women	Women's experiences of subjugation	Female typical qualities and characteristics; Female typical experiences	Creating women only opportunities and spaces; raising consciousness; change of attitudes	Sundin & Holmquist, 1989; Brush, 1992
Doing gender	Gendering processes which give power to men and male typical behaviours	Gendered social and symbolic arrangements; gendered power relations; hidden masculine connotations	Exposing gendered power relations; change in social + symbolic arrangements; change of attitudes	Ahl, 2002; Kovalainen, 1995

METHODS AND MATERIALS

Pietiläinen's study (ibid.) applied qualitative methodology to identify what kinds of spaces for entrepreneurial action women business owners are offered in ICT industry. Textual analysis was used on a city's strategy documents, media articles about one female-owned new media company Nicefactory Ltd, and transcribed interviews with the company's female owner-entrepreneurs. Empirical material covered the years 1997-2002. As to the theoretical background gender was examined as doing. "Doing gender" approach was chosen because it allowed for studying gender as a process, not as individual characteristics. In the study, "doing gender" was used both as a theoretical concept and methodological means. Theoretically, "doing gender" allowed focusing away from understanding just the individual entrepreneur to understanding how gendered social

and symbolic arrangements of entrepreneurship in ICT industry are shaped. Methodologically, "doing gender" focused qualitative analysis on that continuous meaning making of gender which is embedded in the every-day activities of people and organisations involved.

THE CASE-COMPANY AND CONTEXT OF THE STUDY

The focal company of the study, Tampere based Nicefactory Ltd, was conceived when its owners observed the lack of well-produced Web contents. Specifically they wanted to provide a Web service to female Internet users. The two founding partners of Nicefactory Ltd. worked in radio, TV and print media for an extended period of time before establishing their own company. One of the partners has a university degree in

naval engineering and the other holds a master's degree in social psychology. In autumn 1998, they launched their first Web site, www.Nicehouse.fi with content featuring information and discussions about various family-related topics. Their next Web site, www.49er.net, providing real time sailing race information, was launched shortly thereafter. In 2000, a technical university commissioned Nicefactory Ltd. to create a customized learning environment, an opportunity for the company to develop yet another type of Internet content service. The same year, Nicefactory Ltd. launched two new Web sites: www.Addiktio.net, which focuses on "all kinds of addictions," and www.Sooda.com, a Web service designed primarily for teenage girls, but expanded to attract teenage boys, too. Since its launch, Sooda.com has become one of the most popular Finnish Web communities.

At the turn of the century, Finland was well known for its excellence in information and communication technology (ICT) and a highly developed, widespread Internet culture. Nokia had led the Finnish ICT-sector's growth and rapid internationalization. There was and still is extensive technological knowledge at all levels of society, and Finns are eager to use the latest technological innovations. What was still lacking from this success story, however, was an innovative and user-friendly media culture and business-oriented content production with international potential (e.g., Castells & Himanen, 2001; Tarkka & Mäkelä, 2002). While the ICT-sector had largely developed through technological innovations the content innovations and production had lagged behind.

ICTs—A World without Women

The masculine image of the ICT industry is so strong that it seems paradoxical to link women and entrepreneurship in that industry. Most explicitly, ICT-industry is a world without women: male engineers run the businesses, develop, and

market the services/products while women tend to be responsible for office work (Vehviläinen, 1997) and human resources function. Women business leaders are bound to stand out and draw attention as a rarity. A well-known example is Carly Fiorino's position at Hewlett Packard.

When it comes to the definitions that are widely used to describe ICT business, a more, subtle, yet distinctively masculine image emerges (Lie, 1995). It is unanimously recognised that the core competencies of the industry build upon high-tech know how (e.g., Lovio, 1993). From this acknowledgment, it is a small step to define technical accomplishments as groundbreaking innovations and maintain that more is to be expected due to heavy investments in product development (e.g., Schienstock, 2004). Expectations are also supported by the qualities of the people working in the industry. Men who found ICT companies tend to have (technical) degrees. This fact is believed to indicate that the companies are more strategically oriented, more prepared to growth, and more prone to risk taking than the case is in an average start-up.

THREE CONSTRUCTS OF SPACE FOR WOMEN'S ENTREPRENEURSHIP

Based on the empirical analysis, Pietiläinen's (2002) study resulted in three constructs for understanding processes which hinder women entrepreneurs from achieving a more significant position in the Finnish ICT business. The three constructs are "gender neutral entrepreneurship," "female entrepreneurship," and "powerful women's entrepreneurship."

The first construct, "gender neutral entrepreneurship," gives support to the notion that entrepreneurship, although a human activity is not linked to gender in any fundamental way. The construct is most explicit in strategic management discourse, which becomes important

when business opportunities, future growth, and internationalisation or globalisation are visioned. These topics point to the issues which need entrepreneurs' attention in emerging businesses.

The construct provides interpretations to fade out femininities that female entrepreneurs inevitably bring with them to entrepreneurship. The gender neutrality is achieved by meaning making, which first, excludes femininities from the meaning horizon of the category of "entrepreneur" (see also Ahl, 2002) and then, equates selected masculinities of competitiveness, rationality, instrumentality, and control with the ideal entrepreneurial figure.

As such, "gender neutral entrepreneurship" provides a highly appealing space of action to a woman. The idea of that female sex presents an exception can be overcome. This space could secure the position of the "real entrepreneur" for women as well, not only for male business owners. There is, of course, a price attached. It is not easy to find acceptable ways to display femininities as they threaten to expose the otherwise hidden masculinities of the "entrepreneur."

As embodied physical women, female entrepreneurs remind constantly that gender cannot be excluded from entrepreneurship for good. The second construct is labelled "female entrepreneurship." It deals with the femininities and maintains that there is a distinction between "entrepreneurship" and "female entrepreneurship." The distinction rests on gender hierarchy, which makes it rational to relegate gender to women business owners and consider their business actions as gendered exceptions. The construct offers space for action, which many women entrepreneurs are not comfortable with. Experiences of gender stereotyping and (dis)credibility problems give no explanation as to why marginalise women's entrepreneurship by yet another separation. The construct opens up also space for positive action, because it allows for appreciative understanding that living the life of a woman creates a valuable source of business information. Often, women's

preferences and ways of doing things are easily bypassed in service and product development as well as marketing, because gender hierarchy prevents from seeing the value of women's activities.

The third construct, "powerful women's entrepreneurship", couples female entrepreneurship with the success stories of start-up businesses in the new economy. It represents selected women entrepreneurs as outstanding representatives of female sex in the male world. The construct dominates media's way of representing female entrepreneurs in the new media business. The positive side of space for action is that media has the power to increase general public's awareness of women's business start-ups. Young men's ICT-business endeavors dominate media publicity and therefore coverage of women's efforts makes a difference. Although women entrepreneurs are treated as a special category, the construct gives meaning making resources to modify particularities of female entrepreneurship into prime means of entrepreneurial advancement.

Ambiguous Spaces for Women's Entrepreneurship

The three constructs offer conflicting and ambiguous spaces for female entrepreneurship in ICT-industry. "Gender neutral entrepreneurship" is a construct which is deeply rooted in strategic management discourse. It is one of the most powerful streams of thinking and acting in the present business world. This connection means that strategic management offers no easy support for entrepreneurial initiative by women, especially if it is innovative in the business field.

"Female entrepreneurship" is more open to women's entrepreneurial behaviour. However, it creates a boundary between entrepreneurship and women's entrepreneurship. The boundary is based on hierarchy, where women's business represents "lesser" form of economic activity. The culturally embedded hierarchy is hard to overcome by individual women.

Yet another type of marginalisation takes place by the construct “powerful women’s entrepreneurship.” Here, media creates an ideal image of a female entrepreneur and presents it to the public. When a real-life woman compares herself to the ideal, she will most likely find herself lacking the qualities, skills and time to perform within the standards set by the ideal image. Research shows that many business women experience feelings of being inadequate when they think that they are not able to meet the expectations created by the ideal.

Typically, people build their entrepreneurial identities on professional identity which is supported by education and work experience (Hytti, 2003). Ambiguity and conflict stemming from the three constructs refer to the puzzling experience that sex as an anatomical fact presents a more decisive factor to evaluate an entrepreneur’s business competence than professional and business experience. In these moments of evaluation, gender is at the same time highly visible and virtually invisible. This is due to fact that entrepreneurship is invisibly male gendered, but thought of as gender neutral and, at the same time, visibly gendered when the actors are women. For individual women entrepreneurs, the dynamic interplay between the visible gendering and the invisible, seemingly gender neutral gendering presents a “rough” field to practise entrepreneurship.

FUTURE TRENDS

The study by Pietiläinen (2002) points out that more research is needed to investigate gender as an ongoing process of meaning making. There is abundant evidence, that to an individual woman entrepreneur, the key question is how to successfully share time between entrepreneurial and personal responsibilities. However, the means by which balancing is achieved by women entrepreneurs, has been overlooked by researcher. The pressure of balancing tends to increase in

knowledge intensive business (e.g., ICT-business) where long working hours, project based work, and travel are prevalent practices. What has attracted less attention is that typically, entrepreneurship is associated with for-profit activities in the public sphere and entrepreneurs’ needs of nurture and emotional support are seen as private matters, not belonging to for-profit world. The division between work performed in public and work performed in the private reveals that entrepreneurship is considered gender neutral, public activity. Individual entrepreneurs, instead, are gendered and therefore gender “intervenes” to female and male typical ways of coping with the division. Consequently, we need new, critical conceptualisations of entrepreneurship, to overcome deeply held divisions and hierarchies.

CONCLUSION

Female entrepreneurship research shows that economic factors explain only partially women’s entrepreneurship. A fairly recent newcomer in this line of inquiry, doing gender studies contribute to understanding that interpretations of entrepreneurship create spaces which men and women are able to occupy differently. These studies alter the theoretical emphasis of entrepreneurship research from examining gender differences per se to analysing how such differences are produced. The theoretical usefulness of examining individual women is questioned. The challenge is to relinquish the stable notions of gender differences and similarities between women’s and men’s entrepreneurship, popular in the extant literature. Even if there are no clear references to gender, there are seemingly neutral articulations that produce different material outcomes for women. In this sense, meaning making of entrepreneurship rearticulates the power imbalance informing relations of gender.

KEY TERMS

Doing Gender: A gender theoretical line of reasoning that gender is a process of power which first, creates and maintains differences between the sexes and second, constructs a hierarchy to the benefit of men and masculinities.

Empowerment Agenda: A proposal of actions which are needed to enable discriminated people to act upon their own interests.

Gender-Based Stereotyping: Using common sense criteria to categorise people into males and females. The criteria include assumptions about gender appropriate characteristics, behaviours, and physical qualities.

Gender Equality: A gender theoretical line of reasoning that overt discrimination prevents women from realising their full potential.

Women's Own Voice: A gender theoretical line of reasoning that meanings and interpretations a woman or a group of women invent and use to make sense of their experiences remain silenced due to prevailing gender order.

Chapter 6.20

Directing Equal Pay in the UK ICT Labour Market

Claire Keogh

University of Salford, UK

Angela Tattersall

University of Salford, UK

Helen Richardson

University of Salford, UK

INTRODUCTION

The UK labour market is dramatically changing, with rapid technological innovations alongside globalisation where organisations are required to place a premium on human and intellectual capital. The demand for labour is outstripping supply, and businesses are increasingly dependent on their ability to attract, invest in and develop their workforce (Kingsmill, 2003). However, a recent comparative report of the information technology (IT) workforce in Holland, Germany and the UK indicates that women are haemorrhaging out of the IT sector (Platman & Taylor, 2004). Given that presently there is an IT specialist's skills shortage of 18.4% (IER/IFF, 2003), and female IT managers represent a mere 15% of ICT managers, 30% of IT operations technicians and 11% of IT

strategy planning professionals (EOC, 2004a), this suggests that the ICT industry is not equipped for equality and diversity at work.

Despite many years of egalitarian rhetoric and 3 decades after the UK Equal Pay Act (1970) was introduced, women still receive on average 18% less than that of their male counterparts working full-time and 41% less than men when working part-time hours. The ESF-funded DEPICT project seeks to identify pay discrimination experienced by women in ICT at a national level throughout England. An important aim is to highlight the impact of pay and reward discrimination has on the underrepresentation of women in the ICT labour market. From this study, we hope to more clearly understand the reasons for the gender pay gap, particularly in the ICT sector; and the impact this has on women's entry and retention to occupa-

tions where they are already severely underrepresented. Equal pay is an issue for all; it's unjust, unlawful and impacts on social justice, equality and economic performance (EOC, 2001b). Pay is a major factor affecting relationships at work; distribution and levels of pay and benefits affect efficiency of organisations, workforce morale and productivity. It is vital for organisations to develop pay systems that reward workers fairly for the work they perform (ACAS, 2005).

WHAT IS THE GENDER PAY GAP?

The Equal Pay Act was enacted in 1970 and came into force in 1975 in the UK. At that time, the gender pay gap stood at 36%—today, 35 years later, the pay gap remains obstinately at 18%. For women who work part-time, the pay gap is even larger, at 40%, similar to 30 years ago. The gender pay gap compares the earnings of female and male employees, while the gender income gap compares the individual incomes of all women and men. The gender gap between women and men's mean individual incomes in 2002-2003 was 46%, and the gender gap between women and men's median income was 47%. (EOC, 2005c)

Thus, the gender pay gap is the difference in average earnings between men and women and is usually measured by hourly rate or weekly wage. Previous to the Equal Pay Act (1970), evidently the main cause of the gender pay gap was direct sex discrimination, and historically, women received up to half the pay of men even when performing the same job. After the introduction of the equal pay legislation, which prohibits employers from paying women less than men purely on the basis of their sex, the continuing gap was attributed to occupational segregation, indirect discrimination and human capital factors (for example, attainment of qualifications and experience).

ROOTS OF THE GENDER PAY GAP

The Equal Opportunities Commission (EOC) set up an Equal Pay Task Force in 1999 to explore the gender pay gap issue (EOC, 2001a). They reported three main contributors to the pay gap: occupational segregation, discrimination in pay systems and caring responsibilities.

- **Occupational Segregation:** The UK labour market is highly segregated, both horizontally and vertically. Horizontal segregation has led to 60% of the female workforce working in only 10 broad occupation types. Vertical segregation has evolved through a cluster of women working in lower-level jobs, often low skilled and low paid. Occupational segregation remains one of the strongest influences on young people's choice of career. Girls are still moving into industry sectors such as nursing, teaching and childcare. Boys continue to enter engineering, building services or ICT. Individuals' "life choices" are seriously compromised by occupational segregation; there has been no significant increase of women entering the construction, engineering, plumbing or ICT industries during the past 10 years (EOC, 2004a).
- **Caring Responsibilities:** In the UK women are still shouldering the main responsibility for childcare and increasingly taking the responsibility for the care of their elderly relatives. In these cases, women often have to work part-time, it is impossible for them to work long hours or they take time out of work. These factors contribute to the impact on women's earning power and promotion potential.
- **Discrimination in Pay Systems:** Organisations assume that because they have the same rate of pay for men and women then they have equal pay systems; however, pay

systems are extremely complex (Neathey, Dench, & Thomson, 2003). Individualised pay is determined on value judgements and includes bonus schemes and performance-related pay. Women experience pay discrimination due to lower starting salaries, exclusion from bonus schemes, inability to qualify for long service awards and being awarded lower marks in performance assessments.

THE GENDER PAY GAP AND THE UK ICT LABOUR MARKET

On first inspection, ICT gender pay gap data gathered from the Office of National Statistics

suggest a relatively small pay gap when comparing women’s and men’s hourly and weekly income (EOC, 2004a). For example, male ICT professionals earn on average £684.80 a week compared to the female ICT professional weekly wage of £619.80.

The figures shown in Table 1 portray the gender pay gap in the UK in a comparatively positive light. IT industry in a comparatively positive light; nevertheless, as most women are positioned at the lower end of the market, we assert that the gender pay gap is, in fact, greater than these statistics suggest and that pay discrimination is inherent in the ICT sector. There are limitations to statistical data on the “IT labour market”— research suggests that “working in IT” is an extremely difficult and complex sector to define (WINWIT, 2004).

Table 1. Gender pay gap data from the Office of National Statistics (2003)

	FEMALE		MALE		Gender Pay Gaps	
	Hourly	Weekly	Hourly	Weekly	Hourly	Weekly
ICT Managers	21.16	784.9	23.69	892.8	10.7	12.1
ICT Professionals	16.35	619.8	17.87	684.8	7.5	9.5
-IT strategy and planning	N/a	N/a	22.19	848.6	N/a	N/a
-Software Professionals	15.20	517.5	16.83	644.5	9.7	11.3
IT Service delivery occupations	12.46	463.8	14.65	562.2	14.9	17.5
-IT operations technicians	13.14	468.2	15.20	582.8	13.6	16.6
-IT user support technicians	10.97	415.0	13.19	507.2	16.8	18.2
Telecommunications engineers	N/a	N/a	11.89	477.6	N/a	N/a
Computer engineers, installation and maintenance	N/a	N/a	12.16	483.3	N/a	N/a
All Occupations	10.56	396.0	12.88	525.0	18.0	24.6

Source: Office of National Statistics (2003), New Earning Survey

There are highly skilled women working in IT departments in many organisations and also in other industry sectors, such as the creative sector with design technologies and in new media industries. Taking this into consideration, we acknowledge that the IT sector is diverse and that much of women's engagement with IT may lay outside the traditional IT sector.

The ESF-funded DEPICT project seeks to investigate issues surrounding equal pay in the ICT sector as a result of the following factors:

- Individualised pay packages are common in the ICT industry, which involves requiring strong individual negotiation skills and a high level of confidence. Women have reported being uncomfortable with this method of pay-and-reward negotiation, and find that masculine and aggressive organisational culture mitigates against success in such negotiation (WINWIT, 2004). Moreover, the ICT skills that women possess are often undervalued, marginalised or unrecognised regardless of achievement (WINWIT, 2004; Woodfield, 2000).
- There is a culture of "salary secrets" in the IT industry, and women have reported that they only find out about pay inequalities once they reach management level and have access to financial or personnel information. In research analysing gender equality in organisational pay structures and pay practices, including an initial evaluation of Equal Pay Reviews (Neathey et al., 2003), data revealed that more than 1 in 5 employers (22%) did not allow their employees to share information about pay with colleagues. Employers often expect confidentiality about pay and disclosing this information to colleagues can lead to disciplinary action.
- The Women in North West IT (WINWIT, 2004) reported gaps in annual salaries between male and female ICT professionals as much as £17,000. Women were also

reported to have experienced discrimination in pay and promotion after returning from maternity leave and choosing to work family-friendly hours.

- Many women with caring responsibilities need to work part-time and this is often incompatible with working in the ICT industry, as part-time working is rarely an option.
- The current pension system operating in the UK is based on full-time, lifetime employment and is excluding workers who work part-time and people whose employment is disrupted by periods of unpaid domestic responsibility, which disproportionately impacts negatively on women (Prosser, 2005).

THEORETICAL FRAMEWORK FOR THE PROJECT

The economic, social and political root of women's inequality in the labour market is a contested theoretical area. This section discusses neo-classical, dual labour market theory and critical approaches to explaining women's inequality at work and the theoretical framework that is shaping this research.

Neo-classical economic theory explains women's pay discrimination in two main ways. First, there is an "individual" explanation suggesting that the wage paid to an individual relates to the value of the output that the individual produces. If women are paid less than men, this must be because the value of what they produce is less; that is, they are less productive (Richardson, 1984). Human capital theorists, on the other hand, try to link women's supposedly lower human capital to their role in the family. This view suggests that women have a "free choice" and indeed choose to obtain less education and training, choosing instead the role of child rearing. If women enter the labour market, this choice, therefore, has an impact on pay rewards.

Of course, these views can be criticised for suggesting an innate and rational economic view of the labour market and family relations divorced from actual experience. The state is involved in much of the organisation of the labour market and society through education and welfare policy, for example. Not all women share the same experience and choice of education and training, and such theories are attributing experiences to all women regardless of whether they work or have children.

Such approaches are now finding resonance in theories of the “information society” or “knowledge economy” (in particular, see Castells, 1996). Giddens (1984), concurring with Beck’s individual and risk society thesis (Beck 1992), suggests that the changing situation of men and women in the family and at work must be seen in terms of individual choice: “We live in a world in which social order of the nation state, class, ethnicity and traditional family is in decline. The ethics of individual self-fulfilment and achievement is the most powerful in modern society” (Beck, 2002).

Taking a more practical view of the labour market, some theorists view a dual structure at work arising out of the need to cope with consumer and market fluctuations (see, e.g., Barron & Norris, 1976). In this approach, women dominate the secondary sector of employment, involving occupations with greater opportunities for dispensability and gender segregation, which more easily enables discrimination; a more acquiescent workforce because the wage is not always the sole income; and finally, a lack of solidarity because of the scattered nature of these secondary workplaces and preponderance of part-time work. This dual-market structure, therefore, affects women’s overall position, and ideological factors both cause and effect women’s inferior position within the labour market and the family.

Again, stereotypic assumptions form the basis of dual labour market theory (Beechey, 1980). It is implied that domestically women are reliant

on men’s wages and are only incidentally part of the workforce. This is not the reality for most women or the experience in most households (German, 2003).

Our research is shaped by critical and feminist approaches to understanding women’s inequality in the labour market. Critical approaches to women’s inequality largely are rooted in Marxist or Feminist theory. Feminist theories often locate women’s inequality in patriarchal gender relations within capitalist relations. Women are thus divided along class lines but share the oppression of male domination. Capitalism and patriarchy in this way continually interacts, affecting women’s position in the economy and family. This leads to the “economics of male advantage” (Cockburn, 1983, p. 8). In Marxist analysis, women’s position in the labour market depends not on market principles, but arises from the organisation of production with roots in class exploitation. Inequality in the labour market is linked to women’s oppression in the family. German (2003) explains that the family is both broken down by the effects of capitalism but also maintained and reinforced by capital as the cheapest, most convenient and most socially stable way of caring for the existing generation of workers and reproducing the next generation. The family fulfils too precious a role to be left to “free market” individualism. In reality, three-quarters of households are still headed by two-parent families, and men and women are moving closer together in terms of work and domestic life, but not in circumstances of their choosing. They do so “against a backdrop of continuing women’s oppression and intensified exploitation for both men and women” (German, 2003, p. 31). Fitting into these roles is hard work—for women, it means working for less than equal wages and, for men, increased unpaid childcare in the home.

Yet the family is a gendered institution and is often taken for granted. Wharton (2005) describes how the family is viewed as “somehow functional for society rather than a social construction and changing in relation to history and culture” and

she continues to observe that though family diversity is a social fact, this is “obscured by a set of taken-for-granted beliefs about the family as a social institution” (Wharton, 2005, p. 105). These include myths of the nuclear family, the heterosexual family, women as mothers and caretakers and men as fathers and breadwinners. However, it is these myths that inform the choices made, including government and employment policies. As Huws (2003) suggests:

... more than this, women’s role in the domestic sphere is used to confirm and legitimate their marginal status in the labour market. The gendering of jobs cannot be reduced to a discussion of women in the domestic sphere, but must be seen as arising from the interplay between their socially ascribed, and therefore shifting, roles in both the public and private domains. (2003, p. 28)

RESEARCH METHODOLOGY

The ESF-funded research project DEPICT began in January 2005, with a detailed look at the causes of pay inequality between women and men. Researchers will draw upon expertise from steering committee members made up of representatives from the ICT industry, trade unions, academics, other agencies and upon background material by the Equal Opportunities Commission and other related literature.

The research will conduct qualitative research to gather primary data and will conduct in-depth semi-structured interviews with women entering, returning, working in or who have left the sector to ascertain their views and experiences on pay issues. Additionally, the study aims to produce supporting evidence via Web-based quantitative questionnaire that will be publicised on women’s ICT forums, the aim of which is to gather data about pay from as many women working in the sector as possible to enhance the understanding of the complexities of the issue.

The project will end in December 2006, when a report will be prepared for the ESF and research results will be disseminated via workshops for organisations, women, local government representatives and other interested parties throughout England.

CONCLUSION

This article provides an overview of current research being undertaken by the ESF-funded DEPICT project at the University of Salford’s Information Systems Institute that aims to investigate equal pay issues in the UK ICT sector. Despite 30 years of equal pay legislation in the UK, the gender pay gap still stands at 18%, the main contributing factors being occupational segregation, caring responsibilities and discrimination in pay systems. The DEPICT project intends to highlight problems of overt and hidden pay discrimination and explore the implications these issues have on women’s progression and retention in the ICT industry, where women are already severely underrepresented. We present the argument that current data is limited, as the ICT sector is difficult and complex to define. We have presented a contextual theoretical framework for conducting the research by describing human capital theory and the dual labour market theory alongside critical approaches to explain women’s inequality at work. The final section indicates a brief overview of the research methods that will be utilised during the research process.

KEY TERMS

Equal Opportunities Commission (EOC):

The EOC is an independent, non-departmental public body, funded primarily by the government. Although independent from the government, they are responsible to the cabinet minister with responsibility for women and equality and to the deputy minister for women and equality in the Department for Trade and Industry.

Equal Pay Act: The Equal Pay Act covers discriminatory contractual terms related to pay and benefits (such as holidays, cars, etc.). The Act was amended by the Equal Pay (Amendment) Act 1983, which stated that men and women should be paid equally for work of equal value to their employers. This intended to tackle the fact that women tend to be occupationally segregated and so often cannot compare “like job with like.” The Equal Pay Act only has jurisdiction for jobs done at an establishment within Britain. (The Sex Discrimination Act applies to any non- contractual payments of money or benefits; e.g., a one-off Christmas bonus payment.)

Gender Pay Gap: The gender pay gap is determined by calculating women’s overall average pay as a percentage of men’s. So, for example, the pay gap is said to be 18% where women’s pay is 82% of men’s. The gender pay gap is said to “narrow” as women’s average pay moves closer to men’s. To arrive at a figure for the gender pay gap, most official statistics compare the average hourly earnings of men and women working full-time as the best way to compare “like with like.” This accounts for differences in hours worked.

Human Capital: Human capital theory suggests that women are rewarded for their previous investment in their own education and training;

women do not receive the same rewards in terms of entry to employment, promotion and levels of pay received as men as a result of “choosing” to invest human capital in labour, such as childrearing.

Occupational Segregation: Occupational segregation is a major cause of the gender pay gap, which currently stands at 18% 30 years after the Equal Pay Act. In the UK, women are concentrated in a limited range of occupation types, predominantly in the lower-paid sectors of employment, such as catering, cleaning and caring.

Pay Discrimination: Since 1975, women and men have had the right to equal pay, but pay discrimination still takes place in many workplaces. Sometimes, women are paid less than men for doing the same job. In other cases, women are paid less than men for doing work of equivalent value for their employer. Both these forms of discrimination may be unlawful. Men paid less than their female colleagues also have a right to equal pay.

Salary Secrets: The “hidden truth” regarding pay inequality between men and women often go unnoticed until women reach senior management levels. Employers often require individual salary levels to be kept confidential.

ENDNOTE

- ¹ Mean individual income is the average, by calculating the sum of all earnings and dividing the total by the number of employees. However this total can be influenced by very high earnings of a few individuals and can present a distorted view of the “average.”

Chapter 6.21

MNE Knowledge Management Across Borders and ICT

Jürgen Kai-Uwe Brock
University of Strathclyde, UK

Yu Josephine Zhou
International University of Applied Science, Bad Honnef-Bonn., Germany

INTRODUCTION

Firms are consumers, producers, managers, and distributors of information (Egelhoff, 1991; Casson, 1996) and as such a repository of productive knowledge (Winter, 1988). Consequently the ability to generate, access, and utilize relevant knowledge is an essential organizational activity in order both to reduce uncertainty about the firm's external environment and improve the efficiency of its internal operations.

Particularly for multinational enterprises (MNEs), efficient implementation of knowledge management processes is of competitive importance. In contrast to their set of indigenous competitors, MNEs face liabilities of foreignness (Zaheer, 1995) and a more complex organizational structure that transcends cultures and countries.

Advances in location insensitive information and communication technology (ICT), in

particular the Internet's marketplace (Rayport & Sviokla, 1994), could significantly facilitate MNEs' knowledge management efforts. Ease of information gathering, communication, and knowledge management is no longer a strict function of geographical proximity. As a result of the Internet, the location specificity of knowledge (von Hayek, 1945) is becoming less location dependent, and thus less costly. Despite this, the role of the Internet in knowledge management has its limits due to its inherent media characteristics and the aforementioned liabilities particular to the operations of MNEs.

This article explores the possibilities and limitations of the Internet in supporting knowledge management in the specific context of MNEs. It is structured as follows. First we will provide a background to the article by discussing and defining the specifics of MNEs, MNEs' knowledge management challenges, and the specifics of the Internet. Subsequently the article will analyze

and explore the potential impact of the Internet on MNEs' knowledge management processes. A discussion of future trends and an overall conclusion close the article.

BACKGROUND

Global trade has grown 16-fold since the 1950s, by far outstripping the growth in GDP (Economist, 1998). A key driving force behind this trend is foreign direct investment (FDI), whereas FDI is defined as an acquisition of an asset in a foreign country (host country) made by an investor in another country (home country) with the intention to manage this asset (WTO, 1996). MNEs are the main driver behind FDI. Although definitions vary, an MNE can be defined as a firm that is engaged in FDI in several countries outside its home country (for a more detailed discussion the reader might refer to, e.g., Vahlne & Nordström, 1993; Rugman & Verbeke, 2004).

Before discussing the specific knowledge management challenges of MNEs and the role of the Internet therein, it is vital to understand why MNEs exist at all. International business theory has addressed this. The core idea of international trade theory—the idea of market imperfections—was utilized by international business researchers to explain international activities at the firm level by projecting these imperfections into the firm. This helped to explain the emergence and existence of MNEs, as opposed to firms only trading with each other by means of importing and exporting. In 1960 (published in 1976), Hymer's market imperfections theory in essence postulated that firm specific advantages like technology and management skills are the core source enabling firms to successfully operate abroad, offsetting cost and information advantages enjoyed by indigenous firms. Hymer's idea was then further refined and developed by Buckley and Casson (1976) to become internalization theory. Buckley and Casson conceptualized the MNE as a firm

that responds to pre-product or intermediate-product market imperfections by internalizing these markets (like components, semi processed goods, knowledge, skills, and technology) across national boundaries (via FDI). Internalization means that a firm makes use of its organizational hierarchy and in-house resources to manage a specific business transaction as opposed to buying it on the market. By internalizing the transfer of a firm's assets and capabilities, firms mitigate transfer problems and at the same time exploit their internal advantage(s) internationally.

At the heart of internalization is the management of knowledge-related imperfections (Kogut & Zander, 1993), which makes effective knowledge management a central task for MNEs. Knowledge management within MNEs is about two interrelated tasks:

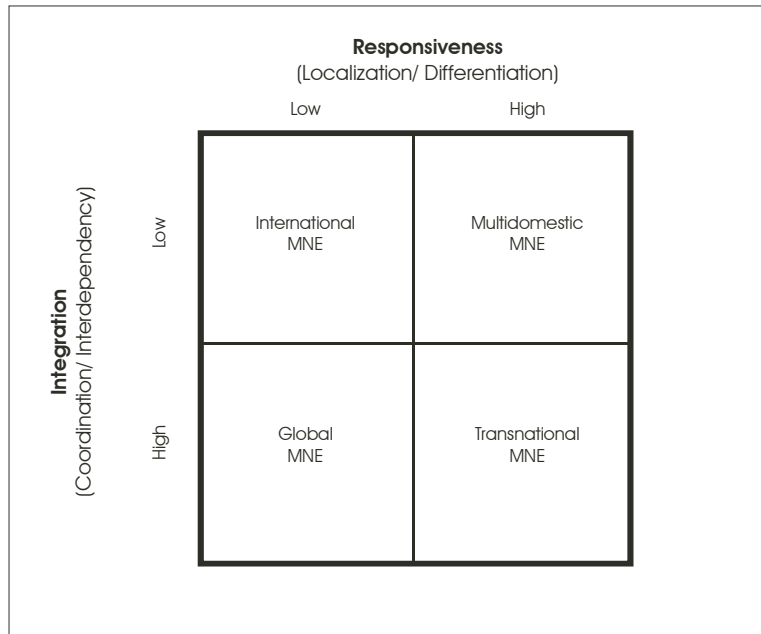

1. Knowledge management within the MNE (intra-MNE) which focuses on continuous knowledge creation, transmission, use, and retention between and within headquarters and subsidiaries.
2. Interface knowledge management (extra-MNE) which is about the continuous identification of the MNEs' external knowledge environment, its scanning, the collection of relevant external knowledge, and synthesis with existing intra-MNE knowledge.

This categorization can be related to types of MNEs (see Figure 1). Intra-MNE knowledge management mainly relates to the integration dimension, and extra-MNE knowledge management mainly relates to the responsiveness dimension. Obviously, as an MNE moves from low to high on both dimensions, knowledge management (intra- and extra-MNE) requirements increase.

This article will focus on the first knowledge management task (intra-MNE knowledge; integration), because it is unique to MNEs.

The key challenge for intra-MNE knowledge management is knowledge transmission (Kogut

Figure 1. Types of MNEs

Source: Derived from Harzing's MNE typology synthesis (Harzing, 1997)

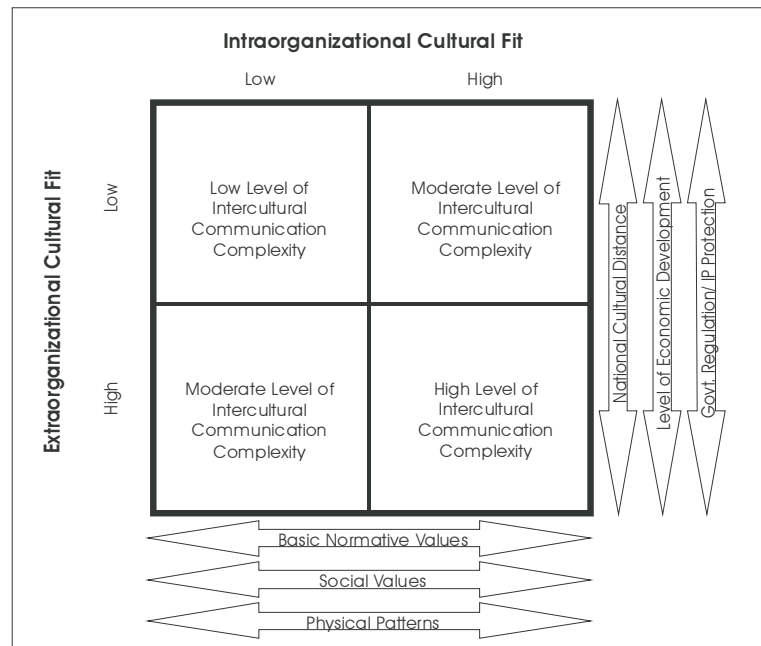

& Zander, 1993). Transmitting knowledge is costly (Teece, 1977). The more tacit—or personal (Polanyi, 1958)—and complex the information, the more difficult and expensive it will be to transmit it. This is so because the codification and teaching costs in the transmission process increase as tacitness and complexity increases. Transmitting knowledge across different cultures and countries further increases the costs due to different norms, habits, languages, and interpersonal processes that can inhibit communication flows (Johanson & Vahlne, 1977). These differences operate at two levels, the intra-organizational level and the extra-organizational level, both defining the communication complexity in the knowledge transmission process (see Figure 2). While the former refers to differences between the different organizational cultures within MNEs (mainly headquarters to subsidiary/-ies), the latter

refers to differences at the national level (home country to host country/-ies). However, the intra-MNE transfer of knowledge can be eased by the development of a common understanding and of capabilities—combinative capabilities according to Kogut and Zander (1993)—how to manage this transmission. Such development emerges—via repeated interactions—over time in the form of organizational routines.

Before analyzing how the Internet's marketplace could impact the intra-MNE knowledge management process, an evaluation of the marketplace is required.

Whereas the marketplace represents the physical world of resources, the market space represents the virtual world of digitized information (Rayport & Sviokla, 1994). The most evident and widely known manifestation of the market space is the Internet. Following key elements of December's

Figure 2. Intercultural MNE communication matrix

Source: Derived from Harvey and Griffith (2002)

(1996) definition, the Internet can be defined as:

- Computer-mediated communication, including
- information dissemination and
- information retrieval that
- involves data (bits) exchanges taking place on the
- global collection of computer networks using
- the TCP/IP protocol suite for data transfer.

The information content can involve a broad range of data types (text, graphics, images, sound, video), and various forms of open and closed (in the case of intranets and extranets) information processes (one-to-one, one to many;

asynchronous, synchronous) are possible. The Internet can thus be used by organizations such as MNEs to process, distribute, and retrieve codified knowledge, and it can be used to interact (communicate) with others. To express this, the terms “information pull,” “information push,” and “interaction” are introduced. Information pull refers to organizational activities related to synchronously or asynchronously pulling information from the Internet (or intranet, extranet). Information pull can be active or passive, with, for example, searching the Web referring to the former and subscribing to mailing lists referring to the latter. Subscribing to corporate mailing lists is a passive, non-specific information pull activity, because the subscriber does not know exactly what specific kind of information he or she receives prior to subscribing.

On the other hand, information push refers to organizational activities related to pushing information onto the Internet (or intranet, extranet). Active information push refers to organizations actively marketing their information push activities. In contrast, passive information push refers to organizations setting up Web sites without any internal or external promotions.

Interaction is the Internet's third potential use for organizations. The main difference between information push/pull and interaction is that interaction involves non anonymous, asynchronous or synchronous personal exchange of information between known communication parties. Both information pull and information push is at least partially anonymous. Interaction as understood here means mediated personal interaction between known users or parties. When an organization pushes corporate information onto the Internet, it does not know *ex ante* who might actually retrieve and read its content. The same applies for posting non personalized messages to newsgroups or mailing lists, because the sender does not know in advance who will read his message and who will not. In addition, the sender does not know the identity of all the receivers, unless he is the initiator and owner of the mailing list requiring subscribers to reveal their identity during the subscription process. The same applies in the case of information pull. Although users accessing a Web page or Internet-based databases leave "digital fingerprints" (Drèze & Zufryden, 1997) and Web sites can send so-called "cookies" to users accessing a Web page, users pulling information from the Internet can remain anonymous if they wish to by refusing cookies or by using anonymizer software. In contrast, interaction as defined here involves the one-to-one or one to many exchange of information between pre-specified and known parties. The defining element of interaction is value exchange between known parties.

All of the aforementioned three use categories are interrelated, with information pull activities potentially being influenced by and leading to

information push activities and interaction activities, and vice versa. Also, the three uses relate to similarly interrelated activities taking place in the non mediated marketplace.

MAIN FOCUS OF THE ARTICLE

Although the role of ICT in organizations in general has been the focus of studies since the 1970s (e.g., Pfeffer & Leblebici, 1977), little is known about the specific role of ICT in cross-cultural contexts (e.g., St.Amant, 2002; Weisinger & Trauth, 2002) and MNE operations (e.g., Petersen & Welch, 2003). With the background provided in the previous section, it is possible to explore possible effects of the Internet's marketspace on intra-MNE knowledge management.

Knowledge management scholars have identified four dynamically interacting processes how organizational knowledge is created and transmitted (Nonaka, 1991). The first process—termed "socialization"—is about tacit-to-tacit knowledge transfers. The traditional German apprenticeship system is an example of such a transfer. An apprentice learns via observation, imitation, and practice. In this process he or she "imports" the tacit knowledge base of the master which becomes his or her own tacit knowledge. The second knowledge transfer process is "articulation," whereby explicit or codified knowledge is directly transferred to become explicit knowledge elsewhere. An example of such a process would be an individual recombining a set of coded knowledge such as a financial report into a different document. The third and fourth processes are about transformative transfers, whereby explicit knowledge is turned into tacit knowledge or vice versa. The tacit-to-explicit transfer is called "combination." Combination takes place when an individual articulates his or her tacit knowledge base, thereby converting it into explicit knowledge that can be shared with others. Finally, "internalization"—a technical term in

the knowledge management literature that has a different meaning to the one in the international business context—is the explicit-to-tacit process of knowledge transfer. This process takes place when employees use the explicit organizational knowledge available, for example in the form of a database, to extend their own tacit knowledge.

How could the Internet support or enhance these four processes in the case of intra-MNE knowledge management?

On the one hand, the answer lies in an understanding of the differences between mediated and unmediated communication. On the other, an appreciation of cultural differences in communication is required. With regards to the former, rational media choice theories, such as social presence theory (Short, Williams, & Christie, 1976) and media richness theory (Daft & Lengel, 1986) postulate that an individual determines his or her choice of media by rationally assessing the requirements of a communication task and selecting an appropriate medium matching these requirements. Media is categorized along a continuum based on the channel's information richness, which depends on the medium's ability for immediate feedback, the number of carried cues, the number of channels utilized, its language variety, and its level of personalization capable of reducing equivocality. This set of theories postulates that the higher the perceived need for social cues and equivocality reduction in a communication situation, the higher the likelihood of face-to-face communication, the richest mode of information exchange with the highest degree of social presence. This would, for example, be the case in tacit-to-tacit knowledge transfers ("socialization"). In contrast, the Internet is considered less information rich. It follows that the reduction in channel capacity on the Internet compared to face to face communications makes knowledge transfers more difficult despite its cost-reducing properties in general.

Mixed empirical findings regarding the predictive validity of the rational media choice theories

(e.g., Markus, 1994; Walther, 1996; Ngwenyama & Lee, 1997) have led to the development of social influence models of communication technology use (e.g., Ngwenyama & Lee, 1997). The social influence models of communication technology use all regard information richness or leanness in communications not as attributable to the properties of the communication medium alone, but as emerging from the interaction between people and contexts. According to this school of thought, media choice is influenced by the attitudes and behaviors of others, as well as norms that have developed within a group, within organizations, or across organizations. Hence, media perception is not fixed, but it varies across people, organizations, situations, tasks, time, and user experience with the medium. Because these models make no a priori assumption about any direct relationships between communication richness and the quantity of social cues (Ngwenyama & Lee, 1997), they in essence detach the message from the medium. Any message can be rich (or lean) relatively independent of the medium, more dependent upon the users' experience with the medium, their experience with the communication topic, and their experience with the communication partner or the communication context (Carlson & Zmud, 1999). Communication richness is therefore an outcome of social behavior, not solely an outcome of the nominal, rationally determined media richness of the communication channel. All this implies that although the amount of social information per communication act via the Internet is lower compared to face to face communication, it is more the rate of social information exchange than the amount of social cues exchanged that constitutes the key difference between the two forms of communication (Walther, 1996). Compared to non mediated communication, the exchange of social cues is "just" temporally retarded. Hence, informal, interpersonal communication can take place over computer-mediated communication channels, as user experience with the medium, the topic, the communication partner, and the

communication context accumulates and increases. This phenomenon has been termed the “channel expansion effect” (Carlson & Zmud, 1999). But when first exposed to new media such as the Internet, it is likely that people’s need for unmediated, face-to-face interactions increases (Nohria & Eccles, 1992).

A similar, albeit media-independent expansion effect can be observed within the organizational context of the MNE. As described by Kogut and Zander (1993), the personnel of the MNE must share a similar background and organizational culture in order to be able to encode and decode messages—in any of the four processes described above—correctly, otherwise misunderstandings will arise. Such capability, constituting the MNEs’ transactional ownership-advantage (Dunning & Rugman, 1985), is MNE specific and only emerges over time through repeated interactions.

Considering communication differences across cultures is the second aspect that requires attention to understand how the Internet could support or enhance the four processes of intra-MNE knowledge management (see Figure 2). Hall’s work on intercultural communication (Hall, 1976, 1983) provides a suitable framework that has been applied widely in similar research contexts, especially its contextual dimension (e.g., St. Aman, 2002; Zakaria, Stanton, & Sarker-Barney, 2003; Matveev & Nelson, 2004). The contextual dimension in Hall’s framework represents the ways in which information is perceived, exchanged, and used by people from different cultures. Hall categorized cultures on a high- to low-context continuum. Low-context cultures such as those in the United States, Germany, and Scandinavian countries tend to present and exchange information in an explicit and direct manner. The implicit assumption is that little or no contextual overlap with the receiver is required, because all necessary information is vested in the explicit code (i.e., words) used. In contrast, high-context cultures such as those in Japan, China, Russia, and Latin America tend to rely less on coded, explicit com-

munication. In such cultures most of the actual information content resides within the physical and situational context, as well as inside the communication parties. Less explicit information exchange is the natural consequence. Research has shown that such cultural differences also impact the way people go about their information pull, push, and interaction tasks, whether ICT mediated or unmediated (e.g., Straub, Keil, & Brenner, 1997; Pook & Füstös, 1999; Kersten et al., 2003; Pauleen, 2003; Zakaria et al., 2003).

Considering these different aspects, it becomes evident that it is likely that the relative role of Internet versus face-to-face-based knowledge management processes depends on the type of knowledge transfer process; the MNEs employees’ experience with the Internet and its three generic uses; the employees’ experience in transferring, absorbing, and using intra-MNE knowledge; and the intercultural communication complexity. Table 1 provides an overview.

For tacit-to-tacit transfers, the role of the Internet is the most limited, and only one of the three generic uses apply. Unmediated face-to-face interactions will play the dominant role with the highest base level, particularly in complex communication situations that require very personal communication strategies (Harvey & Griffith, 2002). Only over time, as the previously mentioned expansion effects occur and the emergence of an organizational communication culture reduces communication complexity, will the interaction use of the Internet increase and the role of unmediated interactions decrease. An exception to this trajectory is a surmised initial increase in face-to-face interaction (Nohria & Eccles, 1992). The overall shift over time will be of a complementary rather than fully substitutive nature (Kraut, Steinfield, Chan, Butler, & Hoag, 1998), especially in high-context cultures (Zakaria et al., 2003). A video conference over the Internet with an instructor practically demonstrating procedural knowledge is an example of a tacit-to-tacit knowledge transfer.

Table 1. Knowledge management aspects, culture, ICT, and MNEs*

Process	Culture	Role of the Internet#				Face-to-Face#	Relevance for MNE I type				Hypothesized, Stylized Relationship
		Pull#	Push#	Interaction #	International		Multidomestic	Global	Transnational		
Tactit-to-Tact ("socialization")	Intercultural Communication Complexity	High	-	Low	High	Low	Low - Medium	Medium - High	High		
	Intercultural Communication Complexity	Low	-	Low → Medium	High → Medium	High → Medium	Low - Medium	Medium - High	High		
Explicit-to-Explicit ("articulation")	Intercultural Communication Complexity	High	Medium	Medium	Medium	Low	Low - Medium	Medium - High	High		
	Intercultural Communication Complexity	Low	Medium → High	Medium → High	Low → Low	Low	Low - Medium	Medium - High	High		
Tactit-to-Explicit ("combination")	Intercultural Communication Complexity	High	-	Low	High	Low	Low - Medium	Medium - High	High		
	Intercultural Communication Complexity	Low	-	Low → Medium	High → Medium	High → Medium	Low - Medium	Medium - High	High		
Explicit-to-Tact ("internalization")	Intercultural Communication Complexity	High	Low	Low	Low	Low	Low - Medium	Medium - High	High		
	Intercultural Communication Complexity	Low	Low → Medium	Low → Medium	Low → Low	Low	Low - Medium	Medium - High	High		

* Focus Intra-MNE; # Over time (t1 → t1+n)

Explicit-to-explicit transfers are the stronghold of the Internet. All three generic uses apply, the frequency of use is the highest, and the face-to-face base level is the lowest. Codified organizational knowledge such as a blueprint stored in an Internet-enabled database is an example. Here, the need for unmediated communication is rather low, with the exception of complex intercultural communication situations. In addition, the need for unmediated communication might increase initially to achieve source credibility and trust.

For tacit-to-explicit transfers, only the push and interaction use of the Internet applies and its relative role lies somewhere between the two processes previously discussed. Turning uncoded, personal knowledge into codified knowledge requires richer, unmediated communication, particularly initially and in culturally dissimilar contexts. However, similar to tacit-to-tacit transfers, expansion effects might reduce the relative importance of unmediated interactions over time. As previously mentioned, an initial increase in face-to-face interactions (Nohria & Eccles, 1992) might be an exception to this. An example of such a transfer over the Internet would be an employee who publishes (pushes) an installation guide that incorporates his experience in installing the described piece of machinery on an MNE's best practice intranet site.

In the case of explicit-to-tacit transfers, both media play a limited role, with the influence of the Internet's pull and interaction use likely to increase over time as users gain expertise in pulling the right set of information from the medium and in interacting with colleagues from different countries. Here the relative role of the Internet for the MNE is similar to its role in the tacit-to-explicit transfer. The two differences are that the pull use of the Internet applies while the push use does not and that the overall use frequency of both media is lower. Internalization is more of a media-independent internal human learning process where mainly the source—face-to-face or mediated—matters. An example would be an

employee in a subsidiary who downloads a new manual containing work rules that he or she will subsequently use in the daily work. Over time the explicit, codified knowledge is absorbed and becomes part of the employee's personal, tacit knowledge base.

As indicated in Table 1, the importance of these effects depends on the MNE type and the associated importance of intra-MNE knowledge management (see Figure 1 and Table 1). If integration is low, the relevance and role of the Internet is limited. If integration is high, the Internet can facilitate intra-MNE knowledge management as described above. In addition, the MNE's overall strategic intent regarding knowledge management matters. If a personalization strategy rather than a codification strategy is followed (Hansen, Nohria, & Tierney, 1999), the role of the Internet will be more limited.

FUTURE TRENDS

The importance of knowledge management in MNEs will increase in the future. As economies' value add shifts to services and knowledge becomes the key asset for firms, productive use of organizational knowledge becomes the main challenge (Drucker, 1999). Moreover, as the international integration of economies increases, cross-cultural communication competence becomes an increasingly important aspect in knowledge management. Research has demonstrated its positive impact on performance (Matveev & Nelson, 2004). What is less clear is how the role of the Internet will change in the future and how this relates to knowledge management within MNEs. Even its present role in knowledge management processes is not well understood. The Internet is a very dynamic and innovative medium, and its capabilities have significantly improved over time, including faster network connections. Therefore one could speculate that the role of the Internet will expand further. As mobile access to the In-

ternet improves, individuals' and organization's skills in using it improve, and its bandwidth further expands richer information can be transmitted. This will reduce—albeit not completely substituting—the need for unmediated communication in the knowledge transmission process. Real time, virtual reality conferencing between headquarters and subsidiaries is but one example. Additionally, as global Internet diffusion further increases, cultural differences might matter less and lead to the emergence of a meta-culture that transcends location-bound aspects of culture in communication.

Yet it is important to understand that the Internet is “only” an infrastructure technology available to every MNE. In other words, it is a competitive necessity, not a source of competitive advantage per se. Only if the MNE integrates the Internet seamlessly into its culturally sensitive knowledge management processes, leveraging its resource-related and transaction-related advantages, will the Internet enable MNEs to sustain their competitive advantage. An understanding of the Internet's limitations and strengths as discussed above will help.

CONCLUSION

This article explored the possibilities and limitations of the Internet in supporting intra-MNE knowledge management. As was shown theoretically, the Internet can support such management tasks, assuming that personal relationships among employees and a joint understanding of the organizational context and culture have developed. Over time, as experience with the medium, the exchange partner, and the exchange context increases, this role becomes more prominent. Despite this, unmediated communication remains of importance. Especially in complex intercultural communication situations, in the early phases of knowledge transmission processes, and in cases where tacit knowledge is dominant, the Internet's

current role is more limited. In addition, the nature of the MNE matters. Especially for MNEs that manage a highly interdependent network of subsidiaries with a high level of integration, efficient use of the Internet is imperative to stay competitive. With this in mind, a more differentiated role of the Internet in intra-MNE knowledge management processes emerges. Neither will it completely obsolete distance and the location-dependency of knowledge, nor will it play no role in knowledge management (for the latter argument see, for example, McDermott, 1999).

Although this middle-of-the-road position might be logically appealing, future research should test these conclusions. Thus far, empirical evidence in this area is scant and mainly anecdotal. Can the hypothesized relationship be found in MNEs? What are the antecedents and consequences of face-to-face versus Internet-mediated knowledge management processes? Does intercultural complexity moderate or mediate antecedents and consequences of media use in knowledge management processes? What overall organizational impact could be expected? Will it lead to—or be the result of—smaller MNEs and/or more decentralized MNEs and/or more integrated MNEs (for such findings in general, see Brynjolfsson, Malone, Gurbaxani, & Kambil, 1994; Dewan, Michael, & Min, 1998)? So far, these questions have not been answered.

KEY TERMS

Articulation: One of four knowledge transmission mechanisms according to Nonaka. Articulation is about explicit or codified knowledge being transferred to become explicit knowledge elsewhere by recombining two or more sets of coded knowledge.

Channel Expansion Effect: Communication over computer-mediated communication channels such as the Internet can increase in richness and social presence over time while keeping its nominal channel capacity. This effect occurs as user experience with the medium, the topic, the communication partner, and the communication context accumulates.

Combination: One of four knowledge transmission mechanisms according to Nonaka. It is a tacit-to-explicit knowledge transfer taking place when individuals articulate their tacit knowledge base, converting it into explicit knowledge that can be shared with others.

Foreign Direct Investment (FDI): An acquisition of an asset in a foreign country (host country) made by an investor in another country (home country) with the intention to manage this asset.

Internalization: In international business and organization science literature, internalization means that an organization makes use of its organizational hierarchy to manage a specific business transaction, as opposed to buying it on the market. In knowledge management literature, internalization is one of four knowledge transmission mechanisms according to Nonaka. It refers to the explicit-to-tacit process of knowledge transfer. This process takes place when individuals use explicit knowledge to extend their own tacit knowledge base.

Multinational Enterprise (MNE): A firm that is engaged in FDI in several countries outside its home country.

Socialization: One of four knowledge transmission mechanisms according to Nonaka. Socialization is about tacit-to-tacit knowledge transfers via observation, imitation, and practice.

Tacit Knowledge: Polanyi's statement "We know more than we can say" probably best explains what tacit knowledge is. In contrast to explicit knowledge, which is expressed in formal language systems (e.g., data, formulae, or any written document), tacit knowledge is personal and difficult to formalize. Personal insights, intuition, and sensing are examples of such knowledge. It is embodied in procedures, routines, activities, values, culture, and feelings.

Chapter 6.22

Is Organizational e–Democracy Inevitable?

The Impact of Information Technologies on Communication Effectiveness*

Bernadette M. Watson

Elizabeth Jones

Griffith University, Australia

ABSTRACT

In this chapter, we consider the relationships between social identity and e-democracy in organizations that exist in the constantly changing global business and technological environment. We also consider the inevitability of organizational e-democracy in organizations undertaking information technology (IT) changes, the technology at the base of e-democracy. Through an examination of employees' experiences of change, we investigate their perceptions of changes in effective communication during major organizational change implementation in a hospital context. While the changes were far reaching, we mainly focus on the

introduction of information and communication technology (ICT). We use an empirical examination of an Australian public hospital's IT change experience as the backdrop to assess the accuracy of the statement that there is an improvement in the autonomy within organizations as a result of IT changes. We discuss our findings in light of the implications that arise for HR practitioners.

INTRODUCTION

In this chapter, we consider the relationships between effective communication, social identity, and e-democracy in organizations that exist

in the constantly changing global business and technological environment. We also consider the inevitability of organizational e-democracy in organizations undertaking information technology (IT) changes, the technology at the base of e-democracy. Through an examination of employees' experiences of change, we investigate their perceptions of changes in effective communication during major organizational change implementation in a hospital context. While the changes were far reaching, we mainly focus on the introduction of information and communication technology (ICT).

We define e-democracy as the technological advances in communication media that provide employees with more information and more direct access to other employees (supervisory and subordinate levels) than previously existed. These changes to communication channels provide organizational connections and lead to e-democracy practices that seek to improve the autonomy of organizational members. Thus there is a freeing of information to help erase or ease organizational boundaries, which changes the relationship between executive and middle management parties.

The chapter uses an empirical examination of an Australian public hospital's IT change experience as the backdrop to assess the accuracy of the statement that there is an improvement in the autonomy within organizations as a result of IT changes. We assert that while hospitals are a very specific type of organization, they represent a typical hierarchical organization that uses the same human resource (HR) practices and principles that underlie all successful ICT implementations. We adopt the theoretical framework of social identity theory (SIT) (Tajfel, 1978) to understand how communication effectiveness and e-democracy evolve during IT change. SIT proposes that individuals understand their self-concept through their identification with salient social groups (1978, p. 63). Such groups include gender, profession, nationality, and religion — to

name just a few. Individuals derive their sense of self-worth and positive self-esteem by viewing their group memberships (in-groups) as better than other groups to which they do not belong (out-groups). Employees will often tend to make favorable in-group comparisons to ensure that their workgroup is perceived as more successful and prestigious than comparable out-groups. Such comparisons lead to positive evaluations of one's own self-worth. This theory, which is discussed in more detail below, has important implications for the ways in which individuals will react to and manage ICT change.

ICT often changes the environment in which individuals work. As the work environment changes, so to do work-related tasks and roles. Changes to role and work functions alter the composition of workgroups and so impact on an employee's identification with his or her workgroup and intergroup relations between groups. From an SIT perspective, we view organizations as cultures. Thus the hospital environment has its own culture; within this, subcultures or groups (e.g., work units, departments) co-exist. We argue that SIT is a theoretical framework that provides insights into how employees absorb and manage ICT-enabled changes.

Thus our chapter highlights the social side of organizational change that is often ignored by the planners and implementers of change. We emphasize the need for HR managers to recognize these social issues. In this way HR practitioners will maintain the good employee environment that they have developed, as well as improve the outcomes of organizational change for members of that organization. Using a longitudinal study, we examine how employees' work identities impact on their understanding and adoption of ICTs. Bearing in mind the chapter's focus on e-democracy, we examine employees' perceptions of communication effectiveness and discuss these findings in the context of the HR focus that frames this book.

Is Organizational e-Democracy Inevitable?

The chapter highlights two important issues within the area of organizational change and new technology introduction:

1. the changes in employees' perceptions of their role and the groups within the organization that they identify with that are brought about by ICT-enabled change, and
2. the implications of these changes for HR practitioners.

Focusing on the ways that individuals in traditionally hierarchical organizations understand and adapt to the changes in their work, we examine the process of change from the viewpoint of both the implementers of change and the employees who must adapt to change. In so doing, we investigate how communication processes and their level of effectiveness change with IT implementation. Our intention is to provide e-human resources management with key recommendations that need to be in place to successfully implement an organization's planned ICT change.

This research is framed by the arrival of the knowledge economy that allows e-democracy practices to exist. As the knowledge economy has evolved, as part of more widespread changes to organizations including ICT, some researchers have examined how employees' identification with organizations explains change outcomes (Terry, 2001).

We recognize that there is a gap in our understanding between the emergence of organizational e-democracy and the potential changes to the organizational structure and communication that can result from ICT implementations. We bridge this gap by highlighting the fact that, because individuals identify with their workgroups, when the current status or existence of these groups is threatened, resistance to the change may result. HR practitioners need to understand the composition and function of employee workgroups — both formal and informal. They will then develop an

understanding of how and why members of these groups resist the changes within the organization and can seek to remedy the issues.

Organizations that typify the knowledge economy are viewed as dynamic and organic (Alvesson, 1995). As a consequence, the nature of organizational change in such organizations can be unpredictable. Understanding that change will bring about unexpected alterations to the way that employees respond to change is, therefore, key to being able to manage these people. In line with this view, Carlopio (1998) notes that the implementation stage of organizational change, while crucial to successful change, has been wrongly considered to be a rational and linear process.

In the subsequent pages we discuss the implementation of ICT change to stimulate discussion on the nature and place of organizational e-democracy. We seek to promote debate on the ways that social identification adapts and modifies itself within an organization undergoing ICT change. We focus on the implications for HR practice as we examine the uptake of ICT changes, the emergence of e-democracy, issues of identification, and the role of effective communication.

In this chapter, we first briefly describe the theoretical background to our research, focusing on the overlap between organizational democracy, change, and social identity. Using the experiences of a large public hospital undergoing change, we then provide evidence to demonstrate the value of connecting ICT innovation with social identity processes and e-democracy outcomes. We discuss the role that social identification with an organization or workgroup plays in an organization during ICT change. Finally, we examine the outcomes of such change as it affects the core business of an organization and make recommendations for HR practitioners. These recommendations will equip HR practitioners with a more appropriate and relevant knowledge base from which to plan and operationalize technology change.

RESEARCH BACKGROUND

The Paradox of Democracy in Organizational Research

Over 100 years after de Tocqueville's (1835) discussion on the triumphs, hazards, and powers of democracy, Slater and Bennis (1964) argued that "democracy is inevitable." They offered democracy as the most efficient and practical form of social organization, mimicking Weber's (1924/1968) philosophy on bureaucracy. At the time of their argument, the Cold War was the center of world attention, making the issue of democracy both topical and compelling. In the context of the global and technological changes occurring over the past five years, our research borrows from Slater and Bennis' thesis, but considers the same issue from an organizational perspective.

Today we live in a knowledge economy whose core assets are the intelligence, understanding, skills, and experience of employees, not the machinery, buildings, or real estate of yesteryear (Drucker, 2001; Manville & Ober, 2002). This environment has focused attention on the role of ICTs and their ability to disseminate information. The emergence of a knowledge economy, where effective information transfer and the decentralization of organizational power structures is paramount, however, raises questions about the nature of organizational democracy.

Despite its prominence in change research (e.g., Beer & Nohria, 2000), organizational democracy within the knowledge economy is confusing. In the contemporary workplace, knowledge is regularly portrayed as the primary resource for individuals (Drucker, 1992). The simultaneous sharing of information through sophisticated technology is viewed as a primary tool of organization (Orlikowski & Iacono, 2001). This process assumes that the militaristic conditions of the industrial organization are antiquated and perhaps even unnecessary. Consequently, changes to traditional bases of power and influence are

believed to occur through decentralization and information access (e.g., Applegate, 1994; Halal, 1996). Change initiated in the knowledge economy is regularly presented as a constant feature of the modern organization, despite the dissatisfaction that exists with the nature of change research (see Tsoukas & Chia, 2002). This perspective that change is constant in the knowledge economy adds a paradoxical tangent to organizational e-democracy.

These changes do not necessarily foster democracy (Mantovani, 1994), even though there are implied benefits of the evolving, boundary-less, and pluralistic nature of organizations in the current global economy. Many organizations are still organized autocratically (Kraemer & Dedrick, 1997; Schwarz, 2002). Corporate ownership structures, governance systems, and incentive programs are still firmly entrenched in the industrial age. Organizations are still primarily organized through small management groups typical of hierarchies (Markus, 1983; Robey & Boudreau, 1999). Any features of employee empowerment are limited.

It would, of course, be negligent not to recognize the advances made in the use of more democratic governance methods, such as participatory management practices (e.g., Drehmer, Belohlav, & Coye, 2000), organizational citizenship (e.g., Lambert, 2000), and communities of practice (e.g., Wenger, 1999). Nonetheless, change research is often too concerned with two aspects of change. First, the research concerns itself with re-evaluating the authority, power, and control features that normally exist in institutions (Scott, 2001). Second, it concerns itself with the promotion of alternative organizational designs and practices (Schilling & Steensma, 2001).

Organizational change in a knowledge economy context is regularly hypothesized to bring about a more democratic organizational shape than previously existed. For example, we expect more information connectivity and freer communication than before. We expect more autonomy, but

Is Organizational e-Democracy Inevitable?

less centralization and less hierarchy than before. Yet there is enough research, and a growing line of argument, to undermine this assumption. Is organizational democracy in the knowledge economy (i.e., e-democracy) inevitable? If organizations change, then logically, so too must employee perceptions of their role in the organization. In a consideration of the objectives of this chapter, we therefore invoke social identity theory (SIT) as a guiding framework that may help understand the outcomes from change and whether or not e-democracy emerges as a result of ICTs.

Social Identity Theory and its Organizational Context

In the section that follows, we provide a preliminary overview of the theory, referring readers to Hogg and Terry (2001, 2000) for a comprehensive review of the theory and its links to organizational contexts. Social identification “is the perception of oneness with or belongingness to some human aggregate” (Ashforth & Mael, 1989, p. 21), encompassing salient group classifications. Social identity theory, therefore, is based on the premise that most often it is our group-based identities that are important in our interactions with others.

The central tenet of this approach is that belonging to a group is largely a psychological state. This grouping confers social identity, or a shared representation of who one is and how one should behave (Hogg & Abrams, 1988). In this way, group belongingness reduces our uncertainty about where we fit in society (Hogg & Mullin, 1999). More recently, SIT has been applied to the organizational context. Implicit in this understanding of organizational identity function is the recognition that organizations are composed of the people in that organization. In essence then, “Organizations are internally structured groups, which are located in complex networks of intergroup relations that are characterized by power, status, and prestige differentials” (Hogg & Terry, 2001, p.1). As a result, organizations are

implicitly dynamic, continually changing entities. Changes that affect the organization can therefore have serious effects on employees in terms of their identification with workgroups and the relationships between workgroups.

While there has been a longstanding research tradition examining organizational identification, more recently SIT researchers have viewed organizations as being composed of individuals possessing multiple group identities. These identities range from the employees’ overall identification as members of an organization, to their identification with specific work units and professions. At any one time different group membership may be salient for an employee. Accordingly, when a manager interacts with a subordinate, he or she is likely to identify with their respective roles of manager and subordinate as most salient in the work situation (Gardner & Jones, 1999). Yet in another context the person’s professional identity may be most salient.

SIT has been used by organizational scholars to better understand how the individual relates to these collectives, and the intergroup relations that accompany the process of identification (see Pratt, 2001, for a comprehensive review of this trend). Such a perspective does not deny the importance of an individual’s personal identification, but sees it as often less relevant than group identification in the workplace.

Social identity theory proposes that individuals will tend to make favorable evaluations about their in-group (‘us’), but make unfavorable evaluations concerning the out-group (‘them’). If we identify at the organizational level, we perceive all employees of our organization as in-group members and employees of competing organizations as members of an out-group. More often though, it is at the sub-organizational level that we make the most relevant comparisons. The result is that employees will then tend to favor their workgroup or department and evaluate it more positively than other workgroups or departments. Organizational change, including

the development of the knowledge economy, may not only lead to the formation of new identities, but may challenge/threaten existing identities and intergroup relations. Thus mergers, acquisitions, and downsizing have increasingly become the subject of research examining organizational change and SIT (Terry, 2001; van Knippenberg & van Leeuwen, 2001).

Such research has been crucial in understanding change from an SIT perspective, but as Hogg and Terry (2000) note, they do not address important developments of SIT in the last decade that are particularly relevant as to whether e-democracy may emerge in response to ICTs. Recent developments include research on identification problems dealing with (1) loyalty, and (2) nested and cross-cutting identities. Looking first at the issue of loyalty, as information intensity becomes more relevant to organizational functioning, many of the traditional roles of identity are undercut (Neef, 1998). Group identification is a process whereby individuals become connected with others and where joint interests may overtake those of the individual. When there are changes in perceived membership or competing identities emerge which make the lines of group belongingness unclear, questions concerning group loyalty may arise. Specifically, employees ask whether their loyalty should be conferred to the group, the organization, the professional association, the occupation, or to workmates?

Thus, before individuals can act in a given organizational context, they need to situate themselves, allowing certain identities to be nested or embedded within others (Ashforth & Johnson, 2001). Nested identities exist at the higher order level, such as an employee's identification with his or her division, which is nested under the organizational identification. Lower order identities are those of identification with an individual's job. Job identification would be nested under an individual's workgroup. Conversely, cross-cutting identities refer to an employee's committee or task force identification that runs across the

hierarchical structure. Cross-cutting identities and lower order level nested identities are more likely, more salient, and more proximal than are higher order level identities (see Ashforth & Johnson, 2001, for a full discussion on this topic). Internal conflicts may arise when an individual perceives competing demands across two of his or her work identities. The cognitions and identity changes that occur during change therefore need to be thoroughly investigated in order to better understand the change outcomes.

The longitudinal study that we present in this chapter acknowledges these aforementioned complexities and seeks to raise awareness levels of HR managers to these issues. Specifically, we contend that an examination of any change implementation without due consideration to the psychological processes that underlie an employee's perception of the change will not provide an accurate picture of the evolution process during change. Nor will such an examination provide an understanding of the potential subsequent changes in e-democracy.

The empirical review that follows describes how employee workgroup identification interacts with technology change and communication effectiveness, and the outcomes in terms of e-democracy. Employee responses include perceptions about changes to their levels of job satisfaction and commitment, as well as changes to the status and prestige of their workgroup and other groups within the organization. For HR practitioners, these are important considerations that, if managed well, allow for smooth transitions during change. Researchers have typically neglected the intergroup nature of change, despite the fact that corporate change involves major reallocations of status, power, and resources across divisions of an organization (Gardner, Paulsen, Gallois, Callan, & Monaghan, 2000).

We present change as a process that impacts on an organization in at least two ways. First, there is the individual impact upon employees in terms of their levels of job satisfaction and

Is Organizational e-Democracy Inevitable?

organizational commitment. Second, researchers — and by implication, HR practitioners — need to consider the significant impacts upon employees' levels of identification with their workgroups or the social categories with which they identify. This second impact is demonstrated by employees' perceptions of changes in the groups they identify with, perceived status, and the levels of in- and out-group bias.

Our approach adds to previous research by considering whether e-democracy is an inevitable consequence of ICT changes, and how a social identity perspective helps us understand the effects of ICT changes. We argue that social identity theory provides an alternative (socially) evaluative insight into the nature of change and the process of how organizations evolve and adapt to the knowledge environment economy. In this chapter, we concentrate on how group memberships within organizations are influenced by change. Our approach differs from other researchers who have applied democracy at the organizational level in debating what the organization and organizational change will look like (e.g., Lammers & Szell, 1989; Mason, 1982).

Social identity argues that organizations are internally structured groups that are located in complex networks of intergroup relations characterized by power and status (Hogg & Terry, 2000). In referring to the processes that underlie the development and maintenance of individual and group identities, social identity allows us to better deconstruct the process of organizational democracy using this prestige differential.

As part of this examination, we discuss change and organizational democracy by focusing on how the social identity of health professionals in a large metropolitan hospital affects their understanding of and adaptation to new ICTs. Our analysis was guided by two research questions:

RQ1: What is the relationship between employees' perceptions of their workplace identification and e-democracy change?

RQ2: How do the features of ICT change and organizational e-democracy relate to employees' perceptions of communication effectiveness during change?

METHOD

Context

Information and communication technologies are regularly promoted as drivers that take costs out of the supply chain, improve the management of customers, and enhance the capability of the organization to quickly respond to a changing marketplace (Glover, Prawitt, & Romney, 1999). ICT developments are perceived as key organizational tools that can alter reporting structures, cultures, job roles, and the identities of employees and their groups. These technologies have been an excellent means of expanding access to information across an organization, empowering employees through added flexibility and enhanced functional integration. These new capabilities have occurred despite the increasing recognition that in reality many very expensive IT systems are abandoned or never realize their full potential (Fahy, 2001). To date, we know that while organizations often have high expectations for change when new systems are commissioned, technology implementations regularly result in the reduced or failed adoption of complex, integrated technology architectures (Koch & Buhl, 2001).

Nonetheless, as with most industries, ICTs are an increasingly essential part of contemporary healthcare. The healthcare industry has recently experienced substantive changes brought about by this new technology, with consequences for health providers, professionals, and patients. These include changes to the way healthcare is delivered through the emergence of new medical professions (e.g., genetic specialists), the devolution of minor medical treatments as nursing staff become more highly trained in new technology,

and less invasive treatments. Future medical ICT-related developments include the use of robotics and telemedicine, enhanced drug design through the use of computerization, and the trend towards electronic services (e.g., e-procurement) as a way to deliver healthcare services. Ongoing developments related to ICTs that will change the nature of healthcare in the next 20 years include emerging medical communication technologies and increasing application of evidence-based healthcare globalization. It is within a hospital context that we sought to examine examples of such industry changes.

The Studies

As previously noted, we focus on change in a large Australian metropolitan public hospital that was undergoing significant organizational re-engineering change both in its infrastructure as well as in the introduction of new technology. We used a sample from a series of 85 in-depth, unstructured interviews with a cross-section of healthcare employees. We examine how these employees described and identified with the change process. This change included staff restructuring; the introduction of innovative wards to trial changes that were planned to occur in the new hospital building; the devolution of finance from management to department level, with the introduction of new financial technologies (i.e., enterprise resource planning system: ERP); and the phasing in of new medical technologies (e.g., the picture archive communication system: PACS). These changes had implications for increasing the knowledge and authority levels of staff. Management of department finances by charge nurses rather than by higher management levels meant that senior nurses were now responsible for the budget of specific wards and units. Thus they would have access to information databases that were previously not available. In theory such changes should empower these nurses. Similarly, the PACS would provide easy access to patient x-rays across the

hospital, and lead to more efficient and effective communication between hospital departments. In fact improved and more fluid communication was a vision for the new hospital with more communication between units and wards than had previously existed. The participants in our study represented a cross-section of different levels and roles in the hospital, including executives (often with medical backgrounds), doctors, nurses, and allied health professionals (e.g., physiotherapists, psychologists, occupational therapists).

In our interviews, we were particularly interested in the ways in which employees' work units or professional identities influenced their understanding of the changes being implemented. To this end we focused on the health professional employees within the hospital as identified above. We investigated the relationship between changed organizational structure and employee perceptions about their role and identification in the organization. In particular, we examined the ways that new IT implementation altered the dynamics of the organization in terms of lines of communication (including communication effectiveness) and democratic structure.

Our research for this chapter was conducted at two stages between 1998 and 2000. At Time 1 (1998), we conducted 67 in-depth, unstructured interviews. From this data collection period, we selected 19 interviews for in-depth analysis. The sample included five executives, four doctors, six nurses, and four allied health professionals. During this time period, the hospital was at the beginning of undertaking many changes (e.g., downsizing and changes to work practices — including ICT implementations such as ERP and PACS). For Time 2 (2000), we conducted 28 in-depth unstructured interviews from which we have drawn a sample of 18 interviewees. During this time period, the implementation of changes initiated at Time 1 were quite advanced (e.g., hospital rebuilding, changes to work practices, and the ICT changes).

For this chapter, we analyzed the interviews of nine executives, one doctor, five nurses, and three allied health professionals. It is unfortunate that at Time 2 we were only able to interview one doctor. For each period of data collection, interview transcripts were analyzed with the use of the QSR qualitative software package called NVIVO. Trained coders identified common themes throughout the data. The interviews conducted at Times 1 and 2 were open and unstructured. The aim at Time 1 was for the interviewees to describe what they felt was good and bad about the changes that were to occur. At Time 2, the interviewees again described what they felt was good and bad about the changes that were occurring. They also described their perceptions concerning the implementation process.

EMPIRICAL EXAMINATION OF THE RELATIONSHIP BETWEEN E-DEMOCRACY, COMMUNICATION EFFECTIVENESS, AND SOCIAL IDENTITY IN A HOSPITAL

In the following results we examine the findings in relation to our two research questions. To this end, using hospital employees' descriptions of change, we summarize our results as they relate to the nature and place of e-democracy, HR practice, and more generally to employees' workplace identification during a period of change. We will include specific examples of hospital staff descriptions as they relate to both our research questions in order to illustrate their perceptions of the change process. We examine our findings across the two times to investigate whether there are distinct differences between the two phases as they relate to identification, e-democracy, and communication effectiveness.

Overview of Findings

With respect to RQ1, we examined the emergence of e-democracy by looking for perceived changes in health professionals' levels of reporting, their increased access to knowledge, and increased levels of authority. Results suggested that over the period of change, while there were modifications to nomenclature and associated rhetoric to describe the change process, control over employee behavior and management authority remained as it was prior to the changes in infrastructure and ICT implementations (e.g., PACS and ERP technology). Thus, despite the potential of the new systems to provide a greater availability of information, serving as a means of empowerment, no changes to the democratic structure occurred. Such systems, while offering employees the opportunity to manage their departmental accounting themselves or to rapidly access patient information in digital format, did not increase employee input or strengthen the knowledge economy. Rather, as shown at Times 1 and 2 respectively, failure to sufficiently train and support the staff led to frustration and reduced efficiency. Nurses and doctors tended to highlight their professional memberships in terms of patient care and did not embrace the ICT changes that would change their management of patients. Regardless of the implied benefits of change, substantive role, function, or empowerment adjustments did not occur.

Hospital executives never perceived their roles or positions to be threatened, and therefore perceived or represented most of the changes (technology and others) as a positive step for the hospital. Doctors were negative about the proposed changes and focused their attention on challenges or problems associated with the hospital's functioning and staff feelings towards the change process. Nurses also spoke negatively of the change in the belief that they were not involved in decisions

made by executives, and that the changes implemented would not enable promised efficiencies. Interestingly, many allied health workers were the most positive about overall change. However, it is interesting to note that one group of allied health workers who worked permanently in one unit rather than moving throughout the hospital (as do physiotherapists, dieticians, and speech therapists) was more affected by ICT changes and was not positive about the outcomes.

With respect to RQ2 — communication effectiveness — health professionals noted that maintaining their perceived levels of communication effectiveness prior to the change was problematic. Their concern stemmed from the fear that because of some ICT innovations (e.g., PACS), there was a reduction in face-to-face communication with other health professionals — a key aspect of communication for health careers. Thus in this organization maintaining effective communication did not align well with aspects of the proposed ICT change.

Clearly, employees who control aspects of their work and working conditions are going to be happier than employees who do not. With relation to our findings, hospital executives who possessed the macro picture of the change and monitored the changes were more positive than those staff members who were confronted with change implementation and new ICTs. Just as clearly, however, despite the potential of an organizational community through ICTs, participatory management and empowerment is not an inevitable component of technology change. Results relating to RQ1 and RQ2 suggested that despite goals of enhanced performance, there was no redistribution of authority. Thus, while the hospital executive perceived that there would be staff empowerment through better ICT systems, this expectation was not realized.

Specific Findings

Workgroup Identity

Social identity theory posits that when change occurs, some employees will react with perceptions of threat to their in-groups. As a consequence, they will act to protect their social group status. Thus in-group bias may increase, but the group may also seek to create a new group identity. If the group does strive to create a new group identity, then social identity theory would predict a new energized in-group identity, as was seen in the creation of the “black is beautiful” new identity in the 1960s for black Americans. When doctors and allied health professionals spoke about the technology change, they identified with two in-groups, the hospital (distal in-group) and their profession (proximal in-group). When discussing the change implementation in more general terms (e.g., patient care), however, both their proximal in-group and out-group salience were more evident, that is, they spoke more about work units and professional identity. Interestingly, nurses did not make their professional identity salient when talking about ICT changes — rather they identified with the more distal in-group of hospital. The reasons underlying this finding are unclear. In contrast, when nurses talked about other general change issues, their identity as a nurse and in particular their unit was salient. This point is taken up below,

Overall, executives identified as being part of the hospital first and foremost. Doctors talked about how medical professionals (the in-group) felt threatened by the change process that was being managed by the executive board (the out-group). For example, at Time 1, a senior doctor commented on a computerized patient file system that he thought would be phased in at a later stage of the change:

Is Organizational e-Democracy Inevitable?

“I’m not so sure it [the new patient file system] will be a success. I suspect they’re trying to save on clerical staff and turn us, all the clinicians, into mini-clerks.” (Participant A, Senior Doctor, Time 1)

This doctor was reporting his perceptions that executives were imposing new work roles on clinicians. The hospital’s non-executive medical employees understood that their roles had changed because of the new system’s information-sharing or task-related initiatives. They were compelled to adapt to these role changes as prescribed by the executive level. In the quote, the doctor stated that his in-group felt threatened as a group by the out-group of executives. The episode demonstrated the broader principle that rather than create a new identity, built on ICT-based participatory practice, the strength of traditionally instituted group affiliation and group status remained in place. A Level 3 nurse at Time 1 also spoke about the executive as the out-group and his perception of threat.

“They [the executives] all say we’re cutting back on jobs, but nobody knows what numbers and to who[m] they’re looking at or who[m] they’re keeping on. It’s that big question mark that everybody’s a little bit scared.” (Participant B, Registered Nurse, Time 1)

At Time 2 a different senior doctor commented on the role of the executive and their power in relation to the government control of the executive.

“Well they [the executives] neither have the given authority nor management skills. They might acquire the management skills if they were delegated the authority, but [health state government] is very much rule and structure, and authority comes from the top down. And any attempts to give individuals management authority are very rapidly squashed by reversal of their decisions

when they are not liked.” (Participant C, Senior Doctor, Time 2)

These comments still focused on the executive as the out-group, but this participant was also viewing the bigger picture of where the executive sat in terms of their power. The comments again validated the lack of change in respect to overall structure and democratic process during ICT change.

Effective Communication

Health professionals expressed concern about the effects of new technology on communication. For example, an allied health professional was of the opinion that the new PACS technology led to reduced communication between health professionals, leading to a loss of relationship with other clinicians and trainee staff. She commented that the medical staff [people] would lose the network connections that currently existed.

“...new residents may not be super-familiar with the techniques...but by seeing them face to face, you can say well, look, you know, how you can determine priorities...the personal [contact] will be lost. People won’t know who to contact when they really need something in a hurry. It’s just punching into a screen [ordering using a computer screen]...rather than coming down and seeing someone and say, ‘Look, what can you do about it?’” (Participant D, Allied Health Professional, Time 1)

A member of the executive level focused on this reduced level of communication at Time 2. However, she looked to the level of efficiency that would be achieved.

“We have images available throughout the organization at the same time, but [do] not have to run around with only one person having access at the

one time.” (Participant E, Member of Executive (and doctor), Time 2)

The sentiments regarding the PACS technology expressed by the allied health professional at Time 1 demonstrated the view of non-executive health professionals that communication still needed to take place at the physical rather than the electronic level. Face-to-face communication was viewed as an important feature of the intra-hospital networking system. A perceived lack of such communication brought about by the ICT change was therefore viewed as a threat to communication efficiencies. For example, PACS technology meant that x-ray requests could now be requested electronically. The old system had meant that forms were filled out and taken down to the x-ray division. As a result of the archaic manual system, however, interns got a better understanding of x-ray procedures and could ask for advice from the radiographers and radiologists because they interacted with them. As exemplified by the allied health professional quote at Time 1, ICT change thereby paradoxically allowed both a reduction in information connectivity alongside an increase in autonomy. But rather than enable the ease of information sharing, as e-democracy practices forecast, our results revealed an atrophy of inter-disciplinary contact and subsequently lower effective communication than previously existed.

In presenting much the same belief in the need for face-to-face communication, doctors suggested that PACS changes did not allow important information relayed by people to be received effectively. A doctor related the medical professional perspective of the PACS change:

“I think that probably medical staff prefer to communicate in person and by voice. That’s the way we spend our day talking to people...and we [doctors] don’t like communicating so much by paper, and yet administrative staff communicate

with us via paper which is seen as impersonal.” (Participant F, Doctor, Time 1)

This doctor implied that owing to the culture of medical staff (i.e., his in-group), important information was continuously lost, ignored, or overlooked as the systems changes started to take effect.

At Time 2 a nurse commented that the structure of the hospital would improve the communication. His comments supported the notion that health professionals recognize the need to communicate on a face-to-face basis. Interestingly, he also addressed the issue of work identities. While this comment does not directly address ICT, it highlighted the face-to-face culture that exists in the hospital context.

“Because of the way the building is laid out, it flows on, there is no defined point of one ward ending and the next ward starting. A lot of units overlap each other as well, so it’s going to force communication between them. That has, I mean, it’s positive in one aspect, but negative in that they don’t have their own identities as such.” (Participant G, Nurse, Time 2)

Change and Adjustment as an Outcome of Social Identity and Communication

Workgroup identity and communication work against each other or together to influence both intergroup and individual adjustment to change. In the hospital setting described in this chapter, the outcomes were such that the hospital remained a highly stratified institution. Both executive and non-executive groupings were able to develop justifications and explanations for the lack of participatory change and for existent structural arrangements. Specifically, although some executives expressed concern for lower level staff as they were experiencing a high workload and

Is Organizational e-Democracy Inevitable?

stress associated with the changes, they were simultaneously convinced that there were more positive issues brought about by the change than there were negative. The system and the processes it set in place did not bring about an amalgamation of different groups, nor did it equalize the way authority was transferred. Non-executive groups adopted a far more reactive outlook to the change, as one doctor states:

“There are some clinicians [who are] very computer literate and very keen on computers — both in work and recreation. Others like me are not the slightest bit interested, and that technology’s going to be forced on us, and I think it’s foolish. I mean we’re not trained and we shouldn’t be paid to put information into computers and operate computers. We are trained and should be paid to be skilled clinicians, not computers jockeys.” (Participant A, Senior Doctor, Time 1)

Such a reaction to changes suggested a difficulty in adapting to some kinds of changes. The view held by this doctor was that medical practitioners should not have to be involved in technology unless they wish it. This reaction also reflected a belief that a lot of time was being spent on change-related activities, without adequate compensation or proper attention being paid to those being forced to use the new system. In particular, doctors believed that executives were making decisions based on budgetary constraints rather than patient care. This opinion clearly emphasized the different group identity outlook (i.e., healthcare professionals versus healthcare managers). Doctors were resistant to technological changes, and perceived that their job was to treat patients and everything else was secondary. Nurses presented a resistance with ICT-enabled changes, based on similar reasoning, and focused on role changes and possible staff reduction.

The difference in individual and therefore intergroup adjustment was further typified by the executive group’s perception of how adjustment

to change should be managed. A senior executive commenting on the voluntary retrenchment of 40 workers as their jobs became obsolete observed that working with the staff who would be laid off made for a smooth transition.

“Most people were quite happy with the outcome. Instead of building it up into something that had to go to an Industrial Relations Commission type thing, we actually managed it at the shop floor level, with the local managers and us giving them some guidance instead of bringing all the heavies all the time.” (Participant H, Senior Member of Executive, Time 1)

The inference made by this very senior executive who was brought in to manage the change was that adaptation to changes is easily made if the correct internal procedures are followed. In his mind, this procedure included talking to staff at the shop floor level and discussing the need for redundancies for the hospital’s own good. This reaction emphasized the view that the hospital’s cumulative needs over-rode those of the group. For this executive, in his mind, he was reaffirming that communication about change is effective if it is well managed through staff involvement. There was, of course, some level of involvement at the non-executive level, with some employees happy to be part of an internal arrangement rather than take industrial action, generally. Nonetheless, the individual risk associated with ICT change overwhelmed the change rationalization offered by executives. In particular, as the change implementation progressed, nurses became increasingly agitated by the potential job losses expected to occur. This concern was linked to frustration about the level of care that would occur as an outcome of the resultant devolution of responsibility. Other nurse concerns related to training and patient care outcomes as a result of role changes.

“...like computers in the wards. They’re everybody’s headache at the present moment, because

the system is not set up to deal with everybody's needs and there are loop holes [problems] getting computers up and running, [and] getting staff [to] use it." (Participant I, Nurse, Time 1)

This observation reflected a common perception that while new technology resources were welcome, they were introduced for spurious budgetary reasons, rather than to improve patient care. Consequently, they initiated a series of problems at the ward level. A belief among some nurses was that the hospital was not prepared for ICT change outcomes. In short, they argued that the hospital's infrastructure was not equipped for the planned IT changes.

The executives were viewed by some medical staff as interested in the benefits to the hospital that arose from the introduction of new technology rather than health benefits. The most visible outcome of this divide was that the good change outcomes brought about by the new system were obscured, as a nurse observes:

"For me personally, it feels like [executives] are only interested in money, more so than patients. Now I don't know whether that's a nursing perspective or the way I've been taught or anything like that, but I feel that they seem to make decisions, but it's not in the interests of the patients. It's always in the interest of the dollar." (Participant J, Nurse, Time 1)

The disparity between identities across employee groups brought about by the different technology change focus led to the new technology being undermined. Whereas the new system offered healthcare professionals a plethora of sophisticated new functions, the widespread belief that the executive grouping was more interested in financial gains than patient care created a serious breach in faith. As a doctor and nurse noted, far from embracing new roles and participatory regimes, caregivers concentrated on the legitimacy of the new system:

"The computerized x-ray facility [is] foolish because I think we're putting in unproved systems. We're going to be the first [using PACS] almost and it's always a very silly thing to do." (Participant A, Senior Doctor, Time 1)

"It's annoying in a way because lots of...the things that seem to get the most money or the most attention are things that aren't for patient care. So even while using the technology for paperwork and things like that, the things that could make nurses' jobs easier, we're not really spending any money on that technology." (Participant K, Nurse, Time 1)

These comments highlighted the inference that patient safety was not improving with the innovations because the hospital is first and foremost interested in institutional outcomes. Thus, while technology advances can aid the patient, they were perceived to also put the patient at risk if the new technology is not supported at all levels of the hospital. Hospital executives may have cultivated a belief that some technology was installed for the sake of the hospital being seen as a state-of-the-art organization, without prioritizing the needs of the patients. Clearly patient outcomes in this context were not as focal as they might be. In this context, ICT change implied patient risk when executives imposed changes on the roles of health professional roles. Health professionals may resist the changes and so resist the ICT.

DEMOCRACY IS INEVITABLE ... BUT MAYBE NOT JUST YET

In this chapter, using the hospital case study, we advance the view that how employees perceive group memberships and their relations with other groups during the introduction of ICT change reinforces the regulatory, evaluative, and obligatory dimensions of organizational life over e-democracy practices. These findings should generalize

Is Organizational e-Democracy Inevitable?

to other hierarchically structured organizations, particularly those employing a range of professional groups.

Using a social identity framework, we reiterate that organizations suffer from problems of intergroup relations. Unlike other research and commentary, however, we assert that group identity and status differences simultaneously impede and enable e-democracy. For instance, whereas Semler (1989) suggests that the participatory features of organizational e-democracy are “just hot air” (1989, p. 3) that needs to be minimized, our results reveal that the features of democracy are embedded in the organization under review, but may not be able to penetrate traditional bases of power and influence. In other words, the organization chooses to appropriate parts of the democracy features of a new technology that seem to best fit its preexisting structure or institutional arrangement. IT-enabled changes therefore paradoxically reinforce normative institutional practices (after Scott, 2001). In response to our focal research question that examines the inevitability of e-democracy, Slater and Bennis (1964) were correct in asserting the place of and importance of democracy. Our results suggest, however, that while aspects of e-democracy are inevitable (i.e., symbolically more information is available to staff), social identity provides a barrier that reduces the extent to which e-democracy will occur.

Our findings have important implications for HR practitioners. Our results show that ICT brings changes to the ways in which employees focus on their roles and identities. In particular, we argue that group identification is a key part of the successful adoption of e-democracy change. At the two phases of changes described here, when ICT changes were highlighted, findings suggest that compared to doctors and allied health professionals, higher order identities (e.g., hospital) are more salient for nurses. This result may reflect that fact that the nurses were less involved with the technology changes than the doctors

and allied professionals at these two phases of change. For example, PACS was highly relevant for some allied health professionals and doctors. Thus, groups who find themselves immersed in the new system, and affected by it, do present their proximal roles as salient. By contrast, when change implementation and patient care was the focal topic, all health professionals identified with their professional in-group.

Individual empowerment through PACS was not translated upward into group changes in the organizational hierarchy. As noted above, our findings focus on a healthcare industry, but their relevance to other organizations with hierarchical structures is self-evident. This finding, concerning employee identities, also raises a second implication that HR practitioners need to bear in mind during ICT change. That is, they need to be aware of the salient identities within organizations and not simply focus on the formal roles and functions that are outlined in the organizational charter. Our findings reveal that, at least for some groups, higher order identities during IT implementation seem to be more salient. We would have predicted that lower order level identities would be more salient in the ICT context, but this is not so. Thus the management of ICT changes is a complex phenomenon that may differ from the implementation of other types of changes. Specifically, rhetoric of empowerment and authority voiced by senior management do not equate to high levels of e-democracy with staff who historically did not have such responsibilities — nor is it sought by these staff. This observation highlights that, at least in our context, the overall good of the organization (the hospital) and professional roles are paramount. This finding goes some way to explaining why role relations remain intact during ICT implementation, regardless of the collaborative practices organizations adopt during new information technology implementations.

A third implication that HR practitioners need to focus on is that employee identity can act as a barrier to the uptake of change. Resistance to

change is not a new phenomenon, but in this chapter we have begun unpicking the elements of that resistance. If ICT brings with it significant changes to a professional's job description and duties, HR must acknowledge this change and address the changes directly with the professionals involved. This last point relates closely to the following two HR implications that arise from our findings.

HR practitioners must recognize the importance of ensuring the participation of key groups in the planning and implementation of changes. They must also recognize the importance of effective and relevant training procedures in the newly acquired technology. The former implication suggests that HR practitioners should put in place an appropriate program of focus groups and workshops for employees which will serve to encourage key personnel to engage in and champion the changes. From such programs, these employees will gain an in-depth understanding of the rationale for each aspect of ICT change. With their increased knowledge and understanding of the change, they will then be able to impart their knowledge to other employees affected by the change. Specifically, the rationale that underlies each ICT introduction needs to be openly explained to the staff. In turn, staff should be allowed to provide input as to their perceptions of the value of the implementation. HR practitioners need to be aware of the critical importance of this level of dialogue throughout all phases of change.

The latter implication, regarding training, relates to our results that reveal that despite the potential sophistication of the new systems, such technology requires effective training procedures to be put in place. Staff training programs need to be timed so that they integrate smoothly with the introduction of new technology. Training must be viewed by the change agents as another important aspect of the change and implemented at the appropriate time in the change program, with back-up and training assistance available as needed. Clearly then, HR managers need to

address resource and training issues and, in the case of some professions, create an environment where the professional will want to engage in the technology. While there are some professionals who will seek to resist new technology, it is important that education and training be aligned with technology preparation and a clear outline of the benefits to the organization. Again, active dialogue at all stages of change is critical.

A final implication for HR is the need to recognize the communication culture of the organization. If the organization is one that relies on face-to-face and one-on-one communication, HR practitioners must not only address the impact of the new technology, but must monitor how employees manage the change in their traditional channels of communication. Not to recognize the huge culture change that new communication media bring to traditional organizations is to jeopardize the efficient functioning of the organization and risk increases in miscommunication and disharmony.

We have highlighted the unintended consequences of new technology implementation. By illustrating the problems with assuming the inevitability of e-democracy, we indicate that integrating HR practices with the task of designing information systems is much more than simply specifying particular equipment parameters. Rather the process is about designing, inscribing, and configuring the system both for users and recipients alike — in this case, health professionals and their patients. This process needs to include ongoing negotiation as the system evolves. We would suggest that patients or other clients may not benefit from new ICTs, at least in the short term and in the current climate of HR-managed change. This disadvantage to patients/clients needs to be addressed by HR practitioners through the suggestions above. Our SIT framework highlights the need for attention on human resource issues during the implementation of new information technology. The impact of information technology improvements on the workforce needs careful

Is Organizational e-Democracy Inevitable?

evaluation beyond a simple assessment of technology outcomes or organizational benefits.

CONCLUSIONS

In this chapter, we illustrate how social identity processes drive organizational e-democracy change outcomes. We emphasize how an organization's communication processes and its levels of effectiveness may change with ICT implementation. Our findings suggest that IT implementations are sometimes installed at the expense of other systems, which may be more directly beneficial to the patient. To generalize to other organizations, we ask: Are organizations installing IT for IT's sake without due consideration of the needs? Paradoxically this approach to IT and, in particular, ICT change may disadvantage the original aims of the organization.

ICT changes do not necessarily equate to improved communication between employees or workgroups. Our findings highlight that as new ICT systems are put in place, communication channels and dynamics alter. This alteration may not align with staff empowerment or increased communication effectiveness. HR practitioners need to examine current communication procedures and involve employees in the potential changes to communication that the new ICT brings. With the introduction of new technology, communication networks within organizations such as hospitals are often likely to break down. If the organizational culture has a tradition of face-to-face communication (as do hospitals), HR practitioners need to be aware that ICT implementation will have a huge impact on practice and on culture. Open discussion of disadvantages in a new system can only be acknowledged and constructively dealt with if there is genuine staff input and dialogue. Our findings suggest that HR managers need to be cognizant of the fact that effective communication may be compromised. Further they need to ensure that the change pro-

gram is communicated and managed effectively. In this way, further miscommunication issues may be reduced or even avoided.

Our current findings suggest that e-democracy is not enhanced through IT change. Rather, we have found that the contrary is true. HR must respond to the frustration expressed by professionals concerning the actual changes and the implementation process. To address these concerns effectively, HR must understand both the formal and informal organizational charter. Without due consideration to the opinions of professionals throughout the change process, our findings suggest resistance.

Chapter 6.23

The Role of Information and Communication Technology in Managing Cultural Diversity in the Modern Workforce: Challenges and Issues

Indrawati Nataatmadja

University of Technology, Australia

Laurel Evelyn Dyson

University of Technology, Australia

ABSTRACT

This chapter demonstrates how managers can use information and communication technology (ICT) more effectively in culturally diverse workforces. Basing our analysis on the cultural dimensions of Hofstede and Hall, we compare a range of ICTs and provide a chart summarizing their strengths and weaknesses. In addition, a framework for developing ICT is proposed, and an example of its application to a global organization is presented. The study shows that none of the existing ICT tools is perfect in all situations and all cultural contexts. Therefore, managers need to provide a variety of ICTs to their employees, and developers should build flexibility into their ICT designs.

INTRODUCTION

With cultural diversity in the modern workforce a reality today, there is a challenge for managers to capitalize effectively on this diversity in order to harness the benefits while avoiding potential problems. To optimize the positive outcomes, information and communication technology (ICT) is an essential tool. Using appropriate technologies is shown to break down cultural barriers and to promote understanding and knowledge sharing among employees of different language backgrounds and, hence, lead to successful collaboration.

First, we will discuss culture and its dimensions according to some of the principal cultural

theorists of today: Hofstede, the GLOBE group, Trompenaars, and Hall. We also will highlight the importance of language in modern-day management practices. The second section will analyze the relationship among management, cultural diversity, and ICT, and how managers can improve employee effectiveness, employee empowerment, and decision making, and also facilitate knowledge management within the organization. Third, a range of information and communication technologies will be compared and contrasted, including e-mail, discussion forums, chat rooms, intranet, groupware, teleconferencing, videoconferencing, and mobile technologies. These technologies will be evaluated in the context of the cultural dimensions outlined in the first section to provide a guideline for managers to choose the best-fit ICT for their needs. Finally, we will provide a framework to develop new ICT systems for a multicultural workplace.

In summary, this chapter's objective is to raise the awareness of managers, administrators, information systems developers, and other knowledge workers about the role of ICT in managing cultural diversity in the workforce. Valuing diversity by welcoming, recognizing, and cultivating differences among people so that they can develop their unique talents ultimately will assist in the creation of effective and competitive organizations.

BACKGROUND: CULTURAL DIMENSIONS

Culture is the set of key values, norms, and beliefs that members of a society or an organization share (Daft, 2000). Hofstede and Hofstede (2005) state that these values can be described in terms of dimensions, a dimension being defined as "an aspect of culture which can be measured relative to other cultures" (p. 23).

Geert Hofstede is one of the most respected cultural theorists. His famous cultural dimensions theory was based on a six-year survey and analysis

of hundreds of IBM employees from 53 countries (Marcus & Gould, 2000). These dimensions have been adopted widely and have been applied to many research studies (Hofstede, 2001):

1. **Power distance:** The degree to which a society accepts inequality in power distribution. High-power distance societies accept that there is an unequal distribution of power. In a low-power distance society, equality and opportunities for all are expected. It has flatter hierarchies, and it is easier for people to move upward in society.
2. **Uncertainty avoidance:** The degree to which the society accepts uncertainty and ambiguity. High uncertainty avoidance societies create many rules, regulations, and procedures to avoid uncertainty and ambiguity. Low uncertainty avoidance societies are less concerned about uncertainty and ambiguity. They are more flexible and more tolerant to different opinions and changes.
3. **Individualism vs. collectivism:** The degree to which the society accepts the individual's rights to look after his or her needs first, in contrast to collectivism in which individuals have to adhere to group needs first. High individualism societies will place individual needs and rights above collective needs and rights.
4. **Masculinity vs. femininity:** The degree to which the society believes in masculine ideals of competition and achievement, in contrast to feminism, which emphasizes relationships, compromise, and quality of life.
5. **Long-term vs. short-term orientation:** The degree to which society prefers working in sequence and its tolerance of interruption. Long-term orientation societies value perseverance, hard work, long-term tradition, and commitment. Short-term orientation societies are more willing to embrace changes and desire immediate results.

More recent research on cultural dimensions conducted by the GLOBE (Global Leadership and Organizational Behaviour Effectiveness) project team identified nine dimensions, six of which originated in Hofstede's work (House, Hanges, Javidian, Dorfman, & Gupta, 2004). The approach only appeared in 2004, and hence, very few studies have been carried out to verify the validity of the model or to apply it to evaluating ICT from a cultural perspective.

Another well-known, cross-cultural theorist is Fons Trompenaars (Deresky, 2006; Trompenaars & Hampden-Turner, 1998). His research was spread over 10 years, representing 47 national cultures. Only a limited number of researchers has adopted Trompenaars' framework when evaluating ICT, and often in conjunction with Hofstede (Gould, Zakaria, & Yusof, 2000).

Edward T. Hall is another respected anthropologist and cross-cultural researcher. One of his important contributions is the concept of communication context. Hall (1976) stated that in low-context societies, communication is direct and explicit. In high-context societies, people have to be aware of verbal and nonverbal cues that carry implicit meaning. In addition, they usually prefer to know the history of relationships and the backgrounds of the communicators. For example, more significance is attached to information coming from a person who has high status or who is respected for his or her knowledge or expertise in the field. Hall's theory has received increasing attention in recent years as more people focus on communication issues with ICT.

Beyond Hall's concept of communication context, there are also other aspects of language that need to be considered in multicultural work environments. Languages have many different parameters, including vocabulary, grammar, word order, intonation, and idiom. For example, in English, intonation applies to whole sentences; however, in Chinese, intonation applies to single words (Manning, 2004). Hence, the same Chinese word with a different intonation can lead to different meanings and different interpretations. These

differences can be a major source of misunderstandings and a source of poor communication or collaboration.

Some researchers would question these theories of national culture as stereotyping and forcing people into fixed cultural patterns (Myers & Tan, 2002). Nevertheless, Hofstede notes that one can identify statistical trends and tendencies despite the fact that not every individual complies with the overall cultural patterns of his or her country (Marcus & Gould, 2000). Furthermore, Trompenaars argues that even though within each culture there is a spread of values and assumptions, this spread forms a pattern around the average for that cultural group (Trompenaars & Hampden-Turner, 1998). Some researchers also have questioned the relevancy of cultural dimensions in the era of the global use of ICT. However, Geert and Gert Hofstede argued that "the software of the machine may be globalised, but the software of the minds that use them is not" (Hofstede & Hofstede, 2005, p. 330).

In this chapter, in order to simplify our discussion in what is obviously a very complex area, we will focus on only some of the cultural dimensions previously outlined. Since most researchers in culture and ICT have utilized Hofstede's dimensions, these will form the main basis of our analysis rather than the theories of Trompenaars or the GLOBE Project. However, because of the fundamental importance of communication in ICT and in managing cultural diversity in the workplace, we also will rely on Hall's theory of communication context in addition to other language issues. These dimensions of culture are summarized in Figure 1.

MANAGEMENT, CULTURAL DIVERSITY, AND ICT

The challenge for management is how to capitalize on cultural diversity. Daft (2000) stated that ICT can provide a better relationship among

Figure 1. Dimensions of culture

managers, employees, and their environments. By being aware of the various cultural dimensions and taking into account language differences when implementing and using ICT, managers can achieve the following:

1. Improved employee effectiveness
2. Empowered employees
3. Organizational learning or knowledge management

Improved Employee Effectiveness

Employees can access information they need and also can share information or insights with each other more easily by using ICT. It can provide information about customers, markets, and competitors through databases, news bulletins, and the Internet. Since they have access to more information, managers are able to delegate more challenging work to employees. Consequently, this will lead to better employee effectiveness. For example, salespeople can research pricing over the network and then use this to close deals by offering more competitive prices to customers (Daft, 2000).

Empowered Employees and Decision Making

ICT can contribute to power sharing and break down power distance by providing information to lower-level employees who otherwise will not get access to it. ICT has resulted in the restructuring of many organizations since the introduction of personal computers in the 1980s; there has been a trend toward a flattening of the organization with the elimination of many middle management positions (Oz, 2002). Employees have been given responsibility to make decisions that previously were made by their supervisors. They have been provided with decision-making tools, such as spreadsheets, decision support systems, and business intelligence tools. ICT communications tools such as e-mail also allow every employee to communicate with every other employee, including top managers. This has broadened the decision-making base of the organization and resulted in people from many different cultural backgrounds contributing and having their say. Without the participation of all members, the goals of capturing the best that diversity brings will not be achieved (Joplin & Daus, 1997).

Knowledge Management

Two components have emerged as of prime importance in knowledge management: people as central to the processes of knowledge creation, sharing, and application; and ICT as a vehicle by which the knowledge processes can work (Daft, 2000). Cross-cultural differences will affect how knowledge flows through the organization. A country that is high in power distance tends to have top-down knowledge flows, whereas a country with lower power distance will accept knowledge flows from bottom-up, top-down, and laterally. Furthermore, knowledge flows *between* cross-cultural groups is more likely to happen along formal, business-related issues. However in informal interactions, most knowledge flow exists *within* cultural groups (Ford & Chan, 2003). To encourage better knowledge flows, management should encourage staff to use the intranet and e-mail for formal and informal news by establishing an open communication strategy, either through incentives or policy. For example, in low power distance cultures like the U.S. and the UK, staff was found to be ready to share knowledge when senior management encouraged them to do so (Forstenlechner, 2005).

Further research by Ford and Chan (2003) revealed that knowledge sharing is affected primarily by language barriers. While they found that some knowledge was transferred between the two groups under study, either directly from knowledge holder to recipient or through a translator, a lot of knowledge was lost due to the inability to express the knowledge in the second language or due to translation. ICT can improve this situation by providing asynchronous technologies like discussion forums that allow employees more time to study information before replying by deploying intranets, groupware tools, and collaborative systems that disseminate information efficiently to staff, and by providing translation software.

CULTURAL DIVERSITY AND WORKPLACE COMMUNICATION USING ICT

Management of cultural diversity involves communication first and foremost. Culture will affect how individuals communicate with others, because culturally learned norms, rules, and beliefs affect the way people communicate as well as predict the effect of their communication behavior on others. Dube and Pare (2001) found that the communication barrier between participants from different cultural and language backgrounds becomes more severe if they communicate using ICT, leading to misunderstandings and loss of information. This occurs because of the lack of contextual clues available in most technologically mediated communication. In addition, the communication style of the dominant culture usually will take over and, consequently, deter people from different cultures participating (Zorn, 2005). However, Massey, Hung, Montoya-Weiss, and Ramesh (2001) proposed that certain ICTs may enhance the ability of some individuals to communicate, depending on the particular communication style inherent in their culture.

Several attributes of ICTs must be considered when assessing their suitability for fostering communication in culturally diverse workplaces. Synchronicity vs. asynchronicity is a simple way of classifying computer-mediated communication. Synchronous ICT tools are those that allow people to talk to each other and to receive quick replies in the same session, similar to a face-to-face conversation. Asynchronous tools usually involve a delay in response, since participants are not necessarily using the tool at the same time and normally do not have any way of knowing when others will be online. Massey et al. (2001) provide a more refined framework of characteristics with which to describe and evaluate ICT tools:

The Role of Information and Communication Technology

- **Richness:** The capacity to convey nonverbal as well as verbal cues and, thus, to facilitate shared meaning.
- **Social presence:** The degree to which individuals feel close. The richer the ICT, the more social presence it provides.
- **Interactivity:** The rapidity of feedback provided by the medium, thus enhancing interactivity among participants.
- **Rehearsability:** The extent to which messages can be fine tuned before sending or posting.

Table 1. ICTs and their strengths and weaknesses in communication

ICT	Strengths	Weaknesses	Cultural Dimensions Fit
<i>Email</i>	<ul style="list-style-type: none"> • Reprocessability provided by record of communication 	<ul style="list-style-type: none"> • Lack of richness and social presence since no non-verbal cues 	<p><i>Good for:</i></p> <ul style="list-style-type: none"> • Uncertainty avoidance • Individualism <p><i>Poor for:</i></p> <ul style="list-style-type: none"> • High context cultures
<i>Discussion Forums</i>	<ul style="list-style-type: none"> • Rehearsability as postings can be edited • Reprocessability provided by record of discussion and sometimes by search facilities 	<ul style="list-style-type: none"> • Low interactivity because of asynchronicity • Lack of richness and social presence since no non-verbal cues 	<p><i>Good for:</i></p> <ul style="list-style-type: none"> • People with poor oral language skills • Uncertainty avoidance • Long-term orientation • Individualism <p><i>Poor for:</i></p> <ul style="list-style-type: none"> • High context cultures
<i>Chat Rooms</i>	<ul style="list-style-type: none"> • High interactivity provided by synchronicity 	<ul style="list-style-type: none"> • Speed of interaction challenging and no rehearsability 	<p><i>Good for:</i></p> <ul style="list-style-type: none"> • Short-term orientation • Collectivist cultures <p><i>Poor for:</i></p> <ul style="list-style-type: none"> • People with poor written language skills
<i>Intranet</i>	<ul style="list-style-type: none"> • Quick dissemination of information across cultures 		<p><i>Good for:</i></p> <ul style="list-style-type: none"> • People with poor oral language skills • Collectivist cultures
<i>Group-ware</i>	<ul style="list-style-type: none"> • Flexibility provided by range of tools • Relationship building across cultures 		<p><i>Good for:</i></p> <ul style="list-style-type: none"> • Collectivist cultures
<i>Tele-conf.</i>	<ul style="list-style-type: none"> • Some added richness provided by more verbal cues • High interactivity and feedback 	<ul style="list-style-type: none"> • Lack of rehearsability and reprocessability 	<p><i>Good for:</i></p> <ul style="list-style-type: none"> • Collectivist cultures <p><i>Poor for:</i></p> <ul style="list-style-type: none"> • People with poor oral language skills
<i>Video-conf.</i>	<ul style="list-style-type: none"> • High level of richness and social presence • High interactivity and feedback 	<ul style="list-style-type: none"> • Lack of rehearsability and reprocessability 	<p><i>Good for:</i></p> <ul style="list-style-type: none"> • High context cultures • Collectivist cultures
<i>Mobile Tech.</i>	<ul style="list-style-type: none"> • High interactivity • Flexibility provided by range of functions 	<ul style="list-style-type: none"> • Lack of rehearsability and reprocessability 	<p><i>Good for:</i></p> <ul style="list-style-type: none"> • Short-term orientation <p><i>Poor for:</i></p> <ul style="list-style-type: none"> • High power distance cultures

- **Reprocessability:** The degree to which individuals can re-examine messages sent to them.
- **Flexibility** (what Massey et al. call “symbolic variety”): The number of different modes of communication or choices provided by any communication tool.

Using this framework, Massey et al. (2001) found that three cultural dimensions could assist in understanding cross-cultural communication differences:

- **Individualism-collectivism:** People from a collectivist culture may prefer synchronous technology (chat rooms, teleconferencing, and videoconferencing), because it allows real-time interaction and makes them feel close to each other, leading to a collective feeling and social presence. In an individualist culture, people may be more comfortable doing the work individually, in parallel to others, and can adjust better to asynchronous technology (e-mail, discussion forums, etc.).
- **Uncertainty avoidance:** Massey et al. (2001) believed that synchronous technology is generally a better fit for reducing task ambiguity because of the greater possibilities of interactivity and immediate feedback and, therefore, may be preferred by people from high uncertainty avoidance cultures.
- **High and low context:** The richer the technology, the better it will be for high-context people because it allows for a feeling of social presence and provides nonverbal as well as verbal cues.

Different communication tools thus have different benefits and may not have universal acceptance with all employees. As a result, the organization should be flexible, provide a range of tools, and allow employees to choose whatever mode of communication with which they feel

most comfortable. In the following discussion, we examine modern ICTs and outline their potential benefits in the context of a culturally diverse workforce. Table 1 provides a summary of the main tools and their advantages and disadvantages.

E-Mail

Some studies have shown that e-mail as a primary mode of communication can help to avoid culture clashes and can overcome more subtle language barriers because many people from a non-English speaking background can write and read English better than speak it, particularly if they have learned English in a formal classroom setting. Another advantage of using e-mail is that both sides will have a record of the communication, which will help to reduce misunderstandings (Jana, 2000); that is, there is a high degree of reprocessability provided by e-mail message banks.

On the other hand, Pauleen and Yoong (2001) say that in high-context cultures, people will rely heavily on nonverbal gestures and on an understanding of the surrounding context, which may include the backgrounds of the people involved, previous decisions, and the history of the relationship. A degree of personal relationship is important. The nonverbal cues used to judge people's true feelings are not available when communicating through a solely text-based channel such as e-mail. It is not a rich medium. However, people from low-context cultures prefer more objective and fact-based information and so have no problem with e-mail. Therefore, when working across cultures, because of conflicting communication styles, e-mail could be an added barrier.

Discussion Forums

Discussion forums provide another means of written communication that may favor people who have studied English formally and, therefore, are more confident about writing than speaking

the language. In one notable respect, forums are superior to e-mail in that people generally have more time to think before posting something, and most forums allow one to edit the posting if mistakes have been made (unlike e-mail in which there is no getting the message back once it has been sent). In other words, discussion forums have a high degree of rehearsability.

In forums, a reply has to be connected to someone else's posting according to a topic (thread), and so, discussions are usually ordered and more formal than many e-mails. Postings can be seen much longer, sometimes even for years, and sometimes can be searched via a search engine, thus providing a useful bank of information (Zorn, 2005). Thus, they have a high degree of reprocessability, allowing individuals to view and consider messages carefully. People from non-English speaking backgrounds may find it easier to follow the more structured discussion, appreciate the extra time that they can spend reading discussion threads, and even feel comfortable with the passive role of reading others' postings without being obliged to post themselves.

The main disadvantages of discussion forums are that there is limited interactivity, because the person must wait for an unspecified period before receiving a reply due to its asynchronous nature, and, as with e-mail, there is limited richness and social presence, which may affect people from high-context cultures.

Chat Rooms

The informal structure of chat, its synchronicity, and ease of use make it a good tool for building relationships among the workforce. Like other synchronous communication tools, it has a high level of interactivity. MSN messenger is one of the free chat software programs that is used widely to share information and to attach documents. However, Zorn (2005) states that in order to participate actively in electronic chat, one has to be able to type quickly and write short, quick

sentences. In fact, there is a special chat language (<http://abbreviations.virtualsplat.com/category/chat-abbreviation.asp>). In chat rooms, people have to post quickly, because they do not want other chatters posting before they have time to respond. It will make them feel like interrupting, and they might lose the thread of the conversation because it has already moved on to another topic. This puts people who don't know the terms used or who are from other language backgrounds at a distinct disadvantage.

Intranet

Many organizations nowadays have found that a company intranet allows for quick dissemination of information among all employees, such as the posting of minutes, action lists, and news. Jana (2000) reports a successful example of a company, Quadstone, that uses an intranet to link its employees from many nationalities across two continents, which has eliminated the problem of different accents and poor understanding of spoken English. With increasing globalization and more and more companies pursuing a geographically distributed organizational model, intranets are an ideal communication tool.

Groupware

For sharing information to a mass audience, messaging and groupware tools such as Lotus Notes may be an appropriate choice (Topi, 2004). Groupware tools such as Notes enable staff to share documents within the organization and externally via the Web; engage in threaded discussions via discussion forums; send messages over e-mail, receive notification and reminders and, in short, communicate and share resources with fellow workers via its intranet capabilities (Hawryszkiewicz, 2003). They can promote opportunities for informal, spontaneous exchanges, which, in turn, can foster more productive work collaborations than are possible without this per-

sonal foundation (Pauleen & Yoong, 2001). This relationship building is particularly important in culturally diverse workplaces. Groupware has the advantage that it is very flexible and provides a range of communication tools from which employees from different cultural backgrounds and with different preferences can select the communication channel that is appropriate for them.

Teleconferencing

Unlike most of the written communication tools already described, teleconferencing provides a high degree of interactivity and allows people to convey emotion relatively easily. However, it is very difficult for participants to actively participate if they are not fluent in the language used in the teleconference. They also will have trouble entering the conversation without seeing the other people and being able to pick up visual cues, and often misinterpretations will occur (Dube & Pare, 2001). It also has the problems of low rehearsability and low reprocessability, both of which give people from other language backgrounds a further disadvantage.

Videoconferencing

Videoconferencing is a good tool for culturally diverse workplaces, because it enables team members to see facial expressions, gestures, and many other visual cues, and so establish a social presence. Pauleen and Yoong (2001) found that “eyeing” people was important in relationship building and that videoconferencing generally enhanced social relationships by allowing people to “put a face to the name” (p. 210). It is better than teleconferencing, which is difficult for people from other language backgrounds. However, Dustdar and Hofstede (1999) found that there were fewer contextual clues in videoconferencing than in face-to-face meetings and proposed that the design of videoconferencing needs to support social protocols and be culturally aware. Further-

more, while teleconferencing and, particularly, videoconferencing are richer communication media than other ICTs, they require a high level of commitment, flexibility, and discipline from the participants (Dube & Pare, 2001); for example, working outside normal business hours to accommodate time zone differences, care in watching for turn-taking cues, and a commitment to including all participants in the conversation.

Mobile Technologies

Mobile technologies, such as cell phones, laptop computers, personal digital assistants (PDAs), two-way pagers, and the blackberry (an e-mail device), have been adopted widely in many organizations in which employees commonly work off-site, roam from one location to another, or need to be on call. They have been responsible for extending a social presence into areas where, before wireless networks, it could not exist before. Generally, they provide a high level of interactivity (either through phone calls or text messages) and an increasing flexibility, as the range of available functions increases every year. Rehearsability and reprocessability, though, are low.

A number of studies have shown that cultural differences affect how at least some of these technologies are used. For example, in the U.S., the number of mobile phone users is high, and there is a preference for graphic mobile technologies such as Palm.Net and Pocket Internet Explorer to send e-mail messages, in preference to text messaging (Urbaczewski, Wells, Sarker, & Koivisto, 2002).

Text messaging has been shown to vary greatly depending on power distance. Sarker and Wells (2003) found that in high-power distance cultures such as Korea, text messaging to supervisors was viewed as highly offensive, whereas in low-power distance cultures such as Norway, text messaging was not offensive, although sometimes it was considered inappropriate in more formal communications due to its reliance on abbreviations and slang.

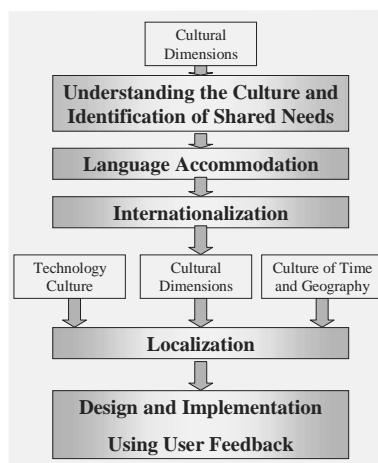

Cultural variables have a large influence on preferred mobile device interface features. One international study (Choi, Lee, Kim, & Jeon, 2005) showed that Korean and Japanese participants displayed a high degree of uncertainty avoidance in their preference for clear, concrete menu labeling and a large amount of secondary information about the contents available to advise their choice of options. The Koreans also were found to be more collectivist, preferring popularity rankings so that they could choose content that many other people had used. The Finnish participants, on the other hand, were characterized as risk takers who disliked secondary information on menu items, instead being happy to click on options and see for themselves what was available. They liked a low-context, simple design with fewer icons and colors. In order for mobile technology to be effective in fostering communication in the workplace, it needs to be designed to take cultural preferences such as these into account.

CHALLENGES IN DEVELOPING ICT FOR THE CULTURALLY DIVERSE WORKFORCE

The design of ICT with a focus on cultural diversity is important if organizations are to optimize the use of ICT in management, knowledge management, and communication. Most system development in the past has been aimed at culturally homogenous groups, but with increasing globalization, this is no longer acceptable. There has been much research into the challenge of developing ICT for culturally diverse user groups, and this work is ongoing. A framework for cross-cultural ICT development is given in Figure 2.

1. **Understanding the culture:** The first step in ICT development is to understand the target cultures (Nakakoji, 1996). The cultural dimensions of Hofstede and Hall provide a systematic basis to begin the description and segmentation of the user group's cultures.

Figure 2. Framework for developing culturally diverse ICT

If different cultural groups are to use the same system, then this stage also should include the identification of any shared needs, interests, and goals in addition to communication strategies among groups (Bourges-Waldegg, Lafreniere, Tscheligi, Boy, & Prates, 2001).

2. **Language accommodation:** Since language is the most obvious difference between cultural groups, language translation, or at least language accommodation, is the next step. Where there is one dominant language, system designers might decide that the cost of providing systems in multiple languages is not feasible. However, providing features to translate and edit the language and allowing users to check their grammar and spelling are necessary (Dube & Pare, 2001). In addition, ICT designers should try to develop cues such as context-adding smiley faces or emoticons in e-mail and chat rooms in order to avoid misunderstandings and provide social presence (Churchill & Bly, 2000; Zorn, 2005).

The most important issue for ICT communication tools is in determining the structures of communication; for example, communication procedures, turn taking, methods of interrupting, and other social protocols. Different cultures have different social etiquette and different levels of power distance; transgressions against these can affect the outcome of communication severely (Churchill & Bly, 2000). The developer, therefore, must consider different cultural communication styles and strive to keep the environment tailorable in order to allow people to develop their own social environments. Design should focus on communications and conversations, not on technology (Churchill & Bly, 2000; Zorn, 2005).

3. **Internationalization:** This step ensures that the design is culture-independent, which is

particularly important when organizations are doing business globally on the Web and when it is impossible to predict exactly who the users will be. This is also a useful preliminary step in tailoring systems to different known cultural groups. Having identified culturally specific elements of the system, as many of these are eliminated as possible. A good example given by Nakakoji (1996) is the method of dealing efficiently with different languages on screen; rather than embed text into figures, it is stored separately. Figures then can be displayed and the text added in at the time of display in the language appropriate to the user. This avoids the necessity of redrawing figures in each language and results in economies of storage, since the number of figures is reduced to a minimum.

A variant on internationalization is universal usability. Some designers believe that universal access to ICT is only possible if systems are designed with all possible users in mind (Shneiderman, 2000). They have developed the Universal Design Principles, which include equity, flexibility, simple and intuitive design, legibility of information, error tolerance, low physical effort, and appropriateness to human physical and environmental limitations (Burgstahler, n.d.)

4. **Localization:** Normally, following internationalization, the system is localized for each user group's culture by including elements of local content and style. The design should accommodate different languages, date and number formats, color and graphic representations, appropriate icons, and an appropriate direction of flow (left to right, or right to left), according to the culture (Nakakoji, 1996). Perhaps more important than superficial appearance is the organization and representation of information structures to represent the users' knowledge framework; explicit representation of the information architecture of the system

The Role of Information and Communication Technology

is also a good idea in order to enhance user understanding (Walton, Marsden, & Vukovic', 2002).

Localization also should accommodate cultural dimensions, since these are also critical for user acceptance. For example, one comparison of Malaysian and U.S. Web sites showed that the Malaysian Web sites reflected the high power distance requirements of their users and a strong emphasis

on collective and social goals, whereas the American Web sites for similar products displayed a much lower power distance, a greater stress on individualism, and a more task-oriented approach (Gould et al., 2000). Research into ICT design for Arabic users has proposed that collectivism and high context communication is important in addition to privacy and security issues (Zakaria & Stanton, 2003).

Table 2. Example of applying the development framework

Development Phase		USA	UK	Indonesia
Understanding the Culture	Identify Cultural Dimensions (ITIM, 2003; Hall, 1976)	<ul style="list-style-type: none"> • Low power distance • High individualism • Short-term orientation • Medium to high masculinity • Low context communication 	<ul style="list-style-type: none"> • Low uncertainty avoidance 	<ul style="list-style-type: none"> • High power distance • Collectivist • Medium-low masculinity • Medium uncertainty avoidance • Long-term orientation • High context
	Identify Shared Needs	Company goals and organizational "culture"		
Language	Language	English		English + Indonesian
	Etiquette	Provide options for turn-taking and other local communication protocols		
Int.	Internalization	Common graphics, layout, tools, functions		
Localization	Local Content and Style	e.g., US spelling; mm/dd/yy date format	e.g., UK spelling; dd/mm/yy date format	e.g., US spelling of English; dd/mm/yy date format; no graphic sexual depiction
	Apply Cultural Dimensions	For example: <ul style="list-style-type: none"> • Low power distance: focus on customers and their needs • Individualistic: focus on recognition of employee achievements via email or electronic noticeboard 		For example: <ul style="list-style-type: none"> • High power distance: focus on company profile to impress customers • Collectivist: allow anonymous postings on discussion board; emphasize group achievement
	Technology Culture	e.g., Greater complexity in customer interface since higher computer literacy rates		e.g., Less sophisticated, easy-to-use customer interface
	Time/Geog. Culture	e.g., Information and alerts regarding public holidays in USA, UK and Indonesia		
D&I	Design & Implementation	Local user testing and reiterative design approach		

In addition to cultural dimensions, the designer also has to consider issues of technology culture, such as:

- The way of charging for technology access, including Internet and phone, which sometimes prohibits people from being online. In some countries, access is charged per minute, and so charges might be high.
- The technological expertise available. The system should be easy to use, provide a gentle learning curve, and allow for different technological capabilities, particularly where expertise is known to be low.
- The understanding of the use and place of technologies. For example there is no need for passwords in certain societies for individually owned computers (Churchill & Bly, 2000).

Churchill and Bly (2000) also list the culture of time and geography as important considerations:

- Different holidays and working hours.
 - Different notions of private and public time. Systems should enable a set of shared expectations about where to leave messages and available times for interaction in order to create a sense of co-presence among participants. They should be capable of providing asynchronous as well as synchronous messages.
5. **Design and implementation:** Refining of the system's design based on user feedback is especially important in multicultural design environments (Nakakoji, 1996). This normally involves reiterations of testing with the user group and sometimes active participation of users on the design team.

Example of Applying the Development Framework

Here we will give a practical scenario to demonstrate how this model might be implemented (Table 2). Let us take the example of a U.S. firm that has subsidiaries in the United Kingdom and Indonesia. It wishes to create a Web site that will provide customers with product and service information and also act as a portal to its intranet and groupware tools for employees in all three countries.

FUTURE TRENDS

There are many emerging technologies that will impact how cultural diversity is managed in the future. To some extent, ICT will evolve to answer existing challenges and issues in a more effective way. However, new challenges will arise as new technologies come on the market and also as the world changes under the increasing impact of globalization.

The use of mobile devices is rapidly increasing, owing to improved wireless technology, cost reduction, and advances in service provision. In addition, people's ways of carrying out their work is changing, with the number of mobile workers rising around the world (Chen & Corritore, 2005). These people rely more and more on mobile devices to keep them connected to the office and connected to clients. For example, laptop PCs are gaining market share. In 1995, there were 31 million, accounting for 13.7% of all PCs in-use, while in 2005, the number was expected to double to 25% of market share (Computer Industry Almanac Inc., 2005 June). However, the design of many mobile devices presents additional and unique challenges that primarily arise from the small size of the interface, limited input and in-

teraction capabilities, slower bandwidth, security risks, and the need to adapt content to the context of where the device is being used (Murugesan & Venkatakrishnan, 2005). The challenge of establishing how one can use these mobile tools effectively in a culturally diverse workplace is magnified by these issues.

New technological developments in other fields also could change the way that modern workforces do business and their preferred ICT. Voice-over IP (VoIP) is already saving costs on international telephone calls for many businesses (Erlanger, 2005-2006). An extension of this technology is video-over IP, which promises to reduce the usage costs by allowing videoconferencing for the price of a local call to the ISP. This is now being employed effectively in some geographically dispersed organizations in which face-to-face meetings are difficult to arrange (Olde, quoted by Housely, 2005). With fewer financial disincentives to using videoconferencing, it well may become the preferred interoffice or interorganizational communication tool, providing a richer medium and a greater social presence than any other ICT. For people from many cultures and, in particular, high-context cultures, this might become the best option after face-to-face communication and meetings. These benefits are likely to be realized as soon as the security challenges of VoIP and video-over-IP are resolved.

Currently, ICT is dominated by the English language. In 2001, the top three languages on the Internet were English (43%), Japanese (8.9%), and Chinese (8.8%) (Gromov, 2002). However, in the future, China may well become the dominant force. By 2005, English showed a marked decline to 31.9%, while China had grown to 12.8% (Miniwatts International, Ltd., 2005). China, which is now in second place in broadband subscriptions, is projected to surpass the U.S. (Computer Industry Almanac Inc., 2005 November), and in mobile telephony, China is already the leader (Computer Industry Almanac Inc., 2005 September). This has enormous implications on the design of Web

pages and ICT generally. More than ever, it will be necessary for the developer to be aware of cultural considerations and to follow a rigorous development framework that focuses on cultural issues.

Ultimately, more research is needed into cultural aspects of ICT development and particularly into comparing and contrasting multiple groups from different cultures. Currently, most research is limited to comparisons of ICT between only two national cultures, such as the U.S. and Germany (Junglas & Watson, 2004) or the U.S. and Malaysia (Gould et al., 2000). There are very few case studies involving multiple cultures in international businesses.

CONCLUSION

With the transformation of the modern workforce into an increasingly culturally diverse one, there is a challenge for managers and administrators in managing this diversity effectively. ICT offers many different tools to assist, each with its own advantages and its own weaknesses. For the manager, there is the challenge of choosing appropriate tools for the workplace to better take into account different communication styles and cultural backgrounds. There is also the challenge for the systems developer in designing new applications that reflect the reality of cultural diversity in the workplace today.

In this chapter, we have discussed the management of cultural diversity using ICT in the context of language and the dimensions proposed by the principal comparative cultural theorists of our day, Hofstede and Hall. Studies have shown that at least some of these dimensions form a valid framework for interpreting and understanding the differences between ICTs and how they can be used most effectively in promoting better work practices, knowledge sharing, and communication in multicultural organizations. These are power distance, uncertainty avoidance, individualism vs.

collectivism, short-term vs. long-term orientation, and high-context vs. low-context communication. Only one study discussed Hofstede's dimension of masculinity vs. femininity (Marcus & Gould, 2000) but was not considered by the authors as providing sufficient evidence.

One of the obvious challenges to the manager is the fact that none of the existing ICT tools is perfect in all situations or in all cultural contexts. For example, whereas one tool, such as e-mail, might provide fast, direct, fact-based communication suited to people from low-context cultures, studies show that it is a problem for people from high-context cultures, because it is not a rich medium and gives few nonverbal cues. As a result, the manager should provide a range of communication and other ICT tools and give employees from different cultural backgrounds the opportunity to choose whatever ICT with which they feel comfortable. Likewise, developers will need to build flexibility into their design of new systems, if they are to be culturally appropriate and gain acceptance.

Chapter 6.24

Creating an Entrepreneurial Mindset: Getting the Process Right for Information and Communication Technology Students

Briga Hynes

University of Limerick, Ireland

Ita Richardson

University of Limerick, Ireland

ABSTRACT

Change in the structure and profile of the industrial base in Ireland emphasises the importance of the small firm sector in certain growth sectors. One such sector is the information and communication technology (ICT) sector, which now demands a more enterprising graduate. This chapter emphasises the importance of third-level¹ education in preparing students for their career, either as employee or entrepreneur. We discuss how entrepreneurship education, through its broad and integrative philosophy accommodates the changing workplace demands. It links together the synergy of enterprising activity and the small firm ICT sector through education courses, specifically entrepreneurship education. This is achieved through the adoption of the process framework for ICT entrepreneurship education. Describing how

they can be modified to facilitate and encourage the more creative and enterprising mindset in the ICT student, we present two courses that have been successfully implemented at the University of Limerick.

INTRODUCTION

A challenge facing policy makers in Ireland is how to encourage more individuals to consider self-employment as a career option and as an alternative to the more traditional career patterns of paid employment in the ICT sector. Since career choices are informed and influenced during the educational experience of the individual, we suggest that the education context of the individual should be examined to determine how it could be developed to encourage ICT

individuals to consider self-employment. To do this we argue that there is a need to modify and devise current programme offerings to include increased exposure in a realistic and practical sense as to what self-employment is about and how it can be a career option to consider. To add value to the competency base of the ICT student, entrepreneurship education can facilitate a more informed choice and exposure to the possibility of self-employment.

The question posed is how can the education context and experience of the ICT student contribute to creating this entrepreneurial mindset? To achieve this, it is necessary to examine the broader philosophy of the purpose of education.

Our answer to this question is the linking of entrepreneurship education to the ICT curriculum through the adoption of a more integrated and interdisciplinary approach. This will create a more entrepreneurial mindset in ICT students in third-level educational institutions. This adds value to the educational experience of the ICT student, providing them with the knowledge, skills, and competencies required for self-employment.

Entrepreneurship education is a process, involving a series of stages and a number of stakeholders who need to be an active part of the process. The central stakeholders are the students, teachers (trainers), the educational institution, and employers within the business community. Entrepreneurship education courses should provide students with a very real-life experience and enhance not just knowledge acquisition but also skills development in areas of idea generation; market research; product and process development; communication; negotiation; conflict management; project management; and people management.

Essentially this chapter addresses a number of related topics such as entrepreneurial activity, entrepreneurship education, and the changing knowledge required by ICT graduates. In doing this, we integrate these topics which are frequently researched independently.

Initially the chapter provides a background to ICT and entrepreneurship within Ireland, thus strengthening the rationale for the chapter. We then propose that an effective means of bridging the entrepreneurship knowledge and skills gap for the ICT student is the development of entrepreneurship education initiatives. To achieve this a process framework of ICT entrepreneurship education is presented and described. Following this, two interdisciplinary entrepreneurship courses at undergraduate level are profiled to describe how this need can be addressed. In the discussion of such courses important issues such as programme design, the role of the lecturer to facilitator, resource implications, and delivery and assessment issues are examined. The chapter concludes with a discussion on the benefits of adopting such initiatives and the implications for policy makers and educators.

THE SMALL FIRM SECTOR: THEIR IMPORTANCE TO THE IRISH ECONOMY

In 2003 it was estimated that the number of small firms in Ireland was approximately 186,114, an increase of 16,114 over a 3-year period since 2000, (The Revenue Commissioners Statistical Unit, 2003). The same report states that the majority of these firms employed less than 50 people (182,916 firms). Overall, these firms accounted for more than 99% of all enterprises in the state and contributed to 68.4% of private sector employment. Furthermore approximately 16,000 new businesses are created each year in Ireland (Small Firms Association [SFA], 2003).

Forfás (2004) indicated that certain sectors were also critical to the continued success of the economy. One such sector is the ICT sector. Current government policy is examining how a greater level of enterprising activity can be developed in the small firms' ICT sector.

This snapshot of the contribution of small firms in Ireland may appear positive and indicate a growing entrepreneurial culture. However, a more in-depth profiling would suggest otherwise. Research completed by O’Gorman and Jones (2000) suggested that as the proportion of employment contribution of Irish small firms was lower than their European counterparts (11% compared with EU average of 15%) there was a need to revitalise the small firm sector as a source of future importance for the Irish economy. This need was more recently reinforced in the Global Enterprise Monitor (GEM) (2003) survey, which found that 6% of already established firms (0-4 years) employed 20 or more people, which would translate into only 16,000 entrepreneurs having significant growth aspirations for their firms.

Regarding the stock of new firms established, GEM (2004) indicated that 45% of respondents perceived good opportunities to start a business, which was a 19% increase in optimism on the 2002 rates. However, while 45% believed that good opportunities existed to start a new business only one in nine Irish adults (10.99%) indicated that they would expect to start a business in the next 3 years. This is the same rate as was reported in 2003 and slightly lower than the rate in 2002 (13%). It should be noted that this indication of intention to get involved in entrepreneurial activity is only half the rate it is in Poland (21.87%) and is also behind other European countries such as France (14.38%), Greece (13.45%), Italy (11.62%), and Sweden (11.73%).

The trends for the period 2001-2004 (time period for which data is available) are summarised in Table 1.

It is important to ensure that this decline is arrested, as it will have implications for both the number of new firms established and for the number of surviving small firms in Ireland in the next few years. Central to the composition of this indigenous sector is the ICT sector.

GROWTH OF THE ICT SECTOR IN IRELAND

The success of the growth of the ICT sector in Ireland is attributed to a number of factors, which include upgrading of Ireland’s telecommunications infrastructure, low corporation tax, English speaking workforce, availability of highly qualified and educated workforce, a strong indigenous firm base, and deployment of European Union (EU) structural and cohesion funds to Ireland (Enterprise Ireland Strategy Group, 2004; Forfás, 2004; Trauth, 2000). According to reports over the past number of years this sector employed an estimated 92,000 people within 1,300 companies, with a combined estimated turnover of €52 billion for the year 2003 (Central Statistics Office, 2004; ICT Ireland, 2005).

One of the “exploitations,” which should occur, is to ensure that the small firms’ ICT sector benefits from the presence of multinational companies in Ireland. In fact one indigenous company in Ireland, Iona Technologies, which was established following a research project at Trinity College (Dublin), is responsible for more than 25 spin-off firms (ICT Ireland, 2003). The same report suggests that partnerships between early stage ICT companies and multinational

Table 1. Entrepreneurial activity in Ireland 2001-2004 (Source: Global Entrepreneurship Monitor, 2004)

Measure of Entrepreneurial Activity²²	2001	2002	2003	2004
Total entrepreneurial activity (TEA)	12.20%	9.14%	8.10%	7.70%
Nascent entrepreneurs	7.34%	5.66%	5.10%	4.39%
New firm entrepreneurs	4.88%	4.20%	3.76%	3.59%

companies would provide the early-stage firms with competitive advantage.

Furthermore, a consequence of Ireland's rapid economic progress over the past decade has been an increase in Ireland's cost base to a point where Ireland is no longer a competitive location for many of the traditional manufacturing companies. Simultaneously, Ireland is facing increasing competition for inward foreign direct investment (FDI) for low, added-value, manufacturing-oriented activities from Eastern Europe and Asia. This reinforces the need to compensate for the demise for FDI in traditional sectors by increasing the number of indigenous firms in growth sectors such as ICT.

This need is reinforced in research findings of GEM (2003) and Forfás (2004), who suggested a need to increase resources to build a more self-sufficient, indigenous industrial base to reduce the reliance on FDI. In Ireland, government industrial policy emphasises the development of these sectors, which have growth potential in added-value service and product areas in a global market. This will provide the country with a small firm sector that is capable of responding to the changing needs of growth in a national and global context. We suggest that the continued creation and increase in the number of new firms established on its own is not an indicator of a positive small firm sector. A sustainable enterprise and small firm sector should consist of a combination of new firms and established growth firms, which compliment each other.

Therefore, to accommodate these trends, policy should encourage more individuals to consider self-employment in these growth sectors as a career option and as an alternative to the more traditional career patterns of paid employment. Since career choices are greatly influenced by the educational experience of the individual, we consider that the role and influence of the educational system should be part of this policy agenda.

As educationalists we have a role to play in this. The education context of the individual should be examined to determine how it could be developed to encourage individuals to consider self-employment. From our experience we have found that this enterprising activity can be linked easily with certain disciplines to add value to the competency base of the student resulting in greater participation in self-employment in that discipline. Given its importance to the Irish economy the discipline that we are interested in is ICT.

EDUCATION: PREPARING THE GRADUATE OF THE FUTURE

According to Rand (2004), education is about developing a student's mind and potential to equip them to deal with the challenges posed in the real world. A broader definition from Baig (2004) states that the primary purpose of education is to provide individuals who can contribute to the economic prosperity of a country. The educational experience should develop students to the best of their abilities, to prepare them for the needs of the workplace and encourage them to generate new ideas and to improve the standards of living of that country. However, as the needs of the workplace are constantly changing, it is important that education providers are aware of the current needs to ensure course offerings are relevant.

Research by Expert Group on Future Skills Need (EGFSN) (2004) indicated the need for a variety of skills to ensure that firms are equipped to meet and be proactive for the changing needs of the international and global environment. These skills can be grouped as follows:

- Practical experience, flexibility/innovation skills
- Management skills for the 21st century
- IT skills
- Generic skills

Practical Experience, Project-Based, and Flexibility/Innovation Skills

Industry is increasingly looking to recruit graduates with practical work experience and commercial understanding. As a result, students with strong technical abilities but little practical experience are losing out on potential jobs. Education courses need to foster adaptability, flexibility, and innovation skills, which must become integral to the education system at all levels if the needs of a changing workforce are to be met. For example, the introduction and expansion of project-based learning will help to provide these skills. By moving in this direction, there is significant scope to improve both the quality of learning and the development of soft skills relevant to the workplace without compromising the intellectual content of courses.

Management Skills for the 21st Century

Management skills to include decision making, risk taking, managing change, and people management have become increasingly important to national economic development. Therefore we need to ensure that students are well equipped in these necessary management skills. In particular, when we focus on innovation and entrepreneurship, the need to ensure technology transfer from the research lab into the commercial arena requires specialised management expertise such as the management of technology transfer and intellectual property.

Information Technology Skills

Given the rapid diffusion of computing technologies into the business and domestic markets, there has been a huge increase in the number of jobs involving the use of information technology (IT). This has resulted in IT skills³ and the use

of desktop packages such as word processing, spreadsheet, and database packages becoming increasingly important. Workforce IT skills are becoming one of the most important factors affecting business competitiveness. Such skills, which are used across all levels in organisations including management levels, are increasingly viewed by employers as a basic requirement. Again, it is imperative that such skills are presented in educating the worker of the future.

Generic Skills

The greater prominence of high-tech manufacturing, internationally traded services, and R&D activities in Ireland's economy require high standards of generic skills to complement academic or vocational ones. Generic skills include basic skills such as literacy and numeracy, and also key skills such as communication, team working, planning, problem solving, and customer-service handling. Furthermore, research indicates that an increased number of people are working in professional and managerial occupations and that the importance of skills such as communication and planning is growing. (EGFSN, 2004)

From the previous findings it is clear that industry requires a graduate who is not just trained as a subject matter expert from a theoretical perspective. There is a definite need for graduates to have skills, which are based on the ability to approach work from a flexible, creative, and innovative approach. It is necessary that graduates are able to perform as a member of a team and have important people management skills.

A Responsive Education Environment

As a consequence of these changes influenced by economic, social, and technological environmental factors there is a clear need for the education system to be responsive to the changing requirements of the enterprise sector and general business community. The industrial sector has to cope with

flexibility and responsiveness and it is incumbent on the educational system to demonstrate the same traits. The educational experience should provide individuals with an attitude, ability, and competency to excel and participate in the highly dynamic business and technological environment of the future (EGFSN, 2004). A better balance between the courses studied, the length for which they are studied, and the requirements of industry should be taken into account. This suggests the need for more interdisciplinary courses. Increasingly, there is a need for graduates to have skills beyond their core disciplines.

Developing These Skills: The Role of Education

So how and where can graduates be equipped with these skills? We suggest that the third-level educational system is a key catalyst to impart these very necessary skills to the ICT student.

The role of the educational system in achieving this is acknowledged by Galloway, Anderson, Brown, and Whittam (2005), who suggested that educators, including universities, “have an obligation to meet students’ expectations with regard to preparation for the economy in which they will operate.” Krueger, Reilly, and Carsrud (2000) argued that career-related decisions reflect a cognitive process that is influenced by the attitudes, beliefs, and intentions which are in turn influenced by the knowledge and experience base of the student. The educational system influences the knowledge base, the acquisition of skills, competences, and attitudes on which future career choices are based. Since these decisions are fundamental to the future of the individual we argue that it is incumbent on the educational system to inform and expose students to a broad range of career options including entrepreneurship.

EXPOSING THE ICT STUDENT TO ENTREPRENEURSHIP

There is a need for all third-level institutions to adopt a much greater and more strategic enterprise focus, both in terms of satisfying the skill requirements of business and industry as well as fostering new business start-ups. From a policy level the importance of enterprise education is acknowledged by the European Commission (Europa, 2003), who advocated that entrepreneurship education is important to create the “correct mindset” to foster greater enterprising behaviour. This need is reinforced by many researchers as summarised by Galloway, Anderson, Brown, and Whittam (2005). This summary suggested the need for universities to develop as entrepreneurial institutions, becoming more proactive in addressing the needs of the employers and the business community when devising programs. They should help to encourage the growth of new businesses thus exploiting the creative potential and depth of knowledge within higher education. Other benefits promoted by De Faoite, Henry, Johnson, and Van der Sijde (2003) found that entrepreneurship education provided for the integration of a variety of business subjects, the promotion of improved decision-making skills, and an increase in technology transfer between universities and the market place. Thus they create improved synergy and added value between both entities and the potential to add value to nonbusiness and technical programmes. The need to broaden enterprise education outwards from business schools has also been endorsed by the European Commission (Europa, 2003) and Galloway and Brown (2002). Galloway and Brown (2002) also suggested that a “cross disciplinary approach” to enterprise education could influence a range of industry sectors including the arts, science and technology disciplines. Hytti and O’Gorman

Creating an Entrepreneurial Mindset

(2004) found that the better or more successful programmes were those who had the ability to integrate learning across the general educational experience of the student and those introducing enterprise education into other courses. The innate abilities of an individual, coupled with the overall socioeconomic environment (ease of establishing a new business, access to finance, and advice as well as the prevailing cultural attitudes to entrepreneurship) are extremely important factors in determining whether they pursue an entrepreneurial path. These innate abilities can be greatly enhanced by education and training.

We are in agreement with a number of researchers (such as Audretsch, 2002; Department for Education and Skills [DFES], 2002, 2003; Martin, 2004; National Committee of Inquiry into Higher Education [NCIHE], 1997) that the focus and objectives of entrepreneurship education programmes should involve the acquisition of a broader set of life long skills and not simply training for business start-up. Entrepreneurship

education should contribute to the development of a range of skills, including the ability to innovate and to provide leadership, which pays dividends for the individual and the economy in any employment context. Furthermore, Martin (2005) suggests that through enterprise education, both students and staff may be more likely to start up new firms and to develop business opportunities and in doing so create a more enterprising culture in the institution.

Essentially, there is considerable scope for the educational system to foster a culture that is conducive to innovation and entrepreneurship. The role it can play ranges from instilling a positive attitude to entrepreneurship among young people, via the promotion of positive role models and presenting failure as a prerequisite for success, to providing the enabling or prerequisite skills needed for success. These enabling skills range from an understanding of business, financial marketing, and legal issues to generic or soft skills such as team-working, communication, and interpersonal skills.

Figure 1. Process framework for information and communications technology entrepreneurship education (Adapted from Hynes, 2006)

Inputs		Process		Outputs
Students	Content Focus	Teaching Focus	Professional / Technological	
Prior knowledge base Motivation Personality Needs/interests Independence Attitudes Parent influence Self-esteem Values Work experience	ICT (science, mathematics, programming, ICT design, development process) Entrepreneurship (entrepreneurship, intrapreneurship, innovation, new product development, innovation, idea generation, research and development) Business (marketing, accounting and finance, human resources) Legal aspects (Intellectual property rights, employment legislation, insurance) Soft skills (Communication, presentation, writing)	Didactic (reading/lectures) Skill building (case studies, group discussions, presentations, problem solving, simulations, teamwork, projects) Discovery (brainstorming, personal goalsetting, career planning, consultancy)	Personal (confidence communication) Knowledge (enterprise, initiative, self-employment, business, management and market skills, analytical, problem solving, decision making, communication, presentation, risk taking) Career (improved knowledge, broader career options, broader less-structured career perspectives).	

How can the enterprise education context and experience of the individual contribute to creating the correct entrepreneurial mindset? To answer this, it is necessary to examine the broader philosophy of the purpose of enterprise education, how current courses may be modified, and how new courses can be developed to address these needs.

PROCESS FRAMEWORK FOR ENTREPRENEURSHIP EDUCATION

In an evaluation of entrepreneurship courses Hynes (1996) suggested that entrepreneurship education is process driven. This process consists of a number of stakeholders who have a range of needs, which may differ in nature and scope. Starting a new business involves more than the development of a final product or service. Rather it encompasses a series of stages which link together and are managed in a subjective way by the entrepreneur. These are influenced by a number of factors both personal and situational. In the specific context of the ICT student the focus is on how it can create an awareness of self-employment as a viable alternative career path upon graduation or in a few years after gaining some practical experience.

Based on Hynes' (1996) work we have modified the process framework for the ICT student (see Figure 1). One of the benefits of the framework is that it is flexible and encourages adaptation to suit both the participant needs and the demands of the workplace.

Overview of the Process Framework of ICT Entrepreneurship Education

The model used has three primary elements: (1) inputs, (2) process, and (3) outputs. The role of entrepreneurship education (and thus the role of the educator) is to put a process in place which will include consideration of broader less-struct-

ured career perspectives. These will ensure that the student at least considers entrepreneurship as part of their professional career path.

How this is achieved is dependant on the content, subject areas, and the accommodation of multiple teaching methods. The emphasis on getting the process right is also raised by authors such as Chell and Allman (2003) and Gibb (1996). They raised issues about the provision of entrepreneurship education and the pedagogical and delivery developments required to appropriately meet the needs of the various stakeholders.

Course Objectives

As with the design and development of any educational intervention, there must be a set of clear realistic and achievable objectives guiding the development of entrepreneurship education courses. There is a need to include multiple objectives incorporating both discrete quantifiable ones and less specific and more behavioural related objectives. This later category may be more difficult to measure as their impact may not be immediate and become more relevant after the student has graduated and is involved in a career choice or change.

Building on the process framework, entrepreneurship education objectives should include creating awareness and knowledge of self employment as a viable career option. It should also facilitate students to more confidently identify business opportunities. It should also equip students with the attitudes, skills, and competences collectively referred to as "entrepreneurial mindset" where the graduate adopts an entrepreneurial and creative approach to the "world of work" either in an employee or employer role. While the student is the immediate and direct stakeholder, it is necessary that the needs of the other indirect stakeholders such as employers and lecturers are considered in course design.

We need to ascertain the various approaches adopted in courses with a view to examine how

they can be modified or incorporated into entrepreneurship courses for ICT students who are, in this case, the primary input to course development.

Inputs: The Student

When students come into courses, regardless of the subject area, they bring with them their own personality, life experiences, and prior learning. These include such factors as motivation, self-esteem, values, personal interests, and work experience. The job of entrepreneurship education is to give students the ability, skills, and tools with which they can mould these inputs to provide the expected outputs.

In some cases, for example, students may enter the course with low self-esteem. Through the educational process, these students may discover some ability that they have, which has not been visible to them prior to this. This in turn can boost the esteem in which they hold themselves. While some Irish students will have experienced entrepreneurship through second-level entrepreneurship schemes, the education system is structured in such a way that many students will not come to third level with any entrepreneurial background. Therefore, it is incumbent on the entrepreneurship educators to ensure that the innovative ability of the student, often hidden until this stage in their education, is brought out during the education process.

The personal profile and personality characteristics of the students (“inputs”) are important to define before the content or teaching focus is finally decided upon. It is at this stage that many of the needs of the workplace can be accounted for and accommodated in the content, teaching, and delivery process. A useful method of ensuring this detail is collected is through the completion of an *entry questionnaire* or *entrepreneurial self-assessment questionnaire*. This assists the students to determine their own levels of self-awareness and interest in both disciplines, which they are studying.

Process

As with any process, it is important to convert inputs to outputs. The education process for entrepreneurship courses should include both content and teaching focus. While these can be dealt with separately, it is important that they are also integrated to ensure that the objective(s) is achieved. Decisions on one of the stages will impact and influence the other.

Content Focus

The process framework includes IT content (Figure 1). The content focus presented provides students with an understanding of ICT topics and of the stages of the entrepreneurial process in a holistic manner to highlight the synergies that exist between both areas. When educating the ICT graduate (regardless of whether they are working towards entrepreneurship), we need to consider the skills that they require. They should be provided with topics such as programming and design; they need to understand the hardware and software underlying computer processing; they need to understand the algorithms and logic involved in computing; and they need to have specialist skills such as graphics design and genetic algorithms. Furthermore, they need to be kept up to date with progressions within science, engineering, and technology, for example, bioinformatics and nanotechnology (EGFSN, 2004). Depending on the focus within ICT courses, different skills will be taught by the educators. What is important is that the content of such a course is given due consideration, and the graduate is provided with the correct mix of skills which can introduce them, in this case, to the entrepreneurship labour market.

Entrepreneurship Subject Focus

The students should be educated in entrepreneurship and innovation for new start-up businesses

in the ICT sector, and entrepreneurial behaviour within larger organisations should be presented in tandem with the aforementioned ICT content. The key topics here introduce students to the theory and practice of entrepreneurial creativity and innovation, providing an understanding of the nature of entrepreneurship and the characteristics of the entrepreneur. They should also examine the role of the sociocultural and economic environment in fashioning innovative entrepreneurship. In addition, the topic should examine technical entrepreneurship and the process of managing innovation. As there is a very practical and applied emphasis on the topic students must be encouraged to generate a number of business ideas. The ideas should be as practical as possible and related to market and business opportunities. After initial research and evaluation, an idea can be selected for the development of the business plan—topics to be covered include the importance of marketing and market research. Issues such as secondary and primary research, industry analysis, competitive advantage, identifying target markets, product/service development, manufacturing/operations, forecasting demand, intellectual property, market/sales strategy, legal forms of organisation, and sources of finance can be presented as to how they apply to the start-up firm.

Other “content focus” topics such as marketing; accounting and finance; and human resources are often not associated with the study of ICT. The provision of these within entrepreneurship modules will add value to the knowledge of necessary business subject areas and also develop the skills base to encourage more enterprising behaviour.

Soft Skills: Content Focus

Furthermore, to survive in their careers, graduates from ICT entrepreneurship education need to have soft skills such as communication, presentation, and writing skills. They need to be able to communicate effectively with their peers, management,

and subordinates. Additionally, as entrepreneurs, they need to be able to present themselves effectively with the business community around them, while also being capable of marketing their potential product/service to customers. They will have to face challenges such as presenting business plans to potential investors and making internal changes which affect employees. The challenge for us as educators is to provide graduates with these skills, while making sure that the breadth of the subject does not cause the depth to be eroded. This is ensured by adopting multiple flexible delivery and teaching methods.

Teaching Focus

Traditional lecture-driven teaching methodologies are not relevant to entrepreneurship courses. Kirby (2002) argues that these traditional approaches may inhibit the development of entrepreneurial skills and characteristics. Therefore, the role of the trainer moves from the traditional “sage on the stage” to becoming a “guide on the side” (Hannon, 2005). The trainer needs to adopt the role of coach, mentor, and challenger and have the ability to provide feedback in a constructive and relevant manner.

The teaching process should focus on “active learning” and “problem based learning” (Postigo & Tamborini, 2002). Active learning places less emphasis on transmitting information to the student. Instead, greater emphasis is placed on the student exploring their own skill, competencies, and general self-awareness. The use of problem-based learning can result in the development of other important skills. In a problem-based learning environment, either on their own or in teams, students assume responsibility for solving problems, which are practical and relevant to the various subject areas. It encourages creativity, resourcefulness and tests the student’s ability to make decisions, take risks, and analyse a situation. Essentially, the combination of both approaches provides students with personal and career de-

velopment. Galloway, Anderson, Brown, and Whittam (2005) suggested that role models, guest speakers, and case studies can inspire urgency in entrepreneurial intent. They can contribute to knowledge about and encourage skills development such as self-efficacy, confidence, initiative, and problem-solving skills. These methods can be used as part of active learning and problem-based learning approaches.

Delivery of entrepreneurship courses is often primarily dependent on a few key faculty members. These faculty members need to be equipped to deliver courses, which are often less lecture driven, less theoretical, and require a level of entrepreneurial behaviour. This is a key issue for consideration and is indeed an area worthy of further research. Research by Hytti and O’Gorman (2004) in a comparative study of entrepreneurship programmes across a number of countries (Ireland being one), found that the trainers lacked the skills and information required about entrepreneurship to provide students with the necessary skills and knowledge for entrepreneurship education. They recommended the need for in-career training to support and address the needs of the trainers to ensure they are better equipped.

As concluded by Hannon (2005), how can growth in graduate entrepreneurship be achieved without competent and capable trainers? There is a need to examine the quality and experience of entrepreneurship educators, their level of experience or exposure to entrepreneurship, and the training and development opportunities that are available and accessible. Other key attributes required are the willingness to give time and commitment to the delivery of such courses. As was previously discussed, entrepreneurship should be delivered across disciplines, therefore there is a need to encourage team teaching where faculty from the business disciplines cooperate with faculty members from nonbusiness disciplines to cover the range of technical and nonbusiness subject topics.

Focusing then on ICT entrepreneurship, teaching should be performed in three ways: (1) didactic, (2) skill building, and (3) discovery. Didactic teaching is important in presenting information to students. This is useful where we need to impart information to students, for example, lectures, reading, and video clips are often used. In the case of ICT entrepreneurship education, topics such as intellectual property rights may be covered solely through didactic teaching. However, most of the subjects presented in the content focus for ICT entrepreneurship will require some element of didactic teaching combined with other forms of teaching.

Skill building allows the students to interactively become involved with the topics being studied. Methods such as group discussions, projects, and problem solving are often used during skill building. In ICT entrepreneurship education, much of what is required is that students build their skills through such interactivity. By doing this, not only do they become more familiar with the skills that are required to become good entrepreneurs, but they also are presented with the situation where they are trying out these skills. In ICT entrepreneurship education, it would be unusual to teach subjects through skill building only—it is normally taught starting with didactic teaching and followed by skill building. Subjects such as design, new product development, and marketing would be part of this process.

Furthermore, discovery can also be used as a teaching method. Discovery allows students to develop their self-awareness and the inputs which they brought with them to a course through reflective practice either in an individual or group situation. In ICT entrepreneurship education, discovery is important as the drive and intuition for entrepreneurship often comes through the “inner-self” combined with prior knowledge. Methods of discovery in teaching include brainstorming, personal goal setting, and consultancy and combined with didactic and/or skill building, can be

used successfully in teaching subjects such as idea generation, innovation, and research.

The teaching process aspect is critical to ensure that identified skills and knowledge objectives are achieved. The teaching focus should also take into consideration the obstacles that militate against participation in ICT entrepreneurship education. The focus should combine both formal and informal teaching methods and also encourage topics such as problem solving and career planning. The teaching focus should provide students with the knowledge of not just “what” to do but “how” to do it.

Teaching Focus and Content Focus: Creating the Links

One of the difficulties experienced by ICT educators is the changing pace of technology. Therefore, we need to ensure that students are not only equipped with the “current” ICT knowledge base at time of graduation, but furthermore, are equipped with the skills to update their knowledge as required. To tell them about current trends and knowledge can be done through didactic teaching. However, to allow them to apply this knowledge, skill building methods emphasising action and problem-based learning should be incorporated. It is not enough, for example, for the student to be shown how to write a program—they must experience writing a program for themselves before they can really understand how to do this correctly. Furthermore, discovery teaching provides students with a learning process which will equip them with the ability to continue educating themselves throughout their career.

The combination of content and teaching focus can provide students with an understanding of the stages of the entrepreneurial process. The completion of a business plan in an interdisciplinary team provides the student with a practical and realistic insight into how self-employment in the ICT field can at some stage be a career option for them. The process focus should combine both formal and

informal teaching methods, encouraging topics such as problem solving and career planning.

Outputs/Assessment

Robertson, Collins, Wilson, and Lyewlyn (2003) stated that assessment and examination form the basis of how well the student has utilised time and resources available to them to accomplish the objectives of the course studied. Conventionally, at third level, a final examination—which is generally theory based—forms the primary component of assessment. Gibb (1996) and Henry, Hill, and Leitch (2003) suggest that entrepreneurship education does not fit neatly into these models of assessment of the traditional examination.

Assessment methods need to mirror the objectives of the ICT entrepreneurship courses and also accommodate the different nontraditional teaching and delivery methods discussed previously.

Institutional Environment for Entrepreneurship Education

In the broader context, an influence on the acceptance and encouragement of entrepreneurship education programmes is the culture, systems, and structures of the actual educational institution. The institutional environment includes the resources, facilities, and general support that entrepreneurship programs are provided, within the educational institution itself. The “entrepreneurial nature” of the institution is tested and exhibited in their recognition and support or otherwise of entrepreneurship programmes.

As is seen from the explanation of the framework, entrepreneurship education is process driven, which requires a level of integration and synergy between a number of elements. It is essential that integration exists between the content and delivery elements and indeed integration can occur within these elements. This level of integration is imperative to ensure the specific needs of the “inputs” are addressed in a relevant

Creating an Entrepreneurial Mindset

manner and the desired outputs of this group are materialised.

In summary, the process framework of entrepreneurship education provides for a flexible and adaptable approach for the delivery of entrepreneurship education to diverse groups of students. The framework can be customised to meet the specific needs of a targeted group. This level of customisation is allowed for by the consideration of and starting the process from the review of the inputs. This customisation is now examined by presenting how current courses offered within the University of Limerick can be adopted to suit the needs of the ICT student.

To date, participating students have come from disciplines such as equine studies, wood science, and public administration programmes. Based on the framework presented, we integrate the content and process of these courses. Given its success with these nonentrepreneurship students, we expect that the use of the framework can indeed support the integration of ICT and entrepreneurship, ultimately creating an ICT entrepreneurship mindset. These programs adopt a multidisciplinary and intercollegial approach.

ENTREPRENEURSHIP AT THE UNIVERSITY OF LIMERICK

The first entrepreneurship initiative was introduced at the University of Limerick in 1983. Courses introduced since then have been designed to develop and transfer knowledge about the enterprise process. They are expected to encourage students to examine entrepreneurship as a viable career option. Courses operate at both undergraduate and graduate levels. They range from structured courses consisting of lectures, assignments, case studies, and readings to innovative integrated courses where students actively participate in the small business sector, develop business plans, and are exposed to prominent entrepreneurs, both national and international.

The two courses that we present are described in terms of their objectives, input (student group) the process (content and teaching), and outputs (assessment) taking ICT entrepreneurship into account. The first course is currently a broad course aimed at students in the third year of their undergraduate business studies degree programs. The second course is aimed at final year students and is thus a “capstone” module within their undergraduate degree programs in business studies, equine science, wood science, and public administration.

Course 1: Enterprise Development

This course exposes students to the process of entrepreneurship and the stages of developing a new business from idea generation to final preparation and presentation of the business plan. It provides hands-on experience in the creation and development of a new business venture. Students, in teams, take a multidisciplinary approach to the preparation of a professional business plan. For the ICT student, this business plan should focus on the changing trends in the industry, thus identifying potential business opportunities that can be developed into viable business ideas. For example, they could focus on the medical device industry, where software is a growth sector in Ireland.

Objectives

A number of objectives, tangible and intangible are incorporated into the development of the course. Primary objectives are:

- To develop sophistication in creating a new venture, including skills in evaluating, preparing, and presenting a business plan (combination of tangible and intangible objectives).
- To create in the student an entrepreneurial mindset and a sense of entrepreneurial behaviour, which can be effectively used in

a number of different work environments (intangible objective).

- To provide the students with the insight and knowledge to understand the changing requirements of the ICT industry and how it might affect future business plans (tangible and intangible objective).
- To facilitate students in the development and application of the analytical and decision-making skills necessary in formulating, implementing, and controlling a business plan and in the development of a prototype of their proposed idea (tangible and intangible objective).
- To establish project creditability and improve students' presentation and communication skills (tangible and intangible objective).
- To encourage students to enter the "Enterprise Ireland Student Awards 2006," a national competition run by Enterprise Ireland (tangible objective).

Inputs: Student Group

The content of the course should assume no prior knowledge of entrepreneurship by the students. However, in this course, students are expected to have prior knowledge of information systems, the ICT industry, and a general understanding of business. Given this requirement, participating students should have a diversity of relevant backgrounds and not be limited to ICT knowledge, which could happen if a number of disciplines are not involved. Team members should also demonstrate this diversity. Other inputs mentioned in Figure 1 will vary depending on the individual students (for example, gender, motivation, and confidence).

Process

The aforementioned objectives are achieved by the integration of the content and teaching process.

Content Focus

The content focus should provide fundamental knowledge and insight into entrepreneurship and starting a small firm. Students need to be given detail on the importance of entrepreneurship activity for the development and future of the ICT sector. They also need to understand how a changing ICT sector will affect the ICT business of the future and be capable of integrating this into their business plan. Other topics to be covered include: evaluation of business opportunities; market research; industry analysis; marketing and sales strategies; management structure; product and service development; manufacturing and operations; start-up finance and return on investment; and financial projections. It is clear from this list that significant business content is required in this module. Through the provision of an understanding of the components of the business plan, students learn to integrate both their prior knowledge brought into the course and the new knowledge that they learn within the course. Students are introduced to the alternative ownership structures (sole trader, partnership, limited company), where the advantages and disadvantages and the legal implications of the options are debated.

From the soft-skills perspective, the course is expected to guide the student on assembling and writing a business plan in a professional manner.

Teaching Focus

To ensure the objectives presented are met, our experience is that we must include a combination of delivery methods in this course.

Formal lectures (didactic methods) are required to present some of the content of this course. This includes the theoretical aspects of establishing a business, how to assess viable business ideas, investigating the market, assessing customer demand, formulating a business plan, and identifying sources of finance. It should also include relevant

Creating an Entrepreneurial Mindset

ICT-related topics such as future expectations of the ICT industry and how developments within the ICT industry will change the nature of their proposed business. Content of lectures would be guided by a recommended text, supplemented by journal/paper articles, reviews, and cases.

In our entrepreneurship courses, we consider the inclusion of guest speakers from government development agencies, financial institutions, professional organisations representing the ICT sector (for example, Irish Software Association, ShannonSoft), and owner/managers from industry as an important aspect to any entrepreneurship course. Through presentation of past experience, they can convey a level of knowledge and context to students. Furthermore, they can encourage discussion and self-analysis by the student as to their interest and ability to pursue self-employment. These methods place emphasis on identifying where the theory and practice link together in a real-world situation.

Workshop sessions (discovery learning) are used to support students in developing their business plans. Students, in their project groups, would be expected to attend one workshop session per week. In these sessions students should provide an update on their progress while the faculty member provides feedback. The workshop will ensure that problems or issues in the progression of the development of the business idea for the group are identified as soon as they arise. Through the use of scenarios, role-playing, and peer review students can enhance their communication, decision making, and presentation skills.

Outputs: Assessment

While we expect this to be a 100% project-based course, the assessment should include a breakdown of milestones, transparent to the student, indicating what is required from them. This is indicated in the course description given to students on the commencement of the course. These include:

Project management

15% - Individual grade

New product/service proposal

10% - Group grade

Progress report

20% - Group grade

Final business plan

55% - Group grade

Project management should examine the student's ability to work in a team and how they contribute in a constructive manner to a team scenario to complete their final project. Criteria for assessment should include time management, people management, conflict management, the ability to adhere to deadlines, the ability to make decisions and their resourcefulness in solving problems. This improves the student's ability to manage their time and resources in a more effective and productive manner.

How the student's creative and opportunity-sensing skills are developed should be examined through the new product/service proposal. This can assess the submitted business idea in areas such as the source of idea; rationale for submission of idea; potential market; knowledge and understanding of ICT industry; and competitive opportunities.

A complete business plan must be drawn up with a design of the product/service to be produced. This should be a significant submission and the guideline length is 25 pages, excluding appendices. Projects should show some degree of *innovation*, must be *feasible* and *marketable*. The business idea should be as practical as possible and relate to direct opportunities observed in the Irish ICT economy.

The progress report and the final business plan will test the ability of the student to link and integrate all the elements and stages of developing a new business idea. It also examines

written communication and presentation skills in report writing.

This course highlights how, with the understanding of the characteristics of the students, suitable and relevant targeted content and delivery methods are devised to create a more enlightened knowledge about the process of identifying a business opportunity and transforming it into a potentially viable business and career option. Through active engagement in this action-based learning process, the student also develops and enhances a range of important life-long skills such as greater self-awareness and increased confidence, team-working skills, communication, and decision-making skills.

Course 2: Small Business Consultancy

The second course we present here also uses the components of the process framework as a guide to its development. However, this course is aimed at fourth year students who are expected to embark on the workplace within the following 12 months. Also the emphasis in the teaching and content area is focused on discovery and problem-based experiential learning. This course is unique in that there is an added component—the small firm. As the course involves small firms they form another input element that needs to be considered in the course development.

To be successful, this course should be promoted by both the institution presenting the course and local development agencies and small firms. It should offer small ICT businesses a consultancy service to identify and solve a business problem. Currently, in the case of the University of Limerick, where this course is run with non-ICT-related courses, interested small firms are matched with a team of students who act as consultants to assist the owner/manager to solve a business problem or develop their business further. Thus, in the future, students can provide confidential managerial assistance to local ICT firms. Typical assignments

would include: feasibility studies, business plans, marketing plans, and market research reports. Students can benefit enormously from this experience as they have the opportunity to apply experiential knowledge and concepts learned in the classroom to real-life business situations. The nature of the business consultancy course will involve close working relationships over a semester, which at the University of Limerick constitutes 14-week period, with owner/managers of the various companies assisted. The students are not placed in the client firm. The students are facilitated and guided through the consultancy process with a faculty member. The emphasis is on problem-based learning.

Objectives

Tangible and intangible objectives need to be incorporated into the development of the course. The focus here is the provision of a capstone course for students who are about to graduate. Consequently, the main emphasis is on intangible objectives. The objectives include the following:

- To introduce students to the principles and processes of management consultancy within the ICT industry (intangible objective).
- To provide practical hands-on experience of engaging with the client organisation in a professional consulting capacity (intangible objective).
- To give the student an opportunity to bring up-to-date ICT knowledge into the industry (tangible objective).
- To provide students with an opportunity to conduct desk research and primary research (tangible and intangible objectives).
- To develop students' report writing skills (tangible objective).
- To improve students analytical, communication, and presentation skills (tangible and intangible objective).

Creating an Entrepreneurial Mindset

- To improve the student's understanding of the practicalities of the roles and tasks assumed by the owner/manager in the operational and strategic management of a small firm. (intangible objective).
- To provide students with the capability of advising ICT owner/managers in a professional manner (intangible objective).

Overall, the course in fulfilling personal and career objectives for the student, in tandem fulfills objective of problem solving and learning for the small firm client.

Inputs

Input 1: Student Group

For this course, students should bring prior knowledge of general entrepreneurship and of general business functions to the course. They would also be expected to have an understanding of basic business terms, an understanding of the ICT theory, and an understanding of the trends in the industry. This understanding should include product life cycles, for example, if they are software students they should understand software process and software development life cycles. Students at this stage are more focused on career decisions.

Input 2: Small Firm (the Client)

The added input dimension, as referred to previously, is the client firm. The characteristics of the firm such as their stage of firm development, the nature of the business problem, the willingness of the client to adhere to the requirements of the course, and the understanding of the client of the limits of student resources and expertise are factors that need to be considered for suitable matching of client and student teams.

The characteristics of both sets of inputs require consideration in the design of the content

and, in particular, the design of the teaching and delivery methods to ensure they successfully facilitate and support the student in the completion of their assigned tasks.

Process: Content and Teaching Focus

A very high level of integration between the content and teaching focus is required to achieve the stated objectives. In order to highlight this, we describe this integration and discuss how the course should be delivered from teaching and content perspectives.

During the first week teams of four to five students should be created in the class. Each team should be interdisciplinary, ensuring a well-balanced focus on entrepreneurship and ICT expertise within the group. The team requires a brief indicating the client needs and expectations. A meeting must be held between the client, student team, and faculty member. The purpose of this meeting is to familiarise the client and student team with each other and to discuss the requirements of the project in detail. Subsequent to this meeting the consultant team should devise a research proposal. The research proposal should indicate clearly what the agreed objectives of the research are, the proposed methodology that will be used to address the objectives, and a project log, which indicates the milestones and the time management of the project. This should be sent to the client, with a follow up telephone call by students to discuss any queries. Any modifications to the research proposal should be made at this stage. This modified document will guide the completion of the research. From a teaching perspective, there will be a minor component of formal lectures. However, teaching should be primarily driven by workshops, thus providing discovery learning. This should be completed by week three of the semester.

During the remainder of the 9 weeks, through some formal lectures, the students should be familiarised with the theory of consultancy. They

should also be integrating this knowledge with the ICT knowledge that they are bringing to the group so that they are familiar with the particular company in which they will be involved. Furthermore, it is useful if guest speakers are invited to talk to the class. This would include at least one guest speaker who is a consultant and who can explain their consulting experience and the methods he/she uses to consult. Members of a development or funding agency who are involved in assessing completed consultancy projects on behalf of the clients can also provide relevant insights to the students.

During these weeks the students should provide a progress report to both the client and faculty member on a weekly basis. They need to meet with their faculty member for a 1-hour workshop to review progress and address issues emerging in the research.

In the 10th week, students should deliver a draft report to the faculty member they work with, who can make suggestions about additions or modifications that will be required to meet the client's needs. In the 12th week, the consulting group should resubmit the draft report with the recommended changes. This can then be presented to the client as the final output of the consulting relationship. In the final week the student team undertakes a formal oral presentation of the findings of the research to the client and faculty member.

This process engages the student in skill building and discovery learning. The use of case studies, interactive workshops, questioning, group discussion, and client briefings will all facilitate the student to take responsibility for their learning and will ensure it facilitates them in the achievement of their objectives within a certain time frame.

Assessment: (Outputs)

As with course 1 that we described, this course assessment will also be based on the project,

but again should be broken into transparent milestones.

Project management and project log
30% - Individual grade

Draft report
30% - Group grade

Final project report
25% - Group grade

Project presentation
15% - Individual grade

The combination of assessments ensures that ongoing learning is assessed on both an individual and group basis. Having individual and group assessment will test the student's ability to work and contribute to a team set up while also demonstrating the ability to perform on their own.

In this course there are two elements that can be assessed individually. Project management is similar to the previous course. An added dimension in this course is the requirement for the individual student to maintain a schedule of their activities and contribution to the project. This examines how the individual contributes to the team in areas such as attendance at all meetings, adherence to deadlines, constrictive feedback to other team members, new ideas/innovations brought to the team, what strengths they brought to the team, and in what areas they could have performed better.

We envisage that less weighting will be given to the final report (25%) than in course 1. This reflects the need for the student team to have ongoing outputs, which feed into the final report. Thus, we include a grade for the draft report. These interim assessments examine the process and not the outcomes or the final physical report.

The final assessment can critique how professionally and articulately the student, as both a team member and an individual, can communicate the

findings of the research and make a set of realistic and practical recommendations to the client. The assessment also includes feedback from the client firms to ascertain their level of satisfaction with the consultancy process. Interestingly they can also learn from the experience and participation.

This course, through problem-based learning, can, in a practical sense, engage the student with the world of work in an ICT small firm. They can be given the responsibility to make decisions that will be implemented in a real life scenario. It can create a sense of confidence of dealing with owner/managers, improve their ability to hold meetings, write proposals, and make decisions. They can demonstrate their ability to justify the rationale for these decisions which are supported by practical suggestions for their implementation.

Educating for ICT Entrepreneurship

For the disciplines where the programs are currently run, the University of Limerick has evaluated the impact of these programs from an employer and student perspective. Feedback received has demonstrated that we are providing enterprising graduates for the existing workplace. This has been particularly evident in the development of skills and competencies in innovation, team work, and decision making. Furthermore, graduates from this program have started their own businesses and an increasing number of graduates consider business start-up as a career option at some stage.

Through the presentation of these two courses we have demonstrated that the process framework for entrepreneurship education is an effective mechanism and guiding tool to devise skills and competency-based courses to create and encourage more enterprising activity in the ICT student. As is seen from the profiling of two courses, entrepreneurship courses need to be flexible and adaptable to meet the needs of the students in different disciplines and can also simultaneously benefit the broader small firm ICT community in that region.

The process framework for ICT entrepreneurship education can be used to achieve the required combination of professional, personal, and competency skills development. However, we argue that if ICT entrepreneurship education is to become more mainstream in educational institutions, then there is a need for more specific targeting of government policy at a number of levels, which are discussed in the next section.

CONCLUDING COMMENTS

Education has the responsibility to prepare graduates to embrace and be equipped to contribute positively to the workplace either as an employer or employee. The third-level educational system needs to address these changing needs through the development of more ICT entrepreneurship courses. This should be supported by effective policies. We have shown how the process framework for ICT entrepreneurship education is an effective mechanism to guide the design and development of such courses. This process framework emphasises the importance of understanding the needs of the student. An informed context (situational and personal) of the student will then allow for relevant and targeted design of the content, teaching, and assessment of proposed courses. The characteristics of the broader educational institution environment also needs to be considered. The courses presented acknowledge these factors and result in effective and integrative courses, which foster the creation of entrepreneurial mindset in the ICT graduate. It is important that such programs are integrated in a more mainstream manner into ICT curricula. In order to do this policy issues need to be considered.

Collaboration and Cooperation

As was discussed, there are a number of stakeholders involved in the design and implementation of effective entrepreneurship programmes. From a strategic policy level there is a need for

greater communication and coordination in the development of policies devised by departments of education and science and enterprise and employment. This coordination will ensure that policies devised for educational courses are relevant to the needs of the changing workplace. It will also ensure implementation and support at the government level.

At an operational level, greater exchanges and discussion should exist between departments of education and science, third-level institutions, and teachers associations. This is important to ensure change is encouraged and implemented without resistance.

During the development of ICT entrepreneurship education, we as educators need to ensure that the needs and changes in the ICT sector are addressed in course design and development. Demonstration of the importance of these programs must be highlighted through formal evaluation of these initiatives. This requires cooperation and strong working relationships between the third-level institutions and ICT representative organisations such as the Irish Software Association, Enterprise Ireland, and Forfás. Furthermore, these linkages would encourage a positive disposition towards sponsorship.

Resource Allocation

As discussed, ICT entrepreneurship education design and implementation requires extra resources in terms of time, faculty, and physical resources. To ensure the development and promotion of such courses, specific funding should be allocated, and resource allocation models should acknowledge their resource-intensive nature. Creating courses that integrate entrepreneurship with ICT will make for a better educational experience for the student, the institution, and the economy. There will be no return on investment without investment in the first place.

Institutional Commitment to the Trainers

We also noted that to implement successful ICT entrepreneurship courses requires that the teaching process is different from traditional lecture-driven approaches. This teaching process must include the different forms of teaching: didactic, skill building, and discovery. Given that this teaching requires involvement from different sources (such as local industry) and use of methods not prevalent in teaching, there is a requirement for the commitment and buy-in of the educational institution and the individual faculty. Also, as skill building and discovery teaching take more time and effort than didactic teaching, those who are involved in this should be rewarded for their involvement. It is imperative that if such courses are to be sustained and become more mainstreamed in universities then there is a need for management and institutional procedures to acknowledge, accommodate, and encourage such courses. There needs to be a general culture conducive to enterprising behaviour in the institution. This may take the form of a reduced teaching load or the recognition for the development of such initiatives in faculty promotions models.

CONCLUSION

The demands of the workplace in Ireland are changing in terms of the type and profile of growth-industry sectors. The development of the small-firm sector continues to be important for the Irish economy, in particular sectors such as the ICT sector. ICT and entrepreneurship must be combined to ensure that we have a strong indigenous ICT sector to continue this economic growth.

ENDNOTES

- ¹ In Ireland, students attend second-level education from age 12-18 (approx). They then attend third-level institutions (universities, technical colleges) to complete undergraduate courses, which range from 1 to 4 years (Undergraduate Certificate, Undergraduate Diploma, Pass Bachelor Degree, Honours Bachelor Degree). The discussion in this chapter relates to Honours Bachelor Degree programs.
- ² Entrepreneurial activity as classified in the GEM (2004) study incorporates two indicators, namely, the level of activity of individuals thinking of starting a business (nascent entrepreneurs) and secondly the established firm (up to 42 months in operation).
- ³ We want to clearly distinguish between IT skills and ICT education. IT skills include desktop packages as mentioned in this section. ICT education is the education of graduates in subjects such as software engineering, computer science, and computer engineering.

This work was previously published in Information Systems and Technology Education: From the University to the Workplace, edited by G. Lowry and R.L. Turner, pp. 105-127, copyright 2007 by Information Science Publishing (an imprint of IGI Global).

Chapter 6.25

Working at Home: Negotiating Space and Place

Tracy L. M. Kennedy
University of Toronto, Canada

ABSTRACT

This chapter explores the work-family interface by investigating home as a potential work space that must still accommodate the social and leisure needs of household members. By examining spatial patterns of household Internet location, this chapter investigates the prevalence of paid work in Canadian homes, illustrates how household spaces are reorganized to accommodate the computer/Internet, and examines how the location of Internet access is situated within sociocultural contexts of the household and how this might affect potential work-from-home scenarios. Data collected from a triangulation of methods—surveys, interviews and in-home observation—also illustrate the relevance of household Internet location from an organizational perspective. The relationship between individuals and business organizations is interactive and integrative, and the home workplace is complex and blurred with other daily social realities, which influence effective work-at-home strategies and potentially shapes productivity and efficiency.

INTRODUCTION

The nature of work is changing in today's information society, especially with the prevalence of information and communication technologies (ICTs) in the home. In many instances paid work is relocating to the home, which offers people more flexibility, yet often less clear boundaries between work and household (Sullivan & Lewis, 2001). There has been considerable literature concerning how paid work at home—or telework¹—is detailed, outlining numerous positive and negative features of working from home, and the impact of paid work at home on the household and organizations (Armstrong, 1997; Dimitrova, 2003; Frissen, 1992; Gurstein, 2001; Haddon & Brynin, 2005; Hardill & Green, 2003; Salaff, 2002; Stanworth, 1997). Despite conflicting analyses and debates about the impact of telework on individuals and organizations, little attention has been paid to the spatial semantics of organizing the location of household ICTs to compliment (or hinder) not only leisure and social use, but also work related tasks and work-at-home scenarios. If indeed busi-

nesses and organizations wish to encourage their employees to work at home, then it is important to think about how individuals spatially organize household ICTs and what impact this has not only on work performance and productivity, but also household members.

Most recent statistics in Canada indicate that Canadian Internet use is highest from home, with 62% of households using the Internet at least once a day, on average, from home (Statistics Canada, 2002). Canadian statistics (Statistics Canada, 2001a) also reveal that from 1996-2001, more people chose to work from home than ever before (1,175,760 billion, or 8% of the working population), and that most people who work at home live in urban areas. Having the Internet in the home has changed the way people think about work, how they do their work, and ultimately where they do their work.

This chapter explores the work-family interface by investigating the construction of the home as a potential work space that must still accommodate the social and leisure needs of household members. By examining spatial patterns of household Internet location, this chapter will:

- investigate the prevalence of paid work in Canadian homes,
- provide an overview of household Internet locations,
- illustrate how household spaces are reorganized to accommodate the computer/Internet, and
- examine how the location of Internet access is situated within sociocultural contexts of the household and how this might affect potential work-from-home scenarios.

We also need to consider the relevance of household Internet location from an organizational perspective. While there may be numerous benefits of paid work at home (or telework) to both the individual worker and the organization, there is a need to think about a construction of

telework that incorporates individual and business needs and expectations. Examining the practices involved in deciding household Internet location provides sociocultural context to decision-making processes regarding paid work and ICTs in the home: “new organizational, social and personal relationships may accompany these new spatial arrangements, highlighting the entangled interrelations between space, work and organization” (Halford, 2005, p. 20).

The Connected Lives Project

The Connected Lives Project is a Canadian study led by Professor Barry Wellman who heads NetLab at the University of Toronto. The project, funded by the Social Science and Humanities Research Council, consists of six graduate students and numerous research assistants in the greater Toronto area. The goal of the research project is to learn about how Canadians communicate with their friends and family, providing an in-depth investigation of how the Internet is affecting the “everyday life” of Canadians and how the Internet is embedded in daily routines and practices. Where most studies until now have focused on who uses the Internet, the Connected Lives Project focuses on how different kinds of users (and nonusers) of new communications technologies engage in social relationships and community. The research design employs a methodological triangulation including surveys, interviews, and observations.

Survey: The 32 page survey for the Connected Lives Project was developed between November 2003 and June 2004 by the NetLab research team. English-speaking adult participants over the age of 18 in East York were randomly sampled in June of 2004 and 621 households were sent an information letter regarding the research project and later contacted in person and by telephone to set up interview dates. With a response rate of 56%, 350 surveys were completed between July 2004 and March 2005. Each survey took 1-2 hours to

Working at Home

complete. Surveys included questions regarding the use of new communication technologies and the nature of their contact, on and off-line, with friends and relatives that are both near and far.

Interviews: The interview schedule was also developed by the Connected Lives team between September 2004 and January 2005. Participants who completed the initial survey were asked if they were interested in a follow-up interview. The response rate was 85% of those survey respondents who wrote “yes” or “unsure” when asked at the end of the survey if they would be willing to be interviewed. In-home, semi-structured interviews were conducted between February and April 2005 with one fourth of the survey participants (n=87).

The interviews were conducted by Connected Lives doctoral students and took 2-4 hours and provided detailed information about household relations, Internet use, travel behavior, social networks, and information seeking, which provided a better and more comprehensive understanding of initial survey questions. In households with a computer, we asked permission to take a digital picture of where the computer with Internet access was located. This provided NetLab researchers a visual depiction of not only computer and Internet technologies, but also a visual representation of where Canadians are using the Internet in their homes and what is going on around them.

Observations: Once the interview was completed and if the interview participant had a household Internet connection, we asked the participant to demonstrate how they actually use the Internet in their homes. Interviewers observed how participants search for information, particularly information concerning health and culture. Of the 87 interview participants, 43% (n=37) were observed using the Internet. The interviews and observations provide a rich understanding of how Canadians use new communication technologies for interpersonal relations and to obtain information.

Overview of Participants

Race and ethnicity: The Connected Lives Project takes place in East York, a distinct part of the current city of Toronto with a population of 114,240 in 2001 (Statistics Canada, 2001b). Its populace represents a wide range of ethnicities, socioeconomic statuses, and household arrangements, which is reflective of Canadian diversity. For example, 40,620 of the East York population are from visible minorities (Statistics Canada, 2001b). Visible minorities (i.e., nonwhite-Canadians) comprise 27% of the survey sample: primarily East Asians and South Asians, with Chinese-Canadians and Indian-Canadians being the largest groups. This is lower than the 2001 Canadian census report that indicates visible minorities comprise 36% of the East York population. Unfortunately these ethnic groups are somewhat underrepresented in our methodological process because of language and cultural barriers. In most other respects, the data reflect census demographics, including gender, age, income, education, and family composition.

Age, gender and marital status: Fifty-eight percent of the survey respondents are women, with a median age of 45. Fifty-nine percent of the somewhat less representative interview sample are women; with a median age of 49. Nearly two thirds (62%) of the survey respondents are married or stably partnered, as are 68% of the interview participants. Three fifths (61%) of the survey respondents have children; as do a somewhat higher 66% of the interview participants.

Education and income: Forty-three percent of the survey respondents have university degrees, while 27% have a high school education or less. Fifty-one percent of interview participants have a university degree, while only 20% of the interview participants have a high school education or less. The bulk of the population is working class and middle class; median personal income is between \$30,000 and \$40,000. Sixty-two percent of the survey respondents are doing paid work, thus

with a substantially higher median of between \$50,000 and \$75,000. Thirty-seven percent of all participants are retired, 16% are students, and 13% are full-time homemakers. Others report that they are between jobs, on leave, or have other reasons for not working.

Paid work at home: Twenty-six percent (n=56 and 16% of all participants) of participants reported conducting paid work at home. Of these participants, 91% conduct work related to their main job. Fifty-seven percent of participants who work at home are female. The reasons given for working at home are catching up with work (42%), saves time (37%), saves money (33%), better working conditions (33%). Twenty-six percent note other reasons such as convenience and ease. Participants who work at home report spending an average of 16.5 hours a week on paid work at home.

DISCUSSION

Internet users: The amount of people using the Internet continues to grow. Computer Industry Almanac² projects that the worldwide Internet population in 2006 will be 1.21 billion users. On a Canadian scale, most recent statistics (Statistics Canada, 2002) indicate that 62% of Canadians are now online either from home, work, school, or public facilities, with 51% using the Internet from the household. Individuals with higher levels of education, working people with higher income, and those with children still at home are the leading users of the Internet in Canada (Statistics Canada, 2002; U.S. Census Bureau, 2001 states similar findings in the USA). This is also the case for other technology such as telephone, television, and so forth (Dutton, 1999; Dutton, Rogers, & Jun, 1987; also the computer Murdock, Hartmann, & Gray, 1995).

Table 1. Mean number of hours per week spent on Internet activities at home by gender, for those with the Internet (N=235)

Working at Home

Most of the survey respondents (79%) have at least one computer at home, and 94% of these computerized households are connected to the Internet. Similar to Canadian and American Internet use (Ekos Research Associates, 2004; Rideout & Reddick, 2005), 75% of Connected Lives are connected to the Internet. Comparable to the Canadian mean usage of 12.7 hours per week (Ipsos-Reid, 2005), Connected Lives respondents reported being online a median of 10 hours per week and sending e-mails a median of 21 times per week.

Internet usage patterns: Considerable research has addressed how people use the Internet in general (see Pew Internet and American Life;³ Howard, Rainie, & Jones, 2001). Overall, there are four general ways of using the Internet—communication, information, recreation, and commerce. Using the Internet for communication—e-mail and instant messaging—to keep in touch with family, friends, coworkers and peers is a popular use for the Internet (Katz & Rice, 2002). Similarly searching for information and Web surfing for

leisure interests is also popular, and people are increasingly purchasing products and conducting their banking online.

The use of the Internet by Connected Lives participants reflects similar documented usage patterns. Communicating with others and seeking general information are still the most common uses of the Internet from home, with women spending more hours a week (3.5) communicating with people than men do (3.1 hours). Men spend 3.7 hours per week searching for general information, whereas, women spend 2.4 hours per week (see Table 1). This reflects gendered usage patterns explained in detail in other research (Kennedy, Wellman, & Klement, 2003).

Location of Internet Access

Concerns have been raised about the effects of Internet use on families and households. For example, in 2000 Robert Putnam suggested that computers are partly responsible for the decline of social interaction between family members.

Table 2. Location of household Internet (N=328)

However, other researchers indicate this is not the case (see Anderson & Tracey, 2002; Frohlich & Kraut, 2002), as more and more households are spending time on the Internet together in the family hub (if that is where the Internet is located) (Frohlich & Kraut, 2002; Lally, 2002) and incorporating it into their everyday lives. Moreover, it is apparent that family, leisure, school, and work activities are becoming blurred and fuzzy, meshing collectively as schedules and tasks blend together and often overlap.

The presence of the Internet in the household has called for spatial considerations on its placement. New homes being constructed are beginning to reflect the prevalence of computers and the Internet, indicating that the Internet is indeed becoming domesticated (Dutton, 1999), with changes in the design of houses reflecting cultural changes (Frohlich & Kraut, 2002). The experiences and contexts outside the household will also ultimately affect the structure of the home itself (Haddon, 1999).

As well as the choices of technology use—such as telephones, personal computers and televisions—in the home and where they are located is determined by beliefs and attitudes about household organization, which is greatly determined by one's culture, socioeconomic status, and ethnicity (Dutton, 1999). Even the choice of the type of Internet connection—dial-up, high-speed phone or cable, wireless, and so forth—is also dependent on this. The place where household members decide to put the computer/Internet signifies its importance in their lives, from communication hub (Rommes, 2002), to information center (Aro & Peteri, 2003) and from entertainment place to work space.

Deciding Internet Location in the Household

Where to place the computer with Internet access, either in a private office in the home, or in a communal space, greatly affects who uses it, and

when they use it (Aro & Peteri, 2003; Frohlich & Kraut, 2002; Haddon & Skinner, 1991). For example, when the computer is placed in a person's private office space, it can deter his/her spouse and children from using it (Haddon & Skinner, 1991). Similarly, if the computer (with Internet access) is placed in a parent or child's bedroom, it can be difficult for other household members to have access to it, for example, when they are sleeping. Household members must make the decision on where to situate the Internet access point. This decision is often contingent on how the computer is perceived; whether the Internet is for work, play, or school will influence where the Internet access point is located. However, there are other factors worthy of consideration as well.

Household Mechanics

East York is located in the greater Toronto area (GTA) with an integration of small wartime bungalows to large-scale homes, and apartment buildings ranging from less than five levels to levels over 25. Fifty-four percent of participants live in houses and 45% in apartments with less than 1% residing in other locations.⁴ Internet space is constructed in ways that suit the household; however, external factors are also influential. The size of the home, presence of children, whether a household member is working or running a business from home, and a household member's perception of the appropriateness of the Internet in various rooms will affect where the Internet is located (Frohlich & Kraut, 2002).

One important factor when considering the location of the household Internet is the mechanics of the house itself. Many Canadians are constricted by electrical wiring, telephone jacks, or cable ports in order to connect to the Internet. Few homes currently utilize wireless connections, and Internet Service Providers are generally only offering dial-up, high-speed phone (DSL), or cable Internet access (though this will likely change in the near future). For households using

Working at Home

Table 3. Number of household computers (N=327)

5	<1
7	<1

dial-up services, where to put the Internet access point is influenced by the number and location of telephone jacks. The same can be said for DSL, which requires a telephone jack, and cable access which requires a cable port:

Interviewer: ...Your computer is kind of near the front there. Is there any reason you put it over there as opposed to say over here or something?

Participant #306: Why over there? Well, because I think—we think—it is the best place, because there is a connection with the telephone. There is connection there, we don't have a connection here. In (another) room we have a connection but we don't have a place to put a computer in there.

Similarly, this participant notes the age of the home and its constraints:

Interviewer: Your access point is in the basement, how did you decide to put the computer down there?

Participant #455: Well you know, that's interesting because these houses are wired from 1952 so that gives me serious limitations to where I put the computer.

Granted in houses with multiple computers, this can be remedied by installing a hub or router so that other computers can access the Internet through a single connection. However, the number of households with more than one computer is still low (see Table 3) and purchasing additional computers certainly would be problematic for lower income households. Modems, routers, and wireless cards for personal computers all cost money and may be considered unnecessary luxury items for some people.

As well, people may not feel they can set up a network connection in their households if they are lacking computer skills and they may not feel comfortable asking someone for help. Importantly, some people are satisfied with using dial-up and do not feel the need for faster access, while others are utilizing DSL or cable access without the need or desire for a wireless network. Regardless, the initial Internet access point is still influenced by where the telephone jacks or cable ports are located.

Another consideration that concerns household mechanics is the layout of the house itself and the number and size of rooms. For example, apartments do not have basements that can be converted into offices or recreation rooms. Often the growth of a household—or having children—converts the initial office space of the childless couple into a child's bedroom, and the computer moves to another spot. In apartments with no children, or single person households that have one bedroom, choices become limited in terms of where to put the computer. For example, one participant notes the restrictions of the layout of the household:

Interviewer: How did you decide to put the computer in the living room...?

Participant #561: That was pretty much decided by the layout of the place. The bedroom would not have had enough space, and there's just not that many locations. It's the layout.

Interviewer: Would you rather have it in a different space...?

Participant #561: If I had a choice? Yeah.

Interviewer: Where would you rather have it?

Participant #561: If I had another room, you know?

Room sizes in apartments also influence decision making, as spaces can become cluttered with the presence of the computer and computer desk in small rooms. One participant reveals how the apartment constrains Internet use from home:

Participant #773: ...The problem is psychological in that being here in this apartment, I feel enclosed like a rat. Sometimes being here one hour, I say I have to go out and do some moving, go downtown...just to breathe some fresh air. Here, being too long and the whole day long, gives a feeling that you are enclosed like a rat in a cage.

Houses can be a similar challenge in terms of space—the size and number of rooms and the existence of a finished basement will all influence the choice of Internet location. This participant has thought about buying another computer, but is constrained by the number of rooms in the house:

Participant #879: And if we buy a home with two or three bedrooms, I think we buy another computer.

Some people are already conscious of office and computer space and potential Internet access points when purchasing new houses, as indicated by this participant (see Figure 1):

Interviewer: Have you always had (the computers) down there? Have you had (the computers) in other places?

Participant #439: Since we've been in this house, no. We've been here about 15 years, and that was

Figure 1. Home office in basement

© 2005 Wellman Associates (Used with permission)

Working at Home

one of the reasons why we bought this particular place because of the basement. We thought it was an ideal space for an office. The place we were in before was a smaller semi-detached with an unfinished basement. It was only my husband who was self-employed at that point, but we had his office set up in one of the bedrooms and it was a nightmare. I mean there just wasn't enough room for anything.

Aesthetics

When East York participants were asked why they placed the Internet access point where they did, aesthetics were important to several respondents. Given the amount of time Canadians are spending accessing the Internet, it seems obvious that the atmosphere or ambience of the computer area should be important:

Interviewer: What made you decide to put the computer out here? You get the plants and the trees...

Participant #239: I sit here, I look out. I see the trees, I see my plants. Ideal. If I had it in the bedroom, which I did some years ago, I'm just looking at the wall, which is terrible. This is ideal.

Whether for work, play, or education, participants note that the “view” from their computer is important (see Figure 2). Placing the computer near a window to see the garden, the neighborhood, the birds, the greenery, and so forth is motivating, calming, and visually pleasing to Internet users, especially if they are at the desk for many hours. Similarly, placing the computer in an open concept space (such as a living room or family room) provides the user with a less closed-in and isolated feeling than when in a separate room. One participant notes discontent over the initial place of the computer and the changes that were made:

Participant #015: Sitting in the basement with the old computer, I found it too dark and dingy, so we made the office upstairs...what we would consider our computer room upstairs.

Figure 2. Computer use with a view

© 2005 Wellman Associates (Used with permission)

Private Spaces

As Table 2 indicates, the majority of participants indicate that their Internet access point is located in a “private” space; 38% utilize an office space or study, 14% have the Internet in a child’s bedroom, and 10% have the Internet in the master bedroom. This gives a total of 62% of participants with Internet access in what might be considered a “private” space. Almost two thirds (59%) of participants who do paid work at home have their computer in an office or master bedroom.

There are some important things to note about these “private” locations. First, we have to remember that often the choice on where to place the Internet access point might be constricted by household mechanics (as discussed previously), therefore, there might not be a choice of location, but instead a default location of Internet access. In these situations, people make do with what they have and work around notions of public and private spaces within the household.

Second, some of these spaces—office/study or bedrooms—might not be considered “private” spaces for everyone. For example, the office or study may be available and accessible to all household members at any given time, instead of belonging to one particular household member. Privacy becomes something that is negotiated or understood by household members, and may change in different circumstances or contexts. In instances where there is only one Internet access point and more than one user, participants are aware that others in the household need to use the computer. When asked what time of day participants accessed the Internet the most from home, the survey data show that the Internet is used most frequently at home between 5PM and 11PM, when many people have returned home from paid work or school. However, during the interviews, participants report that they access the Internet at times when other household members are not home, or when others are not using it. This indicates that what may generally be considered

as a private space in the household—a space that belongs to another household member—may not be so private because everyone in the household feels they can enter at any time.

Privacy means different things to different people. For people doing paid work from home, having the Internet in the household can often be difficult; interruptions by household members can be commonplace, where other household members may not understand the boundaries between work and home when the work is being done at home (Haythornewaite & Kazmer, 2002). Finding a quiet place to work and negotiating household responsibilities becomes tricky for those household members doing paid work or school work and research from home. Participants were also wary of how their working from home might affect others in the household, stating that they do not want to bother others in the household while they are working on the computer.

As well, participants who work from home noted that it was important for them to separate their work life from their home life, and therefore made conscious decisions to have the computer and Internet access in a space where they can go to for work and then leave the room when finished.

Participant #137: I knew I wanted it (the computer) in my office and not visible, and that I could put it out of the way.

One participant notes the division of tasks that is separated by the location of the computer:

Interviewer: Why did you decide to put the computer in that place?

Participant #848: ...I didn't want it in here. This room is big and I just didn't want it in this room that's all. This is a different kind of room. Right here is where I work mostly, and in that room I read, and you get into a habit, at least I do, of doing things in different places.

Working at Home

Separating work and home is situated around the designated private work space. An interesting observation that surfaced while researchers were taking pictures of the Internet access point was the comments participants made about the “mess” of the office area. They were very aware that their computer area was laden with papers, folders, and other indicators of use. “Don’t mind the mess” comments during the interviews revealed that participants were conscious of this disarray. Participants felt that by having the Internet in a private space that is removed from regular household traffic, they were able to contain the mess and visual disorganization. In these situations, the invisibility of the computer and work space area becomes important:

Participant #421: I have things all over the desk but I know that nobody’s going to touch them. You know what I mean? If I had things sprawled out on the kitchen counter or whatever, I can guarantee that they wouldn’t be there when I went back the next night so and we actually had this conversation cause my husband went down there and he was like “when are you gonna put the stuff away? Like haven’t you finished this project already?” and in my mind I’m saying “Yeah, but there’s just that one thing you know I want to put it all together before I put it away” and it’s okay if it takes me a couple of weeks to get it because that’s out of the way and nobody’s going to touch it.

Communal Places

Some household spaces are more conducive to social interaction. Communal areas such as the dining room; living room or family room; spare room; or basement/recreation room allow household members easy access to the computer and the ability to communicate with others at the same time. Fifty-one percent of respondents indicated the location of the computer with Internet access was in the living room, family room, or kitchen area.

The decision to put the Internet access point in a more communal area that is open to all household members occurs for different reasons in different households. Establishing a multimedia portal is a conscious decision for some participants. Having television, Internet, music, video, or DVD all in one place encourages household members to all be in one place, but perhaps doing different things. This notion of togetherness even though household members might be doing different things is important to many participants. Aside from individual usage of media in the hub of living spaces, participants noted that these more accessible or “public” locations in the home encourage household members to “show and share” what they are doing online. Searching for information online is a common practice in many Canadian households. The kind of information that is being shared is often related to real estate; travel and vacation; home repairs or renovations; or product information. Importantly, participants are not only showing and/or sharing, but they sometimes use the Internet together when planning activities such as movies, concerts, vacations, and so forth. Having the Internet in communal household spaces encourages members to share their online experiences with others. Multi-tasking is also easier when working in communal places, and sharing work time with family time is more permissible, indicating the blurring of work and leisure activities.

Also, while communicating on the Internet is often considered a more personal and private activity, the interviews reveal how households spend communal time communicating together—using Instant Messaging, Audio Chats, and Webcams—with family members outside the household, both locally and globally:

Participant #343: ... when I chat with my family, my wife—she sits with me. She also chats with them. I chat with her family too. So she sits with me, and she chats with her family.

This is particularly important for immigrants or people with family and friends in other parts of the world, who rely on Internet communication to maintain their ties when people can be very far away. This is not to say that this does not occur in households where the Internet access point is in an office, study, or bedroom. Despite the location of Internet access in the more private spaces of bedrooms and offices, household members are still inclined to use the Internet together or show and share their online experiences. However what is important here is the ease with which this can occur when the Internet access point is located in a communal space and the easy integration of online and off-line that can occur in these collective spaces. Having the Internet in communal spaces can be beneficial for household members because they are spending time together using the Internet. While computers have been blamed for the decline of social interaction between family members (Putnam, 2000), this might not be the case if the Internet is located in living, family, or recreation rooms.

The decision to put the computer and Internet access point in a visible location is opposite to decisions made for the invisibility of the computer. Besides notions of togetherness and communal activities, participants with children stated that they were concerned with being able to see what their children were doing online and being able to track their activities:

Participant #442: ...and then upstairs, we have a master bedroom, two bathrooms, two bedrooms. It's funny, we talked about putting a computer up there, but I don't want the computer out of my sight yet. My husband would like it out of here, just because he aesthetically doesn't like it here. But I told him I don't want it out of our sight. I want it where, when the kids are on it, someone's aware of them being on it, and we can be in tune with it...It's like, if you want to use the computer, you use the computer here, because we're always

either in the kitchen or the family room. That's kind of where we live in the house, so it's a great way to monitor the use...

The sheer presence of an adult in the room may deter children from using the Internet in ways that parents may deem inappropriate. The visibility of the computer also allows parents to monitor how long children stay online, and if they are on too long parents can easily turn off the computer, or end their session:

Interviewer: Why is your computer out here?

Participant #810: We think about the future to buy my son a computer. But not now because I don't want him to stay in his room on the computer. I permit him one hour on computer to play... I don't want him to play [too long], that's why it's here [in the living room]. I can see my son.

While communal spaces allow for easy monitoring of children's activities, these spaces also allow everyone else in the household to easily view what parents and/or spouses may be doing. Under the watchful gaze of others, searching for information or communicating with others may be limited or constrained. For household members working from home or doing school work, loud communal spaces may not be as useful or practical as a more private space. Location of the household Internet in spaces that are available to others, or in areas where other household technologies may be (such as the television) affects privacy and concentration (Frohlich & Kraut, 2002).

Contesting Spaces and Places

People are aware of the impact that location has on household Internet access and use. While participants are generally satisfied with where they have their computers, some share discontent with the interviewers. Remodeling rooms, finish-

Working at Home

ing basements, and rearranging layouts reflect the active thought process of where to put the household Internet (see Figure 3).

Interviewer: So how does that spot work for you? I mean is that somewhere where you think it's going to stay or is there a place that's better?

Participant #132: Oh no, hopefully not. Our plan is that—eventually turn—we have a spare bedroom back here that were hoping to turn into a den, so we're gonna hopefully (put the) TV, couch, computer in there...

Participant's Spouse: ...we just bought a computer hutch with everything centrally there, the laptop and (the) computer as well—everything will be there, fax, scanner...

Participant #132: God I hate all that...

Another participant talks about how an open area was created for computer use:

Participant #232: ...we have an open area on the second floor that we designed on the second story. So, it could have been a 4-bedroom, but I wanted it to be open. So it's like a big landing where the computer is. So when I'm working at home, or doing something at home, I'm available to everybody still. I don't want to be off in a room somewhere.

What this also reveals is that people have a sense of not only how household members might use the space, but also how it might (or might not) be integrated into the routines and daily tasks of household members.

When remodeling or renovating is not an option, participants who can afford multiple computers use this as a way to challenge constraining household spaces. While purchasing additional computers is often a way to remedy conflicts between household members that occur over Internet use and access, it is also a way to challenge the private and public spaces of the household. In households with more than one computer, often

Figure 3. Renovating household spaces for the computer

© 2005 Wellman Associates (Used with permission)

participants will have computers with Internet access in different rooms—locations that are both communal and private so that there is a choice. If one is doing paid work at home, the use of the Internet in the office is a rational choice. If one is online and does not require solitude, Internet access in the living room with others present is an option.

Many participants are aware of the structural limitations that their household presents, whether it is small rooms, lack of phone jacks, or whether the computer is in the office or living room. What is particularly interesting is how some participants are aware of these potential constraints and actively problem solve and negotiate these restrictions. For example, numerous participants have laptops with a wireless connection that allows them to be online whenever they want and in any room they choose. This can take them from the kitchen to search for recipes, to the office for paid work, to the living room for recreation, or leisure pursuits online. Notions of space and place become more fluid if you are able to take the Internet with you wherever you go:

Participant #373: I'm getting old and stubborn, so now that it's wireless...I want to be where the sun is. I want to be where if it's a cold night, I'll take it down here from upstairs if Chris is not using it and turn on one of the gas fireplaces and be comfortable. So, now that it's wireless, I'm anywhere.

Other participants are aware of the constraints of desktop computers and stated that rather than buy another desktop computer; they are more interested in transportable Internet usage. This notion of portability indicates not only the diversity of daily Internet usage, but that surroundings matter—and that at different times throughout the day there are different needs and expectations of household Internet use. The context of household Internet use is important here as much as the room arrangements. There is a need to think about how

households perceive the Internet in terms of appliance, tool, toy, or perhaps all of these.

CONCLUSION

The Internet is changing the way household members carry out their daily tasks, whether work, school, or leisure related; it is becoming increasingly integrated into people's everyday lives, and households are utilizing the Internet in different ways from paid work, to communication with family and friends; and general information to more context-specific tasks such as seeking health information for children, looking for recipes for dinner, and planning family vacations.

In this chapter, I have addressed the decision-making process of where to position the household computer and the factors involved in how this decision is made. Household mechanics, aesthetics, private spaces, communal places, and how people contest and challenge existing spatial dynamics in the household are important issues to consider as more people conduct paid work from their homes, more businesses hire teleworkers, and organizations move towards creating new virtual work environments. Space and location of household computers and Internet matters, and these spaces must be perceived and understood in lieu of the household dynamics and processes they are embedded in.

Household Internet location is relevant to an organizational perspective. If we conceptualize the relationship between individuals and business organizations as one that is interactive and integrative, and one that includes not only worker and employee but other household members, then we can say that the home workplace is complex and blurred with other daily social realities—housework, school, children, entertainment, and so forth. ICTs are not used solely for work or employment, and the presence of work-related tasks in the home may complicate this further. Ultimately, these are factors that will influence

effective work-at-home strategies and potentially shape productivity and efficiency.

It is difficult to predict whether telework will continue to increase, or whether businesses and organizations will expand further into virtual organizations. However, with the prevalence of the household Internet and the number of people conducting paid work in the home, we might speculate how the construction of households might change. What might the future “smart home” look like? As new housing—apartments, condominiums, and houses—are being built with Internet connections already available⁵ (see Hampton, 2001), people may not be faced with issues concerning household mechanics or where to put the computer with Internet access, these decisions might be already made.

In a future where virtual organizations and telework are widespread, we might expect to see new housing complexes with wireless Internet access, larger open concept living rooms, multimedia centers built into living areas, or perhaps even computers with Internet access already present in homes, much like dishwashers, stoves, and refrigerators. Conversely, we might see floor plans for houses reflecting separate “work” environments already loaded with ICTs. It is hard to envision a digital/virtual/smart household that integrates paid employment, education, and family life. I have illustrated in this chapter that individuals and organizations need to unite to ascertain needs, expectations, and outcomes in order to benefit both employer and employee.

As Baines and Gelder (2003) argue, when home is a site of paid work, household members and daily tasks are often incorporated into the telework routine in ways not found in most forms of employment; there are contentions, there is conflict and negotiation—there is everyday life. As a guideline to organizations and business for effective future planning, Shin, Higa, and Sheng (1997) suggest that the implementation of telework can be viewed as a strategic organizational change to improve organizational effectiveness. However,

we need to think about the intertwining of “business and pleasure” and “spaces and places” in the context of paid work in the household to overcome barriers and constraints of past teleworker experiences; “spatial hybridity changes the nature of work, organization and management in domestic space, in cyberspace and in organizational space” (Halford, 2005, p. 20).

ENDNOTES

- ¹ The meaning of telework itself is often contested within the literature. It can mean working at home or working from home, and often does not include people who are self-employed with their home as the office; or if telework conceptualized better as "homework" (Sullivan, 2003). For the purposes of this chapter, I will refer to telework as any form of paid work in the household that utilizes ICTs.

Chapter 6.26

Writing–Across–the–IT / MIS Curriculum

Stephanie J. Etter

Mount Aloysius College, USA

Jeffrey W. Merhout

Miami University, USA

ABSTRACT

Popular literature not only claims that college graduates are entering the workforce lacking sufficient writing skills but that companies must spend billions of dollars annually to train employees how to communicate effectively through writing (Canavor & Meirowitz, 2005; College Board, 2004). While writing across the curriculum is not a new concept, it seems that only certain areas of the curriculum have adopted it. The integration of writing into the management information systems (MIS)/information technology (IT) curriculum is an important and achievable goal necessary for the overall development of students in IT or MIS degree programs. While traditional IT/MIS programs rely heavily on technology-based courses, we argue that these technology courses must also promote effective writing habits needed for

career growth in the IT/MIS fields. As business proposals, newsletters and reports are frequently being written by those in the information systems department of a corporation, rather than by those in the communication department, it is increasingly important that we prepare IT/MIS students with the appropriate writing skills needed for their careers. For example, in many cases we prepare students to create Web pages, a highly public information source, without providing any instruction on writing within the IT/MIS curriculum. This chapter illustrates how writing assignments can be used in many MIS/IT classes.

INTRODUCTION

The National Committee on Writing surveyed 120 major American corporations and found that

the ability to write clearly significantly impacts the hiring and promotion process among salaried (i.e., professional) employees (College Board, 2004). While business majors may find writing integrated in the classroom at various academic levels, students majoring in IT and MIS are frequently focusing on technical material (e.g., hardware, software, communication technologies, programming languages, database management) rather than refining much needed communication skills like writing. While these students may find themselves employed at the same corporations as the business majors, they may not be granted the same opportunities for advancement.

A report in *Business Wire* (Technology Industry Suffers, 2005) states that writing activities account for an average of 37% of the typical professional's workday in the technology industry. The IT/MIS graduates entering today's workforce will be expected to write various communications, from business proposals and reports to online newsletters and Web sites. Even a simple e-mail requires clear and easily understood writing. In many cases, we prepare students to create Web pages, a highly public information source, without preparing them to fill the pages with appropriate text. IT/MIS students may be required to defend or explain a component of their technical work, either in a formal business proposal or as an answer to an online technical question.

In either instance, a written explanation that is hard to understand could hurt the bottom line. Canavor and Meirowitz (2005) argue that clear and easily understood writing provides a competitive advantage in this time of globalization. They state, "whatever the language, there's a critical need for clear, jargon-free writing that can easily be understood by non-native readers" (p. 31). According to *Business Wire* (Technology Industry Suffers, 2005), "Technology is new and complex by nature; therefore, technology companies depend on strong writing to clearly reveal the value of their products." This same report argues that unclear writing can dramatically affect the success

of technology sales, customer service and overall customer satisfaction, as technology sales tend to be broad and frequently impact hundreds of thousands of users at a time. Effective writing and technical documentation is expected of today's IT workers. Without it, companies will find initial sales difficult and can expect an increase in the types and amount of support services it must provide after the sale.

Many writing deficient students may not get the chance to do any writing on-the-job as some companies now test writing skills as part of the hiring screening process. A 2004 survey concludes that "80% or more of the companies in the service and finance, insurance and real estate (FIRE) sectors, the corporations with the greatest employment growth potential, assess writing during hiring" (College Board, 2004, p. 3). It is important to note that these industries employ a significant number of people in the IT and MIS fields. This same study reports that a "similar dynamic is at work during promotions. Half of all companies take writing into account when making promotion decisions" (College Board, 2004, p. 3). These decisions may be made on formal proposals or reports, but everyday communications such as e-mail may be considered, as well. E-mail has become the predominant writing activity for most business professionals, accounting for more than 2 hours per day on average for each employee (Business Professionals Unprepared, 2005).

The IT/MIS curriculum is often focused so intently on technology that students may fulfill degree requirements without fully learning other skills essential to successful career development. In an era of globalization, extremely competitive job markets and pockets of high unemployment rates, IT/MIS students need to graduate with skills that provide for employability and advancement. Communication skills, especially writing, should play an integral role in the IT/MIS curriculum. In order to accomplish this task, educators should strive to help develop IT/MIS students from a liberal education standpoint (e.g., development

of critical thinking, illustrating critical thinking through writing, consideration of contexts, and engaging with other learners).

The purpose of this chapter is to argue that integrating writing at numerous stages throughout the IT/MIS curriculum is an important and achievable goal for the further development of our students and, more specifically, to illustrate how writing can be incorporated into IT/MIS courses at both the undergraduate and graduate levels. While much of the following discussion may be culturally specific to Western societies and principally to the United States (U.S.) (as discussed by Fox, 1994), educators in any country who are interested in developing well-rounded graduates may benefit from this chapter.

IMPORTANCE OF WRITING

The decline in communication skills of college students is perhaps the best argument for including writing requirements in courses that traditionally do not have a writing component, such as those found in IT/MIS curriculums. Countless educators lament that many (or most) students cannot express themselves well (e.g., Bean, 2001; Epstein, 1999; Plutsky & Wilson, 2001), and this phenomenon threatens a nation's ability to develop citizens who can fully participate in political and economic processes. Moreover, when one cannot write well, it is often a symptom of a failure to think critically, which can be more damaging than just a lack of communication skills, especially for IT workers. In a 2003 survey, employers in the U.S. reported that many college students graduate without the communication and writing skills necessary to succeed in the workplace (Malveaux, 2003). The recent survey published by the College Board (2004) supports the earlier research by reporting that U.S. "corporations express a fair degree of dissatisfaction with the writing of recent college graduates" (p. 14). This problem is not specific to the U.S., however, as

employers in the United Kingdom (UK) are also reporting a shortage of fundamental skills in job seekers who are recent graduates, specifically in the areas of communication and problem-solving abilities (Parrish, 1998).

Since many U.S. degree programs require only one or two composition courses, it is our working assumption that the skills learned in these courses are not sufficient to provide students with appropriate speaking and writing skills. Some institutions still count solely on language (e.g., English) or communications courses as the only sources for developing effective writing and speaking skills, part of a discipline-by-discipline approach in which courses rarely cover concepts outside of a specific discipline. Many institutions, however, have incorporated "writing across the curriculum" programs or, as they are known in Canada and Great Britain, "language across the curriculum programs." Writing across the curriculum calls for the inclusion of writing requirements in courses throughout a student's college curriculum (Bean, 2001). Carnes, Jennings, Vice and Wiedmaier (2001) further explain that a writing across the curriculum program "enables faculty of non-communication disciplines to build on the writing skills taught in communication courses, provides students with the opportunity to strengthen and reinforce communication skills and encourages consistency in communication training and assessment" (p.1). Moreover, this movement argues (and we concur) that the development of writing competence should be a shared responsibility between the various disciplines and the language departments within a college or university (Tynjala, Mason, & Lonka, 2001; Weimer, 2001).

While the push for writing across the curriculum has been around for several decades, a new push, this time for information literacy, is being brought into focus. Thompson (2005) argues that the teaching of writing should be a natural extension of our responsibility to teach information literacy. The teaching of writing and of informa-

tion literacy both involve “ideas generated from information; both stress abundant and accurate information” (p. 48). By teaching information literacy, we are providing students with the skills needed to “recognize the need for information” and determine its “accuracy, relevance and comprehensiveness” (ALA, 1998). Obviously, these skills are also needed for writing.

We believe those responsible for educating tomorrow’s information resources managers should share in the development of these future leaders’ writing and critical thinking abilities by incorporating writing requirements throughout MIS/IT curriculums. This argument is supported by Nelson (1992), who contends that the development of key learning skills, including critical thinking and problem-solving abilities, is imperative for technical workers to keep up with rapid technological innovations. This is not the same as supporting the concept of writing in the disciplines (WID), as WID programs prepare students for the discourse of a specific discipline by showing students discipline-specific models of writing (Ochsner & Flower, 2004). Since the IT/MIS fields are so intertwined in the day-to-day operations of business, students must learn to write for audiences outside of their discipline.

Bean (2001) convincingly argues that writing is a key way to develop critical thinking abilities and problem-solving skills, and notes that “integrating writing and other critical thinking activities into a course increases students’ learning while teaching them thinking skills for posing questions, proposing hypotheses, gathering and analyzing data, and making arguments” (p. 1).

Similarly, Tynjala et al. (2001, p. 17) argue that “writing is a tool for thinking and a tool for learning.” Bonwell and Eison (1991) add that informal in-class writing exercises, which can even be used in large class sections, can assist in student acquisition of course content. Hence, a compelling case can be made that improving MIS students’ writing abilities by requiring and guiding written assignments can enhance their

communication skills and critical thinking abilities while simultaneously assisting in the acquisition of the key concepts of a given course.

CHALLENGES OF IMPLEMENTING WRITING IN THE IT/MIS CURRICULUM

Implementing writing into any curriculum not traditionally considered to be writing intensive can be difficult on several levels. A 2001 study by Plutsky and Wilson found that faculties were especially concerned with their ability to provide appropriate feedback for writing and grammar. According to Bean (2001), in addition to feeling that their own writing skills are inadequate to provide appropriate feedback, faculty may hold other misconceptions about incorporating writing assignments, including the idea that time is taken away from coverage of content, that writing assignments are not appropriate for certain types of courses and that writing assignments will bury the instructor in paper grading. The challenges of incorporating writing into IT/MIS curriculums may also include, as Bean discusses, designing effective problem-oriented assignments, coaching students to be better writers and critical thinkers, commenting on and grading assignments, and dealing with grammar and sentence correctness.

To maximize the effectiveness of writing assignments, instructors must carefully design problem-based assignments that generate in-depth analysis of the course content and develop critical thinking skills while creating a finished product that can be fairly graded in a manageable fashion. Carnes et al. (2001) present a checklist for creating writing assignments: carefully planning the assignment and grading criteria; enumerating the assignment details in writing; explaining the grading criteria, preferably with a checklist; stating the details of when the assignment is due and in what format; providing opportunities for

interim feedback; and using a detailed evaluation sheet that is very similar to the assignment grading criteria checklist. Gelinias, Rama and Skelton (1997) reiterate the importance of careful planning by identifying three critical planning decisions for integrating writing across the curriculum programs: defining measurements of quality for student writing, selecting forms of communication appropriate for the discipline, and selecting the appropriate mix of communication skills to teach in class.

Bean (2001) discusses the significance of coaching the writing process, of writing appropriate (and effective) comments on papers (e.g., positive feedback whenever possible) and of explicating and adhering to detailed grading criteria. The goal in coaching the writing process is to efficiently assist in the development of students' writing abilities by guiding the process without becoming overly burdened by grading requirements. Bean (p. 237) notes the traditional means of coaching writing by making "copious, red-penciled comments on finished student products [is] almost universally regarded among composition specialists as an inefficient use of teacher energy." Rather, the instructor should identify potential problems as early in the process

as possible by having students submit early drafts to peers and/or to the instructor for feedback. Another idea in guiding the process is to refer students to a university writing center, assuming one exists. Once the writing process is near completion, the instructor can make high-level comments that require revision before the final draft is resubmitted. After receiving the final draft, the instructor should make minimal comments as it is unlikely students will benefit from this unless they are required to make revisions. Instead of making detailed notes on the paper to justify a grade, an instructor should use a grading or scoring scale, often called a scoring or assessment rubric, preferably based on the same scale presented to the students at the beginning of the assignment as criteria for evaluating their work. A rubric is an assessment tool that uses detailed criteria to evaluate content knowledge and process skills (Coray, 2000). An example of a rubric used to score a research paper for an MIS course is provided in Table 1.

Faculties often dislike the use of rubrics because they can be time consuming to create. With the help of Web sites that create modifiable rubrics for you, such as *teach-nology.com*, rubric creation should no longer be seen as a barrier for their use in assessment.

Table 1. Grading rubric

Requirement	YES	NO	Maybe
The problem statement is well-developed, and the problem is significant.			
The thesis statement is clear and succinct.			
Evidence to support the thesis statement is relevant (e.g., current) and strong.			
The paper makes a contribution.			
Arguments are logical.			
Ideas are well-developed and logically arranged.			
There are smooth transitions between sections, between paragraphs and between sentences.			
The voice, tone and style are appropriate for the assignment.			
Sentences are grammatically correct with zero misspelled words.			
The use and explanation of acronyms and abbreviations is appropriate.			
Peer review comments are attended to and/or responded to in a separate paper.			
Copies of sources are included (either hard copy or electronically).			
The paper is not plagiarized.			
Grade:			
Comments:			

EXAMPLES OF IT/MIS WRITING ASSIGNMENTS

Bean (2001) classifies writing assignments as formal, or as informal, exploratory assignments. The use of informal assignments, such as in-class writing, journals, reading logs, creativity exercises, practice essay exams, early drafts of essays and memos to oneself (e.g., to explain a process), can serve as a writing component in any course without burdening the instructor with a heavy grading requirement. The goal of these assignments is to get the student thinking about the key concepts of the course. Bean (p. 118) argues that “exploratory writing, focusing on the process rather than the product of thinking, deepens most students’ engagement with course materials while enhancing learning and developing critical thinking.”

Informal writing assignments also have a place in the IT/MIS curriculum, such as 5-minute essays at the end of class that ask students to sum up the key points of the class in relation to another topic, such as a current event or their future career plans. Brief writing assignments during class time are one way to engage students in an active manner and seem to be appropriate for all types of courses, including IT education. For example, when teaching data modeling, we require our students to think about and summarize their thoughts on the process of creating a well-designed data model rather than just grading their finished product (such as their entity relationship model). The purpose of such an assignment is to help the student realize that data modeling is a creative process that often requires iteration and that the finished product should constantly be challenged as to its robustness. Even if an individual student did not actually make these exact points, an ensuing class discussion, perhaps in lieu of grading their writing, could help the student to understand that data modeling is just as much a process as it is an end product.

Formal writing assignments include short write-to-learn assignments (also called microthemes), thesis-based term papers, formal exploratory essays, reflection papers, essay questions on exams and a variety of other assignments that can be tailored to specific disciplines, such as poetry in psychology or creating word problems for mathematics class (Bean, 2001). Microthemes can be an effective way to assess how well the class as a whole is learning (or not learning) the key conceptual material in a course. Bean provides an example of a psychology professor presenting a scenario of cats reacting to being fed and then asking students to write an essay where the student applies several behavioral theories from psychology to explain the scene. Similarly, in a database course, we could ask our students to critique a database design that has several faults, such as not being properly normalized and/or omitting relationships between entities that would be needed to facilitate certain key queries.

Thesis-based term papers are very appropriate for MIS courses that survey the various information technologies and discuss the implications of these technologies from different perspectives, such as from a strategic, managerial and organizational impact standpoint. In thesis-driven papers, the thesis is usually presented near the beginning of the paper, where the purpose of the remainder of the essay is to present appropriate evidence and make persuasive (i.e., logical) arguments in support of the thesis. Assignments requiring a thesis are usually superior to simply asking students to write about a general topic appropriate for the class. Such a general course-related assignment likely would not require the student to develop the deep analysis and synthesis that is normally the product of effectively developing and defending a specific thesis about a topic. An example of a thesis-governed assignment used in a graduate course will be presented in the next section of this chapter.

Adding writing to the IT/MIS curriculum may also include using writing during exams. The ad-

dition of essay or short-answer questions to exams in the IT/MIS curriculum serves several purposes. First, it breaks up the cycle of rote memorization often required for successful completion of a multiple-choice exam, a very common exam method used in IT-related courses. Second, it allows the instructor to see if students really have an understanding of the material or if they have simply memorized the notes for the exam. Bloom, Englehart, Furst, Hill and Krathwohl's (1956) well-known taxonomy of learning (knowledge, comprehension, application, analysis, synthesis and evaluation) proposes that different levels of understanding can be achieved across subject areas. Short-answer or essay exam questions require higher levels of organizational skills to frame cogent answers, higher levels of recall about the subject matters, more integrative knowledge and, of course, good writing skills (Zeidner, 1987). Where an exam entirely made of short-answer or essay questions may not be considered practical, combining the common methods of multiple choice and true/false questions with one or two essay questions may not only help to evolve the communication skills of the student, but it may also help the instructor to evaluate the course by determining whether or not the student can actually synthesize working, productive output from the material provided in the course.

DETAILED EXAMPLES OF WRITING ASSIGNMENTS

For the purposes of providing more specific examples of writing assignments incorporated into IT/MIS courses, this article describes assignments used in two postsecondary schools located in Ohio and Pennsylvania, as well as those found in literature. In MIS survey courses offered at both the undergraduate and MBA level, a semester term paper has proven to be a successful writing assignment. For undergraduate systems analysis and database courses, a semester group project

with a final report write-up has been required. And in some cases, more than one writing assignment is appropriate. For example, a semester group project report and an individual term paper were both required in a graduate-level database course.

An example of a writing assignment currently used in an undergraduate database course is a short event summary paper. The objectives of the short paper are to give students more practice in writing and in critiquing their peers' writing, and to encourage their participation in extra-curricular activities. Students are required to attend at least one of the many outside speaker presentations sponsored by the Miami University Farmer School of Business during a semester. While many of these events have very informative speakers, the sessions are sometimes sparsely attended. Requiring students to attend one of these educational events and to write about their experience is intended to assist in their overall personal development. Students then write a short 300-400-word review of the event attended, including a synopsis of the presentation, an analysis and critique of the speaker's thesis, and a personal reflection about how the speaker's topic was relevant to their IT/MIS education. Moreover, a positive by-product of this assignment is that some students have become so enlightened by these presentations that they voluntarily attend more outside speaker events in the future.

Another example of a writing assignment in an undergraduate database course is a semester group project report. The objective of this assignment is to require students to think about the business purpose for investing in data management systems and to consider the organizational context of the problem domain for which they are designing a database. Students in the course are given explicit guidelines of the types of issues they must discuss and have a significant amount deducted off their project grade if they fail to address this requirement. While the main focus of their semester project is to properly design an

effective relational database, this requirement forces them to think about how communications are part of every systems development project. One of the drawbacks realized up front is that this written part of the project package, which will also include items like data models and query results, will likely be composed by only one (or maybe a couple) of the team members. Hence, the entire group is also required to present their project to the class, which requires, at minimum, that each student practice his or her oral communication skills.

In a graduate program, it is often much easier to incorporate written assignments into the curriculum, as many students now have industry experience and are aware of the communication skills needed to succeed in the workplace. A research paper assignment has been successfully used in a graduate-level IT management course. The objective of the paper is to require students to research an appropriate IT topic beyond what is covered in their textbook and in class to focus on the strategic, managerial, organizational and social implications of investments in IT. These analytical components of the paper, when outlined and explained at the beginning of the assignment, can be used as part of a grading rubric (as discussed earlier) in addition to items such as a clearly defined thesis and argument. The requirement of a thesis forces the student to think in terms of organizational problems and research questions rather than just creating a “data dump” (Bean, 2001, p. 90). In essence, this format requires a deep analysis and synthesis, the type of higher-order thinking instructors should strive for in all IT/MIS courses.

In addition to a thesis, the assignment requires a sequence of deliverables that force students to work on the paper throughout the entire term. The first deliverable is to propose a topic and problem statement early in the semester that includes a discussion of the process of how they formulated their problem statement. Requiring students to write about how they formed their problem state-

ments will force them to think about the development of a problem statement as a process rather than as a finished product. Moreover, it provides feedback so the instructor can guide and coach problem development as a process of asking researchable questions. It may also help to prevent or deter plagiarism, because the student will not be able to simply borrow or purchase (e.g., copy and paste from the Internet) a problem statement. The instructor then reviews the work and makes detailed, written comments about the topic and problem statement, which are then resubmitted with all subsequent submissions.

The second deliverable, due around mid-semester, requires an informal outline; a draft of their introductory paragraph(s), which include a thesis statement; and submission of all drafts created thus far in their writing process (as further protection against plagiarism). Once again, the instructor makes written comments that must be addressed in later submissions. The third deliverable, due 2 weeks before their final submission, is a draft of their complete paper for a fellow student to review and critique within the following week. The first student (i.e., the author) then has 1 week to attend to his or her cohort’s comments (either in the paper or on a separate response sheet) before turning in their final draft for grading. This final draft must be part of a package of all prior submissions that have been reviewed by the instructor, including instructor comments.

By requiring all previous drafts and submissions, the instructor can assess whether students made an honest effort to improve their product as they went through this process. This explicit sequence of steps and deliverables will result in a deeper analysis of a student’s chosen topic, which inevitably will enhance the student’s learning of IT while helping to develop his or her writing and argumentation skills. Moreover, as suggested by writing advocates (e.g., Bean, 2001; Carnes et al., 2001), the instructor should provide a detailed set of grading criteria with the assignment outlining the requirements for an “A” paper and a grading

rubric that provides the checklist to be used for a quick and clear assessment of the paper as it is read to determine the grade. Thus, the student will know up front what is expected. For example, one of the criteria in Table 1 is “the problem statement is well-developed.” On the rubric, the instructor can check “yes,” “no” or “maybe” and provide a brief explanation for answers other than “yes.” This method is usually a much more effective (and efficient) means of assessing each paper rather than making detailed notes in the margins noting relatively minor issues, such as clarity and grammar.

Not all writing assignments have to be conducted outside of the classroom. If an already work-intensive course does not have time during the semester to include a formal paper or group project, smaller in-class writing assignments can be used. For example, an undergraduate introduction to computer security class occasionally includes short writing assignments at the end of a class based on the material discussed in that class or the past several classes. At the end of a class period spent on the discussion of password security and authentication tactics, for example, the instructor may ask students to write an explanation of the necessity of password security for an executive who has limited knowledge and IT background. In addition to practicing writing skills, students are also given the opportunity to try to explain these concepts in basic terms. This exercise also helps the instructor determine if the students truly understand the concepts or are just memorizing facts and figures.

Adding a personal reflective journal requirement to any IT/MIS course is an easy way to incorporate writing into the curriculum. Students may be asked to write in the journal weekly about things such as current events relating to the class or personal reflections on class materials or guest speakers. For example, students can be asked to contemplate how they might use relational databases in their careers, with the goal of having them realize the relevancy of taking a database

design course (this is especially useful for non-MIS majors who might take such a course). Instructors can then collect the journals every few weeks to provide feedback. Again, a rubric can be used as a scoring method. Journals are often a successful way not only to further develop writing skills, but also for instructors to get a feel for student comprehension of the subject matter and perceptions of the course.

As previously noted, short writing assignments can also be used in exams. The same undergraduate computer security class requires students to answer at least one essay question per exam, providing students an opportunity to explain concepts in detail and often argue their opinion. For example, students may be given a brief biography of a company and are then asked to recommend a method of encryption based on the company’s needs and line of business. This recommendation must be directed to a senior manager of a business, who may not be well versed in the need for encryption or computer security methods in general. Another assignment from this course has students designing a written brochure designed to inform middle-school students of ways to protect themselves and their computers while online. Both assignments allow students to provide an appropriate explanation of a topic to an audience outside of their field and demonstrate their comprehension of its application.

The 2004 survey published by the College Board (2004) reports that corporations express dissatisfaction with the writing of recent college graduates, including the academic styles of writing students are taught, which is often unsuited to workplace needs. While the assignments mentioned above do improve writing skills, it is important to focus also on writing that will help prepare students for the workplace. Kretz (2005) argues that assignments that reflect a client-based pedagogy can be useful for business students. We believe this applies to IT/MIS courses as well. A client-based pedagogy “focuses on helping students to understand and respond effectively

to real-world clients and their organizational contexts” (Kreth, 2005, p. 52). Offering students the opportunity to write a proposal for an IT project for a specific company or in response to an organizational problem allows students to analyze the needs of a real-world audience, research relevant information related to the project and practice writing in a style appropriate for the business world, unlike a traditional term paper. One example of this type of writing assignment is taken from a 300-level application of e-commerce technologies course. Students are required to write a paper addressing an area of investigation of personal interest. Examples include an analysis of the presence of electronic markets in a given industry or an overview of an emerging technology not covered in the text. Students frame the report as a summary of research into the opportunities/problems associated with an emerging technology or electronic market applied to a specific consulting project scenario provided by the instructor. Additionally, students must write in a manner that persuades management that the conclusions/recommendations are sound and logically developed (including providing evidence that supports their thesis).

It is often easier to assign client-based assignments in graduate-level courses, because graduate students frequently have some experience in the industry. In a graduate-level impact of technology course, which discusses the influence of technology implementation, students are assigned to reflect on case studies from companies that describe a real-world technology implementation in the workplace. This reflection often allows students to think about the impact from a new perspective and focus on reasons why new technologies are not always adopted as planned, and helps to prepare students for another assignment later in the semester that is focused on planning for and managing an IT implementation project.

AVOIDING PLAGIARISM

Faculty in non-writing-intensive areas have rarely had to deal with plagiarism, so adding a writing requirement to the IT/MIS curriculum often takes them into uncharted waters. An awareness of plagiarism and its hold on colleges and universities in today’s Web-based world is necessary before jumping head-first into writing assignments.

In a recent *New York Times* article, a student from Duke University said that using a small paragraph that has been cut and pasted from the Internet and slightly altered as part of his research paper is “no big deal . . . it’s not cheating” (Zernike, 2002, p. A10). This acceptance of cutting and pasting seems to be common among college students. The same Duke student explained that “as long as I can manipulate it to be my words, change a few, it’s not cheating” (Zernike, 2002, p.10). Information technology, specifically word processing software and the Internet, has allowed students to copy full paragraphs, change a couple of words, and think that they have done nothing wrong. This form of plagiarism is identified by Iverson, Flanagan, Fontanarosa, Glass, Giltman, Lantz, Meyer, Smith, Winker and Young (1998) as “mosaic plagiarism,” but it is also known as “patchwriting” (Howard, 1999) or “paraphragiarism” (Levin & Marshall, 1993).

Moreover, Western academicians indicate that international students often have different notions about plagiarism (Fox, 1994). Evans and Merhout (2004) explain that countries having a more collaborative work style may view plagiarism issues differently than Western countries that focus on individual contributions. Bean (2001) elaborates on Fox’s discussion and further explains that some international students are surprised by the Western acknowledgement that other “individuals can ‘own’ [their original] words and ideas” (p. 43).

Given Western students’ changing view of plagiarism thanks to the availability of Internet

resources and the cultural views brought by international students, it is imperative to make a note on the course syllabus and discuss plagiarism with all students at the beginning of any class that contains writing assignments. It is also wise to check suspicious submissions by doing a Google search on strings of text that seem out of character for the student writer.

The best way to avoid plagiarism is in the design of an assignment where a statement against plagiarism is a necessary component to bring attention to the seriousness of this issue. Requiring multiple drafts of a document, creating assignments that are specific to a school or region and requiring students to use and cite library resources in the document also can be effective ways to avoid plagiarism. Another effective method is to teach proper citation in class or request a class session with a campus librarian.

CONCLUSION

Writing assignments are both appropriate and beneficial for students in MIS and IT courses. Specific examples of writing assignments that have been successfully implemented, including short papers, group projects, research papers and in-class writing, have been discussed. To create employable graduates, faculty must begin to take responsibility for the development of the whole student, and not simply accept responsibility for discipline-specific skills only. Key to the success of incorporating writing into a curriculum is providing clear grading requirements to students as well as feedback. Plutsky and Wilson (2001) suggest some critical success factors for writing across the curriculum, including developing standards for writing and assessment, and providing training programs for faculty. Accordingly, we offer this chapter as a resource that MIS/IT faculty can use as a starting point for incorporating writing into their own courses.

ABSTRACT

Telecommunications companies are facing a challenge in satisfying changing customer demands related to telecommunications services. Historically, the industry challenge was managing the changing technology; today, the industry must also focus on the management of telecommunications services. The purpose of this chapter is twofold: (1) to provide an argument for the importance of the management of telecommunications services as a vital new course area at the university level, and (2) to describe one possible model for a new undergraduate course, Management of Telecommunications Services. The chapter is targeted towards university faculty and administration and

corporate representatives responsible for technology education. The ultimate goal of the course is to align university curriculum with the needs of the telecommunications industry and provide the industry with entry-level information technology (IT) employees who have an understanding of the fundamentals of the management of telecommunications services.

INTRODUCTION

The deregulatory impact of the 1996 Telecommunications Act resulted in fierce competition for customers by telecommunications firms. This competition has intensified, and in order to

increase the size of their customer base, many telecommunications companies are striving to create a competitive advantage through an increased variety of service offerings. These telecommunications companies hope that by adding new types of services to their existing ones they can achieve economies of scope (Grover & Saeed, 2003).

As telecommunications companies face challenges in satisfying customer demands related to telecommunications services, telecommunications providers have been forced to rethink the fundamental way they do business. Historically, the industry was driven by the management of changing technology; today, the industry also has to focus on the management of telecommunications services. Hall (1996, p. 10) summed up the new challenge facing the telecommunications industry regarding the management of telecommunications services: "... services are now being defined in terms of what they provide to users. For suppliers, this requires a radical change of perspective, from being technology providers to becoming service providers, which must also be reflected in the approach to management."

The turmoil in today's telecommunications industry's services sector is a reflection of the state of the service sector in the United States (U.S.). In the U.S. economy, where services account for 73% of the gross domestic product, the entire service sector is in a constant state of change that is causing upheavals in the traditional ways of doing business (Lovelock & Wright, 2002).

Top managers in the telecommunications industry recognize the crucial importance of the effective management of customer services. One industry person noted that, "Several years of good-quality communication service can be shattered in a few minutes if the customer care processes are poor" (Adams & Willets, 1996, p. 1).

In response to the changing critical success factors for telecommunications companies, the field of management of telecommunications services began in the mid 1990s with the initiation of

research and applications geared toward providing better management of telecommunications services. Managing the services that telecommunications providers deliver to their customers is defined by Adams and Willets (1996, p. 29) to mean "the entire customer-service spectrum, including order handling, service quality, problem handling, billing, service development and so on." Adams and Willets stress that, to satisfy customers' requirements, the effective management of telecommunications services involves the continuous rebalancing of three objectives: (1) reduction of cost; (2) improvement of service quality; and (3) reduction of time-to-market of new services (1996).

Organizations are beginning to realize that adequate attention to the service management function can bridge the gap between the technological functions (element management and network management) and the business management function. Telecommunications industry organizations must effectively manage services to satisfy the level of quality services demanded by customers. In turn, effective service management can generate more revenue and have a positive impact on the successful business management function. The Telemanagement Network (TMN) Framework illustrates the four managerial functions of an organization in the telecommunications industry. A pyramid representing the TMN Framework is composed of four layers, listed here in descending order: Business Management, Service Management, Network and Systems Management, and Element Management (Adams & Willets, 1996, p. 28).

Because service management in the telecommunications industry is not well understood, attention is now being directed to management of telecommunications services. Ward said that for the telecommunications industry, service management remains its least understood area, and that, "The next frontier is service management" (Ward, 1998, p. 157).

This chapter will provide support for the growing importance of the management of telecommunications services as a vital new course area at the university level and describe one possible model for a Management of Telecommunications Services course.

WHY MANAGEMENT OF TELECOMMUNICATIONS SERVICES IS A VITAL AREA OF STUDY

A review of the literature provides ample evidence supporting the significance of the management of telecommunications services as a vital area of study for IT majors. This section will discuss four key factors driving the increasing importance of managing telecommunications services and several important responses by the telecommunications industry. These key factors include: (1) increased competition in the telecommunications industry; (2) unmet service needs of customers; (3) telecommunications industry recession; and (4) the unique complexities of the telecommunications industry.

Increased Competition in the Telecommunications Industry

The first key factor is the high level of competition in the telecommunications industry. Today's telecommunications industry is described as "a scene of global hyper-competition" (Korhonen & Ainamo, 2003, p. 2). The key to survival in the competitive telecommunications industry is to make certain that an organization's learning outpaces that of their competitors (Johnson & Jakeman, 1997, p. 234). In the telecommunications industry, one critical success factor in outpacing competitors is effective management of customer services. Successful telecommunications organizations will be the ones that effectively manage customer services (Adams & Willetts, 1996).

Unmet Service Needs of Customers

The second key factor is the unmet service needs of customers. In the mid 1990s, many telecommunication providers strived to secure more customers and generate more revenue by introducing a plethora of services. However, the present level of telecommunications services offered by many telecommunications service providers does not fully satisfy the various customers' requirements (Adams & Willetts, 1996; Forouzan & Fegan, 2003; Korhonen & Ainamo, 2003; Rosenbush & Elstrom, 2001). A resulting problem is that the customers' needs may not be met or customers may not adequately understand the services offered.

Telecommunications Industry Recession

A third factor is the worldwide recession that the telecommunications industry has experienced during the last several years (Eyers & Hahn, 2002; Shannon & Schenker, 2003). A recently authored paper by Malcolm Russell, a strategic business manager with Agilent Technologies (Russell, 2003), argued that if the telecommunications industry is to move forward from its current recession, it needs to focus less on technology for its own sake and more on telecommunications services.

Unique Complexities of the Telecommunications Industry

The fourth key factor is the unique complexities of the telecommunications industry and the inherently intangible nature of telecommunications services. For any service-intensive industry, management of customer services is a challenge. In the telecommunications industry, the nature of the product itself makes the management of services especially difficult. Adams and Willetts

(1996, p. 1) point out that telecommunications “service providers are nearly invisible” and their product “is probably the most intangible product any company might sell.” Furthermore, there are unique complexities present in the telecommunications industry that makes service management much more challenging than any other service-based industry. One such complexity is the proprietary nature of many of the existing systems used to manage telecommunications services; these older systems lack the flexibility and quick reaction time necessary in today’s dynamic telecommunications industry (Lewis, 1999). Adams and Willets described additional unique complexities of the telecommunications industry that impede effective management of services: (1) Telecommunications involves an extensive service delivery chain that is becoming more complex as the industry changes shape; (2) service providers operate on the leading edge of new technology, while dragging along plants and processes that can date back 100 years; and (3) the communications industry is becoming increasingly distributed as geographical boundaries are stretched (1996).

Industry and Firm Responses

In addition to the response by individual firms to addressing challenges in the management of telecommunications services, the industry as a whole responded by founding the TeleManagement Forum (TM Forum) and the TM Forum’s Universities Program. Recognition of the need for better management practices within the telecommunications industry was the impetus that led to the founding of the TM Forum. TM Forum is a “non-profit global organization that provides leadership, strategic guidance and practical solutions to improve the management and operation of information and communications services” (TeleManagement Forum, 2004). Today, TM Forum has a membership of more than 340 companies, most of whom are considered the leading firms in

the worldwide telecommunications industry.

Additionally, the TM Forum is in the initial stages of broadening its mission to include partnering with universities and university faculty by developing TM Forum’s Universities Program (The Charter, 2003). The TM Forum’s Universities Program was established July 31, 2003, to facilitate the formation of much-needed closer working relationships between TM Forum, university faculty and other academic participants. This relationship is designed to assist in promoting teaching and research efforts in the area of the management of telecommunications services and in aligning university curriculum with telecommunications industry needs. Some of the specific goals related to the management of telecommunications services for this new university program are: providing a forum for sharing information pertaining to management of telecommunications services; providing assistance in the teaching of the management of telecommunications services topics; providing new outlets for faculty publication; and sponsoring faculty research (Members of the TM Forum’s Universities Program, 2003).

Currently, a diverse set of universities throughout the world has joined TM Forum’s Universities Program. The number of member universities is expanding rapidly and includes those listed in Table 1.

This new focus on service management must be understood and addressed by those responsible for the telecommunications curriculum in universities. To help meet the immediate needs of the telecommunications industry, universities should begin to educate entry-level employees who have a strong foundation in management of telecommunications services. Such employees can more quickly attain leadership roles in customer service, where they can assist in effectively managing customer services. To align the knowledge and skills of entry-level telecommunications employees with the needs of the industry, this chapter proposes a university course, the Management of Telecommunications Services.

Table 1. Member universities of TM Forum's Universities Program

Country	Universities
Croatia	University of Zagreb

UK	University College London, University of Glasgow
U.S.	James Madison University; Stevens Institute of Technology; University of Maryland, College Park

A PROPOSED MODEL FOR THE MANAGEMENT OF TELECOMMUNICATIONS SERVICES COURSE

As a response to the growing importance of the management of telecommunications services, we describe one possible model for a Management of Telecommunications Services course. The proposed course model is based on prior industry experience in research and development in the telecommunications industry, on recommendations by IT professionals, and on experience in teaching the introductory telecommunications course. This model has been proposed and will be used in a course at our university. Since there is an immediate need in the industry for entry-level employees who possess a better understanding of the fundamentals of managing telecommunications services, the course described in the proposed model is intended for the undergraduate level. However, it could be readily adapted to suit the needs of graduate students.

In both the 1997 and 2002 IS Model Curriculum guidelines, developed by a nationwide committee of IT professionals and faculty, it was recommended that universities offer a required introductory telecommunications course (IS, 1997, 2002). An examination of the Web sites of universities and informal conversations with colleagues at professional meetings indicate that

a growing number of schools are requiring the introductory telecommunications course as part of the IT degree program (Choi & Teer, 2003). Since many IT programs now have a qualified person to teach the undergraduate telecommunications course, those telecommunications professors should be qualified to teach the Management of Telecommunications Services course.

The proposed Management of Telecommunications Services course is designed to give IT undergraduates an awareness of the issues of service management in the telecommunications industry; an understanding of the core technologies interfacing the management of services; and a survey of current management best practices.

The course model is presented in three parts: (1) course content, (2) teaching resources, and (3) course structure.

Course Content

The rationale for including certain topics in the course content is based on: (1) a careful review of the Model Curriculum Guidelines of IS 1997 and 2002 (IS, 1997, 2002) and, in particular, the material in section IS 2002.6: Networks and Telecommunications (IS, 2002); and (2) recognition of the action items needed to address the key industry factors driving the importance of managing telecommunications services. The following general topics are recommended for the

Management of Telecommunications Services course. Under each general topical area are the specific topics to be included.

Fundamental managerial concepts related to services in the telecommunications industry:

1. Introduction
2. What is the management of telecommunications services?

The rationale for why effective management of telecommunications services is needed:

3. Service management requirements of providers of telecommunications services
4. Service management perspectives of private network operators

The technical components of the interface of telecommunications core technologies and the management of telecommunications services:

5. Integration of telecommunications services
6. Systems interoperability as it relates to management of telecommunications services
7. Integration architecture as it relates to management of telecommunications services
8. Service management systems framework

The crucial industry leadership role of TM Forum:

9. TM Forum

Technical topics are addressed with real-world, hands-on experience:

10. Business case design for better service management
11. Individual and group research project

Framework, principles and future directions for telecommunications services:

12. Toward an effective service management paradigm
13. Practical implementation principles for successful management and evaluation of services
14. Future directions in the management of telecommunications services.

TEACHING RESOURCES

Most of the available reference material for the management of telecommunications services is in the form of (1) industry targeted books, (2) online journals and magazines, (3) magazines and newsletters, (4) journals, and (5) Internet resources. Since the management of telecommunications services only became an area of major industry concern in the mid-1990s, there are management of telecommunications services books aimed for an industry audience, but there are no textbooks and related ancillary materials for the university market.

Books. Numerous books were reviewed for material relevant to a course in the management of telecommunications services. We found seven books that contained at least one good chapter on the management of telecommunications services. Information on these seven books, including the depth of coverage of management of telecommunications services topics, is given in Table 2.

We believe *The Lean Communications Provider* (Adams & Willets, 1996) to be the seminal work for the management of telecommunications services. Even though it is presently out of print, it can still be purchased and is available in many libraries. The topics included and depth of coverage of those topics makes this an excellent resource book for the teaching of the management of telecommunications services. This four-part book is based on technical contributions from the members of TM Forum and includes a balance of technical components and managerial issues.

Management of Telecommunications Services

Table 2. Books relevant to Management of Telecommunications Services course

Authors	Title	Year	Publisher	Coverage of Management of Telecommunications Services
Hallows, R.D.	<i>Service Management in Computing and Telecommunications</i>	1995	Artech House	Throughout the book; Chapters 1-12
Adams, E.K. Willets, K.J.	<i>The Lean Communications Provider – Surviving the Shakeout through Service Management Excellence</i>	1996	McGraw-Hill Inc.	Throughout the book; Chapters 1-23
Hall, J. (Ed.)	<i>Management of Telecommunication Systems and Services</i>	1996	Springer-Verlag	Chapter 1 Introduction and Chapter 4 Examples of Service Management
Ward, E.P.	<i>World-Class Telecommunications Service Development</i>	1998	Artech House	Chapters 1-22
Strouse, K.G.	<i>Marketing Telecommunications Services: New Approaches for a Changing Environment</i>	1999	Artech House	Part V Customer Focus Chapter 14 Customer Care Chapter 15 Customer Profiling and Data Management Chapter 16 Customer Loyalty and Managing Churn
Odon, A. Ward, K. Savolaine, C. Daneshmand, M. Hoath, P.	<i>Telecommunications Quality of Service Management: From Legacy to Emerging Services</i>	2002	Inspec	This book surveys the key issues related to the delivery and management of customer quality of service. This book covers especially topics of consumer and user groups and comparisons of performance.
Carr, H.H. Snyder, C.A.	<i>Management of Telecommunications – Business Solutions to Business Problems Enabled by Voice and Data Communications</i>	2003 2 nd Ed.	McGraw-Hill/Irwin Inc.	Chapters 12 and 13 (Part 4 Managing Telecommunications)
Korhonen, T.O. Ainamo, A. (Eds.)	<i>Handbook of Product and Service Development in Communication and Information Technology</i>	2003	Kluwer Academic Publishers	Chapter 3 User Centered Design of Telecommunications Services

The book's first part, "When Service is Your Business," introduces: (1) the emergence, definition and importance of the management of telecommunications services; (2) service management requirements; and (3) the perspectives of service providers and private enterprise network operators.

The second part, "It's All about Integration," covers: (1) service integration and the architecture for service management; (2) the interoperability

between different service management systems; and (3) barriers to excellent service management.

The third part, "It's Best Not to Go It Alone," emphasizes the importance of cooperation with other organizations in the global telecommunications environment.

The fourth part of the book, "Getting to Excellence," covers: (1) the purpose of TM Forum and the importance of a common model for effective

communication among participating members; (2) the service management business process model; (3) major service areas in telecommunications, such as order handling, problem handling, performance reporting, billing and the transition of business process agreements to technical specifications; and (4) a systematic approach on the issues of software platform modeling, interoperability, legacy systems and conformance requirements.

Online Journals and Magazines. Online journals and magazines provide current material on the issues involved in the management of telecommunications services. Some of the more noteworthy publications are:

1. *Institute of Electrical and Electronic Engineers (IEEE) Communications Surveys and Tutorials* (www.comsoc.org/livepubs/surveys/index.html)
IEEE Communications Surveys and Tutorials is the free IEEE ComSoc (Communications Society) online magazine for generalist throughout the field of communications and communications networking. Readers are the people involved in research and development, deployment, or instruction in fields related to communications.
2. *Telephony Online* (www.internettelephony.com/)
Telephony is the leading publication for all communications service providers: new and incumbent, wired and wireless. It delivers insightful and thoughtful coverage of the news, technologies and business strategies driving the industry for more than 70,000 providers. Major topics are access technology, finance, back office, optical, broadband services, regulatory, enterprise and wireless.

Magazines and Newsletters

1. *Telecommunications Magazine* (www.telecoms-mag.com)
Telecommunications Magazine is aimed at satisfying the information needs of service providers, and is targeted mainly to professionals at the decision-making level. A version for the 'Americas' and one for the 'International' markets are published, and provide the latest news on broadband access, optical networking, service provisioning, monitoring analysis, and wireless and service providers.
2. *IEEE Communications Magazine* (www.comsoc.org/pubs/commag/)
IEEE Communications Magazine provides timely information on all aspects of communications: technology, systems, services, market trends, development methods, regulatory and policy issues, and significant global events. It is also available online and is a publication of the IEEE Communications Society. This magazine features issues in March each year on Telecommunications Management.
3. *Service Management Europe Magazine* (www.servicemanagement.co.uk/pages/index.cfm?pageID=872)
Published by **Penton Media Europe**, this is the UK's premier high-tech field service publication. It features a wide range of articles offering in-depth analysis and insights into the spectrum of existing and emerging service challenges that decision makers face today.
4. *Service Management Europe Newsletter* (www.servicemanagement.co.uk/newsletters/index.cfm)
This newsletter complements the *Service Management Europe Magazine* by providing regular issue-driven, electronic newsletters (*SM News*), so that subscribers remain in constant touch with what is happening.

Journals

1. *International Journal of Services and Standards (IJSS)* (www.inderscience.com/catalogue/s/ijss/indexijss.html).

IJSS presents current practice, models and theory in services and standards development, design, management, implementation and applications. The objectives are to develop, promote, and coordinate the development and practice of services and standards. *IJSS* aims to help professionals working in the field of service and standards, academic educators, and policy makers to contribute, disseminate knowledge and learn from each others' work in the area.

2. *Journal of Service Research* (www.rhsmith.umd.edu/ces/Journal_of_Service_Research.html#board)

This multi-disciplinary journal has an international service research scope. The journal's mission is to be the leading outlet for the most advanced research in service marketing, e-service, service operations, service human resources and organizational design, service information systems, customer satisfaction and service quality, and the economics of service.

3. *International Journal of Network Management* (www3.interscience.wiley.com/cgi-bin/jhome/5703)

This journal provides practical information for more effective management, operation and maintenance of communications networks. Articles facilitate the readers' evaluation of equipment and systems, provide a detailed description of performance issues, and discuss the advantages and disadvantages of a variety of networking approaches. Target readers are telecommunications managers, engineers, researchers and students of communications technology.

4. *Journal of Network and Systems Management* (www.cstp.umkc.edu/jnsm/)

This journal covers a wide range of telecom-

munications topics, including: architecture; analysis; design; software; standards and migration issues related to the operation, management and control of distributed systems; and communication networks for voice, data, image and networked computing.

Internet Resources. While one has to be cautious about the credibility of Internet resources, there are some excellent sources for the management of telecommunications services. Some of the best are:

1. Telecommunications services management guide (www.digitalfuel.com/TelecomServices.asp)
2. Telecom service management software directory (www.capterra.com/telecom-service-management-software)
3. Telecommunications management – comprehensive directory of useful resources (<http://homepage.tinet.ie/~slevin/tm/tm-info1.htm>)
4. Telecom management information – resource for better telecom cost and information management (www.telecominfo.com/)
5. Tech library – white papers, case studies and product information on hot telecommunications technologies (<http://techlibrary.commweb.com/>)

Course Structure. Delivery methods for the course material and the associated learning activities should be tailored to each professor's preferred teaching style. The suggested course structure outlined here is one that fits our preferences and is deemed to be a generalized model adaptable to most teaching styles.

Lectures utilizing material obtained through books, journals, the Internet, and trade publications should be used throughout the course to assist in building a framework of understanding that will enhance the students' understanding

of assigned readings and projects. The order, frequency and depth of lectures will depend on the professor's preferences and the previously assigned reading material.

As part of the Management of Telecommunications Services course model, three specific course activities are recommended: (1) an individual research project; (2) a group research project; and (3) a hands-on project using service management software.

The syllabus distributed at the beginning of the semester should include the detailed assignment guidelines for the individual research project and the group research project, a description of the deliverables and the evaluation criteria. It is recommended that the performance of each individual project and each group project be monitored, by requiring students to turn in two or three intermediate progress reports at predefined points in the individual and group research projects. The deliverables from the individual and group research projects should be evaluated on content, format, style, and other predefined criteria.

Individual research project. The instructor should provide students with a list of possible research topics from which they can choose. These topics should coincide with current course content or current issues in the management of telecommunications services. To aid undergraduate students in the literary search necessary for their research, it is suggested that a professional business librarian from the university library be invited to class to provide a tutorial on performing a literary search.

Group research project. After completing an individual research project, group research projects should be assigned to groups of three or four students. The group research project will be useful in stimulating students' learning of new and interdisciplinary concepts in the more flexible and comfortable learning environment of the peer education process. This will also provide students

with experience in working in teams, a skill that they need to further develop and practice before entering the workplace.

It is recommended that the group research topic be based on a real-world business and an existing service in that business. Using real-world cases in the group research projects will afford students the opportunity to experience things firsthand, such as realistic content, real-world business objectives, organizational impacts, social values, and ethical issues (Hackney, McMaster & Harris, 2003; Gendron & Jarmoszko, 2003). The research topic can be selected by brainstorming among group members, or the professor can assign them. The students are asked to complete their group research project as follows:

1. Select a target telecommunications service provider (e.g., a particular mobile phone service provider) and one service delivered by that provider (e.g., family calling plan).
2. Survey existing literature regarding the specific service provider and service selected to fully understand what is happening in today's marketplace.
3. Propose new, improved features to the existing service by using available management of telecommunications services techniques learned as part of the course.
4. Suggest new ideas to improve legacy services currently offered to customers.

At the completion of the projects, each group will present the results to the entire class. In addition to a class presentation, utilizing presentation software such as Microsoft PowerPoint, the students should provide the professor with a presentation file, a written project report and a few test questions the group feels the class could answer after listening to the formal presentation. The questions collected from all the groups may be used on the final exam to test the level of understanding of all students on all research project presentations. Such a procedure can be very use-

ful in garnering student attentiveness during all group presentations. The instructor and all class members will evaluate each of the group research projects based on prearranged guidelines.

Hands-on practice using service management software. To enhance the students' understanding of technology and its application in the real world, it is important to give students hands-on experience with technology in a telecommunications lab in the class room (Greca, Cook, & Harris, 2004). Hands-on practice opportunities in which the students actually use service management software will be beneficial in enhancing their understanding of the course's technical components. Depending on the learning environment desired by the professor, the hands-on practice opportunities can be offered as lab sessions or as individual take-home assignments.

Students' hands-on work with software should follow a process designed to foster the incremental building of students' software skills, from basic to advanced. Therefore, it is recommended that students begin with data service management software, then migrate to network monitoring and analysis software; then utilize network management software; and finally try hands-on practice with management of telecommunications services software.

Unfortunately, due to the high cost of software, there is minimal management of telecommunications services software available for the hands-on training of university students. With limited university budgets, the use of downloadable public-domain software meets the needs of universities' telecom labs (Choi, 2003). Although public-domain software specifically for the management of telecommunications services does not appear to be presently available, public-domain data communications network software can be substituted, since data communication network software closely matches the features of management of telecommunications services software. Through the relationship with the industry fostered through the TM Forum's University

Program, telecommunications faculty should be able to eventually secure full-fledged management of telecommunications services software for their universities' telecommunications lab facilities.

CONCLUSION

Since the effective management of telecommunications services is critical in the telecommunications industry, a new Management of Telecommunications Services course is needed to prepare students for the demands made by employers.

An awareness of the importance of the management of telecommunications services and the developed course model will be of interest to three groups. First, researchers in academic communities should be aware of the important role of management of telecommunications services in the industry and the resulting implications for needed IT research. Second, IT curriculum planners will find this information helpful as they strive to design curricula that will meet employee training needs of the IT industry. And third, telecommunications professors need to know the importance of management of telecommunications services and need to have a working course model from which they can begin structuring a course.

The proposed course model is meant to serve as a call to action and to be an initial step toward the development of a needed telecommunications course. Future research on empirical evidence gleaned from students who have participated in this course and feedback from their employers will provide information needed for adjustments and enhancements to the course content and delivery methods.

Section 7

Critical Issues in Information Communication Technologies

This section addresses conceptual issues related to the field of ICT, such as the existence of a gender barrier and the potential of ICT for realizing social justice. Within these chapters, the reader is presented with an in-depth analysis of the most current and relevant conceptual inquiries within this growing field of study. Particular chapters address attitudes toward ICT in high schools, international ICT spillover, and ICT literacy among members of society. Overall, contributions within this section ask unique and often controversial questions related to ICT study and, more often than not, conclude that solutions are both numerous and contradictory.

Chapter 7.1

ICT, Work Organisations, and Society

Gunilla Bradley

Royal Institute of Technology, Sweden

INTRODUCTION

The present fourth period, the network period, is characterised by a convergence of three main technologies (computer technology, telecommunication technology, and media technology) into information and communication technology (ICT). ICT are embedded in many things and the invisible microcomputerisation that once took off with the chips is enhanced through nanotechnology, biotechnology, and wireless technology—often entitled ubiquitous computing. The author presents ongoing changes in work life and presents a theoretical model: The convergence theory on ICT and psychosocial life environment. The convergence model reflects some main ongoing processes in the network society encompassing various spheres of life (professional, private, and public). Sociological theories on the Information Society are discussed in this context as well as theories from the information systems (IS) community. In the Future Trends section the new international collaboration is addressed where research and policy (including politics) develop

goals and strategies to deal with societal and psychosocial changes related to the development, introduction, and use of ICT.

BACKGROUND

The area, Information and Communication Technology and its interaction with social changes on organisational, individual, and societal levels, has in the 2000s received growing attention, due to the depth and wide use of it. This article is mainly based on my latest two books. The first one, *Humans on the Net: ICT, Work Organization, and Human Beings* (Bradley, 2001) was presented at the first European Union (EU) conference, *Work Life 2000*, during the half year when Sweden chaired EU. The second book, *Social and Community Informatics: Humans on the Net* (Bradley, 2006), summarises and updates the authors research over 30 years. It will hopefully serve as a source for people to better understand and contribute answers to questions such as: How will people live, learn, and work in the future ICT

society? In short, key issues within the organisational change/psychosocial life environment, and their interaction with the use of information and communication technology are analysed.

Some sections were presented at the World IT Forum (WITFOR 2003) in Vilnius in August 2003 addressing “Social and Ethical Aspects of the Information Society” and at the conference, “E-society” in Avila, Spain in 2004.

Empirical experiences show that it is important to keep a balance between pure technical research and development in software and hardware technologies, new fields such as nanotechnology and the behavioural and social science disciplines, for example, psychology, sociology, cultural anthropology, and ethnography.

The ICT-related disciplines have so far been focused too much on the “technology push” instead of on human needs and requirements in the development, introduction, and use of ICT. New universities, sometimes called IT universities, are appearing in many European countries trying to bring together disciplines from the traditional university and disciplines from the technical university to facilitate a necessary rethinking and reorientation of research and development (R&D), sometimes resulting in new centres directly entitled “Humans in the ICT Society” focusing on the human, organisational, and societal aspects of ICT use.

THE NETWORK ERA: CONTINUOUS AND ACCELERATED CHANGES IN THE DESIGN OF ORGANISATION, WORK TASKS, AND MANAGEMENT

The main changes during the network period are summarised in the next five sections and are mainly based on Bradley (2001) and further developed in Bradley (2006). They are primarily derived from our research in the developed countries.

Accelerated Changes at Work in the Net Era

More flexible work processes have appeared regarding both the professional role itself and leadership. Further, the professional role, the learning role, and the role of citizen are becoming more and more integrated. Repetitive jobs and physically strenuous jobs, including routine work, are disappearing and a total upgrading of qualifications has occurred. In parallel with this, the organisation has become flattened out. In an international perspective more work tasks are becoming similar because software programs are sold world-wide and the work tasks are carried out in a more and more similar way.

Organisational structures as networks have become more and more common. Psychosocial and organisational aspects of networking have come into focus in recent research.

Network Organisations are Like Crocheted Table Cloths

- A crocheted lace cloth is a good model for the developing and future structure of how the world—social systems, organisations, and official authorities—will look. The network era has been established and networks interact more and more wirelessly. It is possible to crochet all the time: each new loop (computer) is connected to another loop through the same yarn (tele-technology).
- Power can both be centralised and decentralised in the network structures, but the process is invisible.
- The distribution of power is now possible in quite a deep sense as competence transfers to the periphery, out to the production level.
- The hierarchical structures of companies that mirrored industrialisation and industrial technology during the mainframe period of the computerisation era are fading away.

The present trend toward the flattening of hierarchies can, according to Aulin's law of requisite hierarchy, be explained by the increasing regulatory abilities of individuals and organisations, due to such factors as better education, management, and technological support (Heylighen & Joslyn, 2001). Another way to express this is that hierarchical regulation and hierarchical organisations are built into information systems and ICT.

Network Organisations: New Communication Patterns

Some examples of what characteristics the network organisations have and how people are affected are:

- direct communication between the various levels of the organisation
- barriers between idea and execution are disappearing
- reallocation of power in the organisation
- continuous changes of structure and roles
- openness to the surrounding world
- multidimensional virtual culture

Decreasing Core Workforce in the Flexible Company

At the centre there is a core workforce of permanent full-time employees who enjoy a wide range of employment rights and benefits; however, the core workforce is decreasing. The other growing part is the peripheral workforce. It consists of part-time staff, self-employed consultants, subcontracted and outsourced workers, and temporary and agency employees. Some of these "knowledge workers" are key resources, while others are exchangeable. Through the network organisational structure they might have very strong positions in the company because of their expertise or social contacts, although this is unseen. Power is invisible in these new forms of organisations: power has no

outward manifestation and is not reflected to the same extent as before in properties and gadgets linked to leadership.

Hence more and more organic organisational structures are developing, with a focus on flexible work processes, including dynamic networks for capital and human resources (compare the network organisations above). Economic systems are being created where the present boundaries are increasingly becoming eroded. Advanced ICT support is used for various forms of collaboration. More and more individuals function as self-governing company units.

Reflections

There are both positive and negative impacts on the individual. One critical point is that too much responsibility is put on the individual who:

- loses permanent employment
- has to manage his/her own competence development
- has to market himself/herself
- is expected to take on any position and swallow job enlargement
- is expected to be creative – with little compensation
- is a unit in a competitive world market

One might ask if this means the freedom from paid work in a traditional sense. Other questions are: Should our school system prepare for fostering free agents or portfolio individuals? Should school and learning prepare young people for acting proactively in meeting the ongoing unhealthy development? From an ethical point of view individual responsibility is "a word of honour". People need a basic security as (employees) citizens. Regarding the role as workers and citizens, there is a need for balance between a strong society and strong individuals. Few persons are strong throughout life. The importance of thinking in terms of

sustainability both regarding environment and sustainable human beings is becoming clear.

The Home Becomes a Communication Sphere

The big challenge in the near future is the home in a broad sense, as many human roles are converging to one life role, and the home is more and more understood in terms of virtual space as well as physical. Driving forces are converging embedded technologies. The following trends are enforcing the home as a communication sphere, where the home could be regarded as an extended family centre, a care centre, a multimedia centre, a centre for democratic dialogue, a marketplace, a learning centre, and an entertainment centre.

The Occurrence of an Accelerated Tempo

Research shows that there are reasons to talk about ICT stress or Internet stress. Certain ICT stress is related to the fact that there is an increased dependency on computers and networks and an increased expectancy that these technologies are functioning well. Stress phenomena in the Internet world are information overload, contact overload, demands for availability, lack of organisational filters, and difficulty of separating noise from essentials, changing level of expectations, and an altered perception of time and space in general.

THEORIES ON ICT AND ORGANISATIONAL AND SOCIETAL CHANGE

Theoretical models on “Computer Technology and Changes and Work Life” were developed by the author (Bradley, 1977, 1986/1989) and were empirically tested in three large work organisations in Sweden, representing three main historical periods of computer technology (from

mainframe computers to microcomputerisation). The psychosocial work environment was considered in terms of the following perspectives: three levels of analyses (individual, organisational, and societal), objective and subjective work environments, interplay between the levels of analysis, interplay between objective and subjective work environments, interplay between working life and private life, and a life-cycle perspective.

The roots are in social psychology and organisational theories the way these disciplines were interpreted in the Nordic countries at the time. A main perspective is that the environment/structure on various levels is affecting the individual, but she/he can also impact the society on these levels. The concepts of the model include structural factors, our perception of these, and intervening variables that explain reactions but also have to be focused at the use and introduction of ICT.

Psychological variables were used as general terms covering a number of intermediate, psychologically relevant variables such as the level of aspiration, weight attached to specific work-environment areas. Psychosocial environment referred to the process involving the interaction between the objective environment and the subjective one and, essential concepts within the psychosocial work environment included factors such as contact patterns and communication, organisational structure and design, work content and workload, participation in decision making, promotional and development patterns, salary conditions and working hours. Theories, methods, and results from the RAM programme were summarised in “Computers and the Psychosocial Work Environment” (Bradley, 1989) and appear also in “Social and Community Informatics” (Bradley, 2006), since the measures and tools are still relevant for studies of the social and organisational impact of ICT, but now are applicable in the broad life environment.

The present network period is based strongly on the convergence and integration of three main technologies: computer technology, tele-technol-

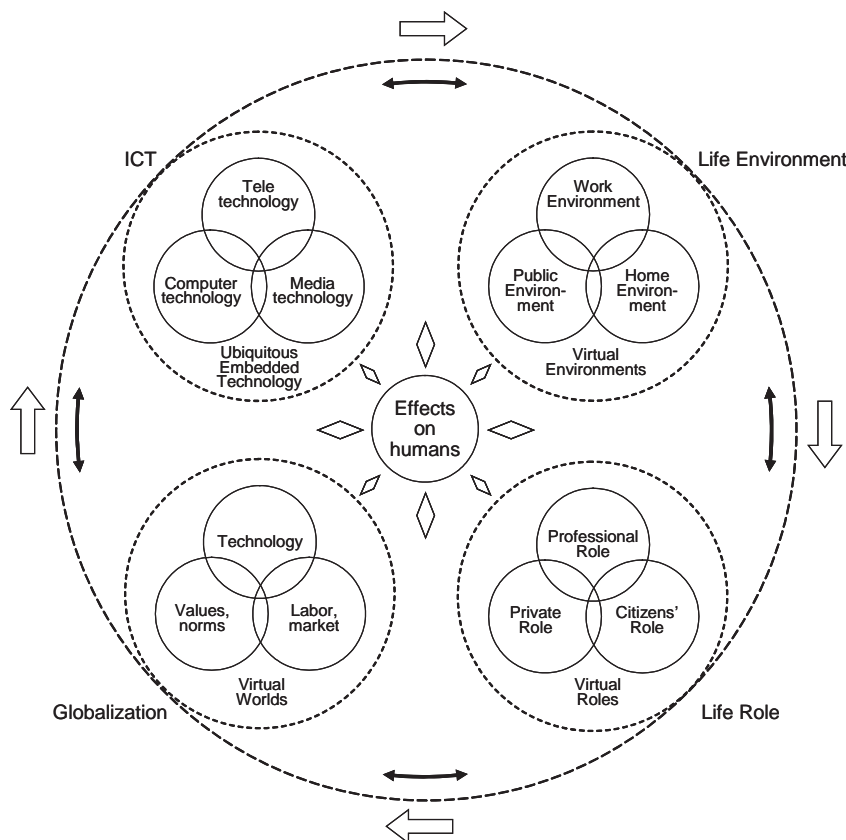

ogy, and media technology. The convergence process (see Figure 1) is enforced all the time by smaller, cheaper, and more powerful components. ICT is more and more being used in almost every activity and embedded in more and more places (ubiquitous computing). Converging circles are reflecting graphically the ongoing process.

Both convergence and interactions are important features in the model. Convergence here means a move towards a common content. Interaction means that technology interacts with the social world with values and beliefs. There is also an ongoing interaction between the “clusters of circles”.

The convergence model on “ICT and the Psychosocial Life Environment” is a graphical illustration of ongoing changes in the Net Society. It is presented in detail in Bradley (2006). Some comments concerning the model in Figure 1 will follow, and the description of structures with reference to concepts (1-5) in the outer circle in the figure.

1. Globalisation: A convergence is occurring between technology, economy, norms/values, and labour market and is entitled globalisation. The geographical span is changing. At present our work life is mainly based

Figure 1. Convergence model on ICT and psychosocial life environment (Bradley, 2005, in press)

- on national and international trade which will be more and more without limits in the future and will take global forms. Electronic commerce and electronic marketplaces are creating a strong change factor behind the structure of work life. The geographical space in the future is both global and beyond—including virtual reality (VR).
2. **ICT:** A convergence of computer technology, telecommunication technology, and media technology is occurring to become what is entitled ICT. Knowledge is managed in new ways. In the 2000s there are multiple channels to choose from: word of mouth, writing, audio visual, and electronic. In the future metachannels, for example, metamedia of VR and controlled reality environments (environments that are manipulated and managed in VR) will become more frequent. In the latest wars it has sometimes been unclear what could be “manipulated reality”.
 3. **Life Environment:** A convergence of work environment, home environment, and public environment are converging to a life environment, where the public issues tend to merge into our homes. A new emphasis on certain dimensions in the psychosocial environment occurs. New dimensions are appearing in the psychosocial environment. Openness for unforeseen implications is required.
 4. **Life Role:** Professional role (work life) and private role (private life) and citizen’s role (public life) converge to become a Life Role. Role and role formation are central concepts in social psychology and represents a level between structures and the individual. The concept “role” is a system of social norms that is directed to an individual as a member of a group or as belonging to a limited category of people. The concept “role” appears where psychology and sociology meet. It is also important that individuals can influence and form their roles.
 5. **Effects on Humans:** Effects on the individual become more multifaceted and complex. This is valid both regarding the psychological and the physical effects on the individual. The way humans handle their situation can roughly be categorised as active or passive reactions. In the Figure 1 this is represented by the circle in the middle, “effects on humans”, with two-way arrows around as a flower showing an interaction. In consequence, the individual is affected by ICT, the Life Environment with its three subenvironments, the Life Role with its three subroles, and globalisation with its three components of values, technology, and labour market. But as an individual, that person can also influence the technology, the environment, and his/her own role and phenomena on the organisational and societal level, and the new virtual reality (see the following).
- Four circles representing VR are marked with dotted lines and surround the four clusters of converging circles. These circles reflect our participation in cyberspace on various levels. In the lower left part in Figure 1, Virtual worlds is a concept that refers to the global level. Within the concept of ICT, the step taken by applied embedded and ubiquitous technology make the technology more hidden for the individual and in the society as a whole. Virtual environments in the upper right part of Figure 1 is already a common concept. Finally, virtual human roles are appearing, which in a more extreme form could be another personality that people play, for example, avatars.
- The thin double-directed arrows represent interaction, and the broader one-directed arrows represent the main direction for the movement and the process described in the circle model. Transferred to actions people can, in the professional role, private role, and citizen’s role influence our

life environment on various levels of analyses (see also Future Trends section).

How do the convergence theory on ICT and the psychosocial life environment relate to other theories on the information society? What do other theories conclude about the information and communication society (ICTS)?

Frank Webster (1995), in *Theories of the Information Society*, provides a point of departure of an interrogative and sceptical view of the concept of an information society (IS). His approach is to start from contemporary social theories instead of social impact approaches. The following are categorised as pro-IS theories: post-industrialism, postmodernism, flexible specialisation, and the information mode of development. The following are against IS theories: neo-Marxism, regulation theory, flexible accumulation, the nation state and violence, and the public sphere. Webster brings forward five definitions of IS which represent criteria for the new society, by its own or combined: technological, economical, occupational, spatial, and cultural. References to some main theories are given in the following: Anthony Giddens (1990, 2000), Herbert Schiller (1993), Jurgen Habermas (1989).

Webster raises the question whether what dominates now is a break or continuity and his conclusion is that there are still features of a capitalist continuity, but also a shift in orientation with some novel form of work organisation and some change in occupational pattern. But there is no system break witnessed so far (Webster, 1995). However a group of theorists categorised as postmodernists (Barthes, Baudrillard, Vattimo, & Lyotard) point out that the information society contains a quite new type of society—a paradigm shift. Jensen (1999) has identified four various directions that for him seems to be plausible for the future: the dream society; the green society; a world of conflict; a world with no changes. He argues that the dream society encompasses the end of human kind's multi-millennium epoch of

material domination and the beginning of the first postmaterialistic era. This is very much in contrast with the view that for a long time people will fight towards the so called digital divide.

The most quoted research during the latest years has been Castells' book on the Network Society. In his latest book (Castells, 2001), he analyses the digital divide from a global perspective.

From the convergence theory (Figure 1) and associated empirical research together with the sociological theories mentioned above on ICT and societal change, the conclusion can be made that up to the beginning of year 2000 there is a continuity as well as new paradigm shift. In other words there are opportunities to influence the direction that will dominate in the future. The question is rather if people are able and willing to engage themselves on various levels of actions.

Theories in the field of this article come from many academic disciplines, academic communities, and cultures which have different perspectives and focus. What are the contributions from the IS community? For many years the focus was in development and design of information systems, and later on, the introduction and use of information systems. The tele-technology and media technology parts of the concept ICT were not addressed for many years. Some contributions after 2000 are as follows.

Melville, Kraemer, and Gurbaxani (2004) have developed a model of IT business value and thereby chose the resource-based view of the firm, which is often used in management literature and international business. They applied the integrative model to synthesise research about IT business value and developed propositions for future research in the field. The principal finding from their analysis was that IT is valuable, but the extent and dimensions are dependent on internal and external factors, including complementary organisational resources of the firm and its trading partners, as well as the competitive and macroenvironment.

Their conceptual model is comprehensive and shows the complexity of the field. It is integrative but is not interactive in the sense that interactions between theoretical levels of analysis are discussed. The following main concepts are of IT resources, technological IT resources, human IT resources, and complementary organisational resources. The other concepts are business processes and performance with focus on competitive environment: industry characteristics, trading partner resources, and business processes. Within a macroenvironment are country characteristics and similar concepts.

Schulze and Orlikowski (2001) have explored the discourse on virtual organising and identified a number of metaphors which characterise various aspects of vitality. They examined the various metaphors in the practitioner-directed literature on virtual organising and concluded that the discourse contained a multiplicity of different metaphors. The identified metaphors were virtual organising as a platform, as existing in space, as composed of bits, as operating as a community, and as engaging in a network of relationships. They suggest that due to the absence of experiences to guide practice, these images are shaping people's views of and actions towards virtual organising. They then analysed these metaphors with regard to aspects of organising, meaning, source, examples, affordance, and challenge. From the conclusion that metaphors are powerful tools of social constructions, they mean that researchers and practitioners should be aware of the critical implications and of unintended consequences.

Another strand of research in the IS literature is user acceptance theory (Davis, Bagozzi & Warshaw, 1989). Van der Heijden (2004) discusses the differences in user acceptance models for productivity-oriented and pleasure-oriented information systems, hence emphasising various values.

In response to the criticism of IS research different types of approaches have been applied, for example, grounded theory, use of the discipline

ethnography, structuration theory, and activity theory to study the design, development, and use of ICT.

Networks of various ICT related academic schools sharing some common perspective form world-wide networks, for example, Network for Value Sensitive Design, Community Informatics Research (CIRN), The International Conference on the Social and Ethical Impacts of Information and Communication Technologies (ETHI-COMP).

In summary, critical research has been more common outside the IS community, but this is changing. Walsham (2005) argues the need for IS research which is critical and aimed at making a better world with technology. He draws implications for actions in terms of research agenda, teaching activities, publishing, and institution building. A better world with ICT should not mean better in purely economic terms, but also related social and spiritual welfare globally. A critical approach is, according to Walsham, a perspective that includes, for example, the social construction of "truth", historical and cultural contingency, and power relations. He concludes that global futures in general, and the IS field in particular, are not predetermined, but result from our own efforts and actions.

FUTURE TRENDS

People are living in a society deeply and broadly affected by the new technology. It might be harder to identify both risks and opportunities at present and for the future. A new generation exists, which has grown up in the digital environment. There are reasons today to go back to classics in research; for example, there are no more work environments in the traditional sense – they are dissolving, although phenomena identified in research in working life, in which the Nordic Countries were very active for many years, have

to be reviewed with a new perspective. How are the human needs of influence, belonging, and meaning met in the new structures and communication patterns?

Regarding “Effects on Humans” (compare Figure 1), important questions for the future are: how is ICT changing our identity and self-perception, social competence, creativity, integrity, trust, dependency, balance between emotional and rational components, balance between female and male, and involvement and alienation?

One way to summarise the discussion on the ICT society and the individual is to address psychosocial processes. These could be formulated as research questions or policy statements. By now there are reasons to start up normative research which later on could be discussed across wider cultures. It concerns the classic question if research is value-free, which at an early stage was challenged by many scholars and with strong arguments.

- Normatively, ICT should contribute to enrichment in the social contact between people and should be used to prevent social isolation and facilitate integration.
- ICT should contribute to a greater autonomy for the individual and prevent stress reactions. Control or freedom is a classic issue often described in the terms of “privacy, integrity”.
- ICT should facilitate information access for all and support individual learning, but at the same time prohibit various kinds of overload, for example, information overload and contact overload.
- ICT should contribute to the deepened development of true human qualities and be used to provide time for people to develop themselves as human beings.
- ICT should contribute to both environmental sustainability and human sustainability.
- E-conflicts must be avoided. E-cooperation and peace is a major goal.

In the Vilnius Declaration at the World IT Forum, the major goals are seen as:

- Bridging the digital divide between rich and poor in the world, urban and rural societies, men and women, and different generations
- Ensuring the freedom of expression enshrined in Article 19 of The Universal Declaration of Human Rights and other such instruments
- Reducing poverty through the use of education and ICT
- Facilitating the social integration of excluded segments of societies
- Respecting linguistic and cultural diversity
- Fostering the creation of public domains with full respect of intellectual property rights
- Supporting communities in fighting illiteracy
- Encouraging e-governance and e-democracy initiatives
- Improving the quality of life through effective health service systems
- Protecting the local and global environment for future generations

There are academic discourses on most of the concepts embedded in the main goals above, for example, digital divide, sustainability, integration, quality of life, and e-democracy. Theories and empirical research in the field have to be balanced with action-oriented, value-oriented research.

WSIS (World Summit on the Information Society) is an opportunity for a wide range of actors to develop principles and prioritize actions that would lead to democratic, inclusive, participatory, and development-oriented ICT societies at the local, national, and international levels. Meetings will continue.

CONCLUSION

With distributed computer power, strong telecommunication (for example, the Internet) and mobile equipment, there is an inherent opportunity for deepening democracy and strengthening individuals and their influence on society. However, there is also an increasing risk of enforcing centralisation and misuse of power. Issues on organisational design and management—especially classics in participation design—are now important areas for R&D, and are valid not solely for the working life and professional role. The organisation and management of our role as private persons and as citizens are becoming crucial.

Within disciplines such as Informatics a discussion of focus in research and development is taking place. Both analysis and design need to address not only the work process and management connected to the sphere of production life, but also people's life environment and the psychosocial life environment. Not only professional roles, but also our roles as citizens and private persons are going through a deep change. Community research in a broad sense comes to the fore, with respect to both physical and virtual communities. Analysis and design of ICT and societal systems at the local level and globally become important. There is also a need for new and additional actors at the deeper and broader integration of ICT in the society (children, elderly, and consumer organisations). Educational programs on community informatics and social informatics are appearing in many academic institutions.

Many academic communities are addressing the complex issue of "ICT and Work Organisation and Society", for example, ODAM within IEA (Organisational Design and Management), ETHICOM, CIRN, CSCW society, and subtracks within HCII (Human Computer Interaction International), and Working Groups within IFIP (International Federation of Information Processing). ECIS (European Conference on Information Systems) and the correspondent international

ICIS (International Conference on Information Systems) are becoming more open to these issues during the latest years. Research becomes easily fragmented and hard to overview. However, new journals are appearing with a broad cross-disciplinary perspective. New centres are established, and widening definitions of disciplines are occurring in parallel with a harder specialisation, especially within electronics and hardware. Hopefully this article will serve as opening the door to a field of research with accelerated speed of change and complexity. There is a need for a much stronger support internationally for cross-disciplinary, cross-cultural, and action-oriented research on the topic, "ICT for Deepening of Humane and Societal Qualities".

KEY TERMS

E-Society: A coherent term referring to a society where information and communication technology deeply and broadly have penetrated and become integrated in the society and its substructures, for example, workplaces, homes, authorities, communities with use of the present terminology, which in the next step could be changed. The prefix “E” refers to electronic communication and/or electronics. Other similar terms used are ICT society, digital society, information society, and computer society. Electronic society or e-society can involve societies that use electronic communications technology over a broad spectrum, for example, the Internet, extranet, e-mail, e-books, databases, and mobile phones.

Convergence: Convergence here means a move towards a common content.

Net, The: Net may mean fibers woven in a grid-like structure, as in fishing net or crocheted cloth. It most often refers to the network (see Network) or Internet (see Internet). In this article it mainly refers to a virtual place where digital information is transmitted and stored and where digital communication has taken place. The term is used for the hardware, software, and structure.

Network Organisation: A computer network is a system for communication between computers. These networks may be fixed (cable, permanent) or temporary via, for example, modem. To network is to interact socially for the purpose of getting connections or personal advancement. Many people network for jobs and information. To get a job in the present economy, it is important to have a strong network. The Internet is the largest of the existing networks. The term network has been transferred to organisational theory and refers to organisations characterised in this article.

Psychosocial: Psychosocial environment refers to the process involving the interaction between the objective environment and the subjective one. Essential concepts within the psychosocial work environment include factors such as contact patterns and communication, organisational structure and design, work content and workload, participation in decision making, promotional and development patterns, salary conditions, and working hours.

Role: The position, task, or function a person has in a certain context and the norms and expectations which are associated with this position or task. Every person has a set of roles which is played in various contexts, for example, professional role, private role, citizen's role. When various roles are hard to combine, a role conflict appears.

Software: Computer software (or simply software) is that part of a computer system that consists of encoded information as opposed to the physical computer equipment (hardware) which is used to store and process this information. The term is roughly synonymous with computer program but is more generic in scope. Software has historically been considered an intermedi-

ary between electronic hardware and data. As computational science becomes increasingly complex, the distinction between software and data becomes less precise. Software may at present be considered an interface between hardware, data, or software.

Stress: Medically speaking, stress is a combination of adjustment measures that is the organisms' reaction to frustrations and other sources of irritation in its surroundings. Stress in everyday speech normally refers to the harmful reactions, even if stress also can be a positive reaction. Stress often refers to the concepts of over-stimulation and under-stimulation. Stress occurs when an individual sees a situation as threatening and cannot reduce his/her frustration by means of socially acceptable and generally appropriate behaviour.

Work Organisation: Refers to the structure of a working place and includes the methods used to allocate work, the basis for decision making and organisational aids. Work organisation is also a part of the social and psychosocial work environment.

Chapter 7.2

A Time Series Analysis of International ICT Spillover

Juan Juan Zhang

National University of Singapore, Singapore

Sang-Yong Tom Lee

Hanyang University, Korea

ABSTRACT

This article studies the role of international spillover of information and communication technology (ICT) in economic growth. We examine the performance of ten countries from 1982 to 1999. By empirically analyzing the relationship between total factor productivity (TFP) and domestic and foreign ICT investment with time series analysis tools, we find limited evidence that there exist international ICT spillovers for a group of countries. Further, we discuss the possible ICT policies to improve productivity and balance out a win-win situation for both ICT spillover sending and receiving countries.

INTRODUCTION

Nowadays, ICT is considered an extremely important factor that contributes to the accelerated rate of productivity of a nation, especially in many newly industrialized economies (NIEs) and developing countries. ICT is the combined utilization of electronics, telecommunications, software, networks, and decentralized computer workstations, and the integration of information media (Granville, Leonard, & Manning, 2000), all of which impact firms, industries, and the economy as a whole. ICT is comprised of a variety of “communication equipment” which includes radio, TV, and communication equipment and

software. Therefore, ICT investment includes “investments in both computer and telecommunications, as well as related hardware, software and services” (Dedrick et al., 2003, p. 4).

In recent years, the combination of computer and telecommunication equipment helps and enables businesses and organizations to share and exchange huge amounts of information. It also eliminates vast amounts of paperwork and speeds up transaction processes by the Internet, Intranets and other networks. In addition, technology and computer production has been a high growth sector in many countries. The ICT industry itself can be a source of economic growth and jobs (Kraemer & Dedrick, 2001). Consequently, it is widely believed that ICT investment helps to enhance productivity and economic growth.

ICT capital exhibits both traditional and non-traditional effects (Dedrick, et al., 2003). As traditional capital, ICT's returns accrue primarily to the firms, industries, or countries that make the investment, and diminish with continuing investment. Contrarily, due to its informational and transformational roles, ICT capital is similar to knowledge capital (Dedrick et al., 2003). ICT capital, if used properly, facilitates knowledge creation. We define knowledge capital as the data, information, knowledge, and wisdom necessary to support and grow an organization or economy. ICT enhances the productivity of employees, and therefore contributes positively to the generation of knowledge capital. Since knowledge capital is not rivalrous and has public goods properties, it leads to potential “spillovers.”

Grossman and Helpman (1991) define spillovers as follows: “By spillovers, we mean that (a) firms can acquire information created by others without paying for that information in a market transaction, and (b) the creators (or current owners) of the information have no effective recourse, under prevailing laws, if other firms utilize (the) information so acquired.” From this definition of spillover, one may derive that ICT spillover is an increase in social benefits without compensating

the ICT investors. If we regard investors as a national economy as a whole, then we have the concept of “international ICT spillover.” In other words, international ICT spillover is an increase in national productivity due to ICT investments in foreign countries.

ICT spillover emerges when social returns on investment exceed their private returns, creating situations in which investment in ICT becomes an innovator or investor, thereby, also benefiting other parties (Leeuwen & Wiel, 2003). “The Information Technology Boom” has given rise to many discussions about the potential of ICT to yield production externalities. Production spillovers or externalities can show up in the form of rent (pecuniary) spillovers or in the form of so-called technology/knowledge spillovers. These arise from the fact that knowledge and technology have some public good characteristics—knowledge capital can be owned and used by many parties simultaneously, leading to potential spillovers (Leeuwen & Wiel, 2003).

Globalization and rapid communications among innovators in different locations facilitate the process of invention and the spread of new ideas across different countries. Scholars have concluded that R&D is transferred from the innovating country to other countries mainly through trade, which helps to stimulate the receiving countries' economic growth. Many researchers have also tried to prove ICT spillovers among firms or industries within a country. However, to our knowledge, studies on international ICT spillovers are rare. Therefore, our main research question is whether foreign ICT investments, just like R&D expenditures, will have spillover effects on domestic productivity growth.

In this article, we would like to examine the relationship between international ICT spillovers and national productivity growth. This article would fill the literature gap on ICT spillovers at the country level. A sample of 10 countries was chosen based on data availability. We deployed time series analysis. If the existence of ICT

spillovers at country level is empirically proven, it may have strong policy implications especially for developing countries.

The organization of the article is as follows: The next chapter is a review of relevant studies in productivity and technology spillovers. Section 3 presents the methodological framework. Section 4 shows a brief discussion of the data sources. The following Section 5 discusses the empirical findings, and comments on the possible limitations. Finally, Section 6 concludes the article with a few thought-provoking issues on policy implications.

LITERATURE REVIEW

TFP as a Measure of Productivity Growth

Total factor productivity (TFP) is not a new concept in the studies on economic growth. Most authors track its origin back to Solow's (1957) empirical work, the so-called "Solow's Residual." TFP is believed to be a residual of production growth, which cannot be explained by increases in factors of input. The unexplained output growth should contain the contribution of new technology (such as R&D, IT, etc.), improved management, and more efficient markets and institutions (Evenson, 1997). TFP as a measurement of technological change is vital because technological change is believed to be the ultimate cause of long-term economic growth (Carlaw & Lipsey, 2002).

The implementation of TFP, or Solow's Residual, offers a better measurement of actual productivity attributed to technology. The majority of earlier research used tangible outputs such as GDP, national wealth, revenue, and other perceptible values in their analysis. These output measures might not have captured ICT's entire contribution to an economy's productivity. Since it had been widely acknowledged that ICT usage provides a wide range of intangible impacts,

such as better processes, improved products, and enhanced services, Solow's Residual better appraises the efficiency of IT, providing better data than using GDP directly.

Technology Spillovers

Technology has become a ubiquitous topic in economic growth theory. Even before technology became so prominent in the mainstream theory, pioneers in the empirical field, like Griliches (1979) and Scherer (1982), were aware of the influence an industry's technology generation can exert on the productivity of other industries, through so-called technology spillovers. In the 1980s and 1990s, many studies confirmed their main findings that technology spillovers have significant productivity effects (Los, 1997).

Technology spillovers are said to exist if market partners receive productivity benefits from technologies developed by others, although there is no monetary compensation for the technology transfer (Meijl & Tongeren, 1999). ICT and R&D can be treated as important technological knowledge. To a large extent, technological knowledge generates public good. The use of a unit of knowledge by one research employee does not prevent other researchers from using it (knowledge is non-rival); however, technological knowledge such as R&D can be appropriated only to a certain extent (knowledge is partly non-excludable) (Mankiw, 2001). Danny Quah defines knowledge-products as "computer software, new media, electronic databases and libraries, and Internet delivery of goods and services" (Granville, Leonard, & Manning, 2000). Hence, both ICT and R&D have the common characteristics of knowledge capital.

Endogenous Growth Model to Estimate Technology Spillovers

An *Endogenous growth model* assumes that technology investment is like knowledge capital investment. Recent developments of endogenous

growth models have stressed the role of knowledge spillovers in generating growth (Lucas, 1988; Romer, 1986). The endogenous theory of growth suggests that technological innovations are becoming increasingly important contributions to economic growth (Evenson & Singh, 1997).

Coe and Helpman (1995) argued that endogenous growth models emphasize innovation and trade as vehicles for technological spillovers, thus permitting developing countries to catch up to industrialized ones. The role knowledge plays in technological progress has been the subject of much recent attention in the economic growth literature. Several studies find that the returns from investment in knowledge are positive; they are greater than returns from investment in equipment, infrastructure, and machinery (Madden & Savage 2000; Griliches, 1994; Nadiri, 1993).

In 1995, Coe and Helpman extended Grossman and Helpman's (1991) "Product variety" model of innovation to show that national productivity increases with the accumulation of both domestic and foreign knowledge (Bayoumi, Coe, & Helpman, 1996). The new knowledge, which prevents diminishing return on capital stock, is produced by investment in technology (Evenson & Singh, 1997). Hence, an endogenous growth model is a very suitable means to measure knowledge capital and technology spillover on economic growth.

If the study result does conclude that ICT spillover exists and is positive and significant, this finding would have important implications for national trade liberalization and economic integration policy. For example, Madden, et al. (2000) argue that ICT is an important source of international knowledge transfer in an emerging global information economy. International trade in ICT equipment and services generates direct productivity benefits through lower transaction costs and improved marketing information, as well as other indirect benefits due to accelerated information and knowledge diffusion across borders (Jussawalla & Lamberton, 1982; Antonelli, 1991). As such, ICT and trade policy are becoming

priorities for many governments and international agencies endeavoring to improve national productivity and economic growth (European Bank for Reconstruction and Development, 1995; Spiller & Cardilli, 1997).

R&D Spillovers

R&D is technological knowledge (Mankiw, 2001), sharing the same characteristic of knowledge capital with IT. As a generator of new technology, the effect of R&D spillover is significant in terms of productivity. Grossman and Helpman (1991) suggested that spillovers from R&D might be one possible engine of endogenous growth in recent years. Much research has been done regarding R&D spillovers both at disaggregate and aggregate levels.

Luukkainen and Niininen (2000) stated that researchers have demonstrated that R&D performed by the original innovating company generates widespread value in the economy through spillovers. Braconier & Sjöholm (1997) suggested that spillovers from R&D exist within industries, both nationally and internationally. The empirical evidence further suggests that intra-industry spillovers are confined to industries that are relatively R&D intensive.

Coe and Helpman (1995) and Engelbrecht (1997) demonstrate an empirical relationship between accumulated R&D expenditures and TFP, and show that the benefits of R&D can spill across countries through trade. These findings have implications for countries considering trade liberalization and economic integration policies. Evenson & Singh (1997) examined the contribution of international technological spillovers using panel data from eleven Asian countries over the period 1970 to 1997. By deploying the new endogenous economic growth models, they offered new insights into the growth process. A country's productivity growth not only depends on its domestic R&D investment but also on the R&D investment from its trading partners. Countries

benefit from purchasing and imitating technology created in other countries as well.

ICT Spillovers at Firm and Industry Level

IT investment, with its informational and transformational roles, is similar to knowledge capital and may generate considerable economic externalities from both network externalities and knowledge spillovers (Dedrick et al., 2003; Mun & Nadiri, 2002). Romer (1986) argued that the knowledge that enables a firm or an industry to adopt advanced technology successfully would naturally spill over to other firms or industries. Knowledge from ICT capital is often diffused by entities such as technology user groups, academic institutions, management consultant firms, and, especially, labor mobility. It is often the case that competing firms rapidly copy ICT investments made by innovative firms (Dedrick et al., 2003).

Leeuwen & Wiel (2003) have argued that ICT spillovers predominantly materialized at the firm level via production efficiency gains arising from the streamlining or upgrade of internal business processes or improved communications. The emergence and rapid development of the Internet is a good example. The Internet increased the ability of firms to transfer information among themselves. Luukkainen and Niininen (2000) also concluded that technology spillovers among firms would increase both customer and competitor benefits.

The empirical results of Mun and Nadiri's study (2002) of US private industries over the period 1984-2000 showed that computerization of an industry's customers and suppliers reduces both labor and material costs for the whole industry. They also found that industries in the services sector enjoy more benefits from ICT spillovers than industries in other sectors because of their high ICT capital intensity and composition of inter-industry transaction.

Results might be substantially different in different industry sectors. An important question is whether there are spillovers from IT-producing industries to IT-using industries. As stated by Ganley, Kraemer, and Wong (2002), the correlation between production of ICT and use of ICT is confined to specific scenarios. There is evidence of a positive spillover effect from ICT production to ICT spending among most developed countries, and a negative spillover effect in East Asian producer countries. They argued that it is because East Asian countries are trapped in low margin ICT manufacturing sectors, that their ability to build their resources in design, ICT services and software development is stifled. Contrarily, the US and other developed countries, where their ICT production has a variety of scope, enjoy a positive effect from IT-producing to IT-using industries.

HYPOTHESES, METHODOLOGY, MODEL, AND FRAMEWORK

Hypotheses

The objective of this study is to determine if ICT investment from foreign countries does, indeed, contribute to domestic economic growth. To investigate the long term relationship among variables, we first deploy the Cobb-Douglas production function. The Cobb-Douglas functional form can be viewed as a linear approximation of the actual underlying production function. It has been shown to be a good approximation in the ICT and productivity contexts by Dewan and Min (1997). It is pervasive in the productivity research literature. The production function approach has been widely used in previous studies of ICT impact on firm performance (Loveman, 1994; Brynjolfsson & Hitt, 1995). Typical production requires labor (L) and capital (K). Hence, we have the following production function:

$$Y = A(E, S) f(K, L) = A(E, S) K^\alpha L^{1-\alpha}, \quad (1)$$

where Y is GDP or output, K is the aggregate capital stock, and L is the labor force. $0 < \alpha < 1$ is the share parameter, representing the share of production contribution elasticity. A is a technology shift parameter, which is a function of the national specific (knowledge) capital, E , and the spillover effects, S . A is also known as the Total Factor Productivity, or Solow's Residual. It is what economists used to refer to when discussing that part of a country's economic productivity which remains "unexplained," but suspected to be a result of technology. Using the Cobb-Douglas production function in Equation (1), Solow's Residual A , can be derived as:

$$A = Y / K^\alpha L^{1-\alpha} = A(E, S). \quad (2)$$

Since data on output (GDP), capital stock, and labor input are acquired, and α is approximated by the share of profit in total output, Solow's Residual can be determined from Equation (2). Economists tend to place the value of α between 0.3 and 0.4. In this article, the value of this share parameter is set to $\alpha = 0.3$ because it is more commonly used.

Now, since the national knowledge capital is a function of domestic ICT investment, and the spillover effect is a function of foreign ICT investment, Equation (2) can be rewritten as follows:¹

$$\ln TFP_t = \beta_0 + \beta_1 \ln DICT_t + \beta_2 \ln FICT_t + \varepsilon_t \quad (3)$$

where t denotes years, $DICT$ is domestic ICT investment, and $FICT$ is foreign ICT investment.

In Equation 3 we may see the impact of domestic and foreign ICT investment on total factor productivity. Hence, we posit our main hypotheses as follows:

Hypothesis 1: Domestic ICT investments would cause an increase in total factor productivity

(TFP). In other words, domestic ICT investments would contribute to national economic growth.

Hypothesis 2: Foreign ICT investments would cause an increase in total factor productivity (TFP). In other words, there exists a spillover effect.

Causality Test

Although hypotheses look simple to test, due to the nature of time series data, we cannot perform the test by estimating Equation (3) with the ordinary least squares (OLS) method. Statisticians and econometricians know that if time series variables are non-stationary and not co-integrated, the OLS results are spurious. In other words, one can never trust the OLS results unless time series variables are either non-stationary or co-integrated.

Accordingly, the implementation of time series analysis tools in this research is aimed to eliminate the spurious regression problems. Before the co-integration tests between ICT investments and TFP, we implement the Augmented Dickey-Fuller (ADF) test to determine whether the variables are stationary (Dickey, 1979). For example, if the order of integration is 2, that is, $I(2)$, the series becomes stationary after the second differences.

If the variables ($\ln A$, $\ln DICT$, and $\ln FICT$) are integrated in different orders, we conclude easily that the variables are not co-integrated. If the variables are non-stationary, but integrated in the same order, then we need to determine whether they are co-integrated. In this case, we perform the Johansen Co-integration test.²

Depending on whether they are co-integrated, different tests would be necessary to determine the causal relationship between the two variables. If the variables are co-integrated, we deploy the vector error correction model (VECM) and the regular Granger Causality test is conducted for non-cointegrated variables. Also, another benefit of adopting causality tests is that we don't need to

worry about intermediating variables from ICT investment to TFP.

When variables are co-integrated, there still can be disequilibrium in the short run. Hence, the vector error correction model (VECM) has to be applied before implementing the causality test. Applying VECM, which is a VAR in first difference with the addition of a vector of co-integrating residuals, results in the so-called Pairwise VEC Granger Causality Test, in contrast to the Standard Granger Causality.

$$\ln A_t = \gamma_1 ECT_{t-1} + \sum_{i=1}^n \alpha_i \ln A_{t-i} + \sum_{i=1}^m \beta_i \ln ICT_{t-i} + u_t, \tag{4}$$

$$\ln IT_t = \gamma_2 ECT_{t-1} + \sum_{i=1}^p \lambda_i \ln ICT_{t-i} + \sum_{i=1}^q \mu_i \ln A_{t-i} + v_t, \tag{5}$$

where $\ln ICT$ is either $\ln FICT$ or $\ln DICT$, and ECT is the error-correction term, which is the residual of the co-integration equation and explains short-term disequilibrium among the variables. Also it is assumed that the disturbances u_t and v_t are uncorrelated.

When variables are not co-integrated, then we perform the standard Granger Causality test that does not include the error-correction term. If the variables are non-stationary, we need to difference the series to make it stationary (Granger, 1969). Corresponding to the stationary time series data of $\ln A$, $\ln DICT$, and $\ln FICT$, the causality test involves estimating the following VAR (Vector Auto-regression) models:

$$\ln A_t = \sum_{i=1}^n \alpha_i \ln A_{t-i} + \sum_{i=1}^m \beta_i \ln ICT_{t-i} + u_t, \tag{6}$$

$$\ln IT_t = \sum_{i=1}^p \lambda_i \ln ICT_{t-i} + \sum_{i=1}^q \mu_i \ln A_{t-i} + v_t, \tag{7}$$

We select the lag structure of the model based on Akaike Information Criteria (AIC), as reported by the EVIEWS software package. Using the models (4) and (5), or (6) and (7), we perform the

Granger Causality test that $\beta_1 = \beta_2 = \dots = \beta_m = 0$. It follows that, if the computed F statistic exceeds the critical value at the chosen level of significance, the null hypothesis is rejected, thus there exists the causal relationship of $FICT \rightarrow A$ (Hypothesis 2) or $DICT \rightarrow A$ (Hypothesis 1).

DATA AND VARIABLES

We selected 10 countries based on the data availability. Each country consists of annual time series data for 4 main variables—GDP(Y), Capital (K), Labor (L), and Information Technology Investment (IT):

- *Developing Countries:* China, India, and Malaysia
- *Newly Industrialized Economics (NIEs):* Korea, Hong Kong, and Singapore
- *Developed countries:* Finland, Ireland, Japan, and the US

The time series data are selected from 1982 to 1999, a total of 18 years. GDP (Constant 1995 US dollars), capital stock, and labor data were obtained from World Development Indicators (WDI). However, WDI only provides value for Gross Fixed Capital Formation (Constant 1995 US dollars), which is actually gross domestic fixed investment (denoted by I), not really the capital stock we need to calculate for TFP. Thus, an adjustment to data of the capital variable is essential. Non high-tech capitals are commonly depreciated with a 10% rate annually. The individual annual values are derived as $K_t = I(t) + (1-\delta) \times K_{t-1}$, where $\delta = 0.1$ the depreciation rate.

Relative difficulty and complexity occurs in collection of ICT data, a long time sequence is necessary in order to implement time series analysis tools. Apparently, data unavailability for ICT investment is quite common in the 1980s, especially for developing countries. Hence, we use telecommunication investment (1981-1999)

from the International Telecommunication Union (ITU) as a proxy for ICT investment. The Foreign ICT investment variable (FIT) is calculated by summing up all the ICT investments except the domestic one. Table 1 summarizes the basic statistics for *A*, *DICT*, and *FICT*.

EMPIRICAL RESULTS

Discussion and Analysis of Statistical Findings

Table 2 shows the basic results of the unit root test on the time series of *DICT*, *FICT*, and *TFP* (or *A*).

Table 3 illustrates the principal findings from the co-integration and causality tests for the sample countries. The variables are co-integrated in most of countries except Japan. Therefore, we apply the vector error correction model for

them. For Japan, we use the standard Granger Causality test. The results for causality test vary across countries.

If the causal relationship of a certain country from *DICT* to *TFP* (Hypothesis 1) or *FICT* to *TFP* (Hypothesis 2) is significant, it is indicated in the second column of Table 3. As one can see in that column, Hypothesis 2 is supported, i.e., there exist positive and significant international spillover effects for Ireland, Korea, Singapore, the United States, and China.

Except for China, the other four countries are notable for governmental efforts to boost ICT industries. The governments provide adequate funding for education and universities and technology institutions contribute major advances in technology innovations and inventions in all four countries. In the meantime, each country has well-trained ICT specialists and workers in ICT-sectors have built up their knowledge base. From the hardware point of view, the telecom-

munication infrastructure and networks are well established.

These four countries all promote trade liberalization and globalization. Therefore, knowledge and advanced information technologies can be comparatively easier to transfer to these countries. At the same time, because of their already established telecommunication infrastructures and human capital, such as education, the ICT investment in foreign countries is not only being transferred, but is also more promptly digested and absorbed (transformed) by the local workforce. Hence, foreign ICT spillovers occurred and the effects are positive and significant.

It is a bit surprising to see that China belongs to this group, because the openness of its economy is limited and telecommunications infrastructure is still restricted compared to other countries. However, China also thinks highly of education. Its human capital is already well established, so that China's local labor forces follow relatively easily what other countries are doing. This may explain why foreign ICT investment has positive impact on China's productivity.

Finland does not have international spillover in our empirical result while its domestic ICT investment causes TFP growth. Finland's government invests a large amount of capital in knowledge and information technology and achieves a huge payback for the investment in economic performance. Thirty years ago, 70% of Finland's exports were wood and paper products. Now, more than 50% of the country's exports are knowledge-intensive products. For instance, Nokia, a telecommunication giant, contributes 4% of Finland total GDP, 35% of total business sector R&D and 25% of the total exports. Compared to Finland's strong contribution of domestic ICT investment, the effect of foreign ICT investments seems less significant.

Japan, the second largest economy in the world and the largest exporter of technology products, did not have the co-integrated relationship between ICT and TFP. Also, only domestic ICT invest-

ment causes national productivity growth while foreign ICT investment does not. This may be due to Japan's special situation of ICT industry. For example, NTT DoCoMo is using its unique standard Personal Digital Cellular (PDC) for 2G mobile phone, which was developed and used only in Japan. Now, as Japan is using WCDMA for 3G mobile phone standard following worldwide trend, we may see international spillover for Japan in the future.

Moral of the Story: ICT Maturity and Network/ Path of Infrastructures

The creation of new ICT knowledge by one firm/industry/country is assumed to have a positive external effect on the production of opportunities for other parties because it is possible to create a large pool of ICT knowledge when the technologies are being used by many parties. With more trade of ICT products and higher mobility of international labor forces, ICT knowledge can be transferred faster and more easily. After being absorbed by local labor forces, ICT spillover effects will take place.

Shapiro and Varian (1999) argued that ICT value does not simply mean implementation of hardware or software, but ICT usage that needs a certain period of time for users to train themselves until they find ICT useful. Put simply, ICT investment generally requires a learning period for users before gains occur. In general, creating an ICT knowledge base requires a longer time period than ICT implementation. ICT-matured countries benefit more from information technology because of the ICT knowledge base. For instance, Singapore and Korea enjoy foreign ICT spillovers much more than Malaysia.

Furthermore, the contribution of ICT investment is a product of individual efforts taking place in a network context where the infrastructure and communication technology, together with changing externalities in the use of ICT, affect

the historical paths taken in shaping the growth of ICT contributions (Shapiro & Varian, 1999). David (1990) also argues that ICT may require substantial changes in complementary infrastructure (e.g., human and knowledge capital, global communications infrastructure, etc.) before the generation of output. In other words, the networks and paths must be built up before benefits of spillover from other countries occur. Therefore, the two main conditions for the existence of ICT spillovers are ICT maturity and networking, which create paths of infrastructures and telecommunications.

Limitations

We have had difficulties in finding a good time series dataset of ICT investments. Relatively better samples were telecommunications investments. Still, we have 19 years, which is just acceptable for time series analysis. In the future, we need to collect longer series of data and will see whether the findings are still robust. Also, telecommunications investments may not be sufficient to reflect the full effect of foreign ICT spillovers towards domestic economic growth.

Another limitation is the number of countries for the analysis. The sample set only contains 10 economies because of data availability. Foreign ICT spillover is limited among the 10 countries, but not in a worldwide aspect. In future study, more countries should be included to generalize the results.

CONCLUSION AND IMPLICATIONS

Productivity is the amount of goods and services produced from each hour of a worker's time. The key role of productivity is to determine a nation's living standards. Policymakers who want to encourage growth in standards of living must aim to increase their nations' productivity by encouraging rapid accumulation of the factors of production and ensuring that these factors are em-

ployed as effectively as possible. From time series analysis, we found the limited evidence of international ICT spillovers which would contribute to economic growth. This article lets the policy makers and scholars look at another dimension of productivity growth, i.e., spillovers.

The ICT spillovers would create a mutually beneficial situation across countries. With productivity growth, the total wealth and welfare of the receiving countries will be higher, which may result in stronger purchasing power in those countries. With stronger purchasing power, these countries would likely purchase more goods, services, and advanced technology from sending countries to further improve their living standards and productivity. Hence, both parties benefit from the spillover effects and it is a win-win situation. ICT spillovers would have very important implications in economic development plans. Thus, international organizations, such as United Nations and World Bank, could formulate possible ICT policies to enhance ICT spillovers by promoting free trade, globalization, and so on.

At the same time, policymakers of each country would consider foreign ICT spillover as a key factor of economic growth. For countries with limited ICT investment, foreign ICT investments may be a good source of productivity growth. They should open up the domestic market, encourage imports and exports, remove trade obstacles, support trade liberalization and globalization, build up ICT infrastructures, and promote education and train their labor force to let foreign ICT investment more easily spill over into domestic industry.

Chapter 7.3

From Information Society to Global Village of Wisdom?

The Role of ICT in Realizing Social Justice in the Developing World

Sirkku Kristiina Hellsten
University of Birmingham, UK

ABSTRACT

This chapter is about the role of ICT in global justice. It will analyze, firstly, the epistemological relationship between new information, knowledge and wisdom. Secondly, it examines the ethical relationship between information technology and the values and ideals that are attached to its use and applications. Thirdly, the chapter studies theoretical and practical obstacles that have prevented the developing countries, particularly in Africa, from fully benefiting from the enormous possibilities provided by the new ICT in relation to realizing human capabilities, well-being and better standards of living and social justice. The analysis applies Amartya Sen and Martha Nussbaum's capability approach to the distribution and use

of the ICT in global context. Finally the chapter examines how global and the local inequality is maintained by the international information and technology markets, and how the distorted international markets as well as misguided local policies tend to create further division between "information rich" and "information poor."

INTRODUCTION

Globalization is the catchword of the day, and the worldwide requirement for more direct democracy, good governance and respect for human rights is at the core of the new millennium's development strategies. In order to fulfill these goals in global social, economic and political cooperation and

development, access to information, knowledge and channels of reciprocal communication are of critical importance. Globalization of economy has been made possible and further expands through the business applications of the Internet and other information and communication technologies. The latest information and communication technology (ICT), which can be used for fast creation, acquisition, storage, dissemination, retrieval, manipulation and transmission of information, could greatly help the marginalized, less affluent countries to benefit from the positive side of globalization and to help them promote local and global democracy and participate more efficiently in the global economy. ICT could provide us powerful means for sharing our global prosperity. However, presently the trends of economic globalization have not led to either to more equal local and global access either to ICT or to the information it transfers. Instead, the Information Age has led to what has come to be called the digital divide between the affluent and the poor, the connected and disconnected, the developed and less developed (Sarrocco, 2002; Warschauer, 2003; Young, 2003).¹

Despite the fact that new telecommunication technology undeniably has advanced rapidly and more and more people around the globe have today direct access to it and to the information it conveys, there are still vast regions in the world which have either no access or very limited access to these new means of communication and information exchange. The limited access is due to various structural, distributive, economic and political problems that have prevented the equal spread of modern technology, as well as its efficient implementation across the world. Some of these obstacles can be overcome through better and fairly planned distributive and implementation policies. Many of these places without access to the latest ICT may, in fact, have very restricted means for even local, let alone global, connections through more traditional information channels such as mail, newspapers and books, telephone,

television, and radio. On the other hand, in many parts of the third world even those affluent and materially well developed countries, which now have access to the ICT, have not succeeded in using new technology internally and internationally to consistently promote national benefit, human well-being and the common good. Instead the technology available and the information it provides are still mostly shared by elites, the already influential, affluent and educated sections of the population. The poor and illiterate, and those in acute need, tend to remain beyond the information reach; local, and particularly rural, development and quality of life gain very little from the new technology.

This chapter focuses on two interrelated issues: firstly, it analyzes the relationship between new information technology and the values and ideals that are attached to its use and application. In this context, this chapter will study the relationship between information, knowledge and power in relation to the ideals of the “knowledge society” and what could be called the “global village of wisdom.” It argues that in global ICT policies there is a need to pay more attention to the realization of human resources and well-being in the development, use and distribution of ICT. In the existing politico-philosophical frameworks, this would mean a shift from the neo-liberal market economy towards the promotion and realization of human capabilities as presented by the capability approach to human well-being constructed by Amartya Sen (1985, 1993, 2001) and Martha Nussbaum (1987, 1992, 1993).

Secondly, the chapter takes a look at the theoretical and practical obstacles that have prevented the developing countries, particularly in Africa, from fully benefiting from the enormous possibilities provided by the new ICT in relation to human capabilities and better standards of living. It will examine how the local and global digital divide between the information-rich and information-poor is created and maintained by international information and technology markets, as well as

by political ambitions. Finally the chapter considers the role of culture and tradition in adoption, allocation and use of new technology.

INFORMATION VS. KNOWLEDGE SOCIETY: IDEALS AND PRACTICE

The developments in new information and communication technology are in general taken to suggest not only efficiency, convenience and productivity but also utopian possibilities—new fortunes to be made, new careers and new lifestyles and, above all, progress that entails revolutionary democracy and increasing equality. This means that, particularly in the West, new information technology is usually seen to provide us with a fast, vast and environmentally friendly “information superhighway” that gives everybody across the world direct access to the sources of influence and the centers of power. In the most optimistic dreams, the possibilities brought to us by technological advancement are believed to mean the actualization of “a global village” which eventually leads us to a new age of wisdom which promotes democratic participation and social justice.

While this utopian ideal of information age may be shared by many ICT enthusiasts, there is no one agreed model of the information society that serves as the standard for sustainable and desirable development. Instead, the significance of the Information Age is that it is a global, diverse and multicultural reality. Thus, in order to realize the utopian visions and ideals, there is an urgent need to clarify further how the values we are striving for can be related to practice in various economic, political and cultural circumstances, as well as in globalization of ICT markets themselves. If we are to use the new information technology in order to strive for what we could consider as the ideal of the “knowledge society,” we need to reflect on

the values involved in the developmental realities in various global and local contexts.

Before that we need to clarify the values involved in the information utopias by making a clear distinction between what we have come to call “information society” and what we could call a “knowledge society,” which, in an international context, could be also extended into a “global village of wisdom,” based on the maximum use of not only physical, but also—and maybe particularly—intellectual and moral human capabilities.

Theoretically, I base this ideal of a “global village of wisdom” on the theoretical framework of the capability approach introduced by Amartya Sen (1990, 1992, 1999) and Martha Nussbaum (1987, 1992, 1993). The capability approach defends the moral appropriateness of the concept of well-being measured in terms of valuable human functioning and capability. More generally, it concentrates on our freedom to promote objectives we have reason to value, such as democracy, human rights and equality. According to Sen and Nussbaum, human capabilities that define human well-being, and should be the goal of development and distribution, are first—such basic capabilities as life and health. Second are capabilities relating to integrity, thought, emotions, practical reason, affiliation/participation, control over one’s fate/environment. There are extensive studies on the capability approach in development. This chapter, however, does not try to analyze or criticize Sen’s or Nussbaum’s arguments in detail, but rather to search for ways of applying the capability approach as a criterion for a fair distribution of ICT in the global context. The reason for this choice of approach is that my main aim is to look for alternative approaches to global distribution and implementation of ICT. While problems in using a capability approach are important to take into account, the space available in this chapter does not allow me to go into these in detail, but leaves them to the critical reader’s further assessment.

Using a capability approach as a normative ethical framework for distribution and implementation of ICT means that we need to reconsider the role of ICT in relation to what people can do with the new technology or what the technology can do for them in different cultural, political and economic settings, and geographic or environmental conditions, rather than assume that technological development has some intrinsic value, as the most eager proponents of information society appear to assume. Thus, if the distribution and implementation of global ICT policies would set the realization of human capabilities and the formulation of human capital at the core of ICT strategies, the presently digitally marginalized populations need not only to get access to necessary technology but also to gain the means to process the information available into knowledge that empowers them to participate actively and democratically in local, national and international development. Today, however, both the technology, and the data, information, intelligence, ideas, facts and figures it transfers, are often considered as commodities that are to be bought, sold and traded in expanding markets, rather than as basic goods in the Rawlsian sense (Castells & Himanen, 2002, pp. 2-3; Stovel, 1984).

Commercialization of information and knowledge is based on neo-liberal or libertarian market rationality that focuses on economic and technological development. It tends to pay less attention to the wider and more even realization of human capital and human capabilities in local and global contexts.² ICT and information trade is then, in many senses, the final result of the Information Age transition from an industrial economy to information economy, in which information itself is seen as raw material. The latest ICT, for its part, can provide not only the means of production, but also its own markets. Technological means, know-how and access to information will then shape the characterization of nations by digital divide as either (information-) rich or (information-) poor, and their categorization accordingly

as developed or underdeveloped. This division, however, in most cases tends to be based on the physical access to ICT rather than on political, social and economic benefits of such technology (Jimba, 1999, pp. 79-83; Warschauer, 2003; Young, 2003).

If we want instead strive for the ideal of a “knowledge society” or “global village of wisdom,” we need to see both technology and information as essential instruments in realizing the various human resources that they themselves can be used to develop each nation culturally, and in a locally sustainable manner. Information and communication technology could play a central role in realizing this ideal, but only if more attention is paid to the development of human capabilities and social, political and economic inclusion that can be realized with the help of the new technologies. At the moment the focus, however, tends to be on the advancement of technology itself and the markets of technology, rather than on the use of technology to improve the worldwide, reciprocal access to all markets.

IT: MEANS FOR DEVELOPMENT OR AN END OF DEVELOPMENT

The millennium development goals emphasize good governance, human rights, democracy and social justice. In order for these goals to be convincing, they are to be striven for in both the local and the global context. While the gap between developed and developing countries has been gradually narrowing, the least developed countries (LDCs), still often marginalized in (local) technological development, are failing to catch up with ICT and, thus, are bypassed by its benefits. ICT, for its part, is directly related to both national and international development, because ICT brings the means to communicate beyond the interpersonal level and makes geographical distances between continents and states disappear. Since ICT today goes far beyond mass media

communication and offers possibilities for change, knowledge and new perspectives on development, it permits rapid dissemination of ideas, values and processes, supplements education, science, health care, culture and, above all, economic interaction and markets. It provides the potential for two-way exchanges of information to learn what people really need, and to manage resources and data to facilitate the production and distribution of prosperity and wealth. Thus, while it is evident that ICT clearly cannot be used to solve all the problems of developing countries, it represents a potential that can be used to actualize human resources and human well-being in the form of capabilities within less affluent countries (Annan, 2003; Stover, 1984, p. 3).

If information age policies emphasized the realization of human capabilities, there would be a need to make a clear distinction between the concepts of information, knowledge and wisdom in our strategic plans and policies. The capability approach attempts to give human well-being a content that goes beyond rights and rational choice. Instead it focuses on the basic human condition by defining well-being in terms of valuable human “functionings” and capabilities that make our (ability to make) any choices possible (Nussbaum, 1992, pp. 202-246; Crocker, 1992, pp. 589-590; Sen, 1992, 2001).³ This approach moves from mere technical protection of rights to the promotion of “human flourishing” by defending the moral appropriateness of the holistic concept of human well-being measured in terms of human capabilities. Thus, our rights, as well as our responsibilities, should be set in a context that increases our capabilities and promotes various human functionings—in a teleological sense, as the human beings that we (essentially) are. Thus, human capabilities provide fundamental moral categories for the evaluation of resource distribution that goes beyond protection of rights or satisfaction of needs and sets human beings in a wider social context. The capability approach then concentrates on our freedom to promote objectives we have reason to value, such

as participation/democracy, human rights and the value of equality. According to Sen and Nussbaum human functionings and capabilities define human well-being and, thus, can be seen as the goal of distribution of social and material resources—in the end these resources include our moral and legal rights. By human functionings, they mean a person’s physical and mental states or “beings” and activities or “doings.”

There are many extensive studies on the capability approach in development, as well as critical analysis of some of its problems. In this chapter my purpose, however, is not to reintroduce or criticize Sen’s or Nussbaum’s arguments in detail or to point out theoretical differences and dispute between the two. Instead, I am searching for ways of applying the capability approach as a basis for a model for an ethical justification, where fewer of the needed resources and commodities can sometimes be better than their abundance, depending on their proper use for realizing human capabilities. In their search for a foundation for an ethic, Nussbaum and Sen both reject an “externalist” account that would depend on a metaphysical or scientific realism that purports to give, as Crocker has stated, a “God’s eye view” of the way things, including humans, are in themselves. Sen and Nussbaum suggest that what we need instead is an “internalist” foundationalism. This, in part, means that we start digging from within human experience and discourse to find the things that we do and should count as intrinsically worthwhile in our human lives. We must ask what are the things that are so important that, without them, we would not count a life as a human life. This allows us to move from objective value statements on the value of human life to the value of human functionings and capabilities.

Thus, despite various criticisms presented against the capability approach, the value statements regarding human capabilities can still be considered fairly objective and universal in a sense that they are valid for all human beings, since basically all rational humans consider their

capabilities and well-being valuable—no matter how they might otherwise react to cultural differences and/or difference in resources and to the various rights-based distributive frameworks for resources. In relation to the ICT, it then requires us to consider not only the distribution of resources but also the overall capabilities that can be realized with these resources.⁴

DEMOCRACY, WISDOM, AND INFORMATION

In political philosophy, modern pluralistic democracy, particularly when described as a reciprocal social contract between morally autonomous, rational and reasonable individuals who rule themselves in their own interests and by their own considerations, values and decisions. This description leaves the individual participants in a context based on self-interest and promotion of one's own benefits. However, working democracy should be based on decision-making and self-government of enlightened citizens. This enlightenment is possible only if the decision-makers have a chance to realize all their human potential, that is, all their human capabilities.

This definition is not often an accurate picture of political reality, but it does give us the abstract ideal of modern democracy that we are hoping to realize in practice in our societies (Weinberger, 1995, p. 218). The formula of democracy can then be stated as follows: a functioning democracy presupposes a form of political liberty that realizes human capabilities in a manner that guarantees the participation of enlightened citizen in public matters. An enlightened citizen is not the same as a knowledgeable or well-learned citizen. A moral agent with full human capabilities differs from a mere self-interested and rational decision-maker who attempts to maximize his or her personal benefits (Clark, 2000, p. 84; Weinberger, 1995, pp. 218-222). Political liberty postulates freedom

of individual will and the individual's own commitment to use this will to promote good—not merely the promotion of one's own good, but also the good of society in a form of sustainable and democratic development. Freedom of individual will, for its part, postulates a capacity for critical reasoning as well as knowledge of the options and alternatives available. This means that “knowledge search” has to go hand in hand with “knowledge use,” which should, in turn, aim for wisdom.

One of the first steps towards solving some of the problems of the world's poorest countries is to find a way towards more democratic governance. ICT can play a central role in enhancing democracy if it is used to disseminate information freely, to provide open communication channels for mutual dialogue and unrestricted participation, and to enhance the responsiveness and accountability of those in public positions. However, in this context its use has to be tied to the realization of human capabilities at several levels. This means that in global ICT policies we need not merely focus on distribution of technology to those who have not previously had access to it, but we also need to pay attention to the use of technology—both in the form of training as well as in its content and goals.

This is a vicious circle. The democratic ideal does not work unless it gets the support of enlightened citizens. Ignorant, uneducated or merely self-interested leaders and citizens can use technology for counter-productive purposes and for their personal benefit rather than for the promotion of public good and public interest, all with are part of overall capabilities of human kind. Thus, ICT should be considered as the means to realize the essential human capabilities (from basic capabilities, to life and health in general, to more the complex combination of practical and theoretical reasoning, moral agency and social participation) needed to build and maintain any democratic process. It should not be seen as merely a means for participation. Participation without

commitment to the democratic values of freedom, equality, moral autonomy and tolerance does not lead to social wisdom.

In order to understand the role of ICT in today's globalized world, we need to pay more attention to the complex relationship between knowledge, wisdom, democracy and power, as well as to the relationship between human capabilities and individual citizens' political (and moral) agency. A proper place to start is the relationship between the concepts of "information" and "knowledge." According to the classical Platonic definition, knowledge is a true, justified belief. By this very definition knowledge is given some intrinsic, positive value, that is, it is considered to be both justified and true. The same value judgment does not apply to what we call information. In fact, the value of information depends on what we do to change it into knowledge and wisdom. Information can be relevant or irrelevant; it can be honest or dishonest; it can be straightforward or misleading; it can be entertaining or educating. In other words, it can be justified or unjustified, true or false. Also information coming from different directions can feed our beliefs, but, in order to test or justify these beliefs, we usually need interactive, critical dialogue with others.

The relationship between information and knowledge can be summarized as follows: knowledge is information that is produced by our critical reasoning and tested by our communicative actions. Knowledge is then always more than pieces of information that are distributed in the media and computer networks. The idea of knowledge includes the human ability to produce and process information and judge its validity with the help of social dialogue. However, in the Information Age the very concept of knowledge has become more and more directly embodied in new technology. Thus, its usefulness appears to depend increasingly on the context of its application. This means that the production of knowledge is no longer centralized in the institutions of science and research or the media, but rather in the institutions

with political and economical power. The focus on the acquisition, access and use of knowledge has become instrumental in economic and political activities. It is less often seen to be the intrinsic part of global human capital formulation that promotes well-being by helping to realize human capabilities in various circumstances (Clark, 2000, p. 84; Castells & Himanen, 2002).

KNOWLEDGE, POWER, AND DEMOCRACY

From the earlier-noted analysis of ICT in distribution of information and in production of knowledge, we can move to the relationship between knowledge and power. Because of its influence and usefulness for us, knowledge is also often equated with social power. In practice this is still the case in most parts of the world. With knowledge we can control not only our own but other people's lives; we can get authority over those who know less. This authority we can use either to dominate or to serve our communities. Thus, the obstacles—whether these are technological, economic, political, or cultural—in the way of the free flow of information are also obstacles in realizing human capital and human capabilities.

The main obstacle is related to the gain and use of power, which, for its part, is directly related to the concept of knowledge. Knowledge as power has traditionally held an intrinsically positive value. However, those who have access to and control of knowledge, and know how to apply it, can use the power knowledge gives them either in a positive and constructive way, or in a negative and destructive way, in regard to the ideals we have set for ourselves. We can use power to suppress and control others by keeping them in ignorance, or we can use it to pass on and share information and to promote individual freedom and democratic practices. If power and authority are used wisely, both developing and post-industrial countries can recognize the ideal of enlightened democracy that

realizes the wide variety of human capabilities equally, locally and globally.

Thus, when and if information is turned into knowledge and knowledge into power, there is still no guarantee of equal and just political order. This is because democracy can work only if a nation's leaders and citizens use their personal social power with wisdom. Wisdom, however, is often difficult to come by in a modern market-led information age—regardless of whether we are talking about post-industrialized or developing countries. Wisdom, after all, does not follow directly from our access to information, from our capability to turn this information into knowledge, or from the power this knowledge gives us. Wisdom is a result of the development of the moral and social consciousness that integrates our intellectual capacities with our ethical outlooks and with our sense of justice, which is related to understanding the responsibility that comes with knowledge that is turned into power. Because the ideal of modern pluralist democracy is generally defined as the self-government of rational and reasonable autonomous moral and political agents, just as there is no knowledge without “knowers,” there is no working democracy without wise and morally responsible citizens, whether at the grass-roots or the leadership level. Therefore, if we set full realization of human capabilities in all their forms as our goal, any discussion of development of a global knowledge society that is based on the more efficient and equal use of ICT cannot be detached from the civic, professional and ethics education.

FREE MARKETS AND GLOBAL ETHICS

If human capabilities as the basis for increasing well-being were to be the goal of the ICT distribution, advancement, access and use, there would be a need to change the focus from business and economic benefits to education and civil partici-

pation. This does not apply merely to developing countries, but also to affluent information societies. Participation in global democracy does not follow directly from the number of Internet or mobile connections, though having them available naturally helps the process. As Warschauer (2003) has noted, access to technology does not guarantee its efficient or beneficial use. Thus, the practical problem is that the prevailing information society policies seldom follow the formula of democracy or pay enough attention to the human capabilities that are to be realized by and for democracy. They too often disregard the fact that the data that is disseminated and stored in information networks and in new media can be processed into knowledge and wisdom only by critical and autonomously developed human reasoning.

While access to relevant information has a central role in the globalized economy and profitable markets, free-market practice, civic education and democratic ideals do not always go hand in hand, particularly when technological advancement and information resources often do not reach those who need them most and would benefit from them most. Instead, free markets tend to enforce the development of information society and lead to the marginalization of groups of people in a manner that prevents all citizens from realizing their capabilities as rational, moral and political agents in the first place. If the distribution and use of ICT is left to the care of the invisible hand of market forces, the resulting society will tend to be fragmented by egoistic pursuits and self-interest. The division to the haves and the have nots, that is those who have access to technology and information and know how to use it for their benefit and those who are left to be socially and politically even more disconnected from the centers of power, knowledge and influence than they were before (Gauthier, 1986, pp. 11-30; Rawls, 1972, pp. 3-22, 54-81; NAME, 1993, pp. 11-39; Reiman, 1990, pp. 25-29; Weinberger, 1995, p. 218).

One main problem is that often technology is itself offered as a cure to the economic mar-

ginalization. Improved economy, for its part, is regularly needed in order to get into the technology markets. Thus, there appears to be no direct connection between globalized information economy and global justice. Instead, people, particularly in affluent countries, who have access to all the information channels possible are not using the information they receive, or the knowledge they process out of this information, to share their prosperity and abundant resources any more equally and in a way that will diminish global suffering. The fact that we can now, through satellite connection of television, radio, mobile phones and the Internet, get information more easily, more quickly and more accurately about any natural disasters, famines, victims of war and conflict, sufferers of diseases, or about any human agony that happens anywhere in the world, has not radically increased our solidarity or changed our habits in sharing our prosperity with those who are in urgent need and/or live in absolute poverty. The question then remains: if we cannot use the new ICT to take up our global responsibilities in affluent countries, how can we expect this technology to bring about local equality in the form of shared power and other essential resources in the underprivileged countries which have much fewer resources available, much poorer infrastructure, less efficient and inclusive educational systems, and limited civic participation? If we are not using ICT to enhance human capabilities at the local or global level, it can become a part of the problem rather than a solution for world inequality.

GLOBAL OBSTACLES: PROSPECTS AND PROBLEMS IN INTERNET USE

Knowledge is still power in the hands of a few—globally as well as locally speaking. Knowledge and know-how guarantees power and influence also in international relations. International dia-

logue and the free flow of information both play a vital role in local and global social, political and economic development. Thus, new ICT could help us to increase efficiency and productivity, improve democracy and promote human rights. Access to new information and telecommunication technology could be used to empower the poorest and the weakest by helping them to connect with each other, share their problems and find solutions together and empower them economically and politically (Annan, 2003; Heldman, 1994, pp. 328-330; Hudson, 1997, pp. 179-205; Sarrocco, 2002; UNESCO, 2002; Williams, 1991, pp. 38-50; Wresch, 1996, pp. 23-91).⁵ Since people no longer have to travel physically in order to communicate, exchange essential information, share knowledge or participate in different types of decision-making processes, we now have a realistic and unique chance to establish a global village of wisdom and social justice. At present, however, despite some positive development and the ambitious information society strategy papers with their global ethical guidelines and public rhetoric on social responsibility, the “information gap” and “digital divide” between industrialized and developing nations, and between the rich and poor in general is widening further (Annan, 2003; Gore, 1995; European Union, 1995 & 1997-2002; Sarrocco, 2002; UNDP, 2001; World Bank, 1999).⁶ Instead of providing essential channels of interactive communication to those who need it most, new information technology is still for the most part connecting those who are better off and better connected to start with. Simultaneously in many parts of the world, the worst-offs have become even more disconnected from the centers of influence, power and resources (Heldman, 1994, pp. 264-265).⁷

Even in this information age, many of those who are living in isolated rural areas around the Third World have never read a book let alone a newspaper. About half of the world’s population has never made a telephone call. Once again markets play an essential part in this inequality.

For instance, in a poor nation local publication is minor, because production costs are high compared to those in industrialized countries. Paper prices are high, because most of the paper has to be imported; printing costs are high because all local presses are small and slow; editorial expenses are high because few people have editorial or design experience. While costs are high, sales are small and profits practically non-existent.⁸ The problems are similar with telephone services. For instance, in Africa, still the poorest continent, the cost of getting a phone line and making telephone calls is, in absolute terms, higher and, in relative terms, extravagantly higher than in the United States or in Europe.⁹ And even if one could get access to a telephone line and could afford to pay for the calls, it is not always possible to get an open line when wanted. Reasons for this are due to criminality (bugging of phone lines, looting of copper wire, cutting of cables, corruption with licenses and billing) and erroneous technology (Hudson, 1997, pp. 182-183).

Statistics also show that even if the know-how and technology are already there and there are some signs of change, the distribution of the latest telecommunication technology is globally and locally still very uneven. In 1996 about 700,000 people in Africa had access to the Internet, which meant that Tokyo had almost twice as many telephone lines than the whole African continent. The number of lines has rapidly grown; during 2000, sub-Saharan Africa passed the threshold of one telephone per 100 inhabitants. In the same year, all African countries achieved connection to the Internet. According to a report by the UN Information and Communication Technologies Task Force (UNICT) in September 2002, the proportion of Africans with Internet access rose by 20% between January 2001 and 2002. However, altogether only 0.2% of Africa's population has Internet access, and the lack of infrastructure and affordability has centralized these connections in the bigger cities and business centers.¹⁰ In Tanzania, for instance, the best connectivity

is essentially in Dar es Salaam, Arusha, Moshi, Mwanza and Zanzibar, all of which are centers of business, tourism and international events. Government institutions are still the most backward in connectivity. Many local government offices in smaller towns have no Internet, fax, mobile, or even fixed line connections.¹¹

The increase in the Internet use in Africa does not match the proliferation of mobile phones on that continent, mainly because of the lack of fixed line technology. More Africans possess mobile phones than fixed line telephones, making the continent one of the very few regions in the world where this is the case. As a result of the mobile explosion, dilapidated fixed line infrastructure has suffered further as many governments and companies believe that the continent can skip the fixed line era and move straight into the mobile age. While mobile connections can help to expand access to the Internet in the long term, it makes access to the Internet more difficult in the short term. Mobile connections in third world countries are still unreliable, very slow for Internet use, and relatively very expensive (Ford, 2003, p. 52; Parker, 2001).¹²

Another option for wider Internet access and use would be to design computers that can be used away from electricity distribution grids. Such technology would enable potential users to bypass the inefficiencies of downstream power grids. Some initiatives are already beginning to put the concepts of non-grid dependent PCs into the Mtabila refugee camp in Tanzania, where people have been given access to the Internet as a result of a new source of electricity generation. The camp lies well away from the existing Tanzanian power distribution grid, so power is being generated using methane gas produced by fermented cow dung. However, there are no signs yet that computers powered by solar energy, for instance, are to be widely available in the near future (Ford, 2003, pp. 53-54; Sarrocco, 2002).

All in all, the mobile phones and other telecommunication devices available are still very

unevenly distributed both globally and locally. In poor developing countries, it is mostly only the wealthy people who have access to new information technology and telecommunication services. The gaps are even greater between urban and rural areas. For instance, in Africa there are almost three times as many fixed telephone lines per 100 people in the largest city of the lower-middle-income countries than there are in their rural areas, and more than seven times as many lines per 100 people in the largest city of the low-income countries as there are in their rural areas. These gaps are even more significant given the fact that more than 50% of the population, and as much as 80% in the poorest countries of the world, lives in rural regions (Ford, 2003, pp. 52-54; Hudson, 1997, pp. 180-181; Kyaruzi, 2003, p. 8).

Thus, obstacles in access to information and knowledge, which are related to the global economic inequalities, are also connected to local conditions. In most parts of the developing world, the very same obstacles that we could overcome with the help of new information technology are the ones that prevent its widespread use in the poor parts of the world. Geographic isolation with no reliable means of transportation, lack of infrastructure, together with ignorance and poverty, mean that there are very few people who could use even the traditional communication channels, let alone the new technology. This means that providers must charge exorbitant fees to make up for their high investment costs. Because most private companies have to play according to the rules of market rationality, service providers are locked in charging higher prices in regions where there are fewer customers and where connections are more difficult to establish. Therefore, the use of new technology such as the Internet or cellular phones in much of Africa remains limited to a minuscule elite, often consisting mainly of foreigners or others who can afford the relatively high costs. This keeps demand low, which means lack of competition and little interest from private investors, which, in turn, keeps

the prices unaffordable to the wider public at the grass-roots level.

What makes the situation even more difficult is the fact that not only is information technology and its allocation led by market forces, but information has itself turned into a commodity one has to pay for. The more valuable the information is the more people are willing to pay for it. This, once again, results in a market mechanism that makes it certain that the poor have even less chance of obtaining the most wanted and vital information.¹³ In summary, the vicious circle is created by lack of infrastructure, unfavorable regulatory environment, high pricing, and an uncompetitive market structure, which cannot be broken without decisive intervention that focuses on the realization of human capabilities rather than the invisible hand of the globalized economy.

GOOD FELLOWS' NETWORKS: MEMBERSHIP OF THE GLOBAL VILLAGE

One of the cruder ironies of the Information Age is that rich people get their information practically free, while poor people pay dearly for every morsel, be it a telephone call, a newspaper, a drive to the store, postal services or use of the Internet (Wresch, 1996, pp. 117-136; World Bank, 1999). Thus, the vast majority of information and communication channels are still today accessible only to those who live in the industrialized world, or in the prosperous urban centers of the developing countries. Access to information and communication all around the world remains elitist, since our virtual membership of the "global village" may make us close our eyes to the injustice just outside our own doors.

Thus, ironically enough, the new communication technology that was to be used to connect people with each other has created a digital divide, which actually often efficiently "disconnects" many from the problems of their own societies.

A large part of the information people receive in developing countries through such international channels as the Internet, cable and satellite broadcast, fax and telephone lines, mobile. The information they receive can be quite one-sided, and sometimes even biased. It presents the views and lifestyles of those who rule the commercial markets, entertainment industry, news media—that is, the views of the financial, political and industrial powers, mostly, those of the North and the West. Movies, television, international news agencies and publishers and the Internet all spread information that originates in the Western world, especially in the United States. This means that the information received in the developing world is often very limited in its scope. It is not an exaggeration to say that, for the better-off who live in urban centers of many developing countries, it is often easier to know what is happening on the other side of the world than to find out what is happening in the slums or villages just a few miles away from them.¹⁴

While the developed countries rhetorically demand that developing countries support the free flow of information, they evidently do not mean that information is going to be cost-free for them. Neither do they mean that information is free to flow in any direction (Wresch, 1996, pp. 117-136; Ford, 2003, pp. 52-53). After all, if we seem to live in a particularly productive time in the history of science, there is a wide division of those who are admitted in the global science community. Countries of the industrialized world do not pay much attention to scientific and research done in the developing world, unless they are involved in that research or are giving funding for particular research projects. Local scientists working in local universities without international financial support or connection networks have a much harder time in getting their results published internationally than do many of their Western colleagues. Consequently, when their work does not get international recognition, it easily loses its chance to be further developed.

Information from developing countries that could be spread to the important research centers of the world and processed further into important knowledge that in the end could benefit everyone is often partially disregarded (Wresch, 1996, pp. 79-91). Only if it is regarded more fully could it consistently contribute to the realization of human capabilities and a holistic view of well-being. When information is used merely commercially or as technical means for information production, the goals of wisdom and full human development are set aside or ignored.

Thus, it appears that many Western countries have maintained their role not only as technological or economic advisers, but also as “intellectual advisers” and “the sources of proper knowledge.” Instead of looking for equal partnership, the industrialized world tends to tell the third world how to do things, to put conditions on aid and give or take information it sees as suitable for its own purposes. As a result lots of important local knowledge is wasted and lost.

LOCAL OBSTACLES: LOCAL POLITICS AND AMBITIONS

In addition to the unequal distribution of information technology and information itself, there are other local cultural and political obstacles that prevent us from turning the information society into a global community of wisdom and that further widen the global gap between “the information privileged” and “the information beggars.”

While new communication technology could provide citizens a channel to get involved in public matters and policy decisions, the ruling elite of many developing countries use this technology merely for their own purposes and for their own personal benefit. This is often due to authoritarian political orders in which the head of the state (or the ruling elite) declares a country a democracy. In reality, however, “politics of no choice” is practiced. Often there is only one serious political party

and policy line and no real room for opposition. In this one-party “illiberal” democracy, the distinction between party and the state (or government or regime) is blurred and corruption, bribery and nepotism become common problems. The ruling elite lack the links to the problems of most of the society, particularly to those of rural populations. Nor do they encourage citizen involvement in public matters.

The only real citizen involvement in governance of a nation is often through taxes. The governments of many developing countries originally set high taxes on the new information and communication industry, basing these taxes on the attitude that the latest information technology is a luxury rather than a necessary and integral part of overall development. The tendency to prioritize basic services, such as building roads, educational facilities and health care units, sometimes disregards the possibilities that new communication technology could have in establishing these very services more quickly and more efficiently. However, it should be noted here that recently changes in this attitude have been evident and that taxing of ICT has become more customer friendly.

Nevertheless, earlier taxing policies have influenced the slow progress in nationwide adoption, distribution and use of ICT in the developing countries. For instance in Tanzania the rate of import duty on information technology accessories used to be the highest in East Africa, because computers were for a long time considered as luxury items rather than an integral part of setting up a working infrastructure in all fields of development. The heavy taxing made most Tanzanians unable to buy computers privately, and this led to a digital class divide in society. Even today many local educational institutions, including those that specialize in the use of new computer technology, have to wait until someone donates them the technology (often already outdated or short-lived and unable to give students

up-to-date know-how or access to the most advanced information/data/media resources). High taxes also prevented many computer centers from registering themselves officially. The result of this was usually inferior teaching and/or high fees. Import duty on a computer was, only a couple of years ago, 20% of its value, and a further 20% was charged for value-added tax. As well as these taxes, international shipping costs had to be paid. Thus, in the United States, one of the richest industrialized countries, a new computer can be sold at US\$1000 or even less, while in poor countries like Tanzania the price of the same computer is almost double, unless you settle for an out-dated model or used computer (Heldman, 1994).¹⁵ However, the heavy taxes on ICT do not prevent foreign residents and big businesses from obtaining the latest technology—usually tax exempt. In Tanzania the situation has recently changed with tax policy change and with the recognition that ICT is an essential element in the overall development of the country and not merely a luxury commodity (Mutula, 2001, 2002).

In many other developing countries with stricter authoritarian political order there are other coarser reasons for the heavy taxes and high prices on new technology. Some rulers simply prefer to keep most of the citizens ignorant and uneducated in order to secure their own position and power. History has shown that most of the totalitarian regimes take very tight measures to control information and citizen communication.¹⁶ In many third world countries, for instance, there has been a tendency to protect existing power structures and hierarchies by limiting access to information and by suppressing the capabilities to process information into useful knowledge. As long as the citizens believe in their own “underdevelopment,” social and political hierarchies can be maintained. Official documents are stamped confidential, secret, for limited distribution, depending on who we think deserves and has the right “to know” about particular issues. Infor-

mation that is distributed widely is often trivial, misguided or unclear. For example, in various African countries the passing and distribution of information has turned out to be one of the biggest obstacles in developing “good governance” and participatory democracy.

People in positions of power and influence are protecting their authority by blocking, distorting and censoring information so that people’s capabilities are not sufficiently realized so that they can efficiently and plausibly evaluate government actions, functions of state institutions and policies, monitor business management, and, in general, demand their rights, recognize their duties or complain about the misuse of power. Thus, the idea of an information “revolution” can be directly related to political revolution, which may not be appealing to many leaders. Instead, information and knowledge, with the help of the new technology, can be used to cover up corrupt activities that increase rather than decrease global and local inequality (Mutula, 2001, 2002). After all, when people do not know what is happening around them and when they are not informed about the abuses of political power, or if they do not understand how the political system works, they are much easier to control and keep satisfied. People who are disconnected from the outside world are less likely to stand up for their rights, fight against injustice and demand political change. One central question is then—while there were increasing technical possibilities for e-democracy, would the cultural and political context welcome wider participation and more open and transparent politics? Here again, in relation to the capability approach, new directions in national policies would help to find such a focus. When people participate and can more fully realize the capabilities they have, the leaders themselves learn to understand the benefits that democratic regime can bring to the whole society, and not feel threatened by giving power to people rather than hanging on to it as long as they can.

CULTURE AND TRADITION

All the previous text is at least partly related to the attempts of many countries to maintain their cultural independence and to avoid what they consider to be the negative effects of globalization. In some cases governments set restrictions and censorship on the Internet, since these are seen to import the culture of globalization, consumerism and Western individualism. In contemporary Iran, for example, while the use of Internet is encouraged up to a degree and its possibilities are seen as positive for the spread of the Islamic culture and ideology, the sites that are considered to pass on Western propaganda, moral deterioration or otherwise culturally or politically harmful materials and information are blocked and access to them is denied.

In relation to this, it is evident that in addition to economics and politics, culture plays an important role in development and in the adoption of new technology. Some cultures are more recipient to change and promote technical progress, while others are more oriented towards traditional wisdom. According to well-known philosopher from Ghana, Kwasi Wiredu, this is no accident. Instead, it is due to the cultural differences in worldviews and attitudes towards technology and mechanics. Wiredu (1980) notes that, for many African communities, development does not often mean merely the acquisition of sophisticated technology and material benefits; it also means searching for the intellectual and social conditions that will permit internal, positive freedom for human beings in the form of self-realization. In their search for self-development many African peoples simply do not care about new technology. When development is seen as self-development, learning about mechanical and technological details loses its importance. This is almost the opposite of the Northern view, which conceives development as external rather than internal progress. On the other hand, there has

been some local resistance to modernization in a sense that it is seen to be a sign of further cultural colonization of developing countries.

These differences in attitudes are, at least in part, based on very distinctive intellectual traditions and value systems. If we make some very wide generalization, we could note that the Northern and Western countries have, at least ever since the Enlightenment, had a very individualist, atomistic and mechanistic world-view, which has traditionally equated a human being with a machine.¹⁷ Many non-Western cultures, for their part, have more collectivist value systems which emphasize social harmony and communal interdependency, with understanding of the wholeness of the universe and our social interdependence. In the Western individualist culture the emphasis on reason and rationality requires that we constantly seek more specialized and specific information, which we can turn into scientific knowledge about the way world really is. In many more collectivist cultures with more holistic worldviews and value systems, knowledge about the world can better be achieved by understanding of the whole, with the help of mystical experience that computers and mobile phones cannot produce. In such cultures too much outside information can, in fact, be seen as taking attention away from our internal powers, personal moral development and wholesome wisdom. This is not always the way, however; some of the most technologically advanced countries are based on very holistic worldviews and have very collective social structures, for example, Japan and the technologically fast developing nations of southeast Asia. However, the personal or cultural experiences of the new technology might be very different. In the Eastern context, the idea of virtual reality may be seen as a sign of the holistic nature of the universe and the interconnectedness of (physical, intellectual and mental) human capacities with the immaterial dimensions of our world, while in the more atomistic Western worldview virtual reality may be seen merely as a

device that provides us with the means to extend physical senses and capabilities further across our material world.

The Western emphasis on reason as the source of knowledge gives value to specialized data, that is, external information. In many other cultures the knowledge of the world is rather accomplished by inner awareness, that is, internal information. Achieving the understanding of the interdependence of all things requires us to empty our minds rather than fill them up with distracting piecemeal information. From an African point of view, for instance, the Western world may be seen to conceive knowledge as political and economic power, and thus it tries to monopolize, patent and commercialize all the knowledge it can produce. Since the Industrial Revolution, Westerners have used knowledge to control nature and to exploit it. In many parts of Africa knowledge is equated with moral and social wisdom and understanding the profound interdependence of people and nature and the universe as a whole.

Humans do not produce knowledge about nature. Instead they discover it with the help of the nature itself. While, in the Western worldview, wise men create or produce more knowledge, in Southern cultures it is often “the knowledge” that makes people wise. And wise men know that knowledge should not be used to technologically and commercially suppress and manipulate nature, but to live in harmony with it. After all, humans are merely partners or shareholders, with all other creatures, inanimate objects and invisible forces, in the resources of the earth, of which knowledge itself is one (Tangwa, 1999, p. 276).

Thus, different cultural traditions are often based on very different metaphysical outlooks and thus, may have very distinct views of knowledge and wisdom. People with different cultural backgrounds may therefore have very different ideas and ideals for how to form a global knowledge society. People coming from individualist cultures may see the holistic respect for universal

harmony as inefficiency and primitive ignorance, while people from collectivist cultures may take the emphasis on individuals as arrogance and morally indifferent selfishness (Wiredu, 1980, pp. 53-59, 83, 105).

Understanding cultural differences is an integral part of global development. Part of this understanding requires that we accept that neither attitude towards technology is, in itself, superior to the other. Instead, both have their strong and weak sides and have a lot to learn from each other. While the Northern and Western mechanistic view is eager to develop new means to conquer nature, its emphasis on efficiency and profit often leads to environmental destruction, social inequality and moral indifference in an endless market race. While the Southern holism may not take full advantage of the technological progress and may sometimes disregard individuals' special practical abilities and rights, it can also encourage environmental harmony, social solidarity and personal peace.

Here discussion on human capabilities can also help us to overcome some cultural differences and different understandings of human well-being and good living. As noted in the beginning, people may have very different view of whether the aim of development is material, spiritual or social, but most human capabilities we are looking after in life are universal. We might have different cultural, political or economic contexts to realize them, but, nevertheless, our goals are shared. Thus, promoting human capabilities as the end that justifies the distribution and implementation of ICT should not mean that we have to adopt one global culture, but rather that, with the help of new technology, we have equal capacities to understand, promote and maintain our different cultural values and practices within a context of modern globalized world.

PRIMITIVE AS AN IDEAL?

If we are to build a global society of knowledge and wisdom, different cultures have many important lessons to learn from each other. However, instead of seeing local in global, very often there are hasty polarizations made between modern and traditional. Instead of promoting the best parts of both, people (individuals or groups of people) are forced to make a dichotomized choice between modern and traditional ways of life.

These fallacious polarizations lead to cultural conflicts and to assumptions that local and global are incommensurate. When the fundamental differences in metaphysical, ethical or social outlooks of different cultures are not fully understood, there is a danger that we justify clear injustices as cultural diversity. Also, sometimes people from highly industrialized countries with materialistic values may be skeptical about the value of technological progress as such. Instead, they may romanticize traditional ways of life as resistance movements against technology and consider those who do not have modern technological access to outside world as noble savages.

In fact, those who defend traditionalism and set against modernization are not always residents of technologically and economically less developed countries. Quite the contrary, in many instances it is the information-rich rather than the information-poor who may envision the primitive way of life as an escape from the modern world and the information and consumption anxiety it creates. Some may even themselves sometimes join "the disconnected," on a desert, in a jungle or in the mountains for few days or even weeks.

The difference between the information-rich and the information-poor, however, is that the rich ones always know how and have enough resources to get back to civilization when the times get too rough. Anytime they want to, they can get back to their phones, faxes and communicators, drive

their cars back to cities, and take an airplane back home. The idealized noble savage is usually isolated, poor, and in many other ways disabled. They have no hope for a better life, nor do they have any control over their fate, which is often decided for them by others living in the centers of power and influence. In most cases and most areas people have not chosen their own isolation. The poor simply lack the options to live in any other way (Wresch, 1996, p. 136). Helping these people to get connected with the outside world, and become involved in matters concerning their own lives, is not an attempt to rob cultural traditions; it may be the only way to maintain those traditions. It increases their chances to realize the full set of human capabilities and to see the plurality of human existence and well-being. Keeping people disconnected and ignorant may respect cultural difference, but shows moral indifference. It clearly blocks people from using their full potential, in whatever cultural, social, and material environment they live in.¹⁸

CONCLUSION

New ICT can play a central role in helping developing countries to improve their standard of living and quality of life in relation to realizing human capabilities. However, markets alone cannot bring the technology to those who would most benefit from it and technology alone cannot bring about positive changes. Instead, technology can be made to be a vehicle of positive or negative affects, depending on our personal values and goals, and our cultural beliefs and norms. Information technology can just as easily be used to gain one-sided market benefits or to impose a dominant political culture on different people as it can be used to build a just world order that promotes tolerance, equality and social justice. If we look for new ways to share our global prosperity, it is essential that we make a clear difference between means and ends in the advancement, application

and distribution of ICT. An alternative normative framework that gives a promising start in finding new options for distribution and implementation of ICT is capability ethics that remind us that all material resources are a mere means—never the end in themselves—towards holistic well-being. Since ICT brings together in an intriguing manner both material resources as well as intellectual development, it is important to be clear about what are looking for in our attempts to create global connections. Are we realizing human capabilities and building a global village of wisdom? Or are we creating a superficial global information culture that focuses on market exchange of hardware, software, data, time and social relations?

While it is clear that world neo-liberal economic policies play a central role in global injustice, the Western neo-liberal market capitalism and cultural imperialism cannot alone be blamed for the existing inequalities within developing countries. In many developing countries governments abuse power and resources, as well as people's commitment to tradition. If we are serious about building a global knowledge society, we therefore need to consider first what the ideal of the knowledge society is and how it is related to the realization of human capabilities which are the basis of a working democracy and the moral development of any society. Second, we need to understand the fundamental differences between cultural traditions. Third, we have to conceive technology as a means to better quality of life as well as to more open cultural dialogue, instead of seeing it as an end in itself. If we want to build a global knowledge society, we have to acknowledge that technology *per se* is always value-neutral and, thus, all of us share the social responsibility to develop and use it for the common good and the realization of human capabilities, as is suggested by application of capability ethics to the global distribution and implementation of ICT. While this approach certainly needs to be further studied and its potential problems taken into account, it at least can give us a starting point for debates

on global distribution, particularly in relation to technological advancement.

While there is no clear indication that any comprehensive change in our attitudes is to be expected immediately, keeping the dialogue going is important. Without any change the present trends of global development show that while Internet and other new telecommunication technologies reach more and more people rapidly, at least as many people are at the same time losing their connections to the sources of essential information, local knowledge and basic political participation and power to influence their own fate. This not only deepens material inequality, but also widens further the digital divide and communication gap between the information-rich and the information-poor.

ENDNOTES

- ¹ The term “digital divide” may be defined as the gap between individuals, households, businesses and geographic areas at different socio-economic levels, with regard both to their opportunities to access information and communication technologies (ICTs) and to their use of the Internet for a wide variety of activities. There are divisions between those individuals and businesses who can enjoy the advantages of the information age, and those who are still waiting to see these benefits. The concept of “digital divide,” however, has been questioned as making a normative distinction between the technology savvy and technology ignorant.
- ² When, for instance, we talk about knowledge workers, we mainly refer to those who can manipulate, control, transfer and store the growing amounts of data and information, and not to those who are working intellectually in order to process and distribute relevant knowledge out of all the information available. In the information society true knowledge is often the by-product of information markets rather than a valuable goal in itself.
- ³ According to Sen (1992, p. 42), functionings belong to the constitutive elements of well-being. Capability reflects freedom to pursue these constitutive elements and may even have a direct role in well-being itself, in so far as deciding and choosing are also parts of living.

- ⁴ See, for example, Sen (1985, pp. 6-11; 1990, pp. 113-114; 1993, pp. 30-50). There is no escape from the problem of evaluation in electing a class of functionings. This is particularly problematic in choosing the objects or commodities of distribution. Whose capabilities should have priority, and at what level? The focus has to be related to underlying concerns and values, in terms of which some deniable functioning may be important and others quite trivial and negligible. Many functionings are of no great interest to a person; for example, using a particular washing powder is much like using any other washing powder (Sen, 1993, pp. 31-32). For a criticism of Sen's capability approach, see Cohen (1993).
- ⁵ The new information and communication channels could promise poor countries a better life in the following ways: schools and hospitals could be assisted with online access to information resources all round the world. Computer conferencing and electronic mail could enable students to participate in distance learning projects, seminars and tutorials in vocational schools or universities on the other side of the globe. Scientific researchers and doctors who lack the money to subscribe to leading journals and other publications could keep abreast of the latest work in their fields. Information on health issues could prevent and help to cure many illnesses. Health care workers in isolated areas could receive information on possible epidemics. They could also get distant specialists to diagnose rare conditions and recommend the proper treatments through telemedicine. The poor themselves could learn how better take care of their health and their children's health through access to professional health education and information, that, for instance, helps them to leave behind harmful practices based on ignorance, misinformation or coercion. Local journalists, news offices, development agencies and non-governmental organizations (NGOs) could use new technology to collect and disseminate essential information for rural areas. Information on local government policies and legal matters as well as access to national and international news could, for instance, help people to prevent abuse of power and educate them about their social and legal rights. Also businesses, large and small, would be able to market their goods widely, receive vital information about local and global market conditions, pricing and financial management or they could hunt for foreign partners cheaply. See also APC (2003) and Perry (1996).
- ⁶ Several international and regional organizations have undertaken new projects to bring the benefits of the information technology revolution to the developing world. These projects are often aimed at improving the access capacity of the least developed countries and providing their populations with equipment or multi-purpose telecenters and the knowledge necessary to use information resources. Among these are the ITU Multipurpose Community Telecenter pilot projects in Benin, Mali, Mozambique, Tanzania, Uganda and elsewhere sponsored by ITU, ICRC, UNESCO, UNDP and by national and private entities.
- ⁷ Multinational corporations have become more information-oriented, but they are also taking over the information markets. Now most of the exchange of information between countries is no longer controlled and regulated by governments, but by local individuals have become more tied to the information provided by the international corporations and local businesses have become more dependent on their multinational partners.
- ⁸ If people can read and can afford newspapers or books, they often have to buy imported

ones, written by foreigners and published in a foreign language. For instance, in Tanzania, no history books were published at all by 1980. Thus, if Tanzanians wanted to learn about their own nation's history, they had to learn it from foreigners.

⁹ Miller (1996, p. 371) refers to how the prices spread piracy and vice versa, creating a vicious circle in technology and information markets in developing world.

¹⁰ The world distribution of online connections in 1999 was: World – 134 million (2.4% of the total population); Africa – 1.2 million (0.1% (excluding South Africa)); Asia – 22 million (0.6%); South America – 4.5 million (1.3%); North America – 70 million (14.9%); Europe – 34 million (4.7%) (In many Scandinavian countries, the percentage is considerably higher, now reaching close to 40% of the population) (Molosi, 1999). Since 2000, there were only about 580,000 regular Internet users in the LDCs, representing less than 1% of the population and 0.16% of global Internet users (Sarrocco, 2002).

¹¹ Based on an interview with a Tanzanian *Business Times* ICT journalist, Samuelson Makilla in Dar es Salaam, 1 July 2003. His suggestion of a solution to poor connectivity was based on joint-ownership of a satellite link sponsored by donor and a local stakeholder conglomerate.

¹² Internet connections are slow and commercially fragmented. For example, an e-mail to Somalia from Kenya may go by satellite to the U.S., under the Atlantic by fiber-optic cable to Europe and the Middle East and back up by another satellite from the United Arab Emirates and then to Somalia. Multiple strands of bandwidth connect individual Internet service providers to the central thoroughfares of the Internet, mainly in the U.S. and in Europe. Each international ISP connection costs many thousand dollars to maintain. Most of sub-Saharan Africa in

connected by satellite, which brings echoes and delays to Internet traffic.

¹³ Thus, at present the Information Age is not an age of equality and justice. The poor have enormous obstacles to overcome before they can even get to the global sources of useful information. Not only do they have to be able to read and write in their native language, but also they have to be educated enough to understand at least one foreign language (usually English). Then they have to have access to sources of information and they have to be able to pay for the information they are looking for. However, paying \$US49 a year for the *Wall Street Journal* (US\$29 to print subscribers) in a country where the average income is much less than \$US50 a month is a rather irrational choice.

¹⁴ Even local television and radio stations and the local press often use the same stories because they are easier and cheaper to get than those gleaned by sending a local reporter abroad or to hard-to-reach parts of their own country. Stories about Third World countries are reported mostly by journalists and researchers from the industrialized world. Thus, they present a Western point of view and Western concerns about development aid, natural catastrophes, war, poverty, famines. Positive success stories are seldom reported and traditional wisdom from local sources is usually overlooked (Wresch, 1996, pp. 23-41).

¹⁵ Local development policies can affect poorer members of society adversely. As information education has taken hold in developing countries, priority has been given to the increase of food production and economic resources. Many of the poorer people have been forced to give up some of their land holdings to enable the growth of a more educated society.

¹⁶ Many conservative or fundamentalist religious nations have accepted the use of new

technology itself, but mainly for their own propaganda purposes and they have blocked people's access to, for instance, what they consider to be sexually or politically sensitive data. Sometimes they may deny individuals' access to anything other than government information and may even spread misinformation about opposing views and possible enemies of the state.

¹⁷ See, for instance, Hobbes (1962), whose work presents the Western mechanical position on the norms of social and political order.

¹⁸ Within many traditional societies old social harmony is based on strict social hierarchy and suppression. The poorest and the weakest are often women living in patriarchal societies. They have the least chance to access external information and educate themselves in order to improve their lives. They are too exhausted from work, too sick from serious diseases, gender violence and continuous childbearing, and they are too suppressed and brain-washed by traditions

to attempt to fight for their position in life. Everything these women know and learn comes from their physical environments and focuses on everyday survival. In a local village in the middle of Africa, for instance, the ideas of global village or virtual reality do not make much sense. Not only are these concepts obscure, but the reasoning behind them seems totally incomprehensible. People there see themselves as members of smaller and closer physical communities, hardly even as citizens of any particular state. They certainly do not relate to abstract cosmopolitanism and see themselves as citizens of the world, while, at the same time, they may hold a holistic worldview that acknowledges individuals as not only physical but also spiritual parts of the universe as represented in the world/nature around us. In such circumstances, direct spiritual connection, not technological devices, is needed to mediate needs, wants, hopes, desires, and despair.

Chapter 7.4

What Kinds of Organisations do We Want to Build in Africa with Information Communication Technology?

Rembrandt Klopper

University of Zululand, South Africa

ABSTRACT

In the first half of this contribution, the author focuses on what information communication technology (ICT) could be implemented in Africa in order to integrate the continent into the emerging global culture and associated economy. In the second half, he assesses the state of ICT implementation in Africa. The emergence of worldwide information and communications technology (ICT) networks in the last quarter of the 20th century has steadily effected vast and permanent changes with regard to how people in free market open societies communicate, work, do business, and spend their leisure time. In spite of the recent bursting of the dot com bubble and increasing strains experienced in the ICT

manufacturing sector, advances in information technology and telecommunications (ICT) will continue to reshape the major institutions of society in the 21st century. This ought to lead to a more efficient way of life for at least some people. However, it is not clear whether this “progress” will actually be satisfactory for all. There are many more facets to the application of ICT than simple business efficiency. This chapter asks, “after 50 years of ICT, what kind of society do we want to create for ourselves, and what level of choices are available to individuals and corporate entities?” As was pointed out at the EU meeting in Lisbon in 2000, we need to be particularly aware of the potential for ICT to improve the lives of those who are disadvantaged.

INTRODUCTION

It has increasingly become clear that ICT plays an important role in how society develops. This is apparent from the plethora of initiatives we have seen in the past few years ranging from computer applications in business, education, transport, government, and medicine—to mention only a few areas of application. This relentless application of information and communications technology (ICT) has developed a momentum during the past 50 years during which personal computing has developed and grown in the workplace, and at home to an extent that could not have been envisaged when the first business computers went on sale in 1952. Despite the obvious importance of this technology in shaping the way we live, work, and play, we hardly ever hear the question asked, “*What kind of society do we want to build with our ICT?*” We seem content to have the providers of ICT shape the institutions that will ultimately determine the quality of our lives.

IT: The Shape of Things to Come

The central role of technology in shaping our society is not disputed by many. In fact, there is the argument that technology is a primary driver of history (Smith & Marx, 1994). This type of notion implies that we are on a technological treadmill, which gives us very little option, but to adopt technological innovations as soon as possible. This view suggests that we cannot escape from racing after each new wave of technology. And although in a number of ways this view is clearly true, we suggest that we are actually in a position as individuals to make important decisions about the society we actually want or believe to be appropriate. We may not have complete control over how technology influences our society, but at the same time neither do we have no control at all.

The first step in deciding how we might like to see ICT implemented in the future is to have a view of how the technology will develop in the

medium term. To look into the future and suggest what we can and perhaps should be achieving with the help of ICT is no mean task. There is an old quip sometimes made by stand-up comic entertainers (which has also been attributed to the quantum physicist Niels Bohr); “Prediction is always difficult; especially prediction about the future.” And when it comes to the application of ICT, the ability to predict is especially daunting. Furthermore, there is also an interesting admonition against prediction in Dante Alighieri’s *Inferno* where he suggests that the 8th level of hell—the second worst out of nine levels—is reserved for futurists and fortune tellers (Jacoff, 1993). It is also very sobering to remember the famous remark of Lincoln Steffens upon his return from the Soviet Union in 1919, “I have seen the future, and it works.” It is just as well that Steffens wasn’t attempting even a rudimentary course in prediction or forecasting.

Therefore, from fear of the fires of hell or just simple embarrassment about being wrong, this author will not attempt to foretell the future of ICT, but will instead identify potential trends based on the technological options presently available to us. The options are of course many and it can be very difficult to see which are real and which are just figments of the imagination of technicians, the digitrati, and others. It is always interesting to remember how wrong important people have been when they spoke about how computers might develop in the future. For example, Thomas Watson Sr., the founding father of IBM said, “There is a world market for five computers!” Ken Olsen, the founder of Digital Computer Corporation said rather to his regret one supposes, “Who would ever want a computer in their home?” Also, let us remind ourselves of Bill Gates’ contribution to these faux pas “Who could ever need more than 640K of memory?” Furthermore, in this chapter we are not just interested in the technology but rather in how it will be used in our society, which actually makes forecasting even more problematical.

However, we need to start with a view on how the technology will develop in the short and medium terms. From a pure technological point of view, there is every prospect that computers and telecommunications technologies—the bedrock of the IT revolution—will continue to improve in leaps and bounds. Computers will no doubt relentlessly continue to become more and more powerful. Moore's Law is alive and well and living in Silicon Valley and other parts of the world. At the current time, no foreseen limit is envisaged to this law. Our capacity to process and store data seems virtually limitless. It is now being said that we are producing some one to two exabytes¹ of data per year. This will no doubt continue to grow. In the next five to ten years, even greater advances in computing and memory power may be derived from the suggested amalgamation of biotechnology and electronics. Telecommunications will continue to become faster and faster. This will be done while the price of the equipment and facilities will continue to fall. This does not necessarily mean that computers will become cheaper as such, but rather that the price will probably stay at about the same level with much more power being provided for the same amount of money.

A more fundamental problem with IT adoption relates not to whether communications technologies will improve, but to human problems around IT adoption in Africa. The real question is whether the potential users of ICT in urban and rural communities of Africa would be willing to incorporate ICTs into their daily lives. The answer probably is that regardless whether they live in urban or rural communities, most Africans would adopt ICTs if they consider them to provide a cost effective and sustainable way of solving a range of problems that beset their daily lives. Those problems are formidable: all-consuming poverty fuelled by unemployment, drought, diminishing land resources, poorly developed health care and educational resources, rudimentary transport in-

frastructures, local political and global economic exploitation, and so on.

As economies of scale make established technologies evermore affordable and because conscious efforts are presently being made to develop a new generation of light, affordable, and ergonomically efficient ICT, increasing numbers of African consumers will be willing to invest in ICT—provided that they even faintly believe these instruments will enable them to break the grip of poverty and isolation on their lives.

On the telecommunications front we will see bandwidth increase and prices fall dramatically, provided that governments deregulate telecommunications to ensure that the monopolistic stranglehold of telecommunications providers is broken through competition in the market place. In deregulated economies, international phone calls are charged in pennies an hour.² This will completely open up communications in a way hard to currently envisage. Technology changes such as this will impact Telco's and their employees as traditional pricing models break down video-on-demand will become a reality as will domestic and mobile video conferencing, probably even from wristwatch type devices as envisaged in the Dick Tracey stories, will eventually become ubiquitous.

It appears that nearly everyone on the planet (at least in the more developed countries) actually wants mobile teleconferencing in some form or another. The mobile phone has become a very much superior version of the security blanket by which those who are lonely and who need to feel connected to others anywhere in the world can do so instantly. The mobile telephone has changed the focus of communication to the individual rather than a particular location.

It also seems that many people want to be able to talk using the most modern and fashionable handset and in this respect, a piece of telecommunication equipment has become a personal fashion accessory. As a result of this attitude to-

wards these hand sets, it is estimated that there are more than 100 million discarded mobile phones in the United Kingdom alone, awaiting ecologically clean disposal. Furthermore, it is interesting to note that the race for new features accompanying these handsets and the corresponding generation of additional revenue streams can have interesting consequence. The advent of mobile phones capable of taking and sending pictures or video clips has led to a variety of enterprises banning their use. Banks, schools, gyms, and exclusive nightclubs³ for example have all barred the taking of pictures or video footage on their premises.

Not only do we put computers and telecommunications abilities into many in all kinds of domestic devices, we also install tracking chips into our pets and our children's clothes. Sooner or later, someone may even propose that we put a microprocessor and a telecommunication device into a diagnostic toothbrush, enabling it to report problems to the dentist and to schedule an appointment, and in between even doubling as a telephone!

Remotely operated electronics is increasingly being used by the authorities for crime control. Great Britain already uses thousands of closed circuit television cameras (CCTVs) in urban communities, linked to computer networks and other telecommunication devices to detect criminal activities, to enhance private and public security, and to serve as evidence by helping to identify perpetrators. On the other side of the Atlantic, there is disagreement between the president of the USA and Congress about the legitimacy of co-opting Internet service providers to enable the Federal Government to monitor the communications of American citizens as part of ongoing an anti-terrorist campaign.

The recent upsurge of phishing e-mail messages and the successful swindling of banks and governments are examples of evasive criminal behaviours, as are evermore innovative ways trading in pornography over the Internet. There is little doubt that in the next ten years smart

computers and telecommunications devices will exist, many of which have not yet been invented at this stage as a ubiquitous part of a global fully wired society. The jury is still out on where citizens will eventually draw the line between being willing to be under constant surveillance for safety's sake, and insisting on the right of individual privacy.

Where communication networks with proper bandwidth permit fast electronic communication, we are beginning to integrate intelligent decision making protocols in networked appliances that form part of smart kitchens and other intelligent devices throughout our homes (Herper, 2001, Levinson, 2003). Ovens, kettles, and climate control devices can already be operated remotely, curtains drawn and TVs or audio devices activated via cell phones, or baths filled to just the right level and temperature as we approach our homes at the end of the day. During the day, our fridges will have placed orders for us with our grocers, supermarkets, or fast food vendors, to be delivered just in time as we arrive at our homes, kept clean by roving bots.

Fault detection will be incorporated into many of our domestic appliances, which will alert us about worn out equipment. We will use the technology in an attempt to remove as many domestic chores as we can as we become more efficient in our home life. Hopefully, not many of us will buy these fully wired homes as they will take away much of the familiar routine that actually constitutes human life. But they will be on the market for those who want them and who have a lot of spare cash to buy them, as they will not come cheap—at least initially. Of course, it will also be necessary to be trained in how to use one of these at home. Perhaps one day some entrepreneurial university will offer a master's degree: *Mastering your fully wired home*. In a similar vein, smart communication devices are disappearing off our desktops into our clothes and bodies, soon to be followed by companion robots (Cowley & Kanda, 2005; Klopper, 2005).

Generally, software use will become more user-friendly and intuitive. This will allow computers to undertake many more tasks for us. On the advanced software side, we will make progress with artificial intelligence (Kehal & Khurshid, 2001). Computers will not only dominate chess tournaments, but will take on and eventually become champions in the game of Go. We will produce more intelligent programs, which will increasingly help us in many different situations from medicine to banking, and travel selection to cooking. The computer will indeed help us make smarter decisions. It is however worth noting that sometimes smart decisions are at the expense of wise decisions, which generally need a broad and long term perspective and which often have to cope with paradoxes—one aspect of human thought that will remain a challenge to computers and companion robots for a while yet. It is thought that in the next 5 to 10 years we will make some progress towards a robotic or silicon brain. However, in all probability the quintessential essence and extreme complexity of human intelligent decision-making will elude us for the foreseeable future. Until we understand natural intelligence it is not likely that we will be able to fully master artificial intelligence. Given the reality that human cognition is a continent of which we have only begun to explore the beach on which we landed, Arthur C Clarke's estimate that by 2001 there would be mature artificial intelligence (AI) that could interact with human intelligence, represented by HAL in Clarke's visionary film *2001: A Space Odyssey* was clearly quite overoptimistic. Sophisticated and mature AI will almost certainly be only realized by the middle of the 21st century, if not in hundreds of years' time. Gene Roddenberry's fictional portrayal of the android *Data* in the Star Trek series, set about three hundred years in the future, is probably a more reasonable estimate of when mature AI could be available.

On the business front, ICT has been well established and should grow in leaps and bounds,

making organisations more efficient. There will of course always be computer project failures with the concomitant lost of money. But on the whole information technology investment will continue at an increasing rate and it will turn out to be successful. DotComs and e-business will probably play a lesser role (Remenyi, 2001) while applications such as knowledge management (Depres & Chauvel, 2001) will become increasingly important.

Computers will interface with the public more and more. As a consumer, it will become harder and harder to find a human assistant to talk to. We will buy increasingly either on the Web or through a telephone or via some sort of electronic interface. It will become hard to find a bank staffed by people rather than ATM type devices. Companies will continue to increase their fees to those of us who want to deal with human assistants. Furthermore, we will buy just about every type of ticket from a machine, or download prepaid tickets remotely onto our cell phones or credit card size cash cards. Train tickets, bus tickets, airline tickets, theatre tickets, and meal tickets will be dispensed by machines 24 hours per day and seven days a week. This could be seen as the siliconization of relationships between entrepreneurs and clients. Many companies see this as an improvement in efficiency. But for some people, siliconization is simply a synonym for depersonalisation and for many depersonalisation means a reduction in service. As the application of information technology and telecommunications continues to show good returns for their organizations the so-called productivity paradox (Brynjolfsson, 1993; Willcocks & Lester 1998) will be seen for the misunderstanding that it was. Computers will insinuate themselves into every aspect of the organisation whereby these machines will automatically reorder inventory, plan production, redesign products and reschedule vehicles, and so forth. Customer relationship management (CRM) will come into its own and will ultimately play a significant role in driving the day-to-day affairs

of the business (Leavitt & Whistler, 1958).

In fact, with regard to corporate entities, the pervasive nature of ICT is pushing business organisations towards embedding technology deeper and deeper within their business models. For competitive reasons, there is increasing pressure to be more cost effective and ICT is seen as a central way of achieving this. The application of this technology can be with little or no concern for the individuals whose jobs are either lost or dumbed down. Seeing this through the technologic determinism lens, we could say that at present it seems that businesses do not have much choice as to whether or not they embrace this technology. If a particular business refused to “modernise” and its competitors so do then it could be forced out of the market place. It can be seen that the logic of the market has now begun to drive the logic of technological determinism.

To add to this situation, it is important to note that to prosper, businesses will increasingly need to have the capacity to interact seamlessly with other enterprises and dynamically create and dissolve relationships (Kalakota, 1998). This is most effectively facilitated by ICT. There are many examples of enterprises extending beyond their boundaries and acting as a virtual enterprise using ICT as the primary facilitator. Thus, the pressure to use ICT is nothing less than enormous and this has been reflected in the sales figures of this industry sector over the past decade.

When this trend is examined in detail, the concerns of business with generating a demand for their product or service, selling, and delivering their product to the customer, getting paid, managing the relationship with the customer, conforming to regulatory requirements, and managing the relationship with the shareholders, all lend themselves greatly to facilitation by ICT. If we look at each of these generic areas in a business, we can see an almost endless list of possibilities for ICT applications. Even if the enterprise has reservations about the use of this technology and does not want to continually chase after and adopt

the latest ICT, the technological determinist argue that they may have no choice due to inevitable disruption of the traditional business paradigm by ICT. It is relatively clear that in order to survive, enterprises have to and will have continue adopting new technology that gives them a temporary advantage over their competitors.

Given the reality of this determinist approach, the choice facing the corporate sector is how ICT can be introduced and how these systems will be put in place, and how sound policies for their use and governance will be developed. This concern is reflected in the current focus within large enterprises on project and program governance, enterprise architecture, and program office concepts. This emphasis allows the enterprise to manage the application of the technology within the context of the corporate strategy, processes, rewards systems, organisation, technology, and measures. In addition, while a lot of research indicates that the technology should be put in to support of business change, a number of organisations appear to be forcing change through the organisation using the technology. Of course, this sometimes leads to poor systems or even to outright failure of ICT projects.

A hard line technological determinist would say that given these circumstances, there is no choice but to chase after the technology and that individual employees need to enthusiastically embrace the new systems by becoming an early adopter of technology, and make full use of it. But this a rather simplistic and incomplete view of the issues involved. Given the above, it is clearly hard to argue against the fact that ICT is rapidly becoming ubiquitous to the point at which it will be a central facilitator to virtually every aspect of our lives. But there are still real choices as to how we implement ICT. For example, as business continues to siliconise,⁴ so relationships change. The human-machine interface changes attitudes as well as work practices. As mentioned before, the highly impersonal ATMs, ticket vending machines, and Web sites become the client interface.

Telephone systems with multiple menu options may well be efficient from the company's point of view, but we have never heard one single phrase from a client in praise of them. It is hard to find any discussion on this type of issue. In general, this debate is simply avoided. Many corporate systems are either not ergonomic or simply downright user-unfriendly. Repetitive strain syndrome has now become an accepted complaint for office workers. Fortunately, the use of computers to monitor too closely individual work practices is unacceptable. But despite these issues, there seems to be an unquestioned implicit assumption that ICT leading to efficiency is simply good. But this is clearly not always the case. It is not at all clear that the users of ICT always obtain more satisfaction from their work or deliver a better level of service to the organisation.

Furthermore, large swathes of people are almost automatically left out of this ICT driven type of world (Morino, 2001). In general, those who are in any way traditionally disadvantaged have reduced access to ICT. One important group that is paid very little attention is people with disabilities. Virtually no accommodation is currently made for such individuals. Examples of this abound. Few Web sites have facilities for the visually impaired. Few ATMs are placed at a convenient level for those in wheelchairs. Few organisations make braille or voice recognition systems available for blind individuals.

Yet, for people with disabilities, ICT can radically change their lives through emerging neuro-informatics, the melding of electronic, and neurological signalling (Klopper, 2005). In the case of the blind or visually impaired, it is now possible to facilitate their reading of computer screen using various high-tech assistive technologies. Speech input, screen readers have changed the way people communicate. Furthermore predictive text, typing aids, and alternative input devices are available.

If accessibility is not taken into account during the design of technology, it becomes very

difficult and expensive to retro-fit it. Clearly, it is desirable that all individuals can obtain the maximum benefit from the developments in ICT and this was recognised by The European Commission when it stated that "It is accepted that in today's Information Society 'learning to use technology' and 'learning to learn' with technology is necessary" (EU, 2000a). In the European context, national government in member countries is expected to encourage this by ensuring that teachers can provide the necessary skills training and by encouraging teachers to teach using technology. Furthermore, the EU has recognised the importance of the issue of inclusion. The EU commission has examined the opportunities, which an ITC empowered society could bring "the information society promises new digital opportunities for the socially disadvantaged" (EU, 2001). For the socially marginalized, technology could educate and inform, bring people closer together and provide them with new services—of course basic computer literacy and access to technology would be necessary. These issues were highlighted at the Lisbon Summit in March 2000 where the challenges of the Information Society and the actions needed to address them were defined in the eEurope Action Plan (EU, 2000b).

So the application of ICT opens up a lot of important issues and we will be forced to face a number of choices. We will need to think hard about our basic values and what sort of society we really want or need to create. We could create a highly siliconised society where the only issue is how to be more efficient in the market place. We could ignore personal preferences as to how people want to work and we can just pay for redundancies and repetitive strain syndrome cases. We can disregard our customer's dislike of telephone menus etc. This is the sort of world where we chase after technology for technology's sake not caring for the human impact of what we are doing.

On the other hand, we could be much more sensitive to individual preferences and also we

could create a society where we use technology to enable people to overcome difficulties, to provide high-tech assistive technologies to people with disabilities, to provide support and education and to minimise exclusion. Furthermore ICT can be used to inform those who are struggling for freedom. In this world, we actually face the question of whether we get a better feeling from buying from a machine or drawing cash from an ATM or obtaining information from the Web than we do from having real live people help us. We also face up to the fact that although machines are generally more reliable than mere people, when they breakdown they can have a greater and more catastrophic effect than an inadequate people based service. Remember the last time your credit card was swallowed by an ATM in a far away town leaving you on a Saturday night without cash and without your credit card. Of course, most of us know about having back up arrangements or business continuity plans to use the modern parlance. But even that doesn't always work! Perhaps we will need to cultivate a culture that understands there is more to life than efficiency. Therefore, we need to seriously ask the question and face the implications of its answer: *Do we actually want to deal with machines rather than people?* We can withhold our business from those who want as much siliconisation as possible just to maximise their profit.

It is beyond the scope of this chapter to definitively state what kind of society we want to create for ourselves globally. However, it is clear from the information provided above that we feel that ICT should be used in a sensitive way that bears in mind the preferences and aspirations of the individual. It is also clear that ICT could play a very significant role in improving the circumstances of disadvantaged people including those with disabilities. We argue that not enough attention has been given to this and that it is now necessary to move quickly on this front. It is hoped that this article will generate a more debate and discussion as to how this may be achieved.

THE STATE OF INFORMATION COMMUNICATIONS TECHNOLOGY IN AFRICA

Introduction

As the deal with the Second Network Operator in South Africa takes shape, many questions will remain in the minds of the consumers of information communications technology (ICT), be they private individuals or business, about what benefits may be realised from the deal. However, at the same time we must not ignore the ICT trends unfolding in Africa and in particular within South Africa. There has been significant increase in the consumption of mobile telephony over the last 3 years, throughout Africa. BMI-TechKnowledge estimated in 2003 that the mobile content component of the ICT market was the second largest market segment—estimated then at about R150million a year. The main source of this revenue was from SMS content downloads such as ring-tones and icons ⁽¹⁾.

Despite the growing appetite for connectivity, there is still a large portion of the African population that does not have a consistent means of access to connectivity. In a publication on www.bridges.org, one of the definitions given for this digital divide is “*a lost opportunity, with disadvantaged groups being unable to effectively take advantage of ICT to improve their lives—what really matters is how the technology is used, and its incredible potential to improve quality of life for disadvantaged groups; effective use requires computers, connections, training, locally relevant content, and real applications of the technology to fit immediate needs.*”

Understanding the consumption patterns and drivers of ICT, as well as the appetite for ICT, will in the future play a key role in the quest to close the Digital Divide within Africa. In this context, it is believed to be pertinent to first examine ICT in Africa, what is driving it, and where the energy currently resides. With this in mind, a fine balance must be maintained in developing

First World Business Systems to service a Third World Market.

A View of ICT in Africa

Intent

There is a need to address the knowledge economy in Africa if there is to be any progress in closing the Digital Divide. While there is acceptance and recognition by bodies such as New Partnership for Africa's Development (NEPAD) to accelerate broad-based growth and development, Africa generally lacks the resources, policies, and institutions to draw benefit from the knowledge economy.

The developed world provides the majority of theory and understanding of the information age whereas very little comes from Africa in terms of primary research which can be used to develop ICT policy formulation and strategy.

From this background, Research ICT Africa (RIA) was formed as an initiative of the Learning Information Network and Knowledge Centre of the University of Witwatersrand (LINK). The quoted definition of what RIA is, is extracted from their March 2004 ICT Sector Performance in Africa publication as being "An ICT policy and regulatory resource base for decision-makers in the public and private sectors and civil society, developing public-interest research findings through the networking of researchers at African universities."

General Findings

These initial findings have revealed that although there has been a growth in the access to telephony within the majority of African countries, this has been via mobile technology rather than the conventional more affordable fixed-line telephony.

Data available from the International Telecommunication Union regarding fixed line and mobile telephony trends in Africa between 1995 and 2003 (accessible at <http://www.itu.int/ITU-D/ict/publications/world/world.html>), reveal that

of 43 African countries surveyed by 2003, 78% of them had more mobile than fixed subscribers, that almost 70% of African telephone subscribers used mobile telephony, that by 2001 mobile subscription overtook fixed line subscription, and that by 2003 for every 100 inhabitants there were 3 fixed line subscribers, compared with 6.2 mobile subscribers.

Two clear examples of this are Kenya and South Africa where there has been a decrease in fixed-line subscribers of 0.61% and 10% respectively over the period of exclusivity protecting the Public Switched Telephone Network (PSTN). Both Kenya and South Africa have experienced dramatic local-call tariff increases, which has been mirrored by fixed-line disconnections. Cameroon is likewise experiencing similar trends with a decrease in income of over 40% for the fixed-line operator over a three-year period. However, in the case of South Africa, the decrease in fixed-line subscriptions has been accompanied by continuing profitability by the semi-privatised national fixed-line operator. It appears that this may be partly ascribed to their focussing more on the lucrative business market than on investing in network roll-out.

In Africa, although there are reform models in place in terms of ICT and fixed-line policy in particular, the cost of access remains extraordinarily high. Whereas in the Northern hemisphere, the communications cost is on average 3-5% of per capita income, in Africa it reaches highs of 36% of per capita income.

The result of this is to restrict access to the Internet in an extreme manner. Although there is a very large mobile footprint, the cost effectiveness of Internet via this mode is still prohibitive. Information provided by the International Telecommunication Union (at <http://www.itu.int/ITU-D/ict/publications/world/world.html>) correlates Internet access costs, stated in US\$, with the number of Internet users for Cameroon, Ethiopia, Kenya, Rwanda, South Africa, Uganda, and Zambia for 2002. From the data provided,

Figure 1. Growth in mobile subscription in Africa between 1995 and 2003

Figure 2. A comparison of Internet usage and Internet costs in seven African countries in 2002

one can infer that there is no direct correlation between Internet access costs and number of users because Ethiopia and Zambia respectively have hardly any users (below 20,000), in spite of having of the lowest access costs per 20 hours of access, and conversely South Africa has by far the largest group of Internet users (round about 130,000), in spite of having relatively high Internet access costs.

In countries such as Cameroon and Rwanda, Internet access via Internet Cafe's remains the preserve of the fixed-line operator and it is es-

timated that there are some 450 cyber cafes in major centres of Cameroon.

Ethiopia on the other hand has adopted a strong monopoly model when they created the Ethiopian Telecommunications Company and the Ethiopian Telecommunications Agency. Despite having a population of some 70 million, there is still an extremely low network development with a waiting list, which represents nearly 85% of capacity. There is a fixed phone teledensity of only 0.6% and an Internet penetration rate of only 0.0001%, possibly the lowest in the world.

A Perspective of ICT Penetration in South Africa

On the following pages is a perspective of what the ICT penetration picture in South Africa looks like. As can be seen from the tables below, the information was produced in the main to include 2003. The 2004 data has as yet not been made available by the ITU. The extent of the impact of the Second Network Operator is as yet unknown and whether or not there will be real saving achieved by the average man in the street remains to be seen. There are hopes that there will be some form of financial benefit realised by the consumer and that as voice over Internet protocol (VoIP) becomes a reality that further connectivity benefits both in terms of bandwidth and cost will be experienced.

Main Line Subscriptions

Main line subscriptions, the conventional copper landline subscriptions, have traditionally

been provided by the semi-privatised Telkom. Information provided by the International Telecommunication Union (available at <http://www.itu.int/ITU-D/ict/publications/world/world.html>) shows that in South Africa, main line subscriptions peaked in 1998 at 5075.4k subscriptions and that the average number of lines per 100 people has remained the same as in 1996, suggesting that the increased subscription rate has remained in line with the growth of the population.

Cellular Subscriptions

Cellular subscription is a wireless service offered by three service providers in South Africa, Vodacom, MTN, and Cell-C. Although these three ostensibly offer an independent telecommunications service, they all three have licensing agreements with Telkom in terms of legislation and infrastructure. They rely on Telkom in terms of infrastructure and other licensing agreements. International Telecommunication Union data (available at <http://www.itu.int/ITU-D/ict/publica->

tions/world/world.html), show persistent strong growth in South African mobile subscriptions between 1996 and 2003, growing from 953K to 16860k subscribers over that time period.

Along with these impressive growth statistics, we see that there is a very high rate of SMS usage in the mobile world. In 2002, South African mobile subscribers on average sent 17 SMS messages per month, in comparison with a world average of only 4 SMS messages per month.

Internet and PCs

Data provided by the International Telecommunication Union (available at <http://www.itu.int/ITU-D/ict/publications/world/world.html>) reveal that there is no differentiation between

privately owned PCs and non-privately (business, government, NGOs etc.) owned PCs. This applies equally for Internet subscription and usage. The data shows that South Africa has a higher Internet density than the rest of Africa. The major reason for this seems to be the lack of fixed line infrastructure in the rest of Africa in comparison to South Africa.

Analysis of Reflected Data

Data obtained from International Telecommunication Union's subscription Web site is summarised by means of two graphs below. The first graph shows that between 1996 and 2003, main line subscriptions in South Africa remained flat in South Africa while at the same time having grown in

What Kinds of Organisations do We Want to Build in Africa

the rest of Africa. Compared to Africa as a whole, South Africa shows an increase of nearly 184%, this suggesting that the SA market is behaving differently to the continental trend.

In contrast to this, as shown on the second graph, there has been a substantial upswing in the take-up rate of cellular or mobile telephony in South Africa as well as in the rest of Africa, with Africa's rate being substantially higher. This implies that there is an escalation in African consumption rate, but that this does not imply that the SA market has necessarily levelled out. If one compares the two graphs, the results could be interpreted to indicate that Africa is playing catch-up. With SA only having 36.36 cellular units per 100 people in 2003 and a decreasing Main Line consumption, it would indicate that there is both the appetite and scope for further market growth.

Comparing the two means of telephony, it becomes clear that the appetite in South Africa is definitely in the mobile environment and not the fixed line environment and as such. Investment focus should be accordingly aligned.

With reference to Internet and the ownership of personal computers, there appears to be a large market opportunity for ICT growth both from an Internet and from a PC perspective. Firstly, what we see is that there are more PC's than there are Internet users, implying that the market has not been fully tapped from that perspective. However,

the penetration of the PC into the market as a communications device is lagging far behind that of the fixed lines and mobile telephony. At this stage, the reason for this may very well be a question of affordability rather than one of appetite.

Again, it is interesting to note that in excess of 80% of Internet hosts in Africa are in South Africa. But, the same trend displayed in the mobile environment may well be playing out in the Internet environment, where between 2001 and 2002, there has been a significant change in the ratios of South African hosts and users relative to the rest of Africa, suggesting that Africa is playing catch-up in this environment as well.

With Internet access costs being effectively determined by the monopolistic Telkom as infrastructure provider, and with the South African government showing little inclination to deregulate the local telecommunications market, as can be seen from the fact that Internet access costs are twenty times higher in South Africa than in Europe and the USA, affordability is an important issue in Africa and South Africa. Where there is an economic as well as a digital divide, there have been significant steps taken in providing communication technology to these less privileged markets, as can be seen in the graph below.

Using 2002 as the cut-off period for this exercise, between fixed lines, mobiles, PCs, and CA (Community Access Centres), there were some 21.881 million ICT devices for a population of

Figure 6. Increase in community access centers in South Africa between 1994 and 2002

some 45.45 million, which could imply that only 48% of the population had access to ICT. From the perspective of a developing nation, this may look impressive, but more than that, it illustrates the immense opportunity for further growth and acceleration in the field of ICT in South Africa.

CONCLUSION

Two main points emerge from this analysis. Firstly, mobile communications will continue to exceed fixed line growth in Africa. Secondly, there is very little chance of Internet growth if it is based on fixed line deployment in Africa.

The conclusion that Internet growth in Africa will depend on non-fixed-line infrastructure has significance in two dimensions. Firstly, the Digital Divide focuses attention on bringing connectivity to the masses, but is mobile connectivity sufficient to fully close this gap? The cost of bringing connectivity and information to the masses via mobile is prohibitive for a third world country so in reality it is not about availability but about the ability to provide access cost effectively. Secondly, given that this scenario seems set to play out into the foreseeable future, it must have implications for financial institutions like Absa (Amalgamated Banks of South Africa). Consideration must be given to the extent of market reach via the Internet vs. the market reach via mobile. Accordingly, planning for the future and investment in the appropriate technologies should be carefully considered. This is not only from a back-office view when rolling out into Africa, but also from a user interface view.

Alliances with key stakeholders remains critical in order to ensure that the developments in African ICT are brought into business strategy on an ongoing basis to ensure that we remain at the forefront of banking in Africa.

Chapter 7.5

Computing and ICT Literacy: From Students' Misconceptions and Mental Schemes to the Monitoring of the Teaching–Learning Process

Antonio Cartelli

University of Cassino, Italy

ABSTRACT

Three main questions guided the author in the writing of this chapter: Is there the need for a widespread and in-depth ICT literacy in mankind? What has to be meant for ICT literacy? And are there special problems in students' learning of ICT topics? And last but not least: How can ICTs themselves improve teachers' work and students' learning on ICTs? The introduction answers the first question and shows how difficult the search can be for solutions to the problem of the digital divide. The answer to the second question comes from a short survey of the experiences that some institutions made for the introduction of basic computing skills and ICT literacy in school curricula. In the meantime the problems that the students usually meet while attending computer programming and ICT literacy courses are described. Finally the author reports the results of some experiences involving the use of ICTs in teaching

and describes how he arrived to hypothesize the adoption of action research strategies, of Web technologies and data mining techniques for the monitoring of the teaching-learning process and its improvement.

INTRODUCTION

In today's society, often defined the knowledge society, the mastery of ICTs (information and communication technologies) is considered very important for future citizens. It is well known, in fact, that computers and communication are everyday more and more present in human life, and that mankind has to be skillful in its use to win the challenge of contemporary and future complexity. As an example of the above remark, lifelong learning and the number of rights everyday needing the basic ICT skills can be considered: in the former case the continuous update of

personal knowledge and skills is more and more, depending on the cleverness in ICT use; in the latter case e-government, e-commerce, e-learning, and so forth are good examples of the relevance that ICTs will have in the exercise of the citizens' rights, both today and in the future.

The importance of ICT influence on mankind has already been analyzed in various contexts, and the term digital divide has been adopted to describe the gap existing between developed and underdeveloped countries. As an example, the words of Malloch Brown (2001), of the UNDP (United Nations Development Program), are reported here:

“...Now, the Internet has become both the fuel and the vehicle for a dramatic spread in democracy, intensifying demand for and supporting the spread of genuinely transparent and participatory and more efficient systems of government at both the national and global levels. The number of democracies worldwide has doubled in little more than a decade. But in too many countries, institutions remain fragile, services are weak, officials unaccountable. And the lack of a democratic dividend—in terms of jobs and better services—has been undermining public faith in these new systems, particularly among the poor. ICT offers real hope in all these areas, offering greater citizen input into decision making and better social services for all....”

Alternatively, it must be noted that digital divide was recently evidenced at different extents in developed countries. Warschauer (2003), for example, stated that digital divide is a social problem marking the differences among social classes (80% of high-income families in the U.S. connect to the Internet, while only 25% of low-income families do) and ethnic groups (55% of the White population in the U.S. uses ICTs, but only 31% of the African-American population and 32% of the Hispanic population do the same). He also stated that there isn't a unique digital divide

marking the difference between “people who can” and “people who cannot” access computing and ICTs. What is more, he argued that there isn't a unique factor responsible for the separation among the different social groups and their ICT use. In other words ICTs alone cannot be identified only with the equipment to be inserted in the poorest contexts or with the people training; there are in fact many examples of failing experiences based on the above assumptions.

From what has been said to this point, it can be deduced that the digital divide is one of the contemporary pedagogical emergencies (Cartelli, 2004), and great efforts have to be made in everyday teaching to guarantee the diffusion of an effective ICT culture. The author's experience with the use of ICTs for the monitoring of the didactic process will show how the same ICTs can be turned into powerful instruments for improving the efficacy of teaching-learning processes and will help people in overcoming the problems they meet when they attend computing or computer programming courses.

BACKGROUND

During the last two decades, all disciplines made progress in analyzing phenomena and developed new paradigms for interpreting reality. As a consequence the traditional procedure of transferring disciplinary knowledge into teaching practice led to a continuous revision of school programs and curricula.

On the other hand many psycho-pedagogical hypotheses were developed to explain the ways people build new knowledge when starting from previous knowledge, and experimental techniques were applied to individuals and communities to find new strategies and instruments for improving teaching.

One of the results of the above experiments was the discovery of misconceptions and mental

schemes in students' minds and more in general in people's minds.

A good survey of the research on misconceptions and mental schemes can be found at the MLRG (Meaningful Learning Research Group, 2004) Web site (www.mlr.org), where the proceedings of some conferences on misconceptions, wrong ideas, and meaningful learning are partially reported. Those studies collect research carried out all over the world and concern differently aged people, from pupils, to middle school, high school, and university students (sometimes they also include workers, professionals, and teachers).

Two main aspects clearly emerge from the above experiences (Cartelli, 2002b):

- a. Preconceptions, misconceptions, and mental schemes can be found in all domains of human knowledge; most parts of the investigated fields concern scientific knowledge such as mathematics, physics, statistics, computer science, chemistry, biology, natural sciences, cosmology, and so forth, but there is a relevant number of studies (and that number is still growing) investigating the wrong ideas that students show with language, literature, history, and other human sciences,
- b. Two main approaches can be adopted in such studies: a former one, labeled by Driver and Erickson (1983) as ideographic or naturalistic, analyzes the pupils' reasoning and more generally the ideas that people show when they explain phenomena with no reference to scientific paradigms—that is, they only evaluate the internal coherence of the people's concepts and ideas; the latter one, defined by the same authors, concerns people who already approached scientific topics (or were beginners), and evaluates the correctness of their ideas with respect to the scientifically accepted ones.

Regarding ICTs and especially computer science, the following events intervened in making more complex the situation: (1) the exponential growth with the time of the discipline topics (i.e., during the last three decades), (2) the spreading of personal computing, (3) the revolution in human-computer interaction induced by graphics interfaces, and (4) the Internet.

The main results of the studies carried out during last two decades concern the presence of wrong ideas and misconceptions in students attending computer programming courses (du Boulay, 1986; Soloway & Spohrer, 1988). More recently it looked as if the introduction of special GUI (graphic user interfaces) and WYSIWYG (what you see is what you get) strategies could help novices in overcoming the above difficulties, but the results of other studies did not agree with this hypothesis, and showed the presence of preconceptions and misconceptions, even with the new human-computer interaction (Ben-Ari, 1998; Christozov & Mateev, 2003).

COMPUTER SCIENCE TEACHING AND COMPUTING LITERACY: A SURVEY

It must be noted that before digital divide evidence, many scholars (mostly computer scientists) already assigned great importance to the introduction of computer science elements in the curricula of high schools or junior high schools (at least in Western countries). On the other hand, it must be said that there has never been a general agreement on the computing topics to be taught in the schools; nevertheless, professional associations (ACM and Computer IEEE, first of all) produced syllabi or suggested different solutions in this respect.

The most important consequence of the above uncertainties was the lack of a unique proposal for the planning of the introduction of comput-

ing teaching in education. As an example the analysis of the Italian situation will be reported in the following section (Cartelli, 2002c), and the results of some experiences the author led with his students will be discussed.

The Italian Experience in Computing Teaching

In 1985 the Italian Ministry of Education collected the results of many research projects on computer use in education which were carried out all over the country and which stated that computer science could be used in high school education in the following ways: (a) as an instrument to automate the school administration, (b) as an instrument to help teachers in their work or a resource for students, and c) as a knowledge amplifier to develop reasoning and problem-solving skills in the students.

Among other things it was supposed that computer science could help students in: (a) problem analysis and formalization of its solutions (algorithmic), (b) use of data structures, (c) coding of procedures in computer instructions, and 4) use of CAI (computer-assisted instruction) and CAL (computer-assisted learning) tools. In other words the adoption of all Taylor's (1980) metaphors—tutor, tool, and tutee—in everyday teaching was suggested.

To make concrete the above proposals, the National Plan for Computer Science (PNI—Piano Nazionale di Informatica) was started. This plan was devoted to a revision of the mathematics and physics curricula in the first two years of high school, with the main aim of developing computing knowledge and skills in the more general context of the above disciplines. The same plan had two phases: a former one for the training of a task force (mostly teachers already involved in computing teaching experiences), and a latter one that used the above staff members in training courses for the other teachers.

A few years later a new document of the Ministry of Education analyzed the results of the PNI application and suggested the reconsideration of the introduction of new technologies in education. (It must be noted that the ministry now adopted the term new technologies in place of the previous computer science). The different terminology has its roots in a paper of V. Midoro, G. Olimpo, and D. Persico (1996) at the ITD-CNR (Institute for Technologies in Education—National Research Council); they proposed the term didactic technologies to describe computer use as a special case of technology introduction in education, and focused on the use of special tools for supporting class work more than on computer programming and related skills. Because of the above change, the Ministry of Education in 1997 began a new project called PSTD (a triennial plan for the development of didactic technologies). This project mainly involved primary and junior high schools, and gave to these schools the funds needed to create multimedia computing laboratories for teachers and students.

Recently, mostly yearly, statistical analyses on the evolution of the ICT presence and use in the schools were carried out. The most relevant results can be summarized as follows: (a) all the schools have at least a PC (if not a computer room) and Internet access, (b) a relevant number of teachers (more than 50%) attended or are attending computing literacy courses (mostly online), (c) only a few teachers (less than 10%) systematically use the Internet in their teaching work, and (d) a very little number of students (less than 15%) systematically use ICTs and especially the Internet at school.

Misconceptions and Mental Schemes in Computer Programming

If computer programming is considered very useful in the development of problem-solving and planning skills, the author's experience as a

computing teacher in a high school (the Italian Technical High School, with a specific computer science curriculum) shows how difficult the teaching of the above topics can be.

It is well known, in fact, that computer programming is a complex task for students and that it requires great effort from them (Lemut, 1993), but it is less known that the students' difficulties can persist notwithstanding the change in methods and techniques the teachers can adopt in their work, and that many students also manifest the same incorrect ideas after attending specific make-up courses.

Some computer programming topics (related to imperative languages like Pascal and C) for which students evidenced wrong ideas are reported below (Cartelli, 1994, 1996):

1. The range of the numerical data types: The students almost never verify the correctness of a variable data type if the result of an automatic calculus differs from the handmade one.
2. The use of the cyclic structures (for...to... loop, etc.): Many students cannot write the correct statements for an iterated sum containing a total variable (often they put a specific assignment for that variable after the end of the loop), or would like to use the for...to... structure much more than the other ones (and also when it is impossible to use it).
3. The use of conditional statements: While composing these statements the students always write the relationships among the variables and dislike the use of Boolean variables, when explicitly asked to use these variables they tend to relate them with the values true and false (for example they write: if A = true then ... with A Boolean variable),
4. The use of the structured data types (arrays): Many students cannot manage the single

elements of an array (they use the whole array in input, output, or calculus operations) and almost never succeed in writing the correct statements for finding the least or the greatest values in an array.

5. The subprograms: The students often insert in a function or a procedure many statements better belonging to the main program.
6. The recursion: This is one of the most difficult topics to be taught and learned, and often the students confuse iteration with recursion.
7. The abstract data types (stack, list, queue, tree, etc.): The students have a few problems in understanding the theory and the application principles for these topics, but have great difficulties in the use of the pointer variables for the management of the same data types.

Other problems can be found in logic programming, OOP (object oriented programming), and data file management, so it clearly appears that almost all computer programming fields evidence teaching-learning problems, requiring a great attention from professors and students.

A good aid in the improvement of the teaching-learning process is represented from the individual and group strategies a teacher can adopt in the class (it should be noted that the author's classes, like most nationwide, had no more than 28 students). In the former case the tools making transparent the execution of an algorithm by means of the visualization of the variables' values and the evolution of the system's states are very useful in helping students to overcome some difficulties; in the latter case the individual and social constructivist strategies usually adopted in communities of learners (Brown & Campione, 1994) can lead students to the meaningful learning of the proposed topics (Greening, 2000) (participated lessons, class discussion of problem finding and solving, group discussion of case

analysis, individual and group discussion and evaluation of the procedures to be used, individual and group adoption of metacognitive strategies, cognitive apprenticeship strategies, construction of distributed expertises).

It must be also noted that when both of the above strategies are applied in a class with great success (the measure of such a success is usually taken from the results of the periodic and ending tests the students are submitted to), there is no guarantee for the students' overcoming the problems reported above. The students can in fact show difficulties and make errors, after having attended the above courses, when asked to answer special or misleading questions (Cartelli, 2002a).

ICT Literacy Misconceptions

If there is common agreement on the difficulties the students meet in computer programming study, it is important to note that computing literacy is not seen in the same perspective. Instead, it is commonly seen as a vocational training involving the following topics: computer structure and computer use for data management (use of an operating system), communication (the Internet use), and office automation (word processing, calculus, presentation tools, database management systems).

The author does not agree at all with the above point of view (he is persuaded there is no computing literacy without a computing culture), but his opinion has no relevant influence on the knowledge, the abilities, and the skills people must obtain at the end of a basic computer science course. On another hand, the computing associations joining the CEPIS (the European computing professionals association) greatly supported proposal of a definition of a unique syllabus for basic computing skills; the ECDL (European computer driving license) is now the standard de facto for computing literacy in Europe.

Nevertheless, no syllabus can delete the following question: Are there wrong ideas, misconcep-

tions, and mental schemes in computing literacy or basic computing courses? In the author's opinion this situation is very similar to the computer programming one, and there are many topics needing a great deal of attention from teachers and trainers (Christozov & Mateev, 2003). In fact, the experience the author had in vocational and basic university courses (with first-year students of the educational and social courses at the Faculty of Humanities) evidenced the presence of wrong ideas on the following topics (Cartelli, 2002a):

- Input/output, memory, and processing units: Very often the students do not recognize the category of a given device when they are asked to specify it.
- Operating systems: When asked to specify what this is, most of the students chose the wrong answer, "It is an integrated hardware/software system that makes the PC active," instead of right one, "It is the set of the programs letting [the] user manage the computer resources."
- Icons and pointers: When asked to specify what these are, many students selected the less right answers, "Images letting the user access the computer parts" and "Instruments for the displacement of the objects on the desktop or in a window," instead of the right answer for both questions: "They are the instruments of the computer-human interaction."
- The Internet: Many students state "It is a communication system based on the use of the telephone" rather than "It is a communication system based on computer networks."
- The Web: When asked to explain what it means to browse the Web, many students state "to connect to the Internet" rather than "to use a special program like the MS Explorer or the Netscape browsers to see Web pages."

With respect to computer programming experience, some differences can be noticed: (a) the wrong ideas reported above were obtained from the students' answers to written tests, (b) the number of the students attending the lessons was now higher than in a computer programming situation, and (c) individual and social constructivist experiences were planned and carried out with the help of an e-learning platform and with the cooperation of tutors (who managed online and presence work), but very little ameliorations in the students' ideas could be observed at the final examinations.

E-Learning and Computing Literacy

What has been reported in the above section needs further explanation for its implications. It should be noted, in fact, that the misconceptions were detected during long-term teaching and the results of former experiences led to the development of a special information system for the monitoring of the didactic process (it is a dynamic Web site interfaced with a relational database storing all information coming from the students' browsing of the site). The didactic materials of previous basic computing courses (Cartelli & Ruggiero, 2000, 2001) were integrated into the information system, which was planned taking into serious consideration the results of the research on students' misconceptions and mental schemes.

The system, very similar by its features to an e-learning platform, offered—together with a well-structured knowledge tree of the topics to be taught/learned—the following functions: (a) various communication areas implementing virtual environments for teachers/professors, tutors, and students; (b) a careful management of the students' evaluation and assessment tests; and (c) two functions for the analysis of the students' access to the course materials and their use of the communication services.

The management of all information in the site was guaranteed from five user levels or selected

accesses: (a) the system administrator, (b) the professors, (c) the tutors, (d) the students, and (e) the researchers and scholars (who could only retrieve the information on the students' access to the course materials).

The two information retrieval functions to be used for students' monitoring had the following features:

1. The former one reported the number of times that a single student or a group of students accessed the site's pages until the query date (the numerical data were reported in the tree structure of the site).
2. The latter one gave the sequence of each student's access to the Web site, ordered by date and hour of access. It could also report the messages the student left in the electronic blackboard, in the chat, in the forum, and in the case study areas, and let the teachers compare all the data stored in the same time interval.

After a first positive test of the system on a limited number of students (66), the study was extended to the students attending two first-year courses. The high number of students (more than 350) now made the continuous monitoring of the didactic process impossible and didn't allow an instantaneous control of students' incorrect ideas if the data stored in the system were available for further elaborations (they were analyzed after the end of the courses).

Strictly speaking the experiment was positive for the students—there was only a 20% loss of students at final examinations, and more than 65% of them had positive if not excellent scores.

Alternatively, the subsequent analysis of the students' access to the course's Web pages confirmed the presence of a relevant number of persons still showing misconceptions and wrong ideas. Other results emerging from that analysis were: (a) there is always a good correlation between the highest scores at the assessment test,

and the systematic and repeated browsing of the online materials; and (b) little score increments from the entry to the last test are always related to successful browsing of the online materials.

CONCLUSION AND FURTHER HINTS

The results of the above experiences clearly show: a) the implications ICTs have on the meaning of knowledge both to an individual and a disciplinary extent, b) the computer science topics that should be taught in school, and c) the innovations that must be introduced in everyday class work for the improvement of the teaching-learning process.

Regarding the first point, it must be noted in the author's opinion that psycho-pedagogical hypotheses looking at learning as a static and definitive process need a deep revision. It has been shown that individual knowledge, also when well settled and consistent with discipline knowledge, can be neglected by individuals and can lead to misconception.

As a consequence, teaching and didactic research have to evolve together, and the question on the topics to be taught must be replaced with the following question: Do we have to accept the risk of misconceptions and mental schemes in students' minds and hypothesize a cyclical teaching process leading to a continuous amelioration of the proposed topics, or do we have to carefully plan a deeper analysis of the discipline themes soon leading to a right disciplinary knowledge? In both cases new instruments for a more efficient monitoring of the teaching-learning process are needed.

In the author's opinion a good move in this direction comes from the systematic adoption of Web technologies interfaced with information systems. These systems could store all students' operations, and produce descriptive and inferential statistical analyses on the data stored. An indirect evidence for this need comes from the results of

the experience reported in the last section where the continuous monitoring of the didactic process was impossible because of the lack of statistical analysis features in the two available functions (which only reported the data stored in the system, without making any elaboration on them).

Furthermore the use of the above information system will make possible the systematic adoption of the action-research strategies by the teachers. It will revert the usual strategies until now adopted in the management of the teaching-learning process because, with respect to well-established methods, it will be event driven; that is, the students' learning styles, profits, and scores will be the phenomena to be observed and translated in indices describing the environment within which the teaching-learning process will be continuously re-planned. The statistical analysis of the data stored in the information system will give:

1. the change in the time of the features of a single student (by means of indices describing well-defined behaviors and learning styles);
2. the change in the time of the features of the students' groups, such as the classes and the whole schools; and
3. the change in the space of the features of the students' groups, that is how different environments can influence the evolution of the students' learning models.

In other words data mining strategies could be applied to the analysis of the teaching-learning process, and great improvements will follow for the management of that process and for the students' results.

Chapter 7.6

ICT in Schools: What is of Educational Value?

Aidan Mulkeen

National University of Ireland, Ireland

ABSTRACT

This chapter considers how information and communication technology (ICT) can be used to achieve educational value in schools, and encourages teachers to focus on approaches that promote higher-order thinking. It examines the reasons for use of ICT in schools, and argues that clarity of thinking is needed in the face of popular beliefs about ICT. While highlighting the ways that ICT can contribute to important learning objectives, the chapter stresses that many uses of ICT may have little educational value. It argues that the real value of ICT in schools is in enabling more challenging learning activities that develop higher-order thinking, and offers a simple diagram that teachers can use to evaluate their use of ICT. Various ways in which basic technology can be used to promote higher-order thinking are explored. Finally, the chapter considers the factors within a school that are likely to encourage and sustain worthwhile uses of ICT.

INTRODUCTION

Across the world, there is a rush to include information and communication technology (ICT) in schools. In almost every country there is an ICT strategy, and teachers are being trained to use ICT. Teachers and schools leaders are keen to get the best possible benefits from ICT, and wonder how they should be using it. The aim of this chapter is to identify where the benefits lie, and to identify the general principles of how ICT can best be used.

WHY ICT IS IMPORTANT

Before identifying the best uses, we must first be clear about what we are trying to achieve. National ICT strategies often reflect a series of different aims for ICT. In general, four different rationales for use of ICT can be seen. These can be described in general terms as the economic,

the social, the pedagogical, and the knowledge society rationales.

The economic rationale is perhaps the most obvious. ICT is increasingly a part of working life for many people. As Negroponte (1995) has so eloquently argued, the development of digital technologies is having an impact on economic structures, changing the way businesses operate, where businesses locate, and even allowing a whole range of new businesses to emerge. ICT skills are seen as important in helping to grow the kinds of business that rely on technology. As a result, developing ICT in schools is a key plank of economic development and competitiveness strategy for many countries.

The social rationale centers on the concern that in the spread of ICT skills, some people will be left behind. Technology is becoming a more important part of everyday life. The numbers of computers are increasing dramatically, as they become cheaper and more powerful (OECD, 2001, pp. 12-13). More and more people use ICT as a main source of their information about the world. By 2001, U.S. Internet users were spending more time online than reading newspapers or magazines, and 45% of Internet users even reported a reduction in their time watching TV as a result of their Internet usage (Jupiter Communications, cited in OECD, 2001, p. 14). As ICT becomes more pervasive and more frequently used, those without ICT skills may become increasingly disadvantaged or marginalized by their lack of skill.

The argument is almost parallel to the argument for literacy. In a society where few people can read, lack of literacy may not be a major barrier, as few things will be written down. Once writing is used by enough people, then those without literacy are at a disadvantage. They may not have the same access to information and may have to rely on others to get information for them. Imagine being illiterate 100 years ago, before radio and television. To find out about jobs or opportunities, or to hear political or public news, you would have to hear from someone else who could read.

The same argument can be applied to ICT. Those with good ICT skills have easy access to information about jobs, economic opportunities, learning opportunities, and news from a variety of perspectives. Of course, those without ICT skills have a variety of other media like newspapers and radio to choose from, but they are at a disadvantage in terms of the speed of access and the range of material they can access. For this reason, ICT is often described as a literacy, and the skill gap is seen as a major cause for concern. As Tom Alexander, then head of the Center for Educational Research and Innovation at OECD, stated:

...there are profound concerns now about the gaps opening up between the ICT 'haves' and 'have-nots,' between those who reinforce their access to, and use of ICT in education what they have and do at home, and those who have little of either. The gaps may become every bit as profound as earlier forms of rigid social and education selection. (Alexander, 1999)

In this view, the rationale for having ICT in schools is to ensure that all young people get some exposure to ICT. If this does not happen, then there is a risk of a digital divide between those with ICT literacy and those without. Universal experience of ICT while at school is made more important by the uneven patterns of access to ICT at home. In most societies the richest and best-educated groups are also most likely to have home computers (Russell & Drew, 2001; Ginsberg, Sabatini, & Wagner, 2000). As a result, if schools do not act to redress this imbalance, the benefits of the digital age may fall to the already privileged social groups.

ICT as a Teaching Tool

Educators also make a pedagogical case for ICT. This view argues that ICT can be used to support teaching and learning. In this case, the aim is not to teach ICT skills, but to use ICT to teach

other parts of the curriculum. ICT as a tool to enhance learning takes a variety of forms. For some people, it means using the computer as a tutor, asking the learner questions, and providing feedback to his/her answers. Examples of this approach can be seen in a variety of educational software, ranging from freeware available for download to sophisticated integrated learning systems (ILS). Others have seen the potential of ICT in the development of more open learning environments where exploratory learning could be facilitated. Examples include the seminal LOGO program, designed to provide an environment for learning mathematical and logical skills (Papert, 1980). This constructivist approach to learning may also be facilitated by use of “content free” software such as word processors (Underwood & Underwood, 1991). Use of such software has been reported to increase motivation and result in student work that is longer, better presented, and of better quality (Stradling, Simms, & Jamison, 1994). More recently, the development of the World Wide Web has brought additional possibilities for education. The vast range of material online can be used to enrich teaching. Perhaps more significantly, the Web can be used to allow students to research topics for themselves (OECD, 2001b, p. 22).

Following the rapid development of the Internet and the World Wide Web, new thinking has emerged that is centered on the concept of a knowledge society. This thinking begins with the idea that pervasive technology will change the kinds of things we need to learn in schools. If we have virtually unlimited information at our fingertips, do we really need curricula so reliant on recall of a set body of facts? In some cases we may even be teaching out-of-date factual material prescribed in a curriculum, while the students have easy access to more relevant and current material online.

Equally, it is clear that access to the Internet does not displace the need for education. In fact, making sense of the material you find online is

often quite difficult. In our technological age, we have made information easier to get, but harder to digest. The information available online is difficult to handle for a number of reasons.

First, the material is hidden. The Web can be compared to a huge library, but without an index, and without sections for each topic. Most people either rely on some favorite site that they visit regularly, or they use search engines to find material.

Second, the material is of varied quality. Searching for any given topic, you may find a range of sites. Even when the irrelevant sites are disregarded, you may be left with a wide range of material, some aimed at junior classes in primary schools, and others aimed at postgraduate students. Some may be commercial sites, selling a product. Different sites may reflect different views, different interpretations of history, or different scientific paradigms.

Third, the material on the Web is often read out of context. When you pick up a book, you can read the chapters systematically, or at least look at the contents and see the context in which a particular page is presented. On the Web, search engines often bring the reader to a specific page, presenting just a single item without the sequence or context in which it belongs.

The citizen of a knowledge society may therefore require a different kind of education. They may have less need to memorize large quantities of factual data. On the other hand, to succeed in a world where they are constantly presented with a flood of unstructured and decontextualized information, they may need high levels of other skills. These might include:

- Information-retrieval skills, including searching and refining searches.
- The ability to assess information and select the most relevant, accurate, and appropriate material.
- The ability to interpret, synthesize, and develop a context for information.

These objectives are reflected in the Australian national goals for schooling in the twenty-first century, which includes the expectation that when students leave school they should:

- have the capacity for, and skills in, analysis and problem solving;
- have the ability to communicate ideas and to collaborate with others;
- have qualities of self-confidence, optimism, high self-esteem;
- have employment-related skills and positive attitudes towards lifelong learning; and
- be confident, creative, and productive users of new technologies. (Adelaide Declaration, 1999)

Critics: Risk of Low-Level Thinking

These arguments for the use of ICT in education, or some combination of them, have been widely accepted by governments and education authorities, which continue to invest heavily in ICT. But the drive to put computers into schools has also met with criticism from some writers. One of the frequent themes in the criticism is concern about the quality of work done with ICT. Stoll (1999, p. 4), for example, argues that much of what is done with computers in schools is not very challenging and may be less valuable than what it displaces. Healy (1998, p. 190) also expressed concern. She agrees that the analytical skills outlined above are increasingly important, but she suggests that the use of ICT in schools may actually retard the development of those skills, by providing instant answers and allowing little time for reflection. In addition, working with computers may displace working with real objects (Healy, 1998, pp. 220-221).

These concerns about the quality of work done with ICT raise serious challenges. We cannot simply assume that all uses of ICT in schools are worthwhile. Instead, we must seek the uses that

offer educational experiences that are genuinely more valuable than what is displaced.

Some people are so enthusiastic about ICT that they would argue that any use of ICT is valuable, as it provides useful experience of the technology. However, that view does not stand against the rationales for use of ICT identified above. If ICT is being introduced to help develop a competitive economy, then it is true that giving students sophisticated experiences of the technology may help them to develop technology skills. But surely not all uses of the computer will provide anything that could be described as industry-relevant skills. In the most extreme example, if students used a repetition task administered on the computer, how could this be seen as providing experiences of ICT that would help in economic development or employment? Taking a broader view, industry might benefit more from young employees with good mathematical and scientific understanding, a high level of good sense or logic, and the ability to communicate well. If a student has these, surely he/she can learn the basics of word processing very quickly.

Similarly some very primitive ICT training in school may do little to bridge the digital divide. If the key skill for participation in an information society is good information-handling skills, then simply learning to browse the Web is of little benefit.

Types of Use of ICT: The Value Grid

These are not reasons to avoid using ICT in schools. Rather, they present an argument that we should focus our use of ICT on those types of use that promote the really valuable kinds of education. The diagram below shows one representation of where these valuable areas lie.

The bottom of the grid represents different types of uses of ICT in terms of whether they are concerned with learning about the technology, or concerned about using the technology to achieve

other educational aims. Thus, learning to operate a particular package would be located on the left side, and using ICT to learn history would be on the right.

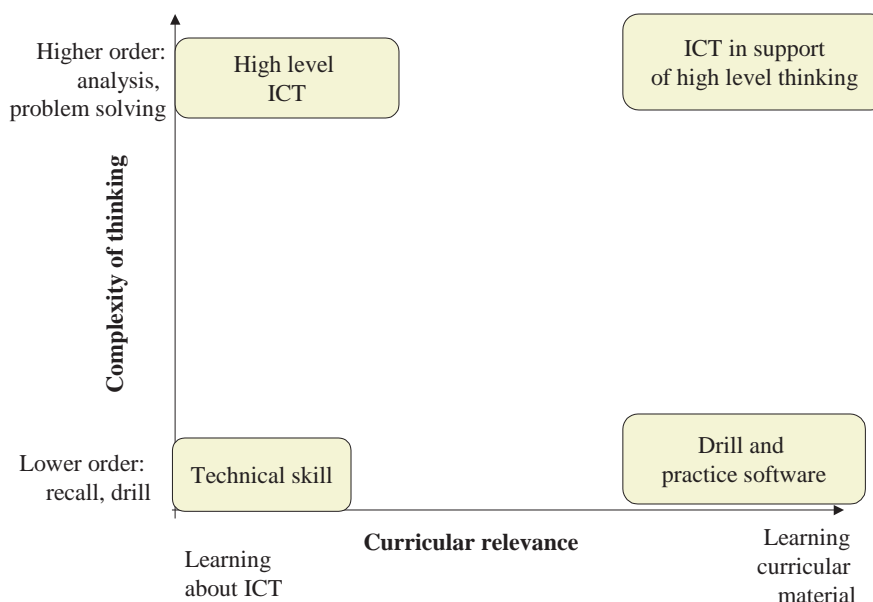

The vertical part of the diagram is used to classify uses of ICT in terms of the level of thinking or analysis involved. Uses that demand higher-order thinking skills are at the top of the scale, while uses involving only memory or repetition are at the bottom.

A few examples may help to illustrate these classifications. If a teacher is using ICT to teach the basics of word processing, and teaching this by working systematically through all of the menus one by one, then this is classified as learning about the computer, and involving only low-level thinking, and so is placed on the bottom-left of the graph. If a teacher is using a drill-and-practice program to reinforce basic recall of facts, then this belongs on the bottom right, involving lower-order thinking but aimed at curricular learning.

If students were doing a project making a complex interactive Web site, this might be classified as involving higher-order skills, but focused on learning about ICT, and so be located in the top-left corner. If they were making a Web site that reported their research in history, that might be located in the top-right corner, as a task that was both challenging and curricular.

It is difficult to make absolute determinations about where each type of activity is located, as the real value of an activity depends a good deal on the subtleties of how it is organized. Take, for example, searching the Web to look for information on a particular topic. This could be a high-level task, involving students in finding material, making assessments of the value of the material, and developing a synthesis of their findings. On the other hand it could be a task involving cutting and pasting without even reading the material found, and have little educational value at all.

Figure 1. The ICT value hierarchy

So which uses are of value? It depends on why we want ICT in schools. If we are introducing ICT to help build an ICT industry, then obviously the activities in the top-left corner are important, and the top right may be useful in helping to build good thinking skills. If the aim is to bridge the digital divide, then any of the uses along the top, those that involve developing high-level analytical skills, are likely to be useful. If the aim is to use ICT to support learning of other topics, then clearly the activities at the top right are important.

But what of the activities at the bottom of the grid, the activities involving only lower-order thinking. Do they have any place in schools? Let's start at the bottom left of the grid, with the teaching of basic ICT skills. At first glance this seems to be a worthwhile area to include. After all, one might argue that without the basic skills, it is impossible to do the more challenging tasks. But this argument leads to a lot of monotonous teaching of very low-level operational skills in schools, and sometimes the schools never find the time for the more valuable high-level uses. In reality, the level of technical skill needed to be able to engage in challenging activities with ICT is very low. Many challenging activities require only basic word processing or the ability to search the Web. Given the speed with which the operational skills can be learned when needed, and the speed with which the details of packages change, there is little to suggest that spending a lot of school time on basic skills represent a good use of resources.

The other popular use of ICT at the bottom of the grid is the use of ICT as a "drill-and-practice" activity to teach or reinforce basic skills. This may involve rehearsal of factual material, testing of factual knowledge, or doing repetitive mathematical tasks. Teachers and students often find these activities motivating, and believe that they are valuable in teaching or learning factual material. There is no doubt that repetition is an

effective way of learning factual material, but it does little to promote understanding or the development of higher-order skills. It therefore does little to serve any of the aims for which ICT is included in schools.

So far, the argument of this chapter has been that ICT is an expensive innovation introduced into schools for economic, social, or pedagogical reasons. To address any of these rationales, it is the higher-order uses of ICT that are needed. Yet sadly, much of the use of ICT in schools is located at the lower end of the grid. These uses may have some value, but they do little to address the reasons why ICT is important in the first place.

So why is so much of the use of ICT directed at these lower-level uses? In part this is because not enough thought is going into why we are using ICT. Often use of ICT is driven by a general uncritical belief that ICT is a good thing. Sometimes this belief is supported by parents, who frequently encourage the use of ICT in schools without a clear analysis of why they believe it is of value (Selwyn, 2001).

Instead of this uncritical acceptance of ICT, we need to be much more demanding of it. We need to recognize that some uses of ICT are actually contra-educational, because they displace more valuable activities. Take for example the teacher who uses a computer drill package to teach the outcomes of an experiment, instead of actually getting the class to perform the experiment. In this case, an educational activity involving higher-order thinking has been displaced by one involving only memory. This is not intended to discourage use of ICT. There are plenty of educationally valuable activities which can be enabled by ICT. However, while recognizing the potential, it is important not to become uncritical enthusiasts. Any teacher considering use of ICT should start with this question: Which uses of ICT will help to move the educational experience into the higher parts of the grid?

WHERE ARE THE REAL BENEFITS?

The preceding section has looked at the reasons that are advanced for the introduction of ICT in schools, and has made the argument that the real benefits lie in uses of ICT that promote higher-order thinking. Assuming that you are convinced by this argument, the next logical question is how ICT can be used to promote the development of these higher-order skills. The answer often lies in the subtleties of how ICT is used.

The basic argument here is that ICT does not have any specific inherent value. It cannot be said that ICT enhances learning or detracts from learning. Instead, the value of ICT depends on the way it is used. The same technology, even the same applications, can be used either to enhance the quality of teaching and learning, or to reduce learning to a memory exercise. Finding the best uses of technology is complex. There are no absolute answers, as the best use depends on the teacher, the context, and the topic. Nevertheless, there are some general principles that can guide the search for the best practices. It seems intuitively obvious that we learn more when we do something to process material, than we do when we sit and passively listen to it. It is similarly obvious that when we are more interested, we put in more effort. We may be more interested in tasks that are real, or have some external purpose, than in tasks that are artificial tasks, invented by the school for no other purpose than to set a task. These basic premises suggest that we should seek teaching activities which involve:

- a. students constructing, organizing, or developing the material; and
- b. an interesting project or task, preferably an authentic project or task that has a function outside of the confines of the classroom, and preferably a task for which there is a real audience.

There are some characteristics of ICT that lend themselves to these types of useful educational activity. The sections below consider some common applications of ICT, and where they may have a role to play.

Word Processing

Word processing provides a very interesting example of how the same technology can be used in very different ways. Word processing is probably the most frequently used application of personal computers, and in many countries it is the most used software within schools (Mulkeen, 2002). Some of the use of word processing involves learning to work the software, often based on copy-typing material from worksheets or books. This is an effective way to teach the various functions and controls of the package, but does nothing to develop higher-order thinking.

The Quality of Output

Word processing also has characteristics that may be useful to a teacher trying to develop higher-order skills. Firstly, it allows students to produce work that is visually of high quality; this can be helpful in motivating students. For many students, working on a word processor is more motivating than working on paper. Part of this motivation comes from the novelty of working with computers, and as such may be short lived. But a more interesting part of the motivation derives from the ability to produce professional-looking work. Most teachers have probably experienced the satisfaction of seeing a document (perhaps a thesis or project) in printed form and the pride that comes from producing work that looks good. Imagine how much greater the satisfaction can be for those whose handwriting is uneven and messy. Word processing may be particularly helpful in developing writing skills in those with poor handwriting.

This effect has been noted in the U.S. in the ACOT schools (Apple Computers, n.d) and in the UK in the schools in the portables pilot project (Stradling et al., 1994). In these cases, it is not suggested that students use the word processor all the time and avoid learning to write well by hand. But using the word processor allows the skills of composing and spelling to be separated from the task of actually forming the letters. In this way, learners can be encouraged to write more and longer pieces of text without waiting for their handwriting to catch up.

This principle may appear to benefit only learners at the early stages of developing writing skills, but of course the motivational power of presentation can be of use at many levels. Take for example a school that asks each student to write a short story, and then produces these stories as a school magazine for distribution to parents. The task that the students are set is to write a story, and this could equally be done with paper and pen. The extra dimension added by the technology is that it is produced to a high quality, and can then be copied and distributed, providing a real audience for the work.

The Mutability of Text

A second major feature of work produced on a word processor is that it can easily be changed. This characteristic of the changeability or “mutability” (OECD, 2001b) of text opens up a range of possibilities. A few different studies have reported a fascinating pattern, that students who type their work produce longer work and use more evidence to support their arguments (Stradling et al., 1994; Mulkeen, 1998). How could this be? One explanation for this may be that when students type their work, they are able to add new ideas at any point. Thus for students who do not have a clear idea of all of the points they want to make in advance, a wordprocessed document can become an evolving structure onto which ideas are hung, rather than a linear document.

Writing is one of the key skills in a modern society, and many jobs require the ability to produce clear written reports. Skilled writers draft and redraft their work, producing a series of improving versions before the finished product. Yet much of traditional school writing is a one-shot process. In this traditional model, students write material, then the material is marked by a teacher, and the students cast a cursory glance at the marks. It seems logical that if we want to teach students to write well, they should have the experience of reworking their documents in response to feedback. The process of producing the second draft can involve more learning than the first. Even the process of repairing minor grammatical and typographical errors can help to focus students on the accuracy of their work. One very interesting study (Gardner, Morrison, & Jarman, 1993) suggested that students who spent a lot of time using a word processor were more accurate in their spelling and punctuation even when handwriting. This is clearly not a feature of simply using the word processor, but a reflection of a structure where students were required to return to their work and correct these errors, thereby developing greater accuracy. In one project, teachers even deliberately devised tasks that involved students in redrafting texts, with a view to teaching them the skill of developing a document (Gardner et al., 1993).

One of the benefits of the ability to change the text is the ability for a teacher to break a writing task into a series of sub-tasks. A language teacher might, for example, ask students to do a small creative writing task, using the word processor. In the first response to the work, the teacher might consider only the story line and the vocabulary. Once some work had been done on these, a second review of the work might focus on grammar. This type of separation of tasks helps to build student confidence, as they are not presented with all the difficulties at once, and it also allows classes to focus on a particular aspect of the work.

Collaborative Writing

Another dimension to the ability to change text is that it facilitates projects involving collaborative writing. Much of the writing at school is done by individual students, yet we know that in the world outside of education, writing is often done by a group and that some of the best ideas evolve from collaborative activities. Within a school context, collaboration can help students to help each other, building confidence and skill. Writing with pen and paper severely discourages collaborative writing, because the only way that text can be merged or adapted is to rewrite the whole thing. By contrast, word processors make collaborative writing easier. Collaborative writing can take a series of forms. In one model, the students sit around a computer and discuss what they want to say, with one person typing the text as it is agreed. Alternatively, students may work on different parts of a text, and then exchange materials and review the materials, before finally assembling the completed document.

Because documents can be transmitted so easily (and cheaply) using e-mail, the technology facilitates collaborative writing at a distance. Schools can now easily collaborate with schools in other locations to engage in collaborative writing tasks. These provide an external motivation for enhanced effort, by providing an external audience for the work. Working together at a distance can also be a powerful way to build understanding in a cross-community or cross-border context.

Two examples will illustrate the potential. In the Irish Tech Corps, two primary schools decided to use a school magazine as a means to encourage student writing. The schools were located in different cities, 150 miles apart. In each class, each student was asked to do a piece of creative writing on the word processor. Each school then produced a class magazine containing all of the work from their own school, and selected highlights from the other school. The schools each sent copies of the magazine to the parents in their own school,

and sent extra copies to the partner school. Thus each child had produced a piece of work that was published and sent home as part of a magazine, and the best writers were further rewarded by seeing their work reproduced in the magazine of another school. This low-cost and very simple project was highly motivational for the children involved, and resulted in great effort being taken with the work (Mulkeen, 1998).

Collaboration at a distance is used in a more formal way in the Dissolving Boundaries project, where schools on each side of the Irish border use ICT to work together on joint projects. The project can be focused on any areas that the teachers and students agree, but the impact is to provide a motivational and authentic task on which the teachers can build real curricular learning while at the same time providing an ongoing contact that helps to build mutual understanding (Austin, Abbott, Mulkeen, & Metcalf, 2003).

Word Processing and Higher-Order Thinking

Word processing, then, is not simply a matter of exchanging handwriting for typing. Instead it offers a new and very different way of writing, writing that can be continuously reshaped and reedited as required. At the same time it produces a very professional-looking product, which is motivating for students. These characteristics of the word processor make it an ideal tool for promoting the higher-level thinking skills identified earlier as so important.

As anyone who writes can attest, organizing your thoughts to produce coherent text is a most challenging task. Writing often forces ideas to be developed with more clarity, and highlights the weaknesses in unclear thinking. Asking students to write their understanding of an issue is therefore a very complex task, which involves making a synthesis of multiple sources, making judgments about what is important, and imposing a structure on the material.

Using a word processor to write allows the writer to experiment with alternative structures, struggle with alternative phrasing, and think more deeply about the choices being made in the writing process. More profoundly, the word processor allows teachers to set tasks that are of a bigger scale, that can be reshaped and modified as new ideas emerge. In short, the word processor makes it easier for students to do project work.

Project work is an attractive approach for a number of reasons. Firstly, it challenges each student to do some creative thinking and to develop ideas and structures for themselves. Secondly, it allows each student to work at their own pace, and at their own level of understanding. Thirdly, the quality of presentation, combined with the ability to improve the document as ideas emerge, means that the output is very rewarding for the student.

This is the essence of the importance of the word processor. It is at its most valuable when used by teachers to delegate more of the responsibility, research, and creativity to the learners. Where this approach works well, it has striking beneficial effects on learners. The ACOT schools, for example, reported increases in the quality of students' work, beyond what the teachers thought was possible. The benefits go beyond simply the quality of work produced. The ACOT schools reported that learners grew in confidence and developed as more autonomous learners (Tierney et al., 1992).

Presentation Software

A very similar set of characteristics make presentation software (such as Microsoft's PowerPoint) useful. Presentation packages allow students to make high-quality presentations with attractive visuals. As with word processing:

- a. The quality of the finished product is attractive and motivating for students.

- b. The ability to change and develop the work allows complex material to be built up gradually, and allows the teacher to guide development by focusing on one aspect at a time.
- c. The ability to change the structure means that different sequences and structures can be tried easily.
- d. The software facilitates groups or collaborative work, as students can merge pieces done separately, and can modify work done by their colleagues.

As with word processing, learning to work the package offers relatively little challenge. The real potential of the software is its ability to inspire and enable students to work on challenging projects.

There are two important differences between presentation packages, and word processors and presentation packages. First, the presentation package is primarily intended to accompany a verbal presentation. Verbal communication is an important skill, and one that, in some traditions, has received less emphasis in school than written communication. Yet many of the important events in life (job interviews, meetings, etc.) demand the skill to present ideas cogently in verbal form. Students, particularly the students with poor verbal skills, are often reluctant to practice making presentations verbally. Even confident speakers are often reluctant to speak in a second language, and so this software is of particular relevance for language teachers. Presentation packages provide an easy way to encourage students to make verbal presentations. The students often become engaged with the technology and want to present, just to show off their product. In addition, the sequence of slides can help presenters to make their presentations even when nervous. Finally, the requirement to have a prepared presentation forces students to plan and research a verbal presentation.

The second important characteristic of presentation software is that it is primarily visual. Much

school work requires that students express their ideas in words, either written or verbally. Visual presentations give students the opportunity to express ideas in a visual form, using pictures or diagrams.

Teachers can use presentation packages to encourage students to do some research, organize their ideas, and make a presentation to the class. Where this is done, the students may be motivated by the opportunity to make a visual presentation, and by the sense of a real audience for their work. Where this has worked well, teachers have reported high levels of motivation, and benefits in quality of work, verbal skill, and confidence (Mulkeen, 2003b; Austin et al., 2003). As with word processing, the argument is not that the software is inherently valuable or that it produces learning gains. The argument is that the software facilitates and enables a teaching method that involves students doing meaningful and challenging projects for a real audience.

The Internet

One of the most exciting dimensions to ICT in recent years has been the development of the Internet. In most countries the Internet forms a key part of ICT strategy for education. National policies often prioritize increased Internet connectivity for schools. In practice, teachers use the Internet in very different ways, and many do not use it at all. The key uses of the Internet can be divided into three broad categories:

- The Internet as resource library (the World Wide Web).
- The Internet as a communication channel.
- The Internet as a place to publish.

The Internet as Resource Library (the World Wide Web)

The World Wide Web (WWW) can be seen as the biggest library in the world. The number

of Web sites is far greater than the number of resources any school library could hope to hold, and the Web has the additional advantage that it is growing and being updated all the time. The Web therefore provides a resource of enormous potential to schools. Students can use it to access more timely, up-to-date materials than in textbooks, and at the same time can have access to a far greater variety of materials than are found within the school.

Following the arguments presented earlier, the key aim of our use of ICT in education should be to promote higher-order thinking skills. Access to a wide variety of sources presents an ideal opportunity to use teaching methods based on students doing research for themselves. Ideally students could find a variety of material, maybe including different perspectives or even opposing views, and make their own synthesis of what they find, based on their analysis and assessment of the material.

However, there are some difficulties. School libraries are generally small collections of carefully selected and classified material seen as appropriate for the students. By contrast, the Web is enormous, but has no central editor, so it is a library without an index, and the material is neither arranged systematically nor selected for its suitability. This presents a series of problems for school use. The first and most obvious is that students can wander into unsuitable material, which often means pornography, but could equally be racist, or material inciting hatred or terrorist acts. There is an enormous volume of pornographic material on the Web, and some of it is specifically designed to present itself to innocent users searching for other things. While there are filtering products available, these are not entirely effective, and schools may be concerned that some unsuitable material may slip through (OECD, 2001b).

Even where relevant material is found, it may not be useful. Material on the Web is at all levels, ranging from material published by primary

schools, to leading-edge research. While this is one of the great strengths of the Web, it also means that a student may be presented with material at a variety of different levels, which may be difficult to handle. School texts are carefully written in age-appropriate language and are careful to explain each term when it is first used. Students accustomed to such carefully refined and selected material may find it difficult to adjust to interpreting material in more complex language.

A third difficulty is that the Web presents material out of context. In a book, the argument is built up systematically. It is assumed that the reader can see the chapters in sequence, and concepts that are explained in one chapter can be used in later chapters. The Web presents information out of context. When using a search engine, the reader is often presented with material from the middle of a text, without always having easy access to the preceding pages.

A further difficulty with the Web is that much of the material can be copied and pasted electronically into other documents. While this makes it an ideal research tool for the motivated student, there is always the risk that the less motivated will simply copy material without understanding it.

These characteristics of the Web make it problematic as a resource for student research. Teachers often report difficulties with students:

- a. wandering into unsuitable material;
- b. getting distracted by irrelevant material;
- c. getting overwhelmed by a series of snippets of information and being unable to make a coherent synthesis; or
- d. falling into the copy-and-paste trap, where material is copied but not necessarily read or understood.

Teachers respond to these problems in a variety of ways. Some conclude that the Web is not a useful learning tool, and simply avoid using it. These teachers may wonder why all

the emphasis on connectivity is justified. Other teachers argue that learning to deal with a huge volume of decontextualized information and make some sense of it is a key skill in an information age, and so it is important that we develop those skills in our students. Of course it is unrealistic to expect that students can simply be “thrown in at the deep end” and expected to develop such skills themselves.

Teachers have tried different ways to make use of the resources of the Web. It may be helpful to see these as a scale with very open and unstructured approaches on one side, and very controlled use on the other. At one extreme there is totally unstructured Web research. In this model, students take a topic and are asked to search for useful material and report their findings. This approach requires that the students do the most thinking for themselves, and so has the greatest potential for learning and especially for the development of those important higher-level thinking skills. However, this approach also has the greatest risk of going wrong, as students can wander into the wrong material or fail to develop a worthwhile understanding of the material.

At the other end of the scale, there are highly controlled ways that teachers can make use of the resources available on the Web. One possibility is that the teacher might search the Web, find useful material, and bring it into the classroom. Alternatively the teacher might direct the students to a specific Web page and ask them to read through the material. These uses are highly controlled and so carry a much lower risk of going wrong. However they also offer much less opportunity for students to be challenged by the material or to have to develop analytical skills for themselves.

In between these two extremes, teachers have tried to develop ways of guiding students to use the Web more effectively, while leaving them with the challenge of finding and processing the material for themselves. One of the interesting models is the WebQuest.¹ A WebQuest is a semi-

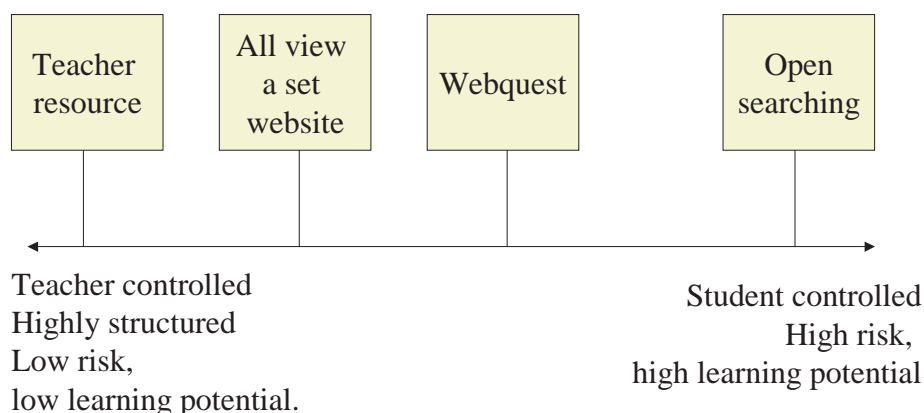

structured research activity, based on the idea that students are given a topic and a series of names sites, and required to develop a verbal presentation on the topic. This structure does not necessarily develop Web searching skills, but it does guide students to the relevant sites, and requires them to read, analyze, and synthesize the information. The model can be used at any level and with any age group. Increasingly, teachers are developing WebQuests and publishing them on the Web, so other teachers can avoid some of the preparatory work and begin by using or modifying an existing WebQuest.

The resources of the Web are not confined to material students can read. Some sites offer interactive activities that can be very engaging. Increasingly, the Web is the mode of distribution for educational software. Where software used to be packaged as a CD-ROM for sale to schools, it is now often available as a download. Much of the material involves a payment before it can be used, but there is still a good deal of material that is available free of charge. This material often falls into one of two main types—tests and simulations. Online texts or multiple-choice quizzes are very

popular both with students and with Web developers (Mioduser, Nachmias, Lahav, & Oren, 1999). For the developers, they are one of the easiest kinds of material to produce. For students they are interesting and engaging, and they provide a useful self-check on learning. Students often prefer to be assessed by machines, because the machine is non-judgmental, and to be measured by it is less intimidating than to be measured by a teacher (NCET, 1996). However, if the aim is to develop higher-order thinking, then online tests are often less than ideal. Many are focused on recall of factual information (the easiest kind of multiple-choice test to devise) and are little more than a modern form of rote learning.

Simulations are less common and more difficult to produce. However, when they are well designed, they offer the student the opportunity to adjust different variables and see the impact on an overall system. The ability to “play around” with the variables contributes to the development of students’ understanding of the relationship between variables. The weakness of the simulations is often their very open nature. Some students may need guidance or some semi-structured tasks

Figure 2. Approaches to Web resources

to help them to experiment thoroughly with the simulation and to get the most from it.

The Internet as a Communication Channel

The focus of the previous section was on the use of the Internet as a resource. The Internet can also be used as a means of communication. This may not involve use of the Web, but may instead involve technologies like e-mail, computer conferencing, and videoconferencing. These are most frequently used to communicate with another school, a relationship that provides reciprocal benefits for both schools involved. One of the most obvious uses of inter-school linkage is in the area of language learning, especially where the schools are each learning the language of the other.

But this kind of linkage has a value beyond language learning. First, any kind of link to another school provides an audience for the work of the students. Having an audience is motivational for learners and encourages extra effort to produce better quality work. Second, linkage with another school provides an opportunity for building understanding across divides of culture, geography, or history. In the Dissolving Boundaries project in Ireland, schools in Southern Ireland are linked with schools in Northern Ireland, and students work together to do curricular projects. The project research suggests that this approach of ongoing interaction over a sustained period is very effective in building a sense of knowing the other students, and a sense that they are “just like us” (Austin et al., 2003). Even when the link is not intended to bridge barriers of historical conflict, there is much to be gained from linkage with another school.

In designing a link with another school, it might be imagined that videoconferencing would be superior to e-mail. Videoconferencing has the advantages of immediate response, moving pictures, and the novelty of a relatively unfamiliar

technology. However, e-mail too has its advantages. First, the communication is asynchronous and so is easier to schedule. Second, communication can be based on individuals communicating with individuals, allowing richer communication than a videoconference, which is more likely to involve larger numbers. Third, the written communication, although slower, may allow more space for reflection than a live videoconference (Austin et al., 2003).

The Internet as a Place to Publish

The Internet also has a value as a place to publish student work. While many schools have a Web site, this is often simply produced by teachers as a public statement about the school. From a learning viewpoint, the real power of the Web may be its potential to turn students into publishers. Encouraging students to produce projects that are published online has four attractive features:

1. It provides a real, and potentially very large, audience for the work. As noted earlier, having an audience is an important contributor to motivation and hence to the amount of effort invested in the project.
2. Publishing on the Web also raises the possibility of feedback from readers. It is very easy to ask readers of a Web site to send a message of response. Schools that have produced material that is of interest to others (such as local history) have often received very gratifying feedback from readers that were unknown to them. Messages from unknown readers further contribute to the sense of an authentic audience.
3. It provides a publishing platform that allows multimedia publications. Publication in a school newsletter may be restricted to text, or at best, color pictures. Publication on a Web site can include sound, moving images, animation, and a range of forms of expres-

sion. These can of course be distractions, but they can also add to the motivation and effort, as long as the focus remains on the intellectual content.

4. Web publishing does not have to follow the strictly linear form of conventional publication media. Publication on paper usually involves forcing interconnected ideas into a linear structure that is not quite ideal. Publishing on the Web allows ideas to be interconnected in a variety of ways, and so in some ways is closer to the way we think.

Numerous projects in different countries encourage student publication on the Web. Some even offer prizes and publicity for winning entries (see, for example, www.thinkquest.org).

Spreadsheets, Databases, and Datalogging

The discussion up to this point has centered on writing, and on students engaging in projects that are presented in writing or verbally. There are other applications that allow students to develop their understanding of numerical information. The most frequently used are probably spreadsheets, databases, and datalogging. In each case, the key characteristic is the ability to change things and observe the impact of the change. This characteristic of mutability allows students to experiment with numerical information.

With spreadsheets, one of the particularly powerful applications is the ability to draw graphs from numerical data. This can be used to give students an insight into graphs, but also to gain an insight into numerical patterns. Take for example the expression:

$$X^2 + 4X - 8$$

The ability to graph that expression provides an insight into the expression itself. Of course, it

could be done by hand, but it is likely that if it is done on a spreadsheet, a greater range of numbers will be included. More importantly, once it is in the spreadsheet, it is very easy to try alternatives. One could ask what would happen if the expression began with “minus X^2 ”? Or what if it began with X^3 ? These “what if” questions are an important part of exploring mathematical expressions and are greatly facilitated by the computing power of the spreadsheet.

The graphing power of the spreadsheet also has uses outside of Mathematics. Spreadsheets can be used to make graphical representation of landforms in Geography, such as the cross section of a river, or translating contour lines into a cross section of a land area.

Spreadsheets and databases can also be used to analyze and correlate research data. A very good example of the power of this kind of analysis to facilitate student discovery emerged from the portables pilot project in the UK. Year 6 pupils in a primary school began to carry out a comparative study of the weathering of different types of rock, using the gravestones in two cemeteries. They entered information about the types and age of the stones used, and graded each entry according to how weathered it looked. Subsequently this information was transferred to a spreadsheet and plotted as graphs and charts for comparison with local headstones. While collecting data on the field trip, some pupils noticed the predominance of certain family names on the headstones. This led to a discussion about how to organize databases in order to facilitate searching and sorting. This project went on to involve an exploration of the impact of industrial pollution (by communicating with students in other regions) and an analysis of the age at death, which led to an exploration of social history (Stradling et al., 1994).

This principle of using ICT to facilitate students in doing research is further enabled by the use of datalogging equipment. Datalogging effectively attaches the computer to sensors, and the computer

collects readings from the sensors at intervals. These allow students to carry out experiments that would otherwise not be possible, and to achieve more accurate findings than with conventional methods. Examples include:

- measuring the heat in endothermic and exothermic reactions;
- measuring the acceleration due to gravity;
- correlating the light intensity and temperature throughout the day; and
- measuring heat loss in liquids stored in different containers.

A full description of the potential of datalogging is beyond the scope of this chapter, but the interested reader may find more information, and example of good practice, on the Web.

These are only some of the uses of ICT that can support the development of higher-order thinking. The aim of this section has not been to provide an exhaustive list of the possibilities, but to provide enough ideas to illustrate the key messages about how to get the best from ICT. These key messages can be summarized as follows:

- Good use of ICT is use that pushes students towards developing higher-order thinking.
- Good use is not tied to any one application or package, but is dependant on how the package is used.
- Key skills to encourage are evaluation, analysis, synthesis, problem solving, and exploration. By contrast, applications that focus mainly on recall are likely to do little to develop higher-order skills.
- ICT can facilitate approaches that focus more on students doing project work that is educationally challenging. Two key characteristics of ICT were noted consistently:
 - Mutability: The ability to change and develop work continually.

- Audience: The ability to present work to an audience outside the classroom.

MAKING IT HAPPEN: HOW SCHOOLS BEGIN TO MAKE GOOD USE OF ICT

This chapter began by looking at the reasons why ICT is important, and focused on the importance of developing higher-order thinking, no matter which rationale is used for the introduction of the technology. The focus then moved to the question of how ICT can be used to develop such skills. The main argument has been that ICT can be used to develop higher-order thinking skills in students. But it is also clear that not all of the uses of ICT achieve that aim.

Reaching those higher-order skills often demands a change in the teaching method. The basis of the shift is a transfer of responsibility to the learner. In each of the example activities described, the use of ICT has not been focused on ICT per se, but has been aimed at using the technology to encourage students to engage in challenging work. The technology was used to motivate and encourage students by providing a real audience for the work done. Students were encouraged to think more deeply about their work by the ability to change and reshape it. Students were encouraged to research material for themselves, and so to evaluate and process the material. Finally, students were enabled to do exploratory research for themselves through spreadsheets, databases, and data logging.

These may be summarized as a shift towards a more student-centered style of teaching, with an emphasis on students taking responsibility for their own learning, and on students constructing and developing their own understanding of the material.

Despite the weight of evidence pointing to the potential of ICT to facilitate higher-order student tasks, and the vast investment in ICT in schools, the reality is that in many countries the progress has been disappointing. Although schools have more equipment than they had a decade ago, and more time is spent in computer rooms, it is not clear that in all schools the technology is being used to promote high-level student thinking. In many cases ICT is being used to teach basic ICT skills or for routine rote learning tasks.

So, what does it take to encourage the use of ICT to achieve those more valuable goals? When teachers are asked why they do not make more use of ICT to support their teaching, one of the most frequent replies is that they do not have enough access to equipment at school. While equipment-rich projects were reporting a change in teaching method (ACOT, 1996) and other schools were reporting that lack of equipment was the barrier, it is not surprising that the idea of ICT as a catalyst emerged, and people began to suggest that provision of ICT could lead to a change in pedagogy.

More recent studies have shown that ICT infrastructure is not the answer. A major international study of ICT in schools showed that the schools that were using a student-centered approach tended to have higher levels of equipment than average, but that there were also other schools with high levels of equipment that were using very traditional didactic approaches (Pelgrum & Anderson, 1999). A series of OECD case studies of schools innovating with ICT revealed that schools use ICT for very different purposes, and that there was little evidence that ICT had caused a shift in pedagogy. ICT had played a major role in helping to support a change in pedagogy in some schools, but it had not started the change (OECD case studies are available online at www.oecd.org). These studies call into question the idea that ICT is the catalyst for change.

Other studies have focused on the idea that the use of ICT to promote student-centered learning is primarily a result of teacher beliefs. In the U.S., Becker (1999) reported that the use of ICT by teachers was associated with a “constructivist orientation” in the teacher.

The case studies of ICT as an innovation suggest that getting the best from ICT depends on a complex web of factors. Even with the same levels of equipment, some schools make better use of ICT than others. But there are also differences within schools, as some teachers begin to make use of ICT sooner than others. In most of the case study schools, even where ICT was well developed, some teachers still avoided using it, and the schools often made arrangements to exchange classes to work around them. So it seems that there are some issues at school level that can encourage or discourage use of ICT, and other issues at the level of the individual teacher.

At the level of the individual teacher, some of the key issues are:

- Easy access to ICT;
- A reliable technical infrastructure;
- Sufficient technical skill to feel confident with the technology; and
- A good pedagogical purpose for the technology. This includes believing that the technology is of real value, and having a good idea about how to use it.

Failing to have any one of these may inhibit the use of ICT by an individual teacher.

Making use of ICT takes time, as teachers need time to prepare their work and time to get familiar with the software. Some dedicated and enthusiastic teachers manage to make good use of ICT even when these conditions are not satisfied, but these teachers are unusually proactive, and often feel isolated and unsupported. The more usual and less dynamic teachers are unlikely to

start using ICT unless it becomes part of a wider school movement. Where schools have successfully gone beyond the “lone pioneer” stage, this has often been associated with a few key factors at the school level.

First, the school leader plays an important role. The drive provided by enthusiastic school management can allow other difficulties to be overcome. The school principal can facilitate teacher meetings, ensure resource availability, and ensure that timetabling and other arrangements are adjusted to facilitate the adoption of ICT. Perhaps more importantly, the sense that use of ICT is an innovation supported by the management is motivating for teachers, and encourages teachers to explore the possibilities.

Second, teachers are often supported in their first steps with ICT by an enthusiast or “ICT champion” within the staff. This is sometimes a formal role, perhaps that of ICT coordinator. In other cases a teacher assumes the role voluntarily. Either way, the presence of a mentor that is supportive and encouraging can greatly facilitate teachers in the early stages of adoption of ICT. This mentor serves a dual role, by providing a point of contact for discussing the pedagogy to be employed, and by solving minor problems with the technology that might otherwise stop the innovation entirely.

Third, teacher adoption of ICT is often encouraged by participation in professional development activities in the school, with colleagues. In most countries, teachers are offered or required to attend training courses in ICT. This kind of training has some benefits, but often fails to address the specific context of the individual school. By contrast, training for the staff conducted in the school has the double advantages of:

- a. addressing the context (infrastructure, etc.) of the school, and
- b. providing an opportunity for staff to come together to consider the possibilities of ICT

as a group. This has often helped to provide a “critical mass” of interested teachers.

CONCLUSION

This chapter began with a question; the question was why ICT is important in schools. It is clear that there is a good deal of ambitious talk about ICT, and that much of this may be overstated. ICT is justified by a series of rationales, based generally on the economy, society, and pedagogy. In each case, it was argued, ICT is only of value if it reaches the higher-order thinking skills.

Using ICT in the classroom does not automatically address these higher-order skills. Many applications of ICT involve learning low-level operational skills or memorizing facts. But there are ways in which ICT can be used to develop higher-order thinking. Many of these involve encouraging students to engage in project work, or work which requires them to discover, assess, and construct information.

Getting the higher-order benefits is not a question of technology, but one of pedagogy. ICT can help. Many of the ideas described would be much more difficult to implement without the technology. But it is also clear that the technology is not the driver. Making the best use of ICT depends on a series of factors, but one central issue is the teacher’s beliefs about teaching. If a teacher is convinced that students can learn well through the kinds of student-centered work described here, then the teacher is much more likely to find a way to implement it. By contrast, where teachers cannot see the value of this approach, any amount of infrastructure can be used to support more traditional didactic practices.

This has a series of implications. For teachers, the key is to focus on how ICT is used, rather than on how much or how often it is used. Quality of use does not depend on the sophistication of the task, but on the sophistication of the thinking involved

in completing it. Using the illustration in Figure 1, teachers should seek to move their use of ICT further towards the top of the graph—towards the higher-order thinking.

For schools, the key is to encourage teachers towards the appropriate uses. If there is not a school-wide interest in ICT, then it is difficult for individual teachers to feel supported to experiment with the possibilities. If the general view of ICT is as a technical skill area, then it is difficult for teachers of other subjects to begin to use it as a pedagogical support. One key task is to build a school vision of the potential of ICT in achieving the important aims; leadership, ICT champions, and whole-school work seem important steps in this direction.

Chapter 7.7

ICT, Knowledge Construction, and Evolution: Subject, Community, and Society

Antonio Cartelli
University of Cassino, Italy

ABSTRACT

After a short introduction on the hypotheses scholars developed for explaining knowledge construction and evolution in mankind, the role that ICT is playing on this phenomenon is described. From the results of many studies and from the separation today well settled between human knowledge and corporate knowledge, the idea of a tri-partition of knowledge contexts arises and is developed and analyzed. The idea of three different kinds of knowledge receives good support from the observation of the effects of ICT on individuals, communities/organizations, and society; it sounds as the confirmation for the three different contexts of knowledge construction and evolution the author hypothesizes. The experiences described in this chapter show how ICT, while playing a relevant role in each of the above environments, influences all the others and determines a continuous evolution of knowledge in the three contexts. The hypothesized perspec-

tive opens to new interpretations for knowledge phenomena, leads to the overcoming of misleading learning explanations, and gives a strong impulse to the planning of projects for the introduction of ICT in education.

INTRODUCTION

The 20th century has marked the transformation of the philosophical definition and explanation of knowledge into a different one, mostly depending on the ideas emerging from human disciplines like psychology, pedagogy, anthropology, sociology, etc. (i.e., many contributions are also due to biology, neurophysiology and cybernetics). Two main ways for interpreting knowledge construction and evolution affirmed during last decades: the former one mostly looking at the individual, the latter one emerging from corporate and organization studies.

In what follows the above perspectives are analyzed and the role IT and ICT had in explaining knowledge construction are recalled.

Theories for Knowledge Development in Individuals

J. Piaget and D. P. Ausubel were among the first scientists stating the importance of subjects' mental actions in cognitive processes. They assigned a great role to subject-reality interaction for the explanation of knowledge development and evolution; for this reason they are also considered cognitivists and precursors of constructivism; the same scholars, on another hand, assign a little or no role to social and cultural interactions in knowledge construction.

J. Piaget hypothesized different stages in cognitive development, for example, he stated that the evolution of knowledge in a subject is marked by the transition from a first stage to the following one; this process is the result of the interaction between the individual and the environment and is based on adaptation processes marked by the assimilation of new stimuli in old mental schemes and by the accommodation of old mental schemes into new ones (Piaget, 1971, 1973). He also hypothesized the existence of a genetic epistemology to explain the genesis of knowledge in mankind, for example, the individual cognitive development runs parallel to history of science and the analysis of pupils' ideas can be used to explain the origin of scientific concepts.

D. P. Ausubel, on another hand, accepted and developed the idea of knowledge construction emerging from the addition of new knowledge to pre-existing knowledge (formerly proposed by Gagné); the bases of his theory can be found on the following three elements:

1. The internal coherence of the topic to be learned
2. The existence of a net of pre-existing concepts the new topic has to connect to

3. The subject's bent to receive and accept the new topic

He also hypothesizes the distinction between meaningful learning and mechanical learning and states that the difference between them rests on the existence of subsumers (special units of previous knowledge making the construction of new knowledge easier), which have great influence on the insertion of new information units into pre-existing knowledge (Ausubel, 1990).

The ideas of J. Piaget and D. P. Ausubel have been verified, integrated and, sometimes, contradicted from further scientists but have retained all their importance for the role they assigned to individuals in knowledge management and development. A different basis moved D. H. Jonassen (1994), who founded the project of learning environments on the following statements:

1. Knowledge construction is based on individual and social influences.
2. Meaningful contexts support problem solving skills (which have to be derived from real situations).
3. Cooperation between student and teacher and among peers is at the basis of learning processes.

Further studies introduced the concepts of multiple intelligence (Gardner, 1993), learning styles (McLellan, 1996), and cognitive flexibility (Spiro & Jehng, 1990) to consider the complexity of the cognitive phenomenon into individuals.

The importance of context and social effects on individuals' knowledge development has been stated in many recent studies, often under the influence of Vygotskij and Leont'ev hypotheses (Varisco, 2002). Most relevant results of these studies concern two specific models of the knowledge transition from the concrete to the abstract: (a) the cognitive apprenticeship, and (b) the expert practical thinking. The former hypothesis rediscovered the well known apprenticeship properties

(i.e., modeling, coaching, scaffolding, and fading properties of training in Renaissance studios), and integrates them with the following new principles: articulation, reflection, and exploration. The latter one, mostly due to S. Scribner research (1997), evidences the properties of the expert thinking in a given context with respect to the novice one; main traits of the expert thinking are:

1. Use of the context's elements concerning the problem to be solved
2. Use of economic strategies in the finding of solutions
3. Use of well settled knowledge units and skills in the definition of problem solving strategies

The most comprehensive theory about the influence of social phenomena on human knowledge and learning is the E. Wenger's social learning theory (1998). This theory has at its bases the following principles:

1. Individuals are social beings and are the focus of the learning action.
2. Knowledge is a specific aspect of competence.
3. Knowledge is the expression of the participation.
4. Meaning is the product of learning.

If the above ideas are mostly concerned with the effects of learning actions on individuals it has to be noted that E. Wenger looks at communities as autonomous realities and, for him, communities of practice coincide with learning communities.

Corporate and Organization Knowledge Theories

While starting from Wenger's research on communities of practice recent studies analyze knowledge

construction in those communities for the importance they have in corporate and organizations. In other words, a theory of knowledge construction and development in communities has been developed, autonomously from the hypotheses on individuals reported in the above paragraph.

Among the starting points for these studies there are Wenger's (2004) basic elements marking a community of practice:

1. **Shared Identity Domain:** Where membership implies a commitment to the domain, and therefore a shared competence that distinguishes members from other people.
2. **Community:** Because in pursuing their interest in the domain, members engage in joint activities and discussions, help each other, and share information; for example, they build relationships enabling them to learn from each other.
3. **Practice:** Because members of a community of practice are practitioners; they develop a shared repertoire of resources for example, experiences, stories, tools, ways of addressing recurring problems (in short a shared practice).

Furthermore, the analysis of knowledge development in communities of practice inside organizations and the study of corporate knowledge construction and transmission led some authors to state the basic principles for knowledge management. S. Denning (2000), for example, proposed the following remarks (usually known as knowledge management laws):

1. Knowledge is the key factor for the organization surviving
2. Communities of practice (CoPs) are the core of any knowledge sharing program
3. Virtual communities need presence interaction
4. Professional enthusiasm sways CoPs

5. Knowledge management activates bi-directional and dynamic information flows inwards and outwards organization
6. Experience and story telling animate and strengthen knowledge sharing

With respect to studies on individuals' knowledge development, new hypotheses were now developed to explain knowledge features and structure within communities and organizations. I. Nonaka and N. Konno (1999), for example, based their ideas on the definition of two different kinds of knowledge: (a) tacit knowledge, which is deeply-rooted in actions and experiences of community's members and can be only difficultly codified, transmitted and shared; (i.e., it is the individuals' know how marking the skills of the community), and (b) explicit knowledge, which is the community's knowledge and can be easily formalized, represented, transmitted and shared.

In regards to learning organizations (i.e., organizations continuously developing new knowledge), I. Nonaka and H. Takeuchi (1995) developed a model for knowledge construction and evolution strongly based on the tacit and explicit knowledge transformations. This model is made by four phases (which initials give the name SECI to it):

1. Socialization: It is the informal process of letting tacit knowledge be shared (often in a non-verbal way). It has features very similar to the modeling phase of apprenticeship and to the on-the-job-training used in many organizational contexts.
2. Externalization: It transforms tacit knowledge in explicit concepts and is the crucial phase of knowledge construction. Formal language, metaphors, and analogies play an important role in helping people making explicit their know how.

Figure 1. SECI cycle for learning organizations

3. **Combination:** It inserts the newly built concepts into organization's knowledge and connects them to previous knowledge, so increasing the knowledge of the community and of the organization.
4. **Internalization:** It closes the cycle by making internal the explicit knowledge and transforms it into know how for the organization. The cycle is now ready for starting again with socialization of tacit knowledge, etc. and the model describing the knowledge evolution process is reported in Figure 1.

The Role of IT and ICT on Knowledge Construction and Evolution

In regards to the influence of IT and ICT on individual teaching-learning processes, it can be useful to remember here the contributions of R. Taylor and L. Galliani. The former one proposed three metaphors for computer use in education: tutor, tool, and tutee (Taylor, 1980), the latter one extended these metaphors while considering the great deal of software tools developed in last decades (Galliani, Costa, Amplatz, & Varisco, 1999). At the end of such an integration, tutor appellation describes the experiences people can make under behaviorist and cognitivist influence with the help of special programs like CAI, CAE, and CAL tools, or with the help of Artificial Intelligence software like ICAI and ITS. Tool metaphor includes special software for analyzing large amounts of data and browsing specific contexts (usually provided with authoring and co-authoring functions). Tutee metaphor mainly includes programs for the creation of special developmental environments, such as micro-worlds made by Papert with LOGO. Together with computer metaphors, meta-cognitive ideas must be remembered. Strictly speaking, they suggest that computer use stimulates functions' development more than learning topics so that meta-cognitive attitudes and learning are better

developed in students systematically working at the computer (Cornoldi & Caponi, 1991).

Furthermore, ICT influence on individuals' knowledge development can be summarized in the following ideas:

1. H. Rheingold (1994) introduced the definition of virtual communities to describe the set of individuals who use the Net for interpersonal communication and knowledge construction.
2. D. de Kerckhove (2000) defined connective intelligence as the set of strategies and cognitive skills developed from individuals contextually to ICT use.
3. P. Lévy (1996) stated that collective intelligences well characterize the situation emerging from the increase in the individuals' communication speed due to the Net and from the great amount of information freely available in it.
4. A. Calvani and M. Rotta (1999) suggest that ICT introduce hypertext and multimedia features in the knowledge structure while the Net extends the social negotiation aspects of knowledge.

On another hand, the impact of ICT on learning environments is mostly due to the role it can play in educational contexts:

1. Repository for information and documents of every kind (CMS—Content Management System)
2. System for the management of Learning Objects (LMS—Learning Management System)
3. Virtual environment letting individuals interact and build communities of learners (CSCLS—Computer Supported Collaborative Learning System)

In communities and especially corporate and organizations, knowledge management has seen a

great application and use of ICT for the collection, organization, sharing and analysis of community knowledge. The tools adopted as instruments for the application of knowledge management principles are devoted to knowledge discovery, and knowledge audit (usually based on knowledge mapping) together with the planning and carrying out of knowledge networks.

G. Trentin (2004) hypothesizes for networks, and especially for the Internet, the role of technical infrastructure letting communities build a shared memory (i.e., shared knowledge basis supporting professional CoPs).

TOWARDS NEW MODELS FOR KNOWLEDGE CONSTRUCTION AND EVOLUTION

At this point of the discussion two main kinds of knowledge can be recognized: the individual and the community ones. They are also marked from different hypotheses concerning the ways they are built up and the involvement of ICT in their management. In the author's opinion, the above separation is still inappropriate to describe today's knowledge phenomenon and a tri-partition of knowledge definitions and environments can be proposed: individual knowledge, community knowledge, and social (scientific) knowledge. In what follows, the reasons for the above hypotheses are reported but the need for a reconciliation of methods and results coming from the different knowledge structures and environments is also evidenced.

First of all, the results on misconceptions and mental schemes are reported to explain the separation between individual and social knowledge (this last one being considered equivalent to scientific knowledge). Soon after the results of the studies concerning a special community of students are analyzed and last, the interaction among all above knowledge environments is described and the positive effects individuals, communities and

science, derived each other from that experiences is discussed.

Individual, Community, and Social Knowledge

Theories reported in the introduction for the analysis and explanation of knowledge management in individuals have at their basis the identification of the knowledge naturally built by subjects (either autonomously or under the effect of an educational program), with scientific and disciplinary knowledge.

During the past decades, the amount of discoveries in all fields of human knowledge produced an exponential growth in the number of sciences analyzing phenomena and many new disciplines were born. Teachers and professors, while submitting new topics to their students, often adopted and still use a different perspective with respect to Piaget's genetic epistemology, they usually start from the history of disciplines to build school curricula and create learning paths for education (i.e., discipline logic structure is proposed as a natural scheme for knowledge construction in individuals).

The positivistic hypothesis that an increase in the number of topics to be taught and the introduction at earlier stages of education of many concepts could help mankind in reaching new and more advanced frontiers of knowledge, showed very soon all its limits. Many studies on misconceptions and mental schemes evidenced, in fact, how difficultly subjects build the right scientific concepts (MLRG, 2005). The same studies evidenced the presence of wrong ideas in differently aged and skilled people (including teachers) and how difficult can be the finding of the right strategies for helping people in overcoming the difficulties they meet in the study of sciences or in interpreting phenomena.

Three main aspects clearly emerge from the above studies (Cartelli, 2002):

1. Wrong ideas involve all domains of human knowledge; the investigated fields concern in fact scientific topics pertaining mathematics, physics, statistics, computer science, chemistry, biology, natural sciences, cosmology, etc. but there is (and is still growing) the number of studies investigating the wrong ideas the students show with language, literature, history, and many other human sciences.
 2. Wrong ideas can be found in people all over the world and no relevant differences can be detected while passing from East to West or from North to South.
 3. Two main approaches can be recognized in the above studies: a former one called ideographic or naturalistic, which analyzes pupils' reasoning and the ideas people show when explaining phenomena, with no dependence from scientific paradigms (i.e., only the internal coherence of people's concepts and ideas is evaluated and the name of natural mental schemes is adopted for them); the latter one, involving people who already approached scientific topics (or were beginners), which evaluates the correctness of people's ideas with respect to scientifically accepted ones (the name of preconceptions and misconceptions is now adopted for wrong ideas).
- b. Only little segments of scientific knowledge can be shared within the members of a given community.
 - c. When students in a class correctly build scientific knowledge in a given domain (with the help of constructivist strategies and technological environments) special ambiguous situations can lead to the detection of misconceptions and wrong ideas in their knowledge.

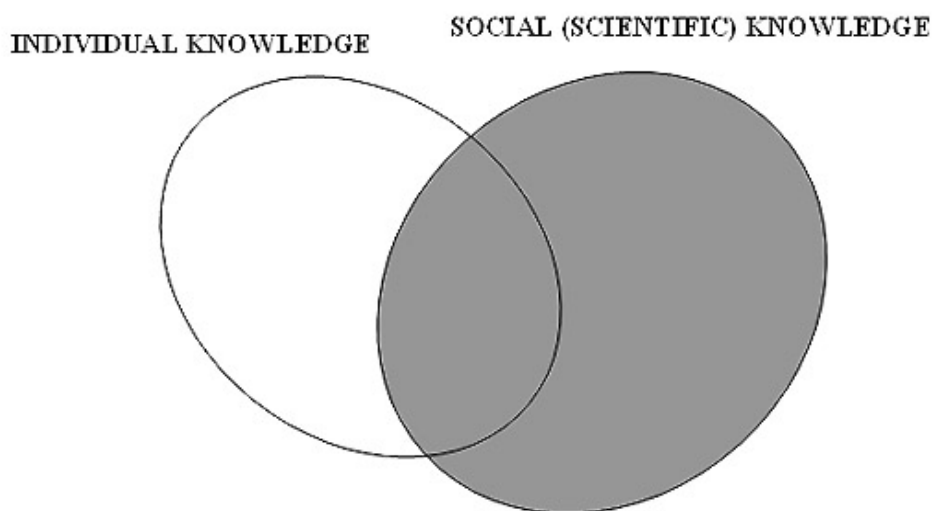

In other words, the high specialization of knowledge in every discipline, the very large amount of elements marking scientific knowledge and the presence of preconceptions, misconceptions, and mental schemes in individuals, all play a relevant role in stating that scientific knowledge (i.e., knowledge certificated and validated from scientific community) is the knowledge of mankind (i.e., a construction of mankind continuously evolving and growing like any human artifact or technology) and not the knowledge of a single individual. Subjects can use scientific knowledge to explain phenomena, and usually do so by adopting the paradigms that the scientific community developed and accepted for that phenomenon (in a given context and time and until new paradigms appear more suitable for the explanation of the same phenomenon); but it has to be noted that the use of such knowledge has very little, if any, element in common with the developmental and evolutionary process of individual knowledge. All the above arguments lead, in the author's opinion, to the following conclusion: individual and scientific knowledge are very different and scientific knowledge is better defined as social knowledge (if we identify mankind with society and look at the contribution to scientific knowledge development from individuals and communities with the time).

Two experiences the author made during the past years with High School and University students confirm what has been stated until now and give support to the idea of a separation between individual knowledge and social knowledge (this last one being identified with science and discipline knowledge) (Cartelli, 2005). In other words, individuals' knowledge can never be identified with scientific knowledge, because:

- a. Only a few subjects can be considered really skilled in a scientific domain.

The draft in Figure 2 synthesizes individual and social-scientific knowledge and the dependencies between them. They surely have common

Figure 2. Separation between individual and social knowledge

parts but don't superpose each other and have elements pertaining specifically to each of them (individual and society-science).

If the above scheme correctly describes knowledge inter-dependencies while looking at individual and society, (mankind) it is certainly inappropriate for the explanation of knowledge phenomena if corporate and organizations' experiences and theories are considered (i.e., the results from studies on communities of practice don't benefit from the above hypothesis). This difficulty disappears if autonomous community knowledge for each CoP a subject belongs to is hypothesized; in such a case, in fact, together with the rules governing individual and social knowledge management, the rules reported in the first paragraph for CoPs can be adopted to explain community knowledge phenomena. A new scheme for the description of the different kinds of knowledge can then be drawn and within it one or more community knowledge find their right place. Figure 3 drafts the author's hypothesized

tri-partition among individual, community, and society/scientific knowledge.

The tri-partition in Figure 3, where multiple communities are reported, finds an explication in the rules governing community knowledge: For example, an individual can belong to different CoPs and can contribute in developing different knowledge in each of them, but the rules governing each CoP and knowledge construction and development within it are just the same (and are derived from Wenger's characterization of a CoP).

The above tri-partition has a relevant influence on further studies concerning knowledge construction and evolution because it states the existence of different fields and methods of investigation for the research in each of the three environments. Furthermore, it implies a great attention to possible results from the same research, for the effects the results obtained in a field can have on all the others. In other words scholars and scientists can now concentrate their efforts on the different ways knowledge (individual, com-

Figure 3. Distribution among subject, communities and society of the components of human knowledge

munity, and social/scientific) is built and evolves, without forgetting the consequences the results they obtain in one of the above fields can have on all the others. A question poses suddenly: what role does ICT play in this way of looking at the knowledge phenomenon? Does it operate across all knowledge specifications (individual, community, and society) or pertain especially to one or more of them? It is perhaps too early to give a definite answer to these questions but in what follows the experience the author made with some students is reported and an attempt for answering to the above questions is made.

STUDENTS' COMMUNITIES AND ICT: THE CASE OF PALEOGRAPHY

What is reported below is the result of the author's work at the Faculty of Humanities of the Uni-

versity of Cassino-Italy, while cooperating with M. Palma, professor of Latin paleography. The cooperation between a researcher in education technologies and a scholar in paleography can seem, and perhaps is, unusual but is the result of the common persuasion that Internet, and ICT more in general, changed the well settled connection and temporal dependency between research and teaching. Before the Internet, in fact, there were separated times and spaces for research and didactics, now they can be contemporary and can reinforce each other.

The experiences the author made and is still carrying out mostly concern the planning and carrying out of special information systems (mostly based on Web sites) both for researching and teaching.

Among them, the most relevant ones and those which have a greatest relevance for their consequences on the hypothesized knowledge

tri-partition are: (1) Bibliography of Beneventan Manuscripts (BMB), an information system hosting the bibliography of manuscripts written in the South Italy national script during the Middle Ages and (2) Women Copyists and Written Culture in the Middle Age, a dynamic Web site interfaced with a database containing women and manuscripts' data.

The Bibliography of Beneventan Manuscripts

The BMB experience (Bibliografia dei Manoscritti Beneventani—Bibliography of Beneventan Manuscripts <http://edu.let.unicas.it/bmb/>) started in 1992 with the main aim of collecting the quotations of Beneventan manuscripts (i.e., medieval books written in the South Italy national script) by means of a MS-DOS program called BIBMAN. In 1997 a first Web site was developed to make it faster and easier for scholars to download new bibliographical data (nearly monthly).

Recently many problems depending on the BIBMAN program induced to plan and carry out a new Web site: the BMB online (Cartelli & Palma, 2004). It is an information system where differently allowed people can store the quotations of Beneventan manuscripts, so that it can be freely queried by general users.

Persons entrusted with the task of collecting the quotations of Beneventan manuscripts are grouped into three categories:

1. Contributors: Who can access a special Web area where they can write, modify, and delete bibliographical data for the materials assigned to them
2. Scientific Administrators: Who can manage all data and write, modify, and certify bibliographical materials, this last operation being done only once because certified records cannot be subsequently accessed for revision
3. System Administrator: Who is allowed to do all operations including the modification or deletion of certified data

The access to certified bibliographic materials is possible according to different query pages: (a) by author's name, (b) by manuscript, (c) by contributor, or (d) by one or more words or part of them concerning title, location, or bibliographical abstract of a given publication.

It has to be noted that the following are implemented in the system also: (1) a closed communication subsystem made by an electronic blackboard letting contributors involved in the collection of bibliographical data exchange messages and texts among themselves, (2) some special functions, available only to system administrator, for the production of the printed version of the data yearly collected.

The Web Site “Women and Written Culture in the Middle Ages”

Main aim of the dynamic Web site on women copyists (<http://edu.let.unicas.it/womediev/>) was to systematize the data emerging from former research while leading to an instrument which could help scholars finding new elements for further studies (Cartelli, Miglio, & Palma, 2001).

Data appearing relevant to the scientific community were:

1. For every scribe: (a) the name of the woman as it appears in manuscripts, (b) her qualification (i.e., if it is known, whether she was a nun or a lay), and (c) the date or the period she belonged to (up to the 15th century)
2. For the manuscripts: (a) their shelf mark (i.e., town, library, and number of the manuscript), (b) the place and the country where they were written, (c) the date or the period they belong to, (d) the authors and titles of the texts, and (e) the bibliography or its source of information

Furthermore, it appeared important to show for each woman, the manuscript/s she wrote and vice-versa and, if possible and available, at least an image of the copyist's hand. The site has not produced until now any printed bulletin or other periodical printed matter and is made of two separated sections: the former one being operated only by editors, who access it by a personal ID and a password (to insert, modify, and delete the data stored in the database), thus ensuring the scientific validity of the information reported there; the latter one at everyone's disposal to obtain the list of all women and manuscripts in the database, or to make queries concerning women and manuscripts with specific qualifications.

Results from Researching and Teaching with ICT in Paleography

The systems and Web sites described above were carried out from the author in different times but they were suddenly introduced in everyday teaching and researching work. The number of students participating each time in the experiences described below was very little (in the best case there were 19) so that students' features, performances, and behaviors could be carefully analyzed each time. Main activities the students were involved in have been:

1. After having attended the basic courses on cataloguing, they were asked to become contributors for BMB online and to produce bibliographical materials. The discussions they had with administrators, professors, and among themselves, the use they made of the electronic blackboard and of the e-mail services for the exchange of messages and, last but not least, the chance of working in little groups on the same problems helped them very much in acquiring the knowledge and in developing the skills they would need (as paleographers) in their everyday work.
2. They not only used the materials reported in the Women Copyists Web site for their study, but were also charged of the description of manuscripts and of the collection/digitization of plates reproducing texts written from women (i.e., they learned to distinguish the different hands of women copyists and their way of writing manuscripts while practically working on the manuscripts and translating them in digital documents). Furthermore, the number of bibliographic notes coming from scholars all over the world has grown with time; main consequence of this unexpected interest for women copyists has been the need for the planning of a new information system (still under development) helping the virtual community born around this theme to continue the study of women copyists (it has to be noted that the system has already been modified since its origin).

The effects produced from above activities on the teaching-learning processes will be analyzed in what follows looking at the three different components of knowledge described above: the individual, the community, and the social (scientific) ones.

1. In regards to single students, and especially the knowledge and skills each of them developed while attending paleography course, it can be stated that ICT, and especially Web technologies and information systems, contributed to creating constructivist learning environments which helped them very much. Furthermore, the careful analysis of students' behaviors during lessons, exercises, laboratory activities, and examinations led the author to deduce that the following skills, never observed before in a paleography's course, could be detected: talent in working in a group (in traditional courses it was a very rare experience), easier

facing of complex tasks (thanks to the help each student could have from colleagues) and raising of the individuals' peculiarities within the community. In other words, the results of the studies by A. L. Brown and J. Campione (1994) and J. Lave and E. Wenger (1991) on communities of learners (CoLs) were fully confirmed.

2. In regards to communities of practice (CoPs) and especially learning organizations, a new model for knowledge development emerged. First of all, it has to be noted that each class or group of students involved in the above experiences was a real CoP (the three elements marking for Wenger a community of practice were in fact observed). Furthermore, the information systems described above had two main features: (a) they helped students and scholars in their everyday research work, and (b) they implemented the best practices researchers developed while accomplishing their studies and obliged students to respect times and procedures in those practices. To better understand the meaning of the above assertions, the BMB online case is analyzed (Cartelli, 2004) in a greater detail: when a student/contributor aims at writing a bibliographic card he or she has to follow the procedure implemented into the system. For example:

- a. He or she has to be authorized to analyze the documents (books, papers, magazines, Web sites, etc.) probably containing the citations of Beneventan manuscripts.
- b. Once scientific administrators attribute documents for the analysis, contributors can compile bibliographic card/s.
- c. Compiled card/s must be reviewed and approved from BMB scientific administrators.

- d. Approved card/s can finally be accessed from general users querying the data base.

The above steps can be seen as the formalization and implementation into the information system of the practices BMB editors adopted before the creation of the Web site (also if, at that time, they used a MS-DOS software for the management of bibliographies) and let us state they help community in covering and completing the SECI cycle. In other words, the BMB online system makes the socialization, externalization, combination, and internalization of community knowledge easier, and, what is more, it implements the community practices, (i.e., the processes leading to the creation of the bibliography shared by people working on Beneventan manuscripts). It also has to be noted that if BMB editors cannot be considered a learning organization at all (i.e., they are not continuously developing new knowledge/practices to share among the members of the community), the elements of at least a cycle of the Nonaka and Takeuchi's SECI model can be recognized in the development of community knowledge and a new element can be added to the former ones: the implementation of communities' practices by means of ICT.

If the BMB online experience can be only partially compared with Nonaka & Takeuchi's SECI model, as applied to paleographers' community, what happened with the site Women and written culture in the Middle Ages (i.e., the changes in its structure following one another with the time), better support the idea of a new model for the cyclic structure describing knowledge evolution in organizations (at least in the special case under analysis). The Women copyists Web site was modified accordingly to the database structure at least two times:

1. When it was made the first time it had only one table containing data concerning both

women and manuscripts, as it was explicitly asked from the paleographers who commissioned its planning and carrying out (paleographers liked a system letting them make their everyday operations easier and faster and asked for a system implementing only and exclusively their knowledge/practices). After the introduction of some information in the system and after the analysis of the stored data, the need for a revision of the structure of that system became evident (i.e., the first SECI cycle came to its end, after socialization, externalization, combination, and internalization of knowledge/practices).

2. The end of the first SECI cycle showed the limits of the system (which were also the limits of former practices) and required changes in the database structure: it had to be split into three tables, former data had to be translated into the new structure and new FORMS had to be made for managing data and for querying the system (i.e., new

data structures were needed, new practices emerged and their implementation by means of ICT in the new system was asked, to let a new SECI cycle start).

Once ready, the new system has been used by editors for managing women and manuscripts data and now, while it is coming to the end of the second SECI cycle, the need for further changes in the structure of the system is emerging; i.e., it difficultly manages external contributions, like the ones coming from scientists and scholars who don't belong to the community.

As a conclusion, at least in the paleographic community (but there is no reason for limiting the above idea to this unique case), the above remarks suggest that the cycle marking the evolution of the community knowledge must be based on a further element with respect to the four initially stated. The new structure of a model inheriting the basic elements of I. Nonaka and H. Takeuchi hypothesis lays, as suggested above, on the fol-

Figure 4. New model for knowledge evolution in CoPs

lowing elements: Implementation of communities' practices by means of ICT, Socialization, Externalization, Combination, and Internalization (as reported in Figure 4).

In regard to social (scientific) knowledge and the influence the above information systems had on it, only a remark is needed. The above information systems are not static in their content and continuously evolve by addition of new information, with the support of individuals and communities involved in their management; the validation of the information stored within them by scientific committees lets us state that they represent a source of scientific knowledge freely available on the Net for students, scholars, and everyone interested in them. As reported above, in fact, both BMB online and Women and written culture in the Middle Ages sites have a public section letting general users freely access data stored in their databases and retrieve them. In other words, they contribute in the construction and diffusion of scientific knowledge concerning manuscripts and the disciplines studying them.

CONCLUSION AND FUTURE TRENDS

It is probably too early to say if the new model hypothesized from the author for knowledge development in organizations can be applied to every kind of community of practice and learning organization as it is, but some conclusions can be drawn.

First of all, it has to be noted that the implications of this study concern all elements involved in the knowledge phenomenon: subjects, communities, and society (science). Subjects' knowledge and skills evolve due to the individuals' belonging to community and society, but they give a valid contribution to community and society (scientific) knowledge evolution too. In regard to communi-

ties, a special attention must be devoted to CoPs, CoLs, and virtual communities for the influence each of them can have on the others:

1. Communities of practice can be virtual. Subjects with special interests in the community's work/practice can, in fact, become members of the community by means of ICT without physically knowing the members of the community. The only requirement seems the level of their basic skills, which must be adequate to those of the community, to guarantee their entrance and permanence in the community.
2. Implementation of practices by means of ICT can help teachers/professors in the creation of new constructivist learning environments and can help students in developing meaningful learning of discipline topics and new skills (very common in CSCLS).
3. Studies on CoPs and CoLs until now, carried out separately, can cooperate and integrate themselves in explaining knowledge phenomena in the two different contexts: corporate and school/university.

At last, the creation of systems letting students freely access scientific knowledge in efficient ways gains new importance so that Semantic Web, ontologies, and learning management systems appear a real need more than an academic exercise. Undoubtedly advanced education (university courses) and lifelong learning can take great advantage from instruments similar to the ones adopted in the author's experiences and the results of paleography students can be obtained also in other contexts. Perhaps the simple transfer of the experiences will not be enough to guarantee the success of the educational process and a reorganization of teaching, new planning strategies for didactics and new functions and meanings for teachers' work will be needed.

Chapter 7.8

Attitudes Towards ICT in Australian High Schools

Kaylene Clayton
Griffith University, Australia

INTRODUCTION

Information and communication technology (ICT) is integrated into almost every daily activity. Yet, few females today are choosing ICT based careers; a large percentage prefer to work in “pink collar” jobs such as childcare, education, and nursing. A recent report (Queensland Government, 2004) states that the average weekly earnings of full-time female workers in ICT, personal services, education, and health careers are \$883.30, \$513.10, \$802, and \$854.20 respectively. Furthermore, even though females consistently earn less than males, female ICT workers record the highest average earnings for all female occupations. Not only are females rejecting the financial rewards associated with ICT careers in favor of jobs that are seen to have a high human concern, they are also denying their voice in the creation and development of future technologies and applications. However, why are they shunning ICT study and careers? How does their educational environment and their perceptions of ICT impact ICT study and career choices? This article explores these

questions through the 2003 case study of Year 9 and 12 students, teachers and guidance officers at two co-educational schools in Queensland, Australia. Data was collected from 490 participants through questionnaires and six students and four teachers took part in interviews. Two theoretical frameworks, organizational culture and information quality, were used as a lens to view the situation.

BACKGROUND

The longstanding debate over whether females are not engaging in ICT careers because they are biologically not suited to technical work (essentialism), or that they have been nurtured to believe that they are not suited to technical work (social construction), continues to be contested. However, new theories, including Trauth’s (2002) theory of individual differences, are emerging to address the flaws and gaps within these theories. The under-representation of females in ICT is also not a global phenomenon; there are cultural

pockets in the world, including Mauritius, where females represent a relatively equal proportion of the ICT vocational and educational cohort (Adams, Bauer, & Baichoo, 2003). However, it is a well-documented problem in Western cultures, including Australia.

Research shows that females are methodically guided away from technical fields during school through classroom culture, traditional gender roles and other societal pressures (Gorski, 2002). Some of the enduring ICT stereotypes are that ICT professionals are Caucasian males with antisocial tendencies (Countryman, Feldman, Kekelis, & Spertus, 2002; Güler & Camp, 2002) and that ICT is boring and “geeky” and involves working long hours in social isolation, (Joshi & Kuhn, 2001; Myers & Beise, 2001; Newmarch, Taylor-Steele, & Cumpston, 2000). Popular media has enabled mass reinforcement of these established and often undesirable ICT stereotypes and there is a distinct lack of both fictional and real ICT role models who are given media coverage (Multimedia Victoria, 2001). Job security is also important to senior school students (Multimedia Victoria, 2004). Today’s youth witnessed the “dot-com” boom and skills shortage followed by mass redundancies and unemployment in ICT during the bust. This episode was highly publicized by the mass media, but the recovering ICT job market has not been given the same level of publicity. According to the Oliver Group director, the technology sector grew almost 56% in the twelve months from March 2004 (Foreshe, 2005). Anecdotally, many students and their parents believe that the ICT job market is still depressed and express surprise when informed about the recovering market.

Many students lack information about ICT work and exhibit little understanding of the nature of ICT jobs (von Hellens, Nielsen, & Beekhuyzen, 2004). They do not know about established ICT occupational roles, such as being a computer scientist, let alone the new opportunities that are being created and thus do not know how their talents

and skills apply in that field (Jepson & Peri, 2002). However, describing the ICT area, including job roles and areas is a non trivial exercise, even for experts in the area (Spencer, 2003). Australian students are also receiving limited information about ICT subjects and choices available to them (Van Der Vyver, Crabb, & Lane, 2004). Students have been exposed to ICT integrated into the general school curriculum, but few have a clear idea of what is involved in ICT subjects (Sheard, Lowe, & Markham, 2001). Compounding the issue within vocational education, career advisors often admit to struggling to understand ICT jargon and job descriptions (Standley & Stroombergen, 2001) leading to the lack of confidence in giving ICT career advice (Multimedia Victoria, 2001).

The way that the ICT curriculum is introduced and the learning environment impacts on the ICT attitudes of students is of high concern. It is imperative that the curriculum provides future ICT students with coursework which interests both sexes whilst providing them with the appropriate skills to enter ICT career paths (Güler & Camp, 2002). Yet, many students report negative opinions of ICT specific subjects and general dissatisfaction with the ICT curriculum (Carey, 2001; Multimedia Victoria, 2001). These opinions could be partially because the predominant content of ICT subjects in schools involve word processing and spreadsheets (Downes, 2004) providing the students with a skewed perception of the true nature of ICT careers (Multimedia Victoria, 2001). ICT educators must not only focus on good teaching, but they must also evaluate whether the subject is seen to be challenging, useful and interesting (Mitchell, Sheard, & Markham, 2000). The ICT learning environment has a number of unique features including a predominantly male teaching cohort, who usually have a science or mathematical background, and a curriculum and associated assessment and exercises driven largely by masculine interests (Logan, 2004). Also, according to Carey (2001), teachers presently receive

little or no training in the ways that technology can be used to create an equitable, innovative and engaging learning environment.

IMPACTS ON ICT PERCEPTIONS

Organizational Culture

Culture is the product of a social environment and evolves through the course of social interaction (Hofstede, 1997, p. 5; Morgan, 1998, p. 130). Cultural influences can shape perceptions about ICT, how ICT is used, and in turn the potential entrants to vocational and occupational areas in ICT and related fields (Harris & Wilkinson, 2004). Allaire and Firsirotu (1984) created a conceptual framework to assist in the analysis of organizational culture that consists of three inter-related components: a cultural system; a socio-structural system; and the individual actors.

The cultural system is a system of shared and meaningful symbols, which is shaped by its surrounding society and organizational history (Allaire & Firsirotu, 1984). There were a number of symbolic artifacts specific to ICTs that were observed amongst the responses from teachers and students, including terminology such as “hacker,” “geek,” “nerd,” and “square” when talking about ICT workers. The students linked ICT success with these symbolic artifacts when 24% of Year 9 students and 41% of Year 12 students stated that it was necessary to be nerdy/geeky to be successful in ICT careers. However, these symbolic artifacts are commonly used in a negative social context and tend to deter students from engaging in activities that would have them labeled as such. Other common beliefs repeated in teacher comments were that computers are seen as toys for boys and tools for girls. Female teachers also identified with these beliefs and one commented: “[computers are] strictly a tool to be used, not to be aspired to.” If computers are continually

portrayed as something serious, rather than enjoyable, this may explain the reluctance of students to become involved in ICT. Students and teachers often regarded ICT subjects as being difficult with some students rejecting ICT subjects out of concern for their academic results and university entrance scores.

The socio-structural system consists of management strategies and policies and formal structures (Allaire & Firsirotu, 1984). All schools must comply to a certain level, with standardizing educational policies of the government, but the way that the curriculum is developed and delivered can affect the way in which the subject is viewed. The cost of providing and maintaining ICT resources and infrastructure is an issue and the lack of financial and physical resources affects the delivery of the ICT curriculum and how it is (negatively) perceived by the students and teachers. One teacher also felt that if a student was ICT inclined then that they would find alternative ICT resources outside of the school. Yet, in low socio-economic areas, many families still do not have access to computers at home and rely on schools and libraries to provide those resources. Many teachers and students complained about the quality and quantity of resources available, with only 25% of teachers at one school saying departmental budgets allowed the purchasing of adequate resources to deliver the curriculum. Teachers also commented that students sometimes cause further damage to broken computers out of frustration or boredom.

Personnel, classroom availability, and timetabling were other ICT resource issues that caused tension. Students were foregoing ICT subjects because of timetabling conflicts saying that “[ICT subjects] have to be sacrificed to fit other first priority subjects in.” Teachers also identified that ICT subjects were the most time consuming to prepare for. “It needs more preparation time because things change so rapidly ... I could go back to teaching chemistry tomorrow and yes, the

syllabus has changed fractionally, but the basic chemistry hasn't changed in 50 years and the level we teach at high school won't change." Another teacher also conceded that it was difficult to foster and maintain student interest in relation to ICT saying, "it's hard to interest them because they have computers and the Internet at home."

Individual actors bring their own experience, personality and legacy to an organization and depending on their status can contribute and mold reality (Allaire & Firsirotu, 1984). Students have their own motives in relation to whether or not they enroll in ICT study and factors influencing these motives include enjoyment of the area, career aspirations, and opinions of friends, family, and role models. When students were asked what influenced their career decisions, the top responses included family and friends, but also high on the list was TV shows. Most students found that ICT subjects were boring, but others planned to combine ICT with other interests: "... this is a way of doing music and technology at the same time." When students were asked about the most appealing factors for an ideal career, the top response was interesting work followed by high salary and working with/meeting other people. These factors recognize social, remuneration and lifestyle aspects of future careers and are generally opposite to what ICT is perceived to involve.

Information Quality

Individuals often have differing opinions, wants and needs, and as such, each individual's definition of quality may vary significantly (Garvin, 1984). Schools are required to teach a certain amount of core information, but the way that this information is taught will differ between different schools and teachers. A teacher reiterated this when asked whether the ICT curriculum prepares students for ICT careers: "Depends which school." Some schools do not offer compulsory foundation ICT subjects in Year 8, whilst others do. Consequently,

students who need to make informed decisions about subject selections in Year 9 and 11 may be disadvantaged at schools who do not offer these foundation subjects. Students also recognized the impact of foundation subjects on subject decisions in senior high school. Comments included: "in Year 9 we do Web pages and in Year 10 we do programming and that whole last semester of programming is like an introduction to IPT [a senior ICT subject]" and "you do math from Grade 1, but you don't do computer programming from Grade 1; you don't know what you are walking into."

Teachers are expected by society to have a wide range of knowledge, skills, and ability in their area of teaching. However, the rapid changes in ICT create problems for ICT teachers. Teachers also recognized the need for qualified ICT teaching staff. One teacher also told of his entry into the ICT classroom: "I arrived in my second school as a third year teacher and the computer teacher had gone away on leave for 6 or 12 months and they said, 'you're young, here is the computer room, you are teaching the class tomorrow' ... and that was my first introduction to computers." ICT teachers also recognized that the ICT curriculum was dated and lacked relevancy, possibly because of the limitations of subject texts. One teacher also commented that the senior ICT subject "is too narrow a context for the modern use of computers ...". Students also expressed general dissatisfaction with the ICT curriculum saying that it was boring and that theory outweighed the practical work. Another problem with ICT subjects in high school is that they are not a prerequisite for tertiary ICT study. Teachers and guidance officers also face difficulties with is the changing job roles in ICTs. As advisors, if they are not well informed, it is difficult to understand how they could give accurate, current, and reliable ICT career information to the students. Who is educating the students about their ICT career options?

FUTURE TRENDS

Investigation into the declining number of females entering ICT study and career paths has been underway for over two decades. Today, we are no closer to finding a solution to this problem, as we were twenty years ago. In fact, the decline of females entering ICT tertiary education is becoming worse over time. Previous studies, including this one, have investigated various points of view and factors that may influence female ICT career decisions. Some of the factors identified include national and organizational culture, lack of or poor quality ICT career information, societal influences, discriminatory work environments, practices and policies along with the need for appropriate ICT role models. Another complicating factor is that the world and the ICT industry are not static. If you add to this volatile mixture, the changing and individual needs of the girls, the puzzle becomes increasingly complex. While these studies have contributed by identifying these issues and making recommendations for change, some which have been instituted, this complex social problem has not been solved.

These factors, however, cannot be looked at in isolation. All things being equal, it would be expected that girls who are given the same information and experience the same social and cultural values and information, would have similar career goals and paths. However, this is not the case. Could it be that we are concentrating on the negativity of this problem rather than celebrating the positive outcomes that already have been achieved? Perhaps researchers in this area need to reverse the question and ask the individual girls already enrolled in ICT subjects and careers, what drew them to the area and what drives them to achieve and succeed. Additionally, individual personalities and academic abilities cannot be disregarded when investigating career choices and the declining female ICT cohort. Individuals have distinct personal likes and dislikes; it has to

be remembered that some females, and males for that matter, will never find ICT interesting, and it is an exercise in futility, to change them.

CONCLUSION

Although the ICT industry is known for its cyclic nature, people working in it are generally well remunerated and seen as being in a position of power and status because of the enormous role that ICT plays in business and everyday life. These benefits of working in the ICT industry, along with having a voice in the design and use of ICT, can impact positively on the quality of life and the lifestyles that women and their families experience. This study found that Australian girls are continuing to reject ICT careers partially due to negative perceptions and stereotypes. There also is a lack of adequate resources and trained ICT teachers passionate about teaching ICT, and students are frequently rejecting ICT subjects because they are seen as dull, boring and not meeting their needs. They are also rejecting the opportunity to work in ICT careers because of school experiences, the lack of accurate, meaningful, and timely ICT career information and positive role models. Finally, the influence of popular media on career decisions is an important area that should be exploited. Perhaps, in the future we may see shows about sophisticated and powerful women in ICT careers leading to increased ICT interest. We can only try.

KEY TERMS

Essentialism: The belief that traits are biologically determined and do not vary between individuals or genders.

Guidance Officer: A person whose role in a high school is to assist students with career information and guidance, assess students with special needs and provide students with support and personal counseling.

ICT: Information and communication technology is a broad grouping of technologies which include IT and telecommunications. Areas incorporated include computer science, software development, the study of organizations and society, mobile telephony and networks.

ICT Role Model: A person who has an interest, background, or career in ICTs whose behavior, attitude, or achievements make them worthy to be admired or imitated.

Pink Collar Jobs: Jobs that generally have a female dominated workforce such as: nursing, cleaning, childcare, primary school teaching.

Social Construction: Hypothesizes about the way that we analyze and categorize our experiences that influence and form our understanding of reality in our own social context.

Symbolic Artifacts: A way of making things known by signs and symbols which can include language.

Robert Morris University, USA

ABSTRACT

The trend in academia to online learning has gained momentum in the past decade, due in part to the cost of higher education, a changing student profile, lack of traditional classroom space and the recognition that distance learning has created a new paradigm of instruction. Universities wishing to maintain or expand enrollments need to be able to respond effectively to the educational

needs of working adults, students in the military and residents of rural communities as well as of other countries. Online (Internet-based) course offerings constitute a creative and increasingly popular response to these challenges. As more and more institutions of higher learning offer online courses, the question arises whether they are, or can be, as effective as courses offered in the traditional classroom format. Answering the question has been the focus of several studies.

Our study compared students enrolled in both online and traditional classroom versions of one business law course where all elements were the same except for the instruction format. The study found no significant difference between the two formats with regard to student satisfaction and student learning. The findings support earlier comparisons of online and traditional instruction modes

INTRODUCTION

Robert Morris University (RMU) in Pittsburgh, Pa., has continued to develop and offer an increasing number of online course offerings to meet the needs of working students, its traditional student base. In 1999, RMU offered 25 online courses. In 2006, the number of online courses grew to 220. With the elimination of the federal restriction on online education (the “50% rule”) in 2006, online course offerings can be expected to grow exponentially. Ensuring instructional quality and learning effectiveness while doing so will be the challenge.

RMU is a private university with an enrollment of approximately 6,000 students. Founded in 1921, the university has experienced rapid growth in the last two decades. It supports six schools, with the School of Business being the largest. A large number of undergraduate and graduate course offerings in this school have had online course development as a focus for several years. A number of courses are available to the students in both traditional and online formats. For the past 3 years, the course Legal Environment of Business (BLAW 1050) has been popular in both formats.

Overview of BLAW 1050

The course is designed to enable students to develop an understanding of the American legal system and attain a working knowledge of ethics,

contract law and consumer protection to a degree sufficient to be useful in business and consumer transactions. The course also helps students better comprehend the rules of conduct they can reasonably expect others to follow, as well as the conduct others may expect from them in various business situations. In this course, students acquire an awareness of their legal rights and responsibilities and gain the ability to apply legal principles to help solve business and consumer problems.

Online vs. Traditional Instructional Issues

In any discussion of online and traditional course delivery and development, some obvious and fundamental differences will be acknowledged by instructors. In general, the traditional course is taught in a structured classroom, the students are physically there, all instruction is in real time and the instructor is present for the class meetings. In the online format, the class is taught in a cybernetic environment, instruction does not have to be in real time, the students are not present in one place, and the instructor monitors most of the activity from a distance.

In defining distance education, Desmond Keegan (1996) identified six significant elements of online learning: separation of the teacher from the student; placement with an educational organization; use of technology to convey content and unite instructor with learner; two-way communication that facilitates student-initiated conversation; potential for face-to-face meetings for social as well as instructional purposes; and participation in an “industrialized form of education” (Keegan, 1996, p. 44).

The fundamental differences between online and traditional instruction pose some major challenges and concerns for course instructors and educational institutions. Online teaching forces the instructor to assume a new teaching role and necessitates reappraisal of the traditional teacher-student relationship. In fact, online teaching

requires the instructor to rethink and reorganize the existing teaching paradigm. The institution must find different ways to monitor the quality of instruction.

In most cases, conveying the basic content to students in the online format is easy to accomplish. A greater challenge is getting the instructional quality of the online course to match, or exceed, the instructional level of the traditional class. It is not sufficient for the online instructor to have an understanding of the technological skills and course development tools alone. He or she must have a strong sense of course design and an understanding of good pedagogy, as well. Good pedagogy is generally accepted by educators to involve: 1) a high level of learner activity, 2) a high level of student interaction, 3) a format for motivation, and 4) a well-structured knowledge base.

As online instruction gains acceptance, researchers have begun to test the proposition that online instruction can indeed incorporate the principles of good pedagogy and effective course design. Schulman and Sims (1999) studied students enrolled in five separate courses, each offered in both the online and traditional formats. Both sections of each course were taught by the same instructor. In their sample, they found that students learned as well online as they did in the traditional classroom environment. This particular study compared the course assessments and final outcomes of both instructional scenarios.

In his 1999 book, *The No Significant Difference Phenomenon*, Thomas Russell reviewed 355 research reports, papers and summaries on the subject of online vs. traditional learning. He found no significant difference in grades, satisfaction or effectiveness when “e-learning” was compared to traditional teaching (Russell, 1999). R.C. Ryan’s study at the University of Oklahoma compared the online and traditional versions of the course entitled, *Construction Equipment and Methods (CNS 4913)*. The final grades for the two groups were not significantly different and survey results

indicated that students perceived no difference in the quality of the instruction (Ryan, 2000). Other studies have found little or no difference between online and classroom learning when such issues as race, gender, technological and academic backgrounds, and socioeconomic status were taken into account (Navarro & Shoemaker, 2000).

Yet, Rivera and Rice (2002) reported that while several studies (including Russell’s 1999 work) have demonstrated that online and traditional courses were found to be comparable with regard to cognitive factors (learning, performance and achievement), the same could not be demonstrated consistently with regard to student and instructor perceptions and satisfaction with online learning.

Our study relied on satisfaction surveys and grade comparisons to assess whether online instruction was as satisfactory as traditional instruction and if student learning were the same or better with online vs. traditional instruction in the area of business and, in particular, business law.

Online Business and Law Courses

Discussing the challenges to the instructor and developer of online law-related courses, Kathy Marcel noted that the best online courses were instructor-facilitated, student-centered and highly interactive (Marcel, 2002). The design of an online law course, as with the design of any online course, is critical. The instructor’s role is one of designing a learning experience and guiding students through the process. Marcel found that in fact, many law instructors tend to work very well with the facilitative aspect of good online course development. Marcel argued that because of the nature of their profession, law professors teaching online courses tended to expect students to be engaged and not merely passive learners. The suitability of teaching law courses online was even more evident, she found, with regard to upper-level law courses, because these courses themselves often rely on case studies, projects and Socratic dialog.

Suanpang, Petocz and Kalceff (2004) addressed the comparison of student attitudes when taking a business statistics course in the online and traditional formats. Working with 230 students (N=112 in the online format, and N=118 in the traditional format), both quantitative and qualitative data were analyzed. The study concluded that "... students taught online develop strongly positive attitudes towards learning statistics, which influence their learning and make understanding statistics easier for them than for students taught in the traditional mode" (Suanpang et al., 2004, p. 17).

Cassel (2003), after having taught law online for more than 6 years, concluded that online learning matched or exceeded traditional environments in several respects. In her experience with online learning, the level of student-professor and student-student interaction through asynchronous (threaded discussion) and synchronous (chat/e-mail) methods was higher than in the traditional classroom setting. Additionally, the various audio and video options enhanced the learning environment for students. Cassel also pointed out a consideration often overlooked as an advantage of the online format; that is, with online learning, classroom and classmate distractions, interruptions and basic annoyances are not present, thus allowing the learner to focus more completely on the subject matter and activities. Shelley concurs. His pilot study of RMU's move to place its entire core undergraduate history courses online demonstrated student satisfaction with the online format, course content, sequencing, as well as with the textbook (Shelley, 2005).

Both Cassel (2003) and Marcel (2002) describe the advantages of online instruction for effective legal instruction. Although focusing on the use of voice-recognition software to enhance online law courses, K.H. Miller (2004) also found that legal education, thoughtfully designed, could be delivered effectively online. Some would argue, as Kristine Ellis does in *A Model Class* (2000), that designing a law course requires going back

to the basics. That would mean constructing an online law program that would teach students how to formulate and deliver a legal argument and to analyze and systematize case decisions.

Why This Study?

Bernard, Abrami, Lou, Borokhovski, Wade, Wozney, Wallet, Fiset and Huang (2004) note in their analysis of studies comparing distance and classroom instruction that the value of such studies lay in their usefulness in determining the impact on desired outcomes, lending credibility to the innovation (online learning in this case) and providing focus for further developments.

The available evidence seems to indicate that, if carefully designed, an online course would offer a comparable, if not better, learning environment for students than the same course presented in the traditional format. However, little has been published on the online delivery of undergraduate business law courses. In a post-Enron environment, incorporating the principles underlying Sarbanes-Oxley into undergraduate law courses intensifies the need for effective instruction in business law. But is teaching business law online as effective as teaching business law in the classroom?

Weaver-Kaulis and Crutsinger (2006) cite considerations of accreditation, budget and accountability as stimulants in the increased attention on documentation of student learning beyond the traditional grading system and the impetus for faculty-driven assessment programs.

In their study of student performance, Frantz and Wilson (2004) note that the increased scrutiny of legislators and accrediting bodies, particularly in business schools, has intensified the need for research into determinants of success. Specifically, they remark on the lack of research on legal studies courses in business schools — "a surprising void given the importance of legal studies to business education" (Frantz & Wilson, 2004, p. 225). This

study seeks to address that void by examining the effectiveness of one core business law course taught both online and in the classroom.

Determining how well students are learning is critical in any educational setting. It is of particular significance to RMU's School of Business, which is in the midst of its Association to Advance Collegiate Schools of Business (AACSB) accreditation process. Measurement of student learning is central to the review of current course offerings and to the development of new ones. Student satisfaction with the learning environment not only contributes to student retention, but it also serves as a measure of faculty performance and pedagogical effectiveness.

Research Questions

This study looked at four research questions:

1. Does student satisfaction with the course overall differ significantly between the online format and the traditional class format?
2. Does student satisfaction with the instructor differ significantly between the online format and the traditional class format?
3. Does student satisfaction with the course structure differ significantly between the online format and the traditional class format?
4. Does student learning differ significantly between the online format and the traditional class format?

METHODOLOGY

Study Structure

The course examined was BLAW 1050, which is required for every business major at RMU. The course is offered in both the online and traditional classroom formats. For this study,

the same professor taught each section of BLAW 1050 surveyed, using the same textbook, required readings, activities, projects, exams, and assessment for both groups.

Comparative data was drawn from four online sections of the course (two in 2004, one in 2005 and one in 2006) and two traditional sections in the spring of 2005. Fifty-eight of the 64 enrolled students completed the online sections of BLAW 1050 (N=58), or 90.6%. Forty-six of the 49 enrolled students in the traditional sections completed the course (N=46), or 93.8%. The total number of students receiving grades for BLAW 1050 during the study period was 104 (N=104), or 94.5%.

Although student retention was not a focus of this study, it should be noted that of the 64 students enrolled in the online sections of BLAW 1050, six withdrew, for a retention rate of 90.6%. The retention rate for the traditional sections was higher, at 93.8%. Of the 49 who enrolled, 3 withdrew.

Course Design

The online sections of BLAW 1050 were developed using the eCollege format. RMU uses eCollege because it is considered to be a more student-friendly platform for e-learning than Web CT or Blackboard. All students taking an online course at RMU are required to complete the Online Learning Training Module prior to being registered for the class. All online sections of the course were developed and maintained by the instructor involved in this study. The online format employed available instructional tools, including digital drop boxes, document share areas, synchronous and asynchronous dialog, e-mail and online assessment. The textbook readings were enhanced and supplemented with lecture notes and illustrations of key points. The classroom sections of BLAW 1050 used the same syllabus as the online course and had the same assignments and assessments. The same topics used in the threaded discussions in the online

format were used in real time in the traditional classroom format. The online format of BLAW 1050 employs both asynchronous tools, such as threaded discussion, and synchronous tools, such as e-mail.

Sample/Participants

The study sample consisted of those students enrolled in the four online sections of the 2004, 2005 and 2006 BLAW 1050 courses and the two traditional sections of the same course in 2005 and who responded to the survey. Respondents from the online sections numbered 33 (N=33). Respondents from the traditional sections numbered 13 (N=13). The total number of participants for this study was 46 (N=46).

Instrumentation

A 24-question satisfaction survey with a five-point Likert scale (Appendix A) was distributed in each class. The survey was administered by the instructor after grading was completed. Participation was voluntary. Thirty-three of the 58 online participants responded, for a 56.9% return rate. Thirteen of the 46 students in the traditional courses completed their surveys, for a return rate of 28.2%. Total number of students participating in the survey was 46 (N=46). The higher rate of return from the students in the online courses might have been due to the ability to respond electronically vs. having to return the survey physically, as was required of students in the traditional classes.

Questions 1-13 applied to students both in the online course and in the classroom course and were answered by both groups. In addition, space was provided on the survey for comments or suggestions to enable both groups to make further observations on the content and quality of the courses.

Question 1 asked if the student felt he or she had learned the subject material. Questions 2 and

10 focused on the performance of the course instructor. Questions 3 and 4 focused on the quality of the selected textbook. (These survey responses were not included in the analysis.) Questions 5-9 and 11-13 dealt with issues involved directly with the course structure.

Participant responses from the online and classroom sections were aggregated and compared. Responses to question 1 formed the basis for comparison for Research Question 1. Responses to questions 2 and 10 formed the basis for comparison for Research Question 2. Responses to questions 5-9 and 11-13 formed the basis for comparison for Research Question 3. Questions 14-25 were designed specifically for the online students and were not asked of students in the traditional course. Final grades from the online and traditional classroom courses formed the basis for comparison for Research Question 4.

The structure of the survey allowed for both quantitative and qualitative data to be analyzed. The survey was available in a template to students who took the course online and in hard copy for students who took the course in the traditional setting.

The study used SPSS for data analysis. For each research question, an independent-samples t-test was run. Within the context of this study, "satisfaction" is defined as having met expectations as demonstrated by the student responses. "Learning" is defined as having acquired knowledge of the subject matter as evidenced by the course grades.

RESULTS

Research Question 1: Does student satisfaction with the course overall differ significantly between the online format and the traditional class format?

Aggregated mean score for the online sections 4.4242

Aggregated mean score for the traditional sections 4.6154

Please see Table 1.

Research Question 2: Does student satisfaction with the instructor differ significantly between the online format and the traditional class format?

Aggregated mean score for the online sections 4.5385

Aggregated mean score for the traditional sections 4.6154

Please see Table 2.

Research Question 3: Does student satisfaction with the course structure differ significantly between the online format and the traditional class format?

Aggregated mean score for the online sections 3.8920

Aggregated mean score for the traditional sections 3.8846

Please see Table 3.

Research Question 4: Does student learning differ significantly between the online format and the traditional class format?

Aggregated mean score for the online sections 2.9871

Aggregated mean score for the traditional sections 2.7609

Please see Table 4.

CONCLUSION

In their meta-analysis of the empirical literature comparing distance and classroom instruction, Bernard et al. (2004) found that the differences between the two modes of instruction were not substantive. They analyzed 232 studies measuring student achievement, attitude and retention. They found the effect sizes to be basically zero on all three measures and wide variability due in part to the disparity in the degree of rigor in the

studies analyzed. Some applications of distance education were better than classroom instruction; some were worse.

Our study found no statistically significant differences between the online and traditional instructional/learning formats with regard to any of the research questions. Student satisfaction with the course overall and with the instructor was slightly higher in the traditional classroom format than with the online format (mean scores of 4.6154 to 4.4242 and 4.6154 to 4.5385, respectively).

Student satisfaction with the course structure was slightly higher in the online format as opposed to the traditional format (mean scores of 3.8920 to 3.8846). The mean scores for student learning in the online courses were slightly higher than for those in the traditional classes (2.9871 to 2.7609). The results reinforce Russell's "no significant difference phenomenon."

Survey results also supported findings in the earlier work by Schulman and Sims and Ryan with regard to research questions 1-13 on student satisfaction with the course, instructor and course design of BLAW 1050. An independent-samples T-test was used to analyze the survey data for each of the questions. Survey responses were grouped according to purpose of the question (course, instructor, text, structure). Responses to the questions on the text were dropped because they were not relevant to the four research questions posed.

Student input under "Comments/Suggestions" was comparable, with the exceptions that students in the online courses also referenced the online features (positively) and that students in the traditional class setting commented on the outside assignments and exams. Seventy-two percent of the online students who participated in the study also added comments, compared with 69% from the students in the traditional classroom setting. The comments are included in Appendix B.

Study limitations include the sample sizes and the difference in participation rates. More than half (56.9%) of the students in the online courses

A Comparative Analysis of Online and Traditional Undergraduate Business Law Classes

	t N=104	Sig. (2-tailed) N=104
VAR0002 Equal Variances Assumed	1.299	.197

participated, while only 28% of the students in the traditional courses participated. This may be attributed to differences in the ease of participation between the two. The online students could respond electronically, while the students who took the course in a traditional environment needed to return the survey by mail or to the instructor.

Fowler (2005) suggests that experience with online instruction now leads to a different dis-

course, asking, “Are on-site courses as effective as online?” (Fowler, 2005, p. 1). This study does not really answer that question. Students in both the online and traditional courses liked the course, liked the instructor and felt they had learned the material. The final grades suggest that students in both the online courses and the traditional courses mastered the material equally well.

Clearly, additional studies comparing online with traditional learning environments, using larger samples, need to be conducted. Further investigation of online instruction vs. traditional classroom instruction of business law courses needs to be done before any definite conclusions can be made as to whether online should replace or simply supplement classroom learning. Both the Bernard et al. analysis (2004) and the Phipps and Merisotis study for the Institute on Higher Education Policy in 1999 argue that more rigorous studies need to be designed for researchers to be able to answer the question, "Is there a difference?"

APPENDIX A. SURVEY

LEGAL ENVIRONMENT OF BUSINESS

Please answer each question based on the following scale:

5=Strongly Agree 4=Agree 3=Moderately Agree 2=Agree Slightly 1=Do not Agree

1. I feel I learned a great deal about the Legal Environment of Business 5 4 3 2 1
2. I feel that the instructor was well prepared for this course 5 4 3 2 1
3. I feel that the course followed the text book 5 4 3 2 1
4. I feel that the text was a good choice for the course 5 4 3 2 1
5. I feel that the overall layout of the course was easy to follow 5 4 3 2 1
6. I feel that the weekly assignments were fair and reasonable 5 4 3 2 1
7. I feel that there should be more outside assignments for this course 5 4 3 2 1
8. I feel that the quizzes that were given in the course were fair 5 4 3 2 1
9. I feel that the course examinations created anxiety 5 4 3 2 1
10. I feel that the instructor was accessible and easy to contact 5 4 3 2 1
11. I feel it was easy to respond and participate in discussions 5 4 3 2 1
12. I feel that I was able to concentrate and pace myself throughout the course 5 4 3 2 1
13. I feel that the course format allowed for easy interaction with my classmates 5 4 3 2 1

The following questions should be answered by **online students ONLY**:

14. I feel that the online quizzes and exams with the ability to review correct answers helped me understand the material 5 4 3 2 1
15. I feel that the threaded discussions added to the course quality 5 4 3 2 1
16. I feel that the curriculum in the course was well-organized and followed a logical progression 5 4 3 2 1

A Comparative Analysis of Online and Traditional Undergraduate Business Law Classes

17. I feel that the Announcements and e-mails set forth clear instructions and expectations 5 4 3 2 1
18. I feel that the instructor made it clear what work was required and what work was optional 5 4 3 2 1
19. I feel that quizzes are a beneficial part of an online course 5 4 3 2 1
20. I feel that the mini-lectures and text provide the appropriate information to achieve the goals set forth on the instructor's syllabus 5 4 3 2 1
21. I feel that the course "due dates" made it easy for me to plan my schedule 5 4 3 2 1
22. I feel that the Doc Sharing was useful and helpful to me 5 4 3 2 1
23. I liked that the e-mail responses from my instructor were private 5 4 3 2 1
24. I feel it is easier for me to learn in an online course than in an on land course 5 4 3 2 1
25. Besides this course, how many other online courses have you taken? _____

Comments/Suggestions

Other Comments

**APPENDIX B.
LEGAL ENVIRONMENT FOR BUSINESS
SURVEY RESPONSES TO "COMMENTS/SUGGESTIONS"**

24 of the 33 students who took the course online and who responded to the survey also added comments:

- Really liked the course; would have liked more threaded assignments and readings; text made for students; did not like "cute" names for cases
- Due date feature and private e-mail instructor responses a big plus; whether online is better depends on the subject matter
- Online worked well; learned more in threads and reading than in taking the exams
- Loved this class
- Really enjoyed the class
- Schedule for exams and quizzes too rigid for busy lives
- Enjoyed class and instructor; one of the best at RMU; learned a lot

A Comparative Analysis of Online and Traditional Undergraduate Business Law Classes

- One of the better classes; open discussions fostered by instructor incorporated current events into the course
- Too restrictive on access dates for assignments and exams
- Overall liked the course; problem with “proofreading” and phrasing of questions
- Pace good; glad did not use “chat” features; most organized taken; liked due date check list to plan ahead
- Enjoyed the course; learned a lot through the threaded discussions and weekly quizzes; online —fantastic, will continue to sign up
- Enjoyed course tremendously; first completely online course — hope others go as smoothly
- Enjoyed first online course very much; workload a bit heavy, but that is to be expected in a fully online course
- Loved this course; threaded discussions most beneficial; appreciated that assignments graded promptly; based on this online experience, wish could have taken entire degree online
- Informative instructor; course planner helped a lot — better than any syllabus; more interaction with this professor than with any other at Robert Morris; would recommend; tough class, need to pace yourself
- Need more time for essays for poor typists
- Enjoyed course; learned a lot, although grade did not reflect it
- Liked the way course set up. Easier to learn and to say what I wanted. “... am now even considering becoming a lawyer ...”
- Great instructor, accessible and willing to answer questions; first online course, felt very comfortable; threaded discussions forced creativity; course harder than originally thought “... wish I would have taken it in a classroom just so I could get more interaction and asked questions as they arose, but for my first online class, I think it went pretty well.”
- Course a success “... wish I had the option of taking another online class ...”
- Learned a lot; “... will remember a lot of the content due to the online class environment”; liked due dates, well organized; liked individual responses to threads; greatly enjoyed the class; online allowed for flexibility needed
- Great class; loved having it online
- Enjoyed doing the work in the online setting; able to concentrate more and work at own pace; test-taking better without other students around.

Nine of the 13 students who took the course in the traditional classroom setting who responded to the survey also added comments:

- Really enjoyed the class; not easy, lot of information; only suggestion would be to add some visual aids
- There should be more outside assignments for those who are not great test takers; that would allow for more points while grasping the material
- Appreciated the abridged book; text and instructor informative; homework manageable; outside assignments not necessary, am a good test-taker
- Within time limits, course taught very well; basic understanding of the law; easy to follow using the book; professor’s knowledge of real-life situations made it easier to follow

A Comparative Analysis of Online and Traditional Undergraduate Business Law Classes

- Really enjoyed the class; exams were difficult since the questions were long and needed to be reread; should be more assignments to compensate for the exam grades
- Course not that hard; lot of reading and studying; one of the best classes so far — enjoyed it thoroughly
- Really liked the class; learned a great deal and was challenged; material interesting, examples helped; still remember a great deal of what was taught
- More out-of-class assignments to add to the experience and ability to retain the information and would eliminate the anxiety of cramming for an exam
- Had to study a lot, but remember pretty much.

Chapter 7.10

Concerns with “Mutual Constitution” A Critical Realist Commentary

Alistair Mutch

Nottingham Trent University, UK

ABSTRACT

The case for “analytical dualism” as a means of approaching sociotechnical action is presented as an alternative to accounts which tend to conflate agency, structure, and technology. This is based on the work of Margaret Archer, whose work is in turn located in the traditions of critical realism. Her commitment to analytical dualism, which stresses both the importance of time in analysis and the emergent properties of structure, is argued to give a firmer purchase on the notion of context than the alternatives based on, for example, the work of Giddens and Latour.

INTRODUCTION

I want to start from the premise that what concerns many researchers in this area is how best to conceptualise the nature of “context.” From the point of view of those researching informa-

tion systems (broadly constituted), the concern is to avoid what they perceive as being, at best, an over-emphasis on technical factors and, at worst, the charge of technological determinism. They are keen, therefore, to emphasise the importance of the organisational, social, and cultural context in situating the development and use of technological artefacts. In this they are joined by those studying information behaviour who are concerned with moving away from a simple model of an “environment” in which behaviours are selected “rationally” towards the ongoing interaction of context and action. In this endeavour, the notion of “mutual constitution” is seductive, and the seduction is reinforced by those whose concepts are turned to for support. For some, this is the actor-network theory (ANT) of Bruno Latour and others, where there is a strong emphasis on action embedded in networks. For those working in this tradition, the removal of the hyphen from “socio-technical” is a deliberate act designed to stress the ineradicable coupling of the social and

the technical. “Sociotechnical” action, therefore, represents the solution of the problem of context by its conflation into networks of actants. Not all analysts in this area, however, would wish to go so far, and so, as in other areas of the study of organisation, the theorist of choice is often Anthony Giddens and his notion of “structuration.” What is taken from this is the mutual constitution of structure and agency, where structures form the ever-present conditions for the production and reproduction of agency. The strength of such notions is their emphasis on the irrevocable interconnections between action and context, but their weakness, it will be argued, is a tendency to privilege action over context. That is, when we explore these approaches in a little more detail, we find that they do not help as much as we might like in the specification of context. These criticisms will be addressed briefly but, as they have been considered elsewhere (Jones, 1999; Mutch, 2002), the main part of the argument will be devoted to the presentation of an alternative approach. The contention is that ideas drawn from the philosophical tradition of critical realism, and specifically from the application to social theory by the sociologist Margaret Archer, are of much more value both in specifying what we mean by context and in conceptualising the relationship between context and action. This is, therefore, an act of what Basil Bernstein (1996) calls “secondary recontextualisation.” That is, the aim is to introduce some of the ideas and show how these can help existing approaches. Accordingly, after a brief introduction to some of the key tenets of critical realism, we look in a little more detail at what Archer has to say about the nature of structures (our “context”) and the relationship of structure to agency (our “action”). The key argument is that, whilst there is no society (and hence no technology and no information) without people, the challenge is to examine the interaction between the structures which people create (including information and technology) and the subsequent action in which people engage. These

more general ideas are then explored in the context of writings on organisations and technology. It is important to stress here that critical realism does not purport to be a substantive theory of either of these two domains; rather, it offers some conceptual clarity on ontological and epistemological issues, which can further help the development of domain-specific theories.

For Latour, the “classic” question of the relationship between agency and structure is a case of asking the wrong question. His focus is on the enrolment of a variety of actors (sometimes “actants,” to distinguish non-humans from humans) in networks of greater or lesser scale and scope (Latour, 1993). The consequence is an extremely helpful language for describing processes that, in the hands of the adept, can be illuminating, but can also lead simply to the production of more or less interesting stories. The particular value from ANT is the notion of “being specific about technology,” but what we tend to get is an excellent language for describing process with the fading of context into the background (Montiero & Hanseth, 1995). It may be for these reasons that rather more attention is paid to the work of Giddens (Walsham, 1992; Yates & Orlikowski, 1992). We need to be cautious here: it is not the purpose of this article to review the way in which Giddens has been employed, but we can take the comment of Hasselbladh and Kallinikos to stand in for many similar examples:

“It is not our task to defend structuration theory. However, we would like to observe that the analysis undertaken by Barley and Tolbert... does not have much in common with Giddens’ basic ideas.” (Hasselbladh & Kallinikos, 2000, p. 716; e.g., Phillips, 2003, p. 221)

What is it, however, that people seem to be drawing from Giddens? It would appear to be the notion that structure is important in forming the context which both enables and constrains action. A series of concepts are provided (structures of

Concerns with “Mutual Constitution”

signification, legitimation, and domination) which provide a more finely grained conceptualisation of structure. However, whether what people take from Giddens and what is actually in Giddens are the same is open to some question. This revolves around Giddens’ conception of structures as “memory traces” instantiated in action. This is a rather weak conceptualisation of structure, possibly weaker in practice than those who use it care to acknowledge (Jones, 1999). A rather large claim might be that in practice those who use Giddens are using the notion of structure in the rather stronger sense than Margaret Archer uses it. She has been one of Giddens’ most trenchant critics, but before turning to her work, we need to briefly explore some key tenets of critical realism, as this might be an unfamiliar set of ideas to many.

CRITICAL REALISM: AN INTRODUCTION

We need to be clear at the outset that critical realism is a philosophical tradition that sees itself as “under-labouring” for other theories in both the natural and social sciences (Sayer, 1992). For these reasons, it is strictly speaking incorrect to talk about a critical realist analysis of organisations, technology, information, or any other phenomenon. Rather, substantive theories that address these domains can use the resources for conceptual clarity (Cruickshank, 2003b). At its heart, critical realism is an endeavour concerned with ontology. The realism indicates that the tradition asserts that there is a reality independent of our knowing of it which has intransitive status. However, it rejects the notions drawn from what we might term scientific realism in the natural sciences, or positivism in the social sciences, that there is any direct access to this reality. Even in the natural sciences, where experimental closure can be reached in some cases, our knowledge of reality is not a reflection. Rather, it involves acts of interpretation at all stages, from observation through to theory

building. Much of our progress in the latter moves through the creative use of language, especially of metaphor (Lewis, 1999; Lopez, 2003). So critical realism makes bold claims about ontology, but is altogether more relaxed about epistemology. Here, there can be multiple contending ways of knowing. Whether one is better than the other depends on its relation to what it is that we seek to know, not on its internal features. Within these basic conceptions, critical realism argues for an ontology of depth. That is, it pays due attention to the emergent nature of phenomena. Thus, in the work of Stephen Rose (1993) on the brain, memory is a system property of the brain which emerges from material substance, but which is not reducible to particular parts of that material. Critical realism is, then, anti-reductionist in method and places emphasis on emergence and systemic properties at the relevant level of enquiry. It also suggests that we need to distinguish between the empirical, the actual, and the real. For critical realists, the empirical are simply surface sensations that are the product of deeper mechanisms. What actually happens may be disguised by these surface manifestations. However, the actual in its turn is produced by the real mechanism, and it is these mechanisms which analysts and scientists seek to explore. The object of study, therefore, should be the underlying mechanisms that produce surface manifestations, mechanisms which might not be apparent. They may, for example, only be activated in certain circumstances, or their impact may be confounded by the workings of counter-mechanisms (as noted later, we will often talk of “tendencies” rather than mechanisms in looking at the social world).

These propositions are derived in large part from the studies in the philosophy of science carried out by Roy Bhaskar (Collier, 1994). However, Bhaskar also has a considerable concern with human activity, and developed a Transformational Model of Social Activity which drew on the work of Giddens. This work has led to the emergence of an interest in his ideas in a number of domains

in the social sciences, with prominent figures being Andrew Sayer (2000) in geography and Tony Lawson (2003) in economics. However, the most trenchant critic of Bhaskar’s use of Giddens — and the theorist to develop the ideas in the most detail in the social domain — has been Margaret Archer. Archer is a sociologist of education who has developed since the 1970s a set of rich and complex ideas which found their fullest expression in a series of (to date) four books (Archer, 1995, 1996, 2000a, 2003). These are closely interlinked, but deal with separate aspects of the relationship between agency, structure, and culture. She terms this the “morphogenetic” approach — “morpho” being the element stressing change, “genetic” emphasising the importance of agency. There has been a move over the series towards a greater degree of concern with the nature of agency, but always with a strong focus on the objective characteristics of the context in which agency operates. In the comments below I am forced to simplify what is a complex body of work, with the twin aims of introducing the work (possibly sending people to the originals) and exploring how it might form a better set of concepts for the exploration of context than notions of mutual constitution.

Let us start with the nature of structures. Archer (1995) identifies two prevailing approaches to the nature of structure and agency. One is that which she terms “downward conflationism,” which she finds in traditions such as structuralism, where social action is, as it were, simply “read off” the nature of structure. In such approaches agency becomes a mere epiphenomenon, with agents merely the bearers of structure. In such a situation the task of analysts becomes simply to find the keys to unlock the code of structure, which once discovered will reveal all the answers. Those approaches which deploy forms of technological determinism might exhibit some of these attributes, where social consequences are seen to flow inevitably from the fact of technical implementation. The other dominant approach,

developed often in opposition to structuralist approaches, is one which places all the attention on the interaction of agents and sees structures as either irrelevant or, again, a mere transient by-product of action. Her targets here are those which operate under the broad rubric of “methodological individualism” and she has been particularly concerned to counter the claims of rational choice theorists (Archer, 2000b). These she would term “upwards conflationists” and these approaches would, in turn, be rejected by Giddens. His structuration theory is designed to avoid the false polarity engendered by either of the approaches we have outlined, but, Archer argues, in his formulations he falls into the trap of what she terms “central conflationism.” The problem here is that in eliding the differences between agency and structure, in arguing for their mutual constitution, Giddens removes the analytical purchase which can be gained from holding the two terms apart. Archer stresses the notions of emergent properties and temporality in arguing for a stronger conception of structure, which then leads to her argument for “analytical dualism.” Her argument is that, whilst structures are created by people, those people are not “those here present now.” That is, the structures that are produced by social interaction then take on objective status for future rounds of social interaction. Their emergent properties, emergent from but not reducible to the previous actions of social actors, have causal powers in shaping and enabling future projects. What do we mean here by “structure?” Archer suggests a number of components — roles, organisations, institutions, and systems — that are inter-related and have primacy, depending on the context of analysis. This allows us some purchase on the relationship between the local and the global. Archer (1996) also further elaborates her account by considering the relationship between structure and culture. She is concerned in her account of culture to explode what she terms the “myth of cultural integration,” the notion that culture presupposes an integrated and necessarily

Concerns with “Mutual Constitution”

harmonious set of relations, and suggests a need to analyse culture as a set of propositions about the world, some of which can be in logical contradiction with each other. We will take this notion of contradiction further below, but having presented an outline of the formation of structure (to use that as a shorthand just now for the combination of structure and culture), we have to consider the implications for agency.

Archer (1995) argues that for the purpose of analysis, we need to hold agency and structure apart. This “analytical dualism” is quite clear in recognising that concrete situations will involve elements of agency and structure in complex interactions. She suggests that the way of getting at such situations is to engage in the production of analytical narratives that aim to tease out the relationship between agency and structure through a series of what she terms “morphogenetic” cycles (the “morpho” referring to the potential for change, the “genetic” referring to agential involvement). In each such cycle we start with the prior structural conditioning, exploring how this shapes and enables social interaction. In turn, such interaction elaborates structures, either by changing them or, perhaps more frequently, reproducing and confirming them. In considering how structures form the context for action, we need to return to the logical relations of contradiction and complementarity. Such relations can exist within structures (such as within the institutions of law or the family), within cultures (such as contending ideas of the family), or between structures and cultures (such as when practices of family life are in distinction to theories about how that practice should be conducted). Archer is anxious to argue that the existence of logical contradictions does not necessarily mean a clash between social groups. Such contradictions may lie unnoticed and “unactivated” if there are no actors with the interest in deploying them. What such combinations of contradictions and complementarities give us (and Archer explores various combinations in considerable depth) are logics for situated action.

Such logics may not be picked up upon, perhaps because social groups lack the weight to be able to deploy them. They may suggest logics of action, but there is no inevitability about them. However, actors who chose differently will have to pay opportunity costs, and their choices may bring them to accept other logical connections which they had not appreciated. So, for example, one argument might be that certain assumptions about how to go on are inscribed into software (Melucci, 1996). This inscription then confronts those who use the software with a “natural” and relatively easy path to follow. However, they may choose to do otherwise and create innovative uses. However, such uses have opportunity costs in terms of the effort needed to, say, customise the software. In turn, these innovative uses form the context for future rounds of social interaction. However, this is to make some assumptions about the nature of social action and those who participate in it, and so we need to consider what Archer has to say about agency.

A prime concern in Archer’s work has been to counter both individualistic, rational choice models of agency and the over-socialised accounts that produce only “cultural dopes.” Her argument is that we need to consider more carefully what we take agency to be, and she suggests a tripartite division into persons, agents, and actors. She starts with the embodied person, emergent from but not reducible to their biological constitution. These persons are strong evaluators, able to form and pursue value-laden projects and to reflect on their progress towards them (Archer, 2000a). Such reflection, however, takes different forms, forms which Archer (2003) relates to modes of internal conversation. We all use, she argues, internal conversation to reflect on our projects, but the forms which such conversations take differ, and in differing affect our relations with the objective world of structure and culture that we face. This is to take a different line from Giddens (1991), whose emphasis is on the knowledgability of all actors, and from others, such as Bourdieu (1990),

who place a stronger emphasis on the shaping of dispositions to act. Archer suggests that there are potentially three categories of reflexivity, all with different impacts on the degree to which persons will collide with structures. Some she terms “conversational reflexives.” These rely on others to complete their internal conversations, and so they rely on a community of others who share their background assumptions. These people will avoid conflict with structures by seeking to steer away from it. Others are “autonomous reflexives,” who conduct their conversations with themselves and take a strategic approach. These form the social actors whose pursuit of projects will lead them into collision with structures, leading to structural elaboration or change. The third category is that of the “meta-reflexive” — persons who reflect on their own reflexivity. They are, argues Archer, society’s conscience, evaluating structure and culture against a moral yardstick and finding them wanting. (Archer recognises a fourth category, that of the “fractured reflexive,” who for some reason is not able to conduct a satisfactory internal conversation and is so condemned to remain a passive primary agent, at the mercy of buffeting forces).

Whilst these conversations and evaluations take place at the level of the person, they are clearly shaped by the category of agency. For Archer (1995) this is a collective category, and is one partially constituted by involuntary positioning. By unequally distributed chance, persons are positioned in various categories of “primary agency” — as men or women, young or old, and so forth. In some cases, action is not needed to attribute primary agency — the simple fact, Archer argues, of an aging population has an influence on wider structures, regardless of whether there are common bonds or perceptions of them amongst the elderly. However, of course, such bonds can emerge and can lead to “corporate agency,” which is when a group of agents perceives a shared interest in joint action to further what they seem

to have in common. Such agency then shapes the persons who engage in it, by, for example, giving them access to differential resources of language with which to conduct their internal conversations (Mutch, 2004). It also forms the preconditions for the role of the actor. This is the individual engaged in social action, shaped and enabled by objective constraints. This could be the occupation of a particular role, the expectations for behaviour in which have been shaped by previous occupants and by the emerging body of knowledge and ideas about how to go on in such a role. These suggest ways in which the actor should go on. The person is, of course, free to do differently, but only if the costs for so doing are paid.

This, then, is a broad sketch of Archer’s bold and sophisticated arguments about the relationship between agency and structure. To recap, they make strong claims about the nature of both structure and agency. They posit the existence of structures as possessing emergent properties which have causal powers. Such structures form the context in which action takes place. That action is undertaken by strong evaluators, with intentions to act formed by their value-laden moral projects. Such projects may cause them to collide with existing structures, reproducing them or challenging them in the process. Structures provide strong situational logics of action, but the simple existence of either contradiction or complementarity in these logics has no necessary consequence for action. Whilst such an approach still insists on the “mutual constitution” of “the parts and the people”, it suggests that we need to hold them apart in order to explore the inter-relationship between them over time. The stress is on the construction of analytical narratives that pay attention to the unfolding of cycles of interaction between agency and structure over time. It should be clear that this is a different perspective on “mutual constitution,” but what implications does this have for the study of organisations, information, and technology?

CRITICAL REALISM: IMPLICATIONS

We need to repeat again the warning that critical realism is not about replacing or creating anew substantive theories of particular social domains. It is entirely compatible with the reworking of existing theories, using the ontological clarity that critical realism claims to offer. We also need to recognise that Archer’s work is a work of social theory, in which the objects of attention are societies in the process of change over large tracts of time and space. However, she would claim that her approach could be deployed at a number of levels of analysis; part of the challenge for those interested in the analysis of organisations, information, and technology is to show how this might be done. It starts, argues Cruickshank (2003b), through the construction of domain-specific meta-concepts through the immanent critique of existing bodies of work. It is not the purpose of the present argument to construct such concepts, nor is there the space for such an endeavour. However, it is possible to point to some avenues for exploration. There have already been some rather limited initial forays, but it should be clear from them that the enterprise is in its infancy (Ackroyd & Fleetwood, 2000; Cruickshank, 2003a; Lopez & Potter, 2001). Two substantial bodies of work which offer material for these endeavours that are worthy of further review are labour process theory and the new institutionalism. A wide body of work has been produced under the stimulus of labour process theory, initially inspired by Braverman’s (1974) deskilling thesis, but often departing far from his original concerns. From this work has emerged the current focus on critical management studies, as well as much other valuable work on the nature of organisations. What unites much of this otherwise very disparate work is the focus on conflict and power in organisations. In recent years much of this perspective has been brought to bear on the expanding area of “knowledge management” (Prichard, Hull, Chumer, & Willmott, 2000). An example that

has considerable relevance for those exploring information and technology in organisations is the careful exploration of the impact of organisational politics on the deployment of Lotus Notes in a pharmaceutical company presented by Hayes and Walsham (2000). This is of importance when set against much of the literature on information use in organisations, when the context, as in Choo (1998), is only lightly sketched in and is simply seen as the placeholder for individual behaviour. However, for many of the excellent empirical studies emerging out of this critical tradition, the context is largely confined to organisational boundaries, with the broader social and cultural context being little explored. If we wish to seek examples of bodies of work that could potentially tie organisations more tightly into their broader context, then the work of the new institutionalists might be of some interest.

The new institutionalism in organisational analysis is a broadly North American phenomenon, with its roots in the rejection of rational choice models (Scott, 2001; Powell & DiMaggio, 1991). This gives it something of a shared agenda with some of Archer’s (2000b) concerns. What is also interesting is the way that in some incarnations it is concerned with relating what happens in organisations to broader forces, particularly in situating action in the context of taken-for-granted understanding about appropriate forms for action and structure. The problem is that in this endeavour, such forces become all powerful and the organisation becomes reified into a unitary body whose actions are largely determined by these taken-for-granted assumptions (DiMaggio, 1998). From the perspective of Archer’s morphogenetic approach, the problem is an excessive focus on culture, with institutions being conceived of as cognitive constructions shorn of their material and social dimensions. These forces are then given excessive weight, in an example of what she would term “downwards conflationism.” The space for agency, both within organisations and on behalf of organisations, is

radically reduced. Such criticisms are articulated by many who work within the parameters laid down by the tradition, notably in recent years by Lounsbury and Ventresca (2003) in their calls for a “new structuralism.” Whilst we might argue that any form of structuralism is a dangerous path to follow, the resources presented by Archer would seem to be valuable for these internal critics; in turn, the arguments presented by these critics are of value in suggesting some elements of a distinctly critical realist approach.

One concern is that, broadly speaking, these approaches give relatively little weight to the inter-twined problematic of information and technology. Archer, for example, has barely anything to say about technology, save for a brief mention in considering theories of post-industrial society (Archer, 1990). However, her approach of analytical dualism based on emergent properties seems to fit well with the perspective elaborated by Andrew Feenberg in his *Questioning Technology* (2001). Feenberg’s work appears to have little impact in our domain, judging by the paucity of citations, but he too starts by recognising the merits of accounts based on constructivist approaches. However, these, he argues, neglect to place their findings in a broader political context. Feenberg, as a political philosopher working in the tradition of Critical Theory, is anxious to provide an account which situates technology in a broader context in order to further a project of democratising communicative practices (Feenberg, 1991). Now, we might recognise a wide range of problems with this project, particularly its reliance on Habermasian idealism, but for our current purposes, the interest is in Feenberg’s account of the nature of technology, in which he argues for a two-level model, which can be recast in the form of analytical dualism. In this case, what is important is to pay equal attention to the constitution of technologies and their implementation in practice, which can be best done by holding the two apart. For Feenberg, the two moments

are “primary instrumentalisation”, which has to do with the constitution of the artefact, and “secondary instrumentalisation,” which has to do with realisation. For each, Feenberg suggests a number of attributes.

For the process of constitution, Feenberg suggests that there is a process of the decontextualisation of some features from their original context so that they can be integrated into a technical system. This depends in turn on reductionism, in which “de-worlded things are simplified, stripped of technically useless qualities, and reduced to those aspects through which they can be enrolled in a technical network” (Feenberg, 2001, p. 203). This enables the object to be considered as an autonomous one, subject to technical laws. This then gives the artefact its seemingly purely technical quality; it has been rendered as such by a process which returns it back to the world as seemingly being not of it. However, in order to be part of that world again, the artefact has to be part of a social process that is more familiar to accounts given from, for example, actor-network theory, with Feenberg using terms such as “enrolment” to construct his account of realisation. For example, he notes:

“To function as an actual device, isolated, decontextualised technical objects must be combined with each other and re-embedded in the natural environment. Systematisation is the process of making these combinations and connections, in Latour’s terms, of ‘enrolling’ objects in a network.” (Feenberg, 2001, p. 205)

He also suggests moments in this process of mediation and concretisation. In mediation, ethical and aesthetic considerations supply new qualities to the technology which help to accommodate it to the new context. In concretisation, the technologies are combined with working practices to form new ways of working — ways of working that are clearly a prime concern of those working in this

Concerns with “Mutual Constitution”

domain. Feenberg’s approach is then an attempt to combine what we have learned through processual views of technology and a concern with the broader context. From the perspective of critical realism, the concern is not with the account of technology, which seems helpful, but with the legacy of Critical Theory. Here again, the ideas of Archer can form a more robust view of structure, but Feenberg’s work provides resources which could help to repair the gap caused by the lack of consideration of technology. The importance here is in the emphasis on both the objective character of the technology as it appears to the user and the potential for reinterpretation in the course of social action.

CONCLUSION

I have argued that ideas derived from critical realism, and in particular the morphogenetic approach of Margaret Archer, have a considerable amount to offer students of organisation, information, and technology. Whilst such ideas start from the premise that it is human activity that is central to the creation of society, they offer a better approach to the intertwined relationship of information and technology than rather vaguer notions of “mutual constitution.” They do so by offering a stronger conception of structure than, for example, Giddens. By using the notion of emergent powers and stressing the centrality of time, they draw a stronger picture of structure and culture, forming an objective context that humans face in their engagement in social action. However, persons can choose — based on their strong evaluation of their personal projects as value laden — to confront or shy away from such structures, although they cannot avoid their implications entirely. As agents, such persons are placed involuntarily in particular positions, positions which shape their interests and resources. Deploying these resources as social actors, they

can act in ways other than their interests and the logic of their situated action would suggest, but only if they are prepared to incur the opportunity costs of their actions. Such is only a brief sketch of the richness and complexity of these ideas. It needs to be stressed that ideas such as these are still under development and elaboration in their home domain of social theory. Their application in the realm of organisations is in its infancy, but such an application is not a question of starting from scratch. Rather, I have tried to point to some existing ideas and approaches which would form a part of any more fully formulated perspective. The work of formulating such a perspective continues, but what can we say at this stage that it offers students of information and technology?

At a very simple level, we could argue that more attention to these ideas would help in sensitising researchers to certain aspects of context that they ought to be aware of. The conceptual clarity offered by the stronger sense of structure would seem to gel better with the way that researchers seem to conceive of structure in practice than notions drawn from Giddens. However, theories also carry with them logical entailments that go further than sensitisation (Stones, 1996). For critical realism the aim of research is the uncovering of the causal powers that are at operation, albeit that in the human domain we would express these as tendencies rather than as laws. We would also be tentative in our approach, recognising that our conclusions, in open systems, can only be corrigible and provisional. However, we would lay a particular stress on the importance of time. To construct an analytical narrative which seeks to explain the tendencies at work, we need to explore a sufficient stretch of time. A criticism of much work that focuses on implementation would be the timescale of the research. This would be in two aspects. One would be that the period examined before the particular focus of the research is relatively short. From the discussion above, it is clear that this period needs to be

long enough to be able to appreciate the shaping of the context that action takes place in. Secondly, insufficient attention is often paid to the period of social action itself and to the subsequent structural elaboration. Often this is because the pace of change at different levels of analysis is compressed, with the impression being given that taken-for-granted social practices change at the same pace as organisational routines (Barley & Tolbert, 1997). Social realism can help us here with its notions of stratified reality and careful attention to definitions. However, even at the level of situated action at the micro level, our analyses are often too quick to conclude that a particular instantiation is a “success” or a “failure,” when we are only looking at a brief snapshot. Given that we are aware of the plasticity of technology and the creative ability of users, albeit it within more or less strong contexts, we need to allow time to unfold to be able to see if what we are recording are durable effects or mere growing pains.

Chapter 7.11

Emotional Digitalization as Technology of the Postmodern: A Reflexive Examination from the View of the Industry

Claus Hohmann

Bergische Universitaet Wuppertal, Germany

ABSTRACT

This article introduces emotional digitalization as a phenomenon of future information systems. It argues that emotional digitalization is a progress that will lessen the gap between technology and humanity, as well as between computer and man. The author develops and verifies his assumption besides theoretical references arising from his experiences with the information technology within the BrandLand Autostadt.

INTRODUCTION

“The inmost force/which binds the world, and guides its course“ is no longer only a philosophical thought or religious voice, as in Goethe’s “Faust,” verse 382-383. But they are also not just bits and bytes, cable and monitors. The connection of these elemental substructures of modern civili-

zation first shows where the path must go. The functional elements of our daily life must subordinate themselves to our principles of thought and aesthetics. And they must also appeal to the people in an aesthetic, as well as communicative and sense. The modern, as a synonym for freedom and democracy, could thereby obtain a new dimension — to become an ethical entity. The technology of the third millennium must also define the new standards.

As the postmodern breaks down the barriers between art and pleasure, it breaks through the wall between technology and emotion. The aesthetic sensation from looking at, for example, a corporate homepage, accessible to all, suggests a fundamental change in the meaning which will be attributed to the presentation of technology today, when in direct comparison with the functional-rationalistic views of modern, purely informational Web sites. The Autostadt, Volkswagen’s new communication platform for marketing and

culture, is on several levels a culmination of different developments, which operate under the term “postmodern” and therefore contribute to theoretical discussion.

This radical change of the basic conditions of our life has put us on a path which will be indicated by a catchy, yet imprecise phrase: “post-modernity.” The rationalization of the modern is being counteracted by the pluralization of our culture and humanization of technology, which was demanded, but not achieved, by the modern (Giddens, 1995). With Anthony Giddens, whose critique is applied here, we regard “posthistory” as “a succession of immanent changes,” in order to face the prevalent conceptual dilemma (Giddens, 1995). One focuses the view to information technologies and sees that the humanization has an effect, particularly on aesthetics. And here alongside the desired effects lies a formidable danger: does IT go in the same ambivalent direction as the classic technologies, and will it give the manipulators of this world a leg up?

THE WORLD TODAY AND TOMORROW

The core problems of the industrial society (saturated markets, over-indebtedness, mass unemployment, etc.) demanded drastic mental reorientation and have at the same time uncovered innovation potentials. Spirituality and mental dimensions begin to replace the abstraction — the dream becomes a legend. The new technologies of the third millennium must also surrender to these new demands. With help from the most current technologies, we learn to tell stories. Contrary to the findings of Lyotard from the end of the great narrations of history¹, one could also speak about a fragmentation, which transfers this narration from people to technology, especially the digital technologies. With a new neologism, one speaks of the necessity of a “homuter society,” which is in a position to propitiate the people with (information)

technologies (Haefner, 1984). Haefner uses this term freely in order to verbalize his skepticism of the possibilities of future developments, which was obtained during the Cold War. However, we could also read it with a conscious hope.

Thus, a great possibility of the future lies in the development of technologies, stimulating creativity and inspiring thoughts. For example, the aesthetic layout of an intranet and the constantly used user interfaces eases the employee’s accessing of the media, prevents fatigue from using information and inspires emotions in the exposure to IT in everyday work. The effect is to state a higher degree of identification to the corporation, a more emotional, eventually better relationship to the employer and, ultimately and ideally considered, an increased labor efficiency accompanied by increased happiness. In this manner, IT of the postmodern can manage the reconciliation of the contradictions between technology and art, which are unimaginably present in the modern.

The IT of the present has the function of supporting the thoughts and actions of the individual and not to automate their work in order to eventually replace them. Comparably, the focus should be put on the installation of technologies that will save time. IT must be used to support work processes in order to optimize the concrete procedures and reduce the time requirements. Networked, Web-based systems with access points for all employees could be a first step. Important here are the user interfaces, which are adjusted to the work processes, aesthetically configured, self-explanatory, intuitive and can be understood spontaneously, thereby helping save time and increase room for further assignments.

The same exposed meaning, which electrification and mechanization had for the modern, could be digitization and computerization in the postmodern. The unreality, which challenges our terminology and understanding in increased measure, seems to be a display of something new in relation to the more palpable technological ad-

vances of the modern. We see, in this transition of information technology, a movement for a new understanding of our time, which can be labelled as “postmodern,” which is in this sense, in the shadows of abstract, fragmentary, and simultaneously emotional media. Thereby, no clearly differentiated epochs or outlined theories should be suggested — it should continue to deal with a change in our perception and “Lebenswelt.” In doing so, we understand postmodern as the “conscious of a socio-historical transition”² and not as a “meta-historical category” of each epoch.³

One of the basic requirements of this transition is the change from a technology that replaces the people to a technology that supports the people because they “understand” it. Thereby, it is imperative to restore various elements of IT, from management decisions and business processes down to connections with trade and commerce, to an original understanding of “experience.” The anchor of the complicated, indiscernible world in tangible lives can show in this manner how postmodernity can be made visible. The metaphor can be helpful to establish the meaning behind the experience.

POSTMODERNITY AND IT

The implementation and deployment of aesthetics in the technological area is a characteristic of the realization that IT is anchored fast in our world and no longer accepted as a modern achievement of an exceptional position outside our consciously experienced everyday life. This insight allows changed societal requirements to be inferred, but what about the above meaning is postmodern? Important is our understanding after the liberation from a conditioned past in a (self-) conscious act. As the technologies of modernity stand out due to their distinctiveness and are clearly contrasted with the people and their emotional world in which they coldly, precisely, and rationalistically fulfill

their duties, the IT of postmodernity goes down a different path.

With the integration of aesthetics and emotion, the digitization completes the circle and appears as a new quality. This is only successful because IT has already begun to reflexively examine and question itself and its success, and not in the least can be measured as a clearly calculated result of other factors. A basic requirement, therefore, is the development of technology that supports activities with which people are discontent as a result of the holistic pursuit of new goals, with the focus on the people. IT must be there for the people, not the other way around, and it must be aware of this. It must be noticeable, but not necessarily visible.

When the technologies in our new world function imperceptibly and no longer distort the view of the contents from the surface, new space for aesthetics and emotion is created. Technological progress can and must give the people more time, space and capacity for creativity and to unleash their imagination to make the fundamental, structural change perceptible and understandable⁴. In sociological terms, postmodernity seems to accompany the departure from middle-class feudalism. Information technology, which has been more or less privatized by the personal computer (PC), can also lead to further democratization and contribute to free communication, but it can also lead to chaos by making corporations unmanageable.

Thus, in the end the various technology images of “two cultures,” which are “Lebenswelt”- and system-orientated, according to Charles Percy Snow, should be brought into unison⁵. But in order to accomplish this, technology will be considered as a social phenomenon, with the help of metaphor and symbolization⁶. The symbols must orient themselves on the life-world, in that they become a part of the life-world. Just as modernity, with its dichotomies and ambivalences, can be said to be a failure in dialect, it is conceivable that the discussion in the postmodern, founded in the defi-

inition of difference⁷, will reveal endeavors leading to the harmony between the various positions. Contrary to Lyotard's assertion, unanswerable contradictions, which lie in the open availability of information, could strengthen the democratizing tendencies of information technologies⁸.

WITH THE EYES OF INDUSTRY

With the beginning of the new millennium, the world changes its vision. The blind trust of technology has a conscious practice of giving way to its possibilities. For example, Volkswagen's new corporate platform culture and marketing-the Autostaalt allows this change, which is currently being experienced by industry and society, to be precisely identified. With this example, we want to discuss the topic of postmodernity from the view of information technology, in order to stimulate further thoughts from the industry. Progress is nowadays something completely different, as it questions itself. Reflexivity and self-criticism take the place of the unconscious self-awareness of modern advances. Technology along with the information technology of modernity has undertaken a rapid development, which leaves the people and their imagination helplessly behind. In the physical sense, it is completely impossible to grasp IT, and an attempt at understanding it requires shifting the focus from a purely technical, modern-rational meaning to the interpersonal: addressing emotions via aesthetics, design and a process-logical functioning.

In practical industrial terms, the example of a "gated community," such as the Autostadt, is used here to illustrate this transformation and discuss postmodernity in the digital light of information technology⁹, in order to stimulate further ideas. The Volkswagen Group's Autostadt presents itself as a holistic concept, which includes all details in a complex structure: "There are no details in the execution"¹⁰. The mass tourism and amusement parks shape the leisure time culture of moder-

nity, but the Autostadt vastly transcends this. It integrates, specifically with the involvement of IT, the science of the world of industry with the goal of getting through to the people.

The privatization of technology has extended continually since the 1980s the influence and impact of IT to all areas of life, but especially to the areas of personal computers and music and television technologies, and also to all other levels of everyday life. With the Autostadt, the attempt is made to take on these societal changes and harmoniously unite them. In the Autostadt, the ubiquity of IT starts with the central purpose of the corporation, namely the delivery of new cars from the Volkswagen Group to its customers. The delivery process is completely supported by digitization. From the ordering to the handing over of the new Volkswagen to the customer, IT technologies are deployed to support the process. Already in the sales dialog, the employee, by making use of online applications, is enabled to have a virtually intimate discussion, having a positive impact.

Also presentations, such as the LupoShow (a dramatic laser show demonstrating the internal functions of an automobile via cross-section model), the SunFuelLab (a plant computer, which generates personally assigned biofuels) or the NavigationsSpiel (a virtual Labyrinth), are entirely digitally controlled. However, even internal support processes such as the lighting controls in the buildings and at events, the watering of the on-site parks and the digital menus in the restaurants are based on IT technologies and displayed systematically. In all of these areas, IT supports the employees, as it is deployed in order to assist them in effectively accomplishing their work and saving time.

Naturally, this all comes with limits: the Autostadt has not realized certain global interactivity, and their video arts suggest only a portion of the "Iconic Turn" of these years¹¹, but even with the example of the Autostadt, it's clear that the practical IT supports a form of the philosophy of

imagery. The Autostadt is thereby also active in the area of bringing to life aesthetic contents in the framework of its marketing scene, and in this lies a threshold experience.

Entities such as the Autostadt must have come into existence, not as a storm of individual thoughts, but rather as a logical consequence of the mentioned societal changes. The Autostadt is then an answer to the liberation of the postmodern individual, unique to the VW Group, and thereby not a blueprint that can be taken as a model for others. In doing so, what can the technology accomplish?

The industry serves here as an aesthetic-philosophical realization, and in the case of the Autostadt, the first deliberate BrandLand. The societal developments have encouraged, if not called for, the opening of more subtle theme parks. Others have just been, or are yet to be, opened: Daimler-Chrysler, the BMW-World and Dr. Oetker, just to name a few from the nearby surroundings. With the help of IT, the economy of aesthetics and art can be greatly improved.

The interfaces of the IT, acting as the window to foreign worlds, allow a new “cultural relocation” in the sense of “immobile mobility”¹², which places the people back in the focus. This liberation of the realm of reality expands, in a virtual manner, the consciously experienced world of the individuals, which would be impossible without IT. The people learn, experience, fulfill desires (and generate new desires) and expand their horizons via purposefully installed, yet unconsciously experienced, IT. The IT gives the phenomenology of perception¹³ a new, different touch. Multiperspective observation possibilities allow a concrete regard to objects and forms of interactivity. In this way, IT allows us to consider something from all sides, without forcing us to change our, or its, location.

The Autostadt is also a symbol for a trend. Corporations today present themselves differently. But what exactly is the Autostadt?

THE AUTOSTADT PROJECT

At a crucial interface, residing between the company and society, and with the old factory in the background in order to illustrate the coexistence of industry and BrandLand, the Autostadt is presented as a landscaped park with integrated, individually configured brand pavilions, where nature and technology are connected in an aesthetic manner so that the relevance of the corporate values are consciously absorbed by the people via the polyvalently applied presentations. The fundamental concept does not view art as a decorative end in itself, but rather as “a link between designed environments and the visitor experiencing them”¹⁴.

*The borders between art and presentation are blurred in this regard. Culture, understood as a variable system of seeking truth and orientation relating to a variety of artistic forms of expression, education, and living, is finally the added value, which allows the Autostadt to obtain visitors. Thereby, it shows itself as an innovative cultural platform in a new understanding of the marketing of experiences and events*¹⁵.

In this context, great significance is given to the development of innovative technologies, as the visible, evident use of digitization would inevitably undermine the functioning of the entire concept of the Autostadt based upon art and aesthetics. The organizational level of the Autostadt has therefore been deliberately made invisible and moved to underground tunnel systems and cable ducts. This form of understatement certainly gives the nearly ambitious technology a poetic touch. And just one step further are the Web-based information systems of the Autostadt with aesthetic aspects taking priority over self-portrayal. User-friendly IT gives the individuals freedom. Obvious complexity, by contrast, puts them in chains.

The glass auto-towers with their transparent aesthetics give the sublimity back to the

technology and astonish the observer, yet their architecture, infused with aesthetics, prevents fright from their size, which large technologies commonly provoke. And in the park, the straight line, as the enemy of everything living, is already conceptually forbidden. Intuition and emotionality operate in the place of regularization and rationalization. The Autostadt triggers as the identification location of a momentum, that which is required of good advertisements (Jung & von Matt, 2003). In doing so, it takes in the danger of a novel logo-centric aberrance, as the brand, for which the logo is emblematic, outshines the product (Klein, 2001). What happens here is the becoming of a metaphor. The BrandLand, with its architecture, becomes a metaphor for the contents, the values of a corporate group, and simultaneously for the manner in which the underlying IT will be deployed in the postmodern.

The implementation of these requirements in the framework of the superior philosophy of a customer-oriented, personal technology seems to be a success. With examples such as the CCC (Customer Care Center) and the IAS (Integrated Autostadt System), the changed awareness with regard to the integration of technology in the personal and organizational relationships allows itself to be realized. It becomes clear that the path to a new, more emotional technology is possible and necessary. The Autostadt takes the first important steps on this long path. Beginning with the installation of networking and dataflow, which are not visible anywhere on the grounds of the park, to the artistic arrangement of the exhibits, which utilize the technical possibilities of imagery, sound and movement without seeming intrusive, and even with the Internet presence, which gives preference to aesthetics over self-presentation, technology gains acceptance and meaning in the service to ideas and content.

THE DIGITAL HEART: INVISIBLE NETWORKS

Embedded in a concept of future-oriented service is where the heart of the Autostadt beats. The “digital heart” is thereby probably only a paradox. Technology no longer presents itself, but rather it puts itself in the service of the people and subordinates to them. Digital technology, originally considered to be cold and sober, should become communicative and people-oriented, only to appear on the surface when necessary. This new “warmth” of the digital world can be transferred from the visitor to the relationship to the Volkswagen Group, and serves as a branding strategy based upon emotions. This is related to the paradigm shift in which technology is expected, regardless of its importance, to adapt to the people and act in the background like a good butler or referee.

The beautifully maintained park should have a convincing effect on the guests, positively touching the senses. Together with the architecture, it subliminally conveys an important message of the corporation; perfection. Thereby, it should convey a constant ability to renew itself. This breaking-out of the limits of style has the goal of higher quality and better service: the guest should feel well taken care of, safe and understood. But in order to ensure that this “emotional work” produces the “right” emotions, the IT systems are trusted with the responsible task of ensuring that the customer is served flawlessly. As the computer, with its algorithmic, binary-coded thinking, simplifies the concept of rationality, IT in the postmodern society can once again combine information with emotion and come across with a humanized approach (Glaser, 1994). “The chip-revolution,” says Glaser, “with its algorithmic, binary-coded thinking, made the concept of rationality radically one-sided” —with the danger of dehumanization, but yet the postmodern society still combines information and emotion (Glaser, 1994).

With the example of the Autostadt, it is recognizable that steps for a realization of the postmodern are just passable in the area of IT. Whereas the postmodern is concerned comparatively little with reality, the people-conscious deployment of IT shows that the path to a new, more emotional technology is possible and necessary. Endeavours such as the Autostadt take the first steps on this long path. To a far greater extent than in previous decades, today one's wishes, demands and requirements constitute the parameters of successful process engineering.

The human aspect, particularly in such a service-oriented environment, assumes absolute priority. Thus, the Autostadt is not to be understood as a demonstration of technology; but rather as putting itself in the service of, and subsequently subordinating itself to, the people and the demonstration. In other words, without IT much of the Autostadt would not have been realizable, and thereby cannot be dismissed, but still presents itself in a gentle understatement. Due to this fact, it is explainable why the CTO (Chief Technology Officer) of the Autostadt is not an IT-specialist, but rather pursues psychodynamic and organizations-logical aspects in the exposure of IT in the Autostadt and thus sees his emphases in this area.

IT AND POSTMODERNITY IN THE AUTOSTADT

The Autostadt is, as the communication platform of the Volkswagen Group, the actual location of direct dialog between the producer and the consumer, the meeting point for the VW Group and its brands. The values of Volkswagen and the delivery of its automobiles will be "staged" here. The "stylistic device" of the Autostadt is infused with emotions and the urbanistic overall concept is based on the paradigm "structure and event." Every square meter is staged, and nature and

technology meet in a dialog, which is significantly supported by IT.

The IT in the Autostadt constantly produces new, surprising, emotion-awakening effects. For this reason, it is correct to assume that the actual core process of the Autostadt is the "process of generating feelings," which should then be subsequently visualized. Based on its philosophy, the Autostadt pioneers new and surprising trails in the world of IT. A paradigm shift takes place, which can rightly be referred to as "emotional digitization."

The concurrence of park, buildings, exhibits, staff and events results in a unity of the main components of emotional stimulants at the Autostadt. The conveyance of perfection is an attribute for which most individuals strive. In this sense, the charisma of the park positively influences the senses and subliminally conveys an important message of the corporate group. The buildings are also in accordance, as they portray a measure of perfection. They are constructed as entirely modern and stylistic. The visitor discovers methods of construction which are seldom, if ever, to be seen in normal surroundings. Beside the perfection, a new effect develops: the progress, orientation to new pathways, and the ability to continually reinvent itself.

With images, metaphors and sequences, the corresponding philosophies of the brands will be conveyed in the individual pavilions, giving further impulses to the above characteristics. In addition, in the events, the impossible will often be made possible with style. Further stylistic devices are also present in the perfection and progress. The Autostadt would like to inform the customer of new trends, acting as the trendsetter for the corresponding impulses.

For example, the POIs (Points of Information) are central components of the information landscape, but in the Autostadt, the POIs are elements of the Lebenswelt. The highly complex network computer with its front-end software allows itself to be intuitively understood and operated. The

guests are not only using systems, but they are experiencing technology. The POIs approach the visitor and they adapt to the user's size and position. Direct contact with the touchscreen can be seen as a metaphor for human interaction with the invisible network of information technology. As "emotional engineering," this connection can be understood as a link between the complexities of IT, human gestures and aesthetics. The physically present technologies undergo an emotional exchange with the intellectual techniques to allow the visitor interactive comprehension.

We strive for understatement — that is how we see post-modern IT, which is what makes it possible to "produce" emotions in this context in the first place. Digital technology must be communicative and people-oriented. The complex system structure clearly shows the workload involved in making IT "invisible." How is it possible to control something that is nearly invisible? Or to state it more clearly, how is the Autostadt itself capable of identifying possible malfunctions at the earliest point in time? Solutions have been found for this. With the bidirectionally media control system "Creston," the presentations and the technology are systematically monitored. Thus the technology becomes self-referential.

All employees of the Autostadt have access, via PC workstations or central lounges for the Web-based intranet, to all information, e-mail and the Internet. The technology would better be described as "experienced" rather than "used." This proves that the possibilities of digitization can be used and exploited to prepare the visitor for what they will experience. The invisible, unobtrusive digital elements can help make sure people will not be forgotten, even in a technological environment. Even the demand of philosophy for avant-garde art "within scientific-technical modernization rationality" can only be fulfilled where technology creates space (and scope) for art and aesthetics.

THE FUTURE OF IT

Has postmodernity found its end in the attempt to unify its differences? Have we at least reached a new level of the postmodern, with our humanization-oriented technology? And we continue to ask: where will information technology go from here? We no longer pull levers, we push a virtual button on a touchscreen and in the real world a reaction follows; a lamp goes on, a door closes or a lawn sprinkler starts watering. The same fascinating moments offered by technology in its early mechanical stages are now being provided by virtual technology. Is modernity simply repeating itself on a higher, more abstract level, or is this the beginning of something new?

In the interactive worlds of virtual media, something like a metaphor crystallizes itself out of reality. Due to IT, we experience and learn things that would normally be far out of reach. And what comes along are the new medias demand and encourage a strengthened inclusion of aesthetics in our daily life, and as each is more unobtrusive, its effect becomes stronger. Thus, the success of IT lies in its inclusion in our daily life, which must take place without obstruction and recognition.

The Internet presence of the Autostadt connects a demand of aesthetics to the POIs. The design quality, in which both Web-based systems will communicate informative content and interactive elements, has already been awarded prizes from, among others, New York and Cannes. In an intranet, which is (regarding its public sister) conceptionally and aesthetically behind in nothing, the employees can inform themselves about all-important concerns of the corporation. Standards will also be set here, almost unnoticeable to the public.

The formative characteristic of this aesthetic demand is not the eye-catching distinctive feature, but rather the opposite: the enjoyable appearance, the pleasing control of the view and the (visual) self-explanatory function and order, which lie

behind the contents. These aesthetics in the simulation of contents is effectively “unmodern” in a cultural sense, as a principal departure from rationalization. The people experience IT, they use it subconsciously. IT, as a medium, will be internalized and no longer understood and perceived as a “machine,” a tool, or means to an end. IT will become a medium for emotions and information. The visualized aesthetics of virtual worlds serve in the same way as the aesthetic architecture in the Autostadt.

One could also see the Autostadt as a metaphor, but it was not planned this way. It is a frame of reference for the characteristics and symbols of the postmodern world (not only for the area of IT). Everything – the automobile, as well as the art – will be presented in a different, atypical context. The character systems interlock virtually, and what results is a BrandLand as a liminal space, an area of the threshold, a location of change and the intervention – the barely apprehensible space between the world, which causes a threshold experience of the senses. A location, where we can foretell the future, without being able to see it.

What remains? The IT has taken a significant step: it has become a production factor; it has retreated to the background of business processes, because an IT-networked implementation is the prerequisite for “the social dimension of processes.” The workforce can no longer continue to work autistically. Interdisciplinary qualities such as commercial knowledge and organization talent are vital, at least in strategically decisive positions. The supporting IT does not serve as only the acceleration of postmodern phenomena such as globality and mobility, but it also serves – in a far more readily available manner – as the bridge between the aestheticizing and emotionalizing of our everyday world!

But it will not stop here. It is conceivable that IT in future mechanical engineering will not exist as a purpose in its own right, but will produce tools (systems) for the generation of products, to transfer knowledge. This forces everyday aspects back

in the place of revolution, and finally integrates IT permanently into our postmodern world. In spite of all the risks of abuse and autonomy that accompany IT, the possibilities are there.

Chapter 7.12

Optimality–Theoretic Lexical Mapping Theory: A Case Study of Locative Inversion

One-Soon Her

National Chengchi University, Taiwan

ABSTRACT

Locative inversion verbs seem to share the same argument structure and grammatical function assignment (i.e., <th-OBJ loc-SUBJ>) cross-linguistically. This article discusses the nature of argument-function linking in LFG and demonstrates how the Lexical Mapping Theory (LMT) rendered in Optimality-Theoretic (OT) terms, where argument-function linking is governed by universal violable constraints that consistently favor the unmarked function, accounts for locative inversion straightforwardly. Within this OT-LMT, locative inversion is due to a universal morphosyntactic constraint, and language variation in locative inversion is due to the difference in its relative ranking. This account also offers a potential explanation for the markedness of the locative inversion construction.

INTRODUCTION

The locative inversion construction, as shown in Figure 1, cross-linguistically has similar characteristics in discourse information packaging, which allows the more familiar information to precede the less familiar information (Ackerman & Moore, 2001b; Birner, 1994; Cheng, 1983; Tan, 1991). Between the canonical construction in Figure 1a and the inverted form of 1b, along with the switch of focus from the locative to the theme, is the change in syntactic function assignment. An example from Chinese is given in the figure. The theme role in Figure 1a is assigned the subject function and locative an oblique function; the canonical linking is, thus, <th-SUBJ loc-OBL>. In the inverted Figure 1b, however, the locative is the subject, while the theme now occupies the object position (Her, 1990; Huang, 1993; Huang & Her, 1998; Tan, 1991).

'On the stage appears to be sitting many people.'
- b. Tai-shang you zuo-zhe henduo ren ma?
stage-top YOU sit-ASP many person Q
'Is it the case that on the stage was sitting many people?'

This <th-OBJ loc-SUBJ> argument-function "mismatch" was first identified and convincingly argued for in locative inversion verbs in Chichewa (Bresnan, 1994; Bresnan & Kanerva, 1989) and in English (Bresnan, 1989; Tan, 1991). Examples in Figure 2 are from Bresnan and Kanerva (1989).

The subjecthood of the inverted locative phrase tai-shang "stage-top" in Figure 1b is evidenced by the fact that it is a bare NP and occupies the usual position for subjects. This is further confirmed by the usual raising test. As shown in Figure 3, tai-shang "stage-top" is, indeed, the raised subject,

while the “demoted” theme in the post-verbal position, also a bare NP, must be recognized as the object (see Figure 3).

Chinese data thus further confirm Bresnan’s (1994) observation that cross-linguistically, locative inversion verbs share an identical argument structure <th loc> and the function assignment of the canonical <th-SUBJ loc-OBL,> in Figure 1a and the inverted <th-OBJ loc-SUBJ> in Figure 1b. This article aims mainly to account for the syntactic assignment of the argument roles in locative inversion verbs.

In any syntactic theory that aims at characterizing UG, it would be a considerable compromise to simply leave the syntactic assignment of argument roles to lexical idiosyncrasies (Pesetsky, 1995). This article focuses on how the syntactic assignment of argument roles is accounted for universally in the syntactic theory of Lexical Functional Grammar (LFG). This article is organized as follows. The first section discusses how argument-function linking is accounted for by the lexical mapping theory (LMT) in LFG. We will also demonstrate how certain versions of this theory do not account for the locative inversion data from Chinese and English straightforwardly. Furthermore, we will demonstrate how the theory can be improved upon for more consistency and computational efficiency. In the second section we propose a revised LMT formulated as declarative constraints in Optimality-Theoretic (OT) terms. The locative inversion data from Chinese is then accounted for in the third section. The fourth section consists of a discussion on the implications of this study, and the fifth section concludes the article.

The goal of the article is, thus, two-fold: (1) to come up with a universal lexical mapping theory based on violable declarative constraints in OT terms; and (2) to account for Mandarin locative inversion within this comprehensive OT-LMT.

LEXICAL MAPPING THEORY

LFG mainly posits three distinct, parallel planes of grammatical description: the argument structure, the functional structure, and the constituent structure (Bresnan, 2001; Dalrymple, 2001; Falk, 2001). The argument structure, or a-structure, consists of the predicate’s thematic and non-thematic argument roles, while the constituent structure, or c-structure, represents the configurational structure, which is the surface structure and allows no syntactic derivation. The functional structure, or f-structure, is the locus of grammatical information, such as grammatical functions (e.g., SUBJ and OBJ), case, person, number, gender, and so forth. The linking of these structures, each with a distinct formal nature, is constrained by correspondence principles. The lexical mapping theory (LMT) is the UG component that constrains the linking between a-structure roles and f-structure functions. The f-structure thus can be viewed as the interface level that links the a-structure and the c-structure. An argument role thus is linked to a grammatical function in the f-structure, which, in turn, is linked to a certain c-structure configuration. The lexical mapping theory (LMT) is the subtheory within LFG, which constrains the syntactic assignment of a-structure roles.

The pioneering work by Levin (1987) started the exploration of more principled accounts to replace the earlier stipulated function-changing rules in LFG. The first comprehensive formulation of LMT was proposed in Bresnan and Kanerva (1989). Since then, even though the essential underpinning assumptions have remained largely stable, the issue of argument-function linking, especially its precise formulation, has yet to be resolved (Butt & King, 2000). A number of different versions of the theory have been proposed (Ackerman, 1992; Ackerman & Moore, 2001a; Alsina, 1996; Bresnan, 1989, 2001; Butt, Dalrymple & Frank, 1997; Her, 1998; Huang, 1993;

Zaenen, 1987), among others. A review of these existing versions is clearly outside the scope of this article¹. Instead, we will outline mainly the version that seems to be the most widely circulated, found in Chapter 14 of Bresnan (2001), which, in turn, is based largely upon Bresnan and Zaenen (1990)².

The Theory of A-Structure

Conceptually, LMT consists of two components: the theory of a-structure and the mapping constraints. LFG assumes a universal hierarchy among a-structure roles in terms of their relative prominence in the event denoted by the predicate. This scale descends from the most prominent agent role to the least prominent locative role (Bresnan & Kanerva, 1989, 1992)³ (see Figure 4).

The most prominent role in an a-structure is called the “logical subject” and is designated \hat{O}

(pronounced “theta-hat”). In Figure 5, the two-place predicate *break* requires two argument roles in a-structure, agent (also \hat{O}) and theme; the three-place predicate *put* requires agent (again the \hat{O}), goal, and theme. Roles in a-structure, by convention, descend in prominence according to the thematic hierarchy.

Grammatical functions (GFs) that can be linked to argument roles are called argument functions. In Figure 6, LFG distinguishes argument functions (shown in bold) from non-argument functions (in italics).

It is important to note that in structure-oriented theories, such as Transformational Grammar (TG) and all its later incarnations, notions such as subject and object are secondary and are derived from structural configurations. In contrast, in relation-oriented theories, such as Relational Grammar (RG) and LFG, these are primary notions in syntax. However, in LFG, argument functions

Figure 4. Thematic hierarchy

agent > beneficiary > experiencer/goal > instrument > patient/theme > locative

 b. *give* < x y z > (x = ag, y = go, z = th)

Figure 6.

TOP FOC SUBJ OBJ OBJ_θ OBL_θ⁴ ADJUNCTS

are further decomposed by two binary features: [r] (whether the function is restricted to having an argument role) and [o] (whether the function is objective) (see Figure 7).

In this system, each argument function is composed of exactly two features and natural classes can be identified, as shown in Figure 8. Furthermore, assuming the minus feature to be the unmarked value, a markedness hierarchy also can be obtained.

Similar to the intrinsic classification of argument roles in Bresnan and Kanerva (1989), Bresnan (2001) assumes that the underlying lexical semantics partially determine the syntactic assignment of different event participants. The universal classification shown in Figure 9 is

proposed to capture these predetermined choices of grammatical function assignment.

Cross-language variation in the syntactic assignment of a-structure roles is thus subject to the above universal constraints. The agent role, for example, as a non-patientlike role, is classified [-o] by Figure 9c and is thus not associated with OBJ canonically. Patient and theme roles, with the [-r] classification, are associated canonically with either SUBJ or OBJ. Under the assumptions in Figure 9, each role in the a-structure is assigned one and only one feature for syntactic function assignment, as morpholexical processes are not allowed to add syntactic features. Language-specific morpholexical operations are allowed, however, to alter the “lexical stock” of an a-structure by

Figure 7. Feature decomposition of argument functions

- c. other semantic roles: $\theta \rightarrow [-o]$

Figure 10. Passivization

adding, suppressing, or binding thematic roles (Bresnan, 2001). Passivization, for example, suppresses \hat{O} , the most prominent role, from syntactic assignment (see Figure 10).

In summary, the theory of a-structure renders the argument roles a given predicator requires into an a-structure representation, where roles are listed in a descending order in prominence, and each role is assigned exactly one feature specification for function assignment. The second component in LMT (i.e., the universal set of mapping constraints) then determines exactly which GF each role is assigned to.

Mapping Principles

Argument-function linking is subject to certain universal constraints; otherwise, each argument role is freely mapped onto any and all GFs with compatible features. Bresnan (2001) proposes the principles shown in Figure 11.

Figure 11. Mapping principles (MPs)

- a. Subject roles:
 - (i) $\hat{\theta}_{[-o]}$ is mapped onto SUBJ when initial in the a-structure; Otherwise,
 - (ii) $\theta_{[-r]}$ is mapped onto SUBJ.
- b. Other roles are mapped onto the lowest compatible function in the Markedness Hierarchy.

Two more well-formedness conditions (WFs) are needed in addition to the mapping principles in order to further constrain the non-deterministic argument-function linking: the function-argument biuniqueness constraint and the subject condition:

- Function-Argument Biuniqueness. Each a-structure role must be associated with a unique function, and conversely.
- The Subject Condition. Every predicator must have a subject.

The function-argument biuniqueness constraint ensures a strict one-to-one mapping relation between roles and functions. Computationally, it forces a deterministic assignment to an “unattached” GF between the two GFs with which a role is compatible. The subject condition serves the obvious purpose to ensure that one role in a-structure must be mapped to SUBJ. This condition also forces a deterministic choice when a role’s syntactic assignment is compatible with SUBJ and some other function and when all other roles in the a-structure, if any, are incompatible with SUBJ.

We demonstrate how three different types of verbs receive correct argument-function linking in the LMT just described. An unaccusative verb is given in Figure 12, while an unergative verb is illustrated in Figure 13. A typical transitive verb is given in Figure 14.

Improvement to the Conventional LMT

There are several areas at the theoretical level upon which the conventional LMT may be improved. First, the uniform underspecification of each role with exactly one syntactic feature can be relaxed to allow the formalism to be more expressive, yet without compromising its formal power. This classification scheme also may be too rigid in that it does not allow the possibility of agentive objects, which have been observed in several languages (Bresnan, 2001; Dalrymple, 2001). A desirable improvement to the theory is to allow such linking possibilities and, at the same time, be able to express the marked nature of such a linking as agent-OBJ.

As for the mapping principles, two disjunctions are observed. The first one is in the mapping principles of subject roles: a disjunction exists between $\hat{O}[-o]$ and $\theta[-r]$, each a stipulation for linking to SUBJ. In a more general theory of UG, it would be desirable not to include such function-specific linking conditions. Notice also the specification that $\hat{O}[-o]$ be the initial role in the a-structure. This principle thus must refer explicitly to the ordering in the a-structure⁵. The second disjunction is found between subject roles

and non-subject roles. For the former, a qualified role is mapped to SUBJ (i.e., the most prominent GF). However, on the contrary, non-subject roles must be linked to the least prominent compatible GF. A consistent principle for all roles would make a simpler and more general theory.

Finally, note that the Subject Condition in LFG states explicitly that every clause must have a subject. Similar constraints are also necessary in other syntactic frameworks; for example, the same is accomplished by the Extended Projection Principle (EPP) in Transformational Grammar and the Final-1 Law in Relational Grammar. However, as it often has been noted, such an inflexible stipulation may not be empirically accurate⁶. As cited in Ackerman and Moore (2001a), clauses may truly be without a subject (Babby, 1989; McCloskey, 2001). Bresnan (2001) thus hinted that this condition should perhaps be stipulated as a parameter. Again, ideally, a UG theory should be able to account for such subjectless clauses and their marked nature at the same time.

Assuming that the conventional LMT takes the same position advocated first in Alsina and Mchombo (1993) and does not allow morphological operations to add features, this version of LMT described previously also does not seem to account for locative inversion straightforwardly.

Figure 15.

Amei zuo zai tai-shang.
 Amei sit at stage-top

 stage-top sit-ASP Amei
 ‘On the stage is sitting Amei.’

‘sit < *x* *y* >’ (*x* = *th*, *y* = *loc*)
 SC: [-r] [-o]

 *O *S

As shown in Figure 16, the argument-function linking of <th-OBJ loc-SUBJ> in the locative inversion construction cannot be obtained, even though the canonical linking of <th-SUBJ loc-OBL,> is accounted for in Figure 16. Therefore, it would make sense empirically to allow morphological processes in the theory to alter syntactic assignments by adding features, as proposed in Zaenen (1987), Ackerman (1992), Markantonatou (1995), and Her (1998, 2003). The default locative classification employed by Bresnan and Kanerva (1989) and Bresnan (1989), which assigns loc[-r] when th is focused, likewise can be viewed as such a feature-adding morphological operation. In the fourth section, we also will discuss the advantages of feature-adding morphological operations from the standpoint of expressivity and formal power.

In the second section, we will propose an LMT in OT terms, thus an OT-LMT, that attempts to incorporate the desirable improvements suggested here.

AN OPTIMALITY-THEORETIC LMT

Optimality Theory has exerted great influence over the field of phonology; however, its appli-

cation in syntactic theory is still in its infancy. Recently, there have been some explorations within the OT-LFG framework (aka Optimal Syntax [Bresnan, 2000]). From the OT point of view, OT-LFG can be seen as OT with a universal LFG as GEN. From the point of view of LFG, a constraint-based grammatical framework, generalizations are interpreted in OT terms with (violable) constraints ranked in relation to one another (Sells, 2001). A number of studies have been carried out within this general framework (Mikkelsen, 2003; Sells, 2001). There also have been efforts to render argument-function linking in OT terms (Butt et al., 1997; Lødrup, 1999).

An OT-LFG Overview

Bresnan (2000) depicts the basic structure of OT-LFG, or Optimal Syntax, where LFG’s correspondence theory of parallel structures serves as a model for GEN. The standard OT-LFG assumes input to be “a (possibly underspecified) feature structure representing some given morphosyntactic content independent of its form of expressions” (Bresnan, 2000). An example is given in Figure 17, which assumes I saw her as its optimal form of expression. Note that in the input structure, <*x*, *y*> is the a-structure of see

Figure 17.

Input f-structure: *I saw her.*

	PRED 'see <x, y>'
GF ₁	PRED 'PRO' PERS 1 NUM SG _x
GF ₂	PRED 'PRO' PERS 3 NUM SG GEN D FEM _y
TNS	PAST

and GF1 and GF2 are unspecified grammatical functions that argument roles with which x and y are associated.

The candidate set comprises pairs of f-structure and corresponding c-structure (and perhaps other corresponding planes of information) generated by the LFG grammar (Bresnan, 2000; Kuhn, 2001). For ease of presentation, I am simplifying the matter by taking the input to be an a-structure <x y>, and a set of <x-GF1 y-GF2> pairs as candidates in OT-LMT, which is a module within OT-LFG that constrains argument-function linking specifically. The candidates are evaluated by a universal set of lexical mapping constraints. The output is taken to be the most harmonic, or optimal, candidate pair; namely, the one with the least (serious) violations (Kuhn, 2001).

A Comprehensive OT-LMT

The OT-LMT proposed here modifies and expands the LMT component in Bresnan (2001) and is

based specifically on the particular formulation of LMT in Her (1997), Huang and Her (1998), and Her (2003), where syntactic feature assignments are simplified, and the multiple mapping principles and well-formedness conditions in the conventional LMT are all unified into a single consistent mapping principle. Here, I will take this further and reinterpret the entire simplified LMT as a set of Optimality-Theoretic constraints and thus offer a comprehensive OT-LMT.

Crucial to the theory are two prominence scales discussed earlier: a universal thematic hierarchy and a markedness hierarchy of grammatical functions (GFs) (see Figures 18 and 19).

Mapping constraints are classified into three categories: well-formedness constraints on argument roles, well-formedness constraints on argument functions, and constraints on linking. Note that we are ignoring athematic arguments in this article⁷. “R” is thus a thematic role in a-structure, and “F” is a corresponding grammatical function. We first examine the well-formedness

constraints on the representation of argument roles (see Figure 20).

UniqRol ensures the uniqueness of each and every role in the a-structure and thus rules out a-structures like <ag ag th> and <th loc loc>. DescendRol further formalizes the a-structure representation, where argument roles descend in prominence. For example, given the locative verb sit and its two roles, theme and locative, in a-structure, <th loc> is the only well-formed representation; <loc th> is ill-formed. Two corresponding constraints are proposed for argument functions (see Figure 21).

UniqFun ensures the uniqueness of each and every function in the a-to-f mapping; thus, both of the following are ill-formed: <θa-SUBJ θb-SUBJ>, and <θa-OBJ θb-OBJ>. DescendFun penalizes a candidate with a violation of the descending order in prominence. For example, because SUBJ outranks OBJ, <θa-SUBJ θb-OBJ> has 0 violation and is favored over the inverted <θa-OBJ θb-SUBJ>, which incurs one violation. Thus, given n GFs in a candidate form, there are at most n – 1 violations as there are n – 1 consecutive pairs (Kuhn, 2001). Inversion is still possible, given that all OT constraints are violable in order

Figure 18.

to satisfy higher-ranked constraints, including language-specific morphosyntactic operations. (We will discuss the possibility of a language-specific component in the next section.) Next, we move on to the general constraints on the linking between roles and functions.

The two constraints in Figure 22, *LinkRol* and *LinkFun*, ensure that each expressed role is linked to a GF and that each GF is linked to a role. A role that is not linked to an argument function causes incompleteness, while an argument function that is not linked to an argument role in a-structure causes incoherence. Notice that there is no need to specify a constraint just to ensure that a role is linked to a GF with compatible features. This is accomplished automatically by the universal constraints on the morphosyntactic properties of argument roles shown in Figure 23.

LinkPtTh reflects the unaccusative hypothesis that cross-linguistically the primary patient/theme is encoded as an unrestricted [-r] GF (i.e., SUBJ or OBJ) (Bresnan & Kanerva, 1989; Bresnan & Zaenen, 1990; Zaenen, 1993)⁸. *LinkRolRes* captures the generalization that a non-patient/theme

internal argument prefers the syntactic assignment of a thematically restricted function. Finally, *LinkUnobj* and *LinkUnres* consistently favor the assignment of a role to the most unmarked function, SUBJ, [-r -o]⁹. Each function thus may have zero to two violations. These two constraints together are more general and insightful than the previous Subject Condition, which simply stipulates that every clause should have a subject.

Note that *LinkRolRes* does not apply to agent, the external argument. Being the highest-ranked role, it is linked to SUBJ due to *LinkUnobj* and *LinkUnres*. This thus accounts for the fact that, for the majority of the world's languages, agent cannot be realized as an object. However, given the violable nature of these constraints and their variable ranking, the possibility of agent-OBJ does exist as a marked morphosyntactic option. This reflects the insight of Falk (1989) cited in Lødrup (2000) that in Norwegian, "what has been called external theta roles are in fact structurally unspecified theta roles" (p. 173).

I will follow the standard view in OT and assume that these constraints are universal, but their

Figure 24. OT ranking of lexical mapping constraints (Chinese)

ranking may be language-specific. For Chinese, I propose the ranking shown in Figure 24.

An Illustration of OT-LMT

We will now look at the lexical mapping of three different verbs in their canonical active construction as examples: “melt<th>,” “laugh<ag>,” and “sell<ag th>.” To save time and space, the (many) candidates that violate any of the five highest-ranked well-formedness constraints will be excluded and we only will be concerned with the

lower five. Following standard OT notation, in Figure 25, a violation is marked with “*”; a “fatal” violation causing a candidate to lose in evaluation is highlighted with “!”. The shaded area covers the constraints that are no longer relevant in the evaluation of a particular candidate, and finally, the  sign indicates the optimal selection.

The candidate C1, <th-SUBJ>, with no violation, is clearly the optimal selection, where SUBJ is an unrestricted [-r] function allowed by LinkPtTh, and also the unmarked [-r -o] function preferred by LinkUnobj and LinkUnres.

Figure 25. Input a-structure: ‘melt <th>’

	Candidate	LinkPtTh	LinkRolRes	DescendFun	LinkUnobj	LinkUnres
 C1	<th-SUBJ>					
C2	<th-OBJ>				*!	
C3	<th-OBL _θ >	*!			*	*
C4	<th-OBJ _θ >	*!			*	*

Optimality-Theoretic Lexical Mapping Theory

Next, we turn to the a-structure of an unergative verb “laugh<ag>” (see Figure 26). Here, the only relevant constraints are LinkUnobj and

LinkUnres, which again select SUBJ, the unmarked function.

Again, the candidate with no violation (C1) is the optimal selection.

Figure 26. Input a-structure: ‘laugh <ag>’

	Candidate	LinkPtTh	LinkRolRes	DescendFun	LinkUnobj	LinkUnres
 C1	<ag-SUBJ>					
C2	<ag-OBJ>				*!	
C3	<ag-OBL _θ >					*!
C4	<ag-OBJ _θ >				*!	*

Figure 27. Input a-structure: ‘sell <ag th>’

	Candidate	LinkPtTh	LinkRolRes	DescendFun	LinkUnobj	LinkUnres
 C1	<ag-SUBJ th-OBJ>				*	
C2	<ag-SUBJ th-OBL _θ >	*!				*
C3	<ag-SUBJ th-OBJ _θ >	*!			*	*
C4	<ag-OBJ th-SUBJ>			*!	*	
C5	<ag-OBJ th-OBL _θ >	*!			* *	*
C6	<ag-OBJ th-OBJ _θ >	*!			* *	*
C7	<ag-OBL _θ th-SUBJ>			*!		*
C8	<ag-OBL _θ th-OBJ>				*!	*
C9	<ag-OBL _θ th-OBJ _θ >	*!				* *
C10	<ag-OBJ _θ th-SUBJ>			*!	*	*
C11	<ag-OBJ _θ th-OBJ>			*!	* *	*
C12	<ag-OBJ _θ th-OBL _θ >	*!		*	*	* *

The final example, *sell*, is a transitive verb with an agent role and a theme role. Again, Figure 27 excludes candidates that violate any of the five highest-ranked constraints.

Among the candidates, C1, <ag-SUBJ th-OBJ>, is the optimal selection, even though it does violate one of the two lowest-ranked constraints (i.e., LinkUnobj) due to the linking of theme to OBJ, a function with the marked feature [+o]. All other candidates, however, violate at least one higher-ranked constraint. Note that a candidate a-structure where both roles are linked to the unmarked function, thus <ag-SUBJ th-SUBJ>, violates the highest ranked UniqFun and, therefore, is not included in the figure.

AN OT-LMT ACCOUNT OF LOCATIVE INVERSION IN CHINESE

We first apply the OT-LMT to the canonical a-structure of the locative verb. The theory correctly predicts the following optimal argument-function linking: <th-SUBJ loc-OBL_θ>, shown in Figure 28.

With C2, <th-SUBJ loc-OBL_θ>, as the optimal selection, this constraint ranking obviously does not account for locative inversion, which is represented by candidate C4, <th-OBJ loc-SUBJ>. An additional constraint is needed.

The constraint shown in Figure 29 draws on the insight found in the default rule for focused

theme posited by Bresnan and Kanverva (1989) and also faithfully reflects Bresnan's (1994) observation on the universals of locative inversion verbs. Given the fact that the complement of the predicator usually carries the discourse function of marking the less familiar information and that the subject is the default grammatical function for topic or more familiar information, the locative inversion operation forces the locative to map onto SUBJ such that the focused theme can surface as a complement of the locative verb. With this constraint in place, we now have an important decision to make; that is, whether to posit LinkLocInv as a language-specific constraint. Recall that locative inversion is found in many languages, and locative inversion verbs share an identical a-structure and function assignment. However, locative inversion certainly does not occur in all

languages. In non-configurational languages with extensive case-marking for grammatical relations (e.g., Korean and Japanese), locative inversion may not be found (Huang & Her, 1998). Figure 30 depicts a Japanese example.

Notice that even though the locative phrase indeed may invert positions with the subject and thus affect the focus in Figure 30b, its grammatical functions remain the same. In other words, locative inversion does not affect argument-function linking. Recall the standard OT view that constraints are universal and that only their ranking is subject to variation. Therefore, if we follow the standard OT view and posit LinkLocInv as a universal constraint, languages such as Japanese also must be accounted for, but only with a different ranking of the same constraints. This is the path we will explore. Figures 31 and 32 show the

revised ranking we propose for Chinese. Notice that LinkLocInv outranks LinkRolRes and is outranked by LinkPtTh. Again, we continue to ignore the five highest-ranked well-formedness constraints.

We also need to point out that LinkLocInv is irrelevant in the selection of the canonical in Figure 28, because there, the theme is not focused. Now, to account for the data from languages like Japanese, where the focused theme does not result in mismatches of the function assignment of argument roles, we posit the ranking in Figures 33 and 34. Notice here that LinkLocInv is outranked by all other constraints.

DISCUSSION

This section discusses three issues in further detail. The first issue relates to the nature and the scope of the OT-LMT proposed in the article. The second issue concerns the potential advantages that the OT-LMT may have over the conventional LMT. Finally, we explore some of the directions for further research concerning the OT-LMT.

Morphosyntactic vs. Morpholexical Processes

Given the often idiosyncratic nature of language-specific lexical information, it is not yet clear how the technical integration of the lexicon should be envisaged in OT syntax, in general (Kuhn, 2001). This article clearly does not address this larger issue. In order to have an insightful lexical mapping theory in OT syntax, we first must be explicit about its nature and scope. The OT-LMT envisioned here is part of a universal OT-LFG theory that constrains argument-function linking. In other words, it constrains the syntactic function assignment of argument roles required by a predicator. Thus, this OT-LMT, as it is currently formulated, has nothing to say about morpholexical processes that alter the “lexical stock” in

a-structure (Bresnan, 2001; Bresnan & Kanerva, 1989). Therefore, it is purely morphosyntactic in nature and scope. Crucially, Ackerman (1992) differentiates and characterizes morpholexical and morphosyntactic operations as follows:

Morpholexical (Operations), affect the lexical semantics of predicates by altering the semantic properties associated with predicates...Morphosyntactic (Operations), assign features supplemental to those supplied by IC assignment¹⁰: these operations can affect the final GF assignments to arguments but cannot affect the lexical semantics. (p. 56)

Morpholexical operations thus are word-formation processes that produce predicates with an altered inventory of argument roles, or a-structures, which serve as input to OT-LMT. Morphosyntactic operations, however, are within the proper domain of LMT. Assuming that only morpholexical operations may be language-specific, the OT-LMT proposed thus universally governs how argument roles are mapped to GFs, with constraints that may vary from language to language only in terms of ranking. Thus, as Huang and Her (1998) have argued, given the nature of syntactic assignment of argument roles in the theory, it, in fact, makes the theory more coherent by allowing syntactic feature assignment in morphosyntactic operations. This is precisely how we treated locative inversion. Similar proposals that allow morphological processes to affect syntactic assignments by adding features are found as early as Zaenen (1987) and Her (1990) and later in Ackerman (1992), Markantonatou (1995), Her (2003), among others.

Allowing feature-adding morphosyntactic operations, in fact, also offers a computational advantage. Morpholexical operations constitute a much more powerful formal device computationally in that they are not subject to the general monotonicity condition that information only can be added but cannot be deleted or changed

(Bresnan, 1990; Falk, 2001)¹¹. Monotonic morphosyntactic operations with the feature-adding capacity enable a formalism that is more consistent and also more expressive, without any increase in its formal power. Empirically, such operations also have been adopted to account for syntactic variations in several languages; for example, Greek (Markantonatou, 1995), Chinese (Huang, 1995; Her, 1999), and English (Zaenen, 1987).

We will now illustrate this view of the OT-LMT with two more constructions from Chinese that are related to locative verbs. The first one is a passivized locative construction. Three-place transitive predicates like *xie* “write,” with the argument structure <ag th loc>, do not allow inversion in spite of the locative role it requires.

However, there may be locative inversion if the agent role is suppressed. This is observed in Chinese (Huang & Her, 1998) and other languages (Bresnan, 1989; Bresnan & Kanerva, 1989). The examples in Figures 35 and 36 are from Chinese and English.

Recall that passivization, repeated in Figure 36, suppresses the logical subject. In effect, it gives rise to an argument structure <ag th loc>, precisely that of a locative inversion verb. Locative inversion, therefore, is allowed, as in Figure 35c. Passivization thus falls outside of the realm of LMT and is regarded as a language-specific operation. One indication of its language-dependence is in the indirect expression of the suppressed agent role as an adjunct; for example, the English

Figure 35.

- a. Amei xie le yi ge zi zai qiang-shang.

- c. Qiang-shang xie le yi ge zi.
wall-top write ASP a CL character
‘On the wall was written a Chinese character.’

Figure 36. Passivization

by-expression (Bresnan, 1994). Chinese, however, does not allow such indirect expressions¹².

The second construction we will examine is the transitivized locative verb. It has been noted that, in Chinese, a two-place locative verb with an argument structure <th loc> in fact allows its locative phrase to be a PP or an NP. The locative phrase thus may be alternatively mapped onto OBL or OBJ, (Huang & Her, 1998). This, however, is not allowed in English, as shown in Figures 37 and 38.

Huang and Her (1998) treat this function change as a morphosyntactic variation of the same argument structure; thus, <th-SUBJ loc-OBL,> in Figure 37 and <th-SUBJ loc-OBJ> in Figure 38. However, further evidence indicates that this view may be incorrect and that locative transitiv-

ization involves a morpholexical change, instead. In other words, without the preposition *zai*, the argument structure is, in fact, no longer <th loc>. Note that the presence of the locative preposition *zai* requires a place noun as its complement in Figure 39. In Chinese, certain nouns are place nouns inherently, such as *xuexiao* “school,” *zheli* “here,” and *gongyuan* “park,” and thus can be the complement of preposition *zai* directly. Non-place nouns, however, must form a constituent with a locative affix such as *-shang* and *-xia*, or a locative noun such as *shangmian* and *xiamian*; or there must be a place noun as the complement of locative preposition *zai*. Notice in Figure 40 that the object required by the transitivized verb *zuo* “sit” and *shui* “sleep” is free of this restriction.

Figure 41. Locative transtivization

$\langle th\ loc \rangle \rightarrow \langle ag\ th \rangle$

Therefore, it is clear that the objects in Figure 40 do not denote the location where the theme that undergoes the movement ends up; rather, they are the entities that receive the action denoted by the verbs. To account for this construction, I propose a morpholexical operation (see Figure 41).

Two more syntactic tests, shown in Figures 42 and 43, confirm that this argument structure

is now $\langle ag\ th \rangle$: passivization and resultative compounding.

In the passive construction, the suppression of the agent results in the theme role's "promotion" to SUBJ, as seen in Figure 42. In Figure 43, the single composite role, formed by the binding of the theme role of the action verb and the theme of the result state verb, maps to SUBJ (Her, 2004)¹³.

Based on the prevailing evidence, locative transitivization should be treated as a morpholexical operation that alters the lexical stock of an argument structure, and, as such, it is again outside of the realm of the OT-LMT proposed here.

According to the previous discussion, it is now possible to indicate exactly how the OT-LMT system is envisaged as the module in LFG

that links the lexical semantic structure and the syntactic structure of a predicator (Bresnan & Kanerva, 1989; Bresnan & Zaenen, 1990). The particular conceptualization of the a-structure assumed here, as shown in Figure 44, is based on Bresnan (1996, 2001), which, in turn, follows Baker (1983).

Figure 44.

Figure 45.

The a-structure is a lexical syntactic representation with the minimally necessary information on the syntactic arguments of a predicator, such as the number of arguments, their thematic and syntactic types, and their hierarchical organization. As shown in Figure 45, the a-structure “sink <ag pt>” states that the verb sink requires two arguments, one of the type agent and the other theme, and also that agent is thematically more prominent than theme. The a-structure thus contains information necessary for the final syntactic manifestation or more precisely, the mapping of agent and theme to SUBJ and OBJ, respectively.

Morpholexical operations interact specifically with lexical semantics and, as such, are outside the proper domain of the LMT, while morphosyntactic operations are part of the LMT, which constrain the syntactic assignment of a-structure roles. All OT-LMT constraints thus are conceived to be morphosyntactic and universal in nature, while morpholexical operations may be language-specific.

Potential Advantages of OT-LMT

The OT-LMT proposed here targets specifically at the universal constraints on argument-function linking. We leave the OT formulation of morpholexical operations to further research. In

this section, we discuss some of the advantages that the OT-LMT may afford.

We start from the fact that all OT constraints are declarative. In the conventional LMT, the two subject conditions must apply sequentially, not simultaneously, to prevent $\theta[-r]$ from mapping to SUBJ, when $\hat{O}[-o]$ is present. Likewise, only after the mapping of the subject role can other roles be mapped. In contrast, all constraints in OT-LMT apply declaratively and, thus, simultaneously. Furthermore, in the conventional LMT, all roles are uniformly assigned exactly one feature for function assignment, while the OT-LMT allows a more expressive system with only the patient/theme role pre-assigned to unrestricted functions. This OT-LMT thus allows the possibility of agent-OBJ as a marked morphosyntactic selection, which is ruled out in the conventional LMT.

Recall also that two disjunctions are observed in the conventional LMT: the disjunction between the two principles of subject role mapping and the disjunction between subject roles and non-subject roles. The OT-LMT, however, consistently favors the unmarked values for all roles. This characteristic ultimately may lead to the replacement of the stipulation in the Subject Condition while preserving its insight. Thus, in general, this revised LMT formulated in OT formalism offers a potentially more consistent and simpler computational system¹⁴.

Figure 46.

	Candidate	LinkPtTh	LinkLocInv	LinkRolRes	DescendFun	LinkUnobj	LinkUnres
 C2	<th-SUBJ loc-OBL _θ >						*
 C4	<th-OBJ loc-SUBJ>			*	*	*	

As noted earlier, the LinkLocInv constraint proposed in the OT-LMT account essentially reflects the insight of Bresnan and Kanerva’s (1989) locative default, which assigns loc[-r] when th is focused. Thus, both accounts are descriptively equivalent in explicating locative inversion in the various languages observed, Chinese included. However, Bresnan and Kanerva’s (1989) account would need to state that languages like Japanese and Korean lack the mechanism of linking loc to [-r]. The OT account, on the other hand, has the advantage of a more general solution in attributing the presence or absence of locative inversion in a language to the relative ranking of LinkLocInv, which, like all OT constraints, is universal¹⁵.

Finally, we will indicate exactly how the OT-LMT better reflects the intuition that the locative inversion construction of <th-OBJ loc-SUBJ> is marked in comparison to the canonical locative construction of <th-SUBJ loc-OBL_θ>. In Figure 46, we examine the constraints that each of the two violates.

Notice that the canonical form constitutes only one violation of one of the two lowest-ranked constraints. The inverted form, on the other hand, violates two of the higher-ranked constraints, LinkRolRes and DescendFun, in addition to one of the two lowest-ranked constraints. Nonetheless,

even with such violations, the inverted form still outranks all other candidates. It is, therefore, still the optimal choice, in spite of its markedness. The OT-LMT is, therefore, more expressive and flexible, accounts for a wider range of data, and reveals the (un)markedness of different linking relations. It is, in short, a simpler, more consistent, and more general theory.

Directions of Further Research

Considering its limited number of principles, LMT is a relatively small theory but with ambitious goals. In the previous sections, an OT version of the theory has been laid out and tested against cross-linguistic data of locative inversion, as generalized by Bresnan (1994). However, there are locative constructions closely related to locative inversion that have not been covered. For instance, locative inversion might bear some relation to sentences with an expletive subject and a locative argument (Bresnan, 1994). Figure 47 is an example from French¹⁶.

The expletive subject is an athematic argument, and, as such, it must receive an intrinsic [-r] classification by the very nature of thematic restrictedness [r], (Bresnan, 2001). Given its initial position, it invariably links to SUBJ¹⁷. Similar

to the locative inversion discussed earlier, this construction also indicates that the object function of the theme role renders it more focal than the oblique locative role. An athematic argument in the a-structure is indicated by an underscore outside of the angled brackets, while thematic arguments are within the angled brackets. Thus, the a-structure of Figure 47 is “arrive _<th[foc] loc>.” An expletive subject also may be associated with the linking of agentive objects. Figure 48 is an example from French.

Similar phenomena also are observed in Bantu languages (Demuth, 1990; Demuth & Mmusi, 1997; Harford, 1990; Machobane, 1995). All these issues are important and interesting but cannot be adequately addressed in the current article.

Further research is needed on how the a-structure “arrive _<th[foc] loc>” and “work _<ag[foc]>” come about, whether they are morphologically or morphosyntactically related to “arrive <th loc>” and “work _<ag[foc]>,” respectively, and how best to incorporate such relations within the OT-LMT proposed here.

Further development of this OT-LMT also will need to address the issue of secondary patient-like roles as a parameter of variation in double object constructions, known as the Asymmetrical Object Parameter (AOP) (Alsina & Mchombo, 1993; Bresnan, 2001). In a non-AOP language, all patient-like roles are linked to an unrestricted function, while AOP languages must link the secondary patient/theme to an object function.

Figure 47.

Il est arrivé beaucoup de gens à la plage
 it is arrived many of people at the beach
 ‘There were many people arriving at the beach.’

Figure 48.

Il travaille deux mille ouvriers dans cette usine
 it works two thousand workers in this factory
 ‘There are two thousand workers working in the factory.’

Figure 49.

Asymmetrical Object Parameter (AOP):

* $\theta \theta \Rightarrow \theta \theta$
 $[-r] [-r] \quad [-r] [+o]$

An additional constraint may be necessary, and constraint ranking then may reflect this variation. This asymmetrical object parameter is stated in Figure 49.

Finally, the OT-LMT developed here needs to be applied to a much wider range of data cross-linguistically; for example, complex predicates in various languages (Abaitua, 1988; Ackerman, 1992; Alisina, Bresnan & Sells, 1997; Her, to appear; Ishikawa, 1985), the valence-changing morphemes and inversion constructions in Georgian (Blevins, 2005; Harris, 1981; Holisky, 1981), among others. A solid analysis of some of these facts would be a significant test of the linking theory proposed here.

CONCLUSION

In this article, we set out to accomplish two goals. The more ambitious one is to come up with a simpler and more general lexical mapping theory in OT terms, or OT-LMT. The second one is to test this theory and account for locative inversion in Chinese, English, and Chichewa on the one hand and Japanese and Korean on the other hand. Following the standard view in Optimality Theory, the mapping constraints we proposed are all universal, and language variation in locative inversion is accounted for by different constraint rankings. The OT-LMT we proposed is the UG component that constrains the argument-function linking, or morphosyntactic processes. It thus does not govern language-specific morpho-lexical processes, such as passivization, locative transitivization, and resultative compounding. Locative inversion, on the other hand, involves only morphosyntactic operations and, therefore, is accounted for within the OT-LMT.

In summary, the OT-LMT we proposed not only covers a wider range of empirical data, but it also affords a simpler, more consistent, and more general theory.

ACKNOWLEDGMENTS

I am genuinely grateful to the three anonymous reviewers for their insightful comments and exceedingly generous suggestions, and also to Adams Bodomo for his encouragement. I also thank Nissa Hui-shan Lin for discussions on OT. However, I am solely responsible for the content of the article. Research reported in this article has been funded partly by NSC grants 92-2411-H-004-024 and 93-2411-H-004-006. Part of the research for the article was done while I visited the School of Information Technology, Bond University in 2003 and 2004. I thank the dean, Professor Ron Davison, for his kind and continuous support.

ENDNOTES

¹ See Bresnan (2001, chapter 14) for a brief exposition of other formulations.

² Falk (2001) also presents a concise introduction to LMT and a more precisely defined theory of argument roles. Dalrymple (2001) offers more examples in her introduction to the theory.

³ The concept of thematic hierarchy is well-established (Grimshaw, 1990; Li 1995). The hierarchy in “The Subject Condition” also might be derived from the proto-role properties proposed by Dowty (1991) (Ackerman & Moore, 2001b; Bresnan, 2001).

⁴ Note that following Zaenen and Engdahl (1994), the two propositional argument functions COMP and XCOMP are treated as instances of OBL.

⁵ Note that \hat{O} refers to the most prominent role in the a-structure. The fact that it is also the left-most role within the angled brackets is inconsequential. \hat{O} is usually also the initial role, unless there is an initial athematic argument.

⁶ Alsina (1996) also argues that the function-argument bi-uniqueness condition, which is fully integrated in the OT-LMT proposed later, is too strong.

⁷ A constraint for athematic roles must restrict such roles to [-r]. Alternatively, a constraint may be proposed to outrank LinkFun in Figure 22b and thus allow a GF in a-structure to be unmatched.

⁸ An additional constraint is needed for the secondary patient/theme, which restricts the secondary pt/th to [+o]. Again, we will ignore this issue in this article.

⁹ DescendFun and DescendRol effect a parallel alignment between the thematic hierarchy and the markedness hierarchy. This parallel alignment is similar to a harmonic alignment, but with an important difference. In a harmonic alignment, according to Prince and Smolensky (2004), the correspondence between a more prominent element on one scale and a less prominent element on the other is worse than the correspondence between two elements that are equal in prominence (Aissen, 1999; Asudeh, 2001; Lee, 2001; Sharma, 2001). Thus, it is better for agent, the most prominent role, to link to SUBJ, the most prominent function, and likewise for locative, the least prominent role, to link to OBJ. However, in our scheme here, due to LinkUnobj and LinkUnres, a more prominent GF is favored, regardless of the prominence of the role.

¹⁰ IC refers to the intrinsic classification of argument roles. See Figure 7.

¹¹ Therefore, as I have proposed elsewhere (Her, 2003), morpholexical operations likewise can add features and, thus, alter syntactic assignments of argument roles, besides changing the lexical semantics of a predicator.

¹² See Her (1989) and Ting (1998), among others, for compelling arguments against viewing the *bei*-NP phrase as a PP by-phrase.

¹³ In fact, the same concept of suppression in passives is used here, as well. See Her (2004) for details of mapping the composite role, formed by two roles, to a single GF.

¹⁴ Note that I am only referring to computational efficiency in formulation and formalism, not in practical terms of an actual computational implementation. See Kuhn (2003) for extensive discussions on the computational aspects of OT. However, there is little practical evidence for the computational efficiency of a large-scale OT implementation of a grammar, as there seems to be no such practical systems yet. For the computational efficiency of LFG in general, see Maxwell and Kaplan (1996, 1993, 1991); for LFG in practice, refer to

Kaplan, et al. (2004). I thank the anonymous reviewer who made this point and provided the references.

¹⁵ I thank another anonymous reviewer for pointing this out to me.

¹⁶ I thank the anonymous reviewer who suggested this direction of further research and provided this French example and its discourse analysis.

¹⁷ Refer to Bresnan (2001, section 14.1) for a more in-depth discussion on athematic arguments in raising constructions.

Chapter 7.13

Trusting Computers Through Trusting Humans: Software Verification in a Safety–Critical Information System

Alison Adam

University of Salford, UK

Paul Spedding

University of Salford, UK

ABSTRACT

This article considers the question of how we may trust automatically generated program code. The code walkthroughs and inspections of software engineering mimic the ways that mathematicians go about assuring themselves that a mathematical proof is true. Mathematicians have difficulty accepting a computer generated proof because they cannot go through the social processes of trusting its construction. Similarly, those involved in accepting a proof of a computer system or computer generated code cannot go through their traditional processes of trust. The process of software verification is bound up in software quality assurance procedures, which are themselves subject to commercial pressures. Quality standards, including military standards, have procedures for human trust designed into them. An action research case study of an avionics system within a military

aircraft company illustrates these points, where the software quality assurance (SQA) procedures were incommensurable with the use of automatically generated code.

INTRODUCTION

They have computers, and they may have other weapons of mass destruction. Janet Reno, former US Attorney General

In this article our aim is to develop a theoretical framework with which to analyse a case study where one of the authors was involved, acting as an action researcher in the quality assurance procedures of a safety-critical system. This involved the production of software for aeroplane flight systems. An interesting tension arose between the automatically generated code of the software system (i.e., ‘auto-code’—pro-

duced automatically by a computer, using CASE [Computer Aided Software Engineering] tools from a high level design) and the requirement of the quality assurance process which had built into it the requirement for human understanding and trust of the code produced.

The developers of the system in the case study designed it around auto-code—computer generated software, free from ‘human’ error, although not proved correct in the mathematical sense, and cheaper and quicker to produce than traditional program code. They looked to means of verifying the correctness of their system through standard software quality assurance (SQA) procedures. However, ultimately, they were unable to bring themselves to reconcile their verification procedures with automatically generated code. Some of the reason for this was that trust in human verification was built into (or inscribed into [Akrich, 1992]) the standards and quality assurance procedures which they were obliged to follow in building the system. Despite their formally couched descriptions, the standards and verification procedures were completely reliant on human verification at every step. However these ‘human trust’ procedures were incompatible with the automated production of software in ways we show below. The end result was not failure in the traditional sense but a failure to resolve incommensurable procedures; one set relying on human trust, one set on computer trust.

Our research question is therefore: How may we understand what happens when software designers are asked to trust the design of a system, based on automatically generated program code, when the SQA procedures and military standards to which they must adhere demand walkthroughs and code inspections which are impossible to achieve with auto-code?

The theoretical framework we use to form our analysis of the case study is drawn from the links we make between the social nature of mathematical proof, the need to achieve trust in system verification, the ways in which we achieve

trust in the online world, the methods of software engineering, and within that, the software quality movement and the related highly influential domain of military standards.

In the following section we briefly outline the social nature of mathematical proof. The next section discusses the debate over system verification which encapsulates many of the ideas of mathematical proof and how such proofs can be trusted by other mathematicians. The article proceeds to consider ‘computer mediated’ trust, briefly detailing how trust has been reified and represented in computer systems to date, mainly in relation to the commercial interests of e-commerce and information security. Trust is particularly pertinent in the world of safety-critical systems, where failure is not just inconvenient and financially damaging, although commercial pressures are still evident here, but where lives can be lost. The model of trust criticised by e-commerce critics is more similar to the type of trust we describe in relation to safety-critical systems, than one might, at first, expect. Understandably, we would like to put faith in a system which has been mathematically proved to be correct. However computer generated proofs, proofs about correctness of computer software, and automatically generated code are not necessarily understandable or amenable to inspection by people, even by experts. The question then arises of whether we can bring ourselves to trust computer generated proofs or code, when even a competent mathematician, logician, or expert programmer cannot readily understand them.

Following this, we describe the evolution of software development standards and the SQA movement. We argue that the development of quality assurance discourse involves processes of designing human ways of trusting mathematical evidence into standardisation and SQA. Military standards are an important part of the SQA story, having consequences far beyond the military arena. Standards are political devices with particular views of work processes inscribed (Akrich, 1992) in their design. We note the way that military

standards, historically, moved towards formal verification procedures only to move back to rely more on 'human' forms of verification such as code walkthroughs and inspections in the later 1990s. The story is shot through with a tension between finding ways to trust the production of information systems and finding ways to control them. Formal methods, based on mathematical proof offer the promise of control, but only if we can bring ourselves to trust a proof generated by a machine rather than a proof constructed by another person. We present the background to the case study in terms of a description of the complex 'post cold war' military and commercial environment. This is followed by a description of the action research methodology employed in the project, an outline of the case study and an analysis of the case study findings in terms of our theoretical framework. In the conclusion we briefly note that mathematicians and others are gradually finding ways of trusting computers.

THE SOCIAL NATURE OF MATHEMATICAL PROOF

At first sight, the concept of mathematical proof appears to be relatively simple. The idea of a logical and rigorous series of steps, leading from one or more starting positions (previous theorems or axioms) to the final conclusion of the theorem seems to be the basis of mathematics. The concept of mathematical proof leading inexorably to true and incontrovertible truths about the world is very compelling. It is not surprising that we would like to apply the apparent certainty and exactness of mathematical approaches to computer programming. However if we consider briefly how agreement on mathematical proof and scientific truth is achieved by communities of mathematicians, then the social and cultural dimension of proof, as an agreement amongst trusted expert witnesses, reveals itself.

With the epistemological and professional success of mathematical proof, many of the cultural processes which go into making a proof true sink from consciousness and are only rendered visible in times of dispute; for example as in claims to the proof of Kepler's conjecture or Fermat's last theorem (Davies, 2006; Kuhn, 1962; Singh, 1997). Only on the margins then do we call into question our ability to trust these people when a mathematical proof cannot be agreed to be true by an expert community of mathematicians, as sometimes happens.

The apparently pure and abstract nature of mathematical proof fairly quickly breaks down when we inspect it more closely. In particular, when there is disagreement about a proof, the nature of proof is revealed as a social and cultural phenomenon; the matter of persuading and convincing colleagues. DeMillo, Lipton, and Perlis (1977, p. 208) wrote

Mathematicians talk to each other. They give symposium and colloquium talks which attempt to convince doubting (sometimes hostile) audiences of their arguments, they burst into each others' offices with news of insights for current research, and they scribble on napkins in university cafeterias and expensive restaurants. All for the sake of convincing other mathematicians. The key is that other mathematicians are inclined to listen!

This traditional approach towards mathematical proof, which could be described as one of *persuasive rigorous argument between mathematicians leading to trust*, is not the only way to address the idea of proof. A quite different approach appeared in the 1950s and was based on the work on logic developed by Bertrand Russell and others in the 1930s and used the newly invented electronic computer. This new logic-based approach was not dependent on the computer, but the computer's speed and accuracy had a major impact on its application to the proof

of theorems in replacing the persuasive rational argument of competent mathematicians with a *formal* approach which sees any mathematical proof as a number of steps from initial axioms (using predicate logic), to the final proof statement (based purely on logical inference) without the requirement of a human being.

Many proofs can be completed by either method. For instance, many persuasive rigorous argument proofs can be converted to formal proofs (MacKenzie, 2004). It should be emphasised, however, that there is a real difference between the two types of proof. We are not simply talking about a machine taking on the role of a competent mathematician. Some proofs which are readily accepted by mathematicians rely on arguments of symmetry and equivalence, analogies, and leaps of imagination, which humans are very good at understanding but which a formal logic approach cannot replicate. Symmetry and analogy arguments of this type cannot be established by formal methods based on logical progression because symmetry relies on understanding semantics and cannot be gleaned from the syntax of a proof.

Whereas the persuasive rigorous argument, the ‘human’ approach, has been used for thousands of years, the formal or ‘computer generated’ approach has been in use for only about half a century. Clearly, the two methods are not treated in the same way by the expert community of mathematicians. With a rigorous argument type of proof, although one may expend much energy convincing one’s colleagues of the validity of the proof, the *potential* for coming to agreement or trust of the proof is there. Essentially, in trusting that a mathematical proof is correct, mathematicians are demonstrating their trust in other competent mathematicians. However, expert mathematicians clearly have trouble bringing themselves to trust computer proofs, for good reason, as a computer cannot explain the steps in its reasoning (Chang, 2004).

COMPUTER SYSTEM VERIFICATION: TRUST AND THE SOCIAL

The preceding section contrasted the *use* of computer technology in a claimed proof: the formal method and the human ‘rigorous argument’ approach to proof. Although this is not the same thing as the proof or verification of a computer system *itself*, in other words the formal, computer generated proof that the computer system matches the specification, the question of whether we can trust the computer is exactly the same.

The idea of *proof* or *verification* of a program is quite different from simply testing the program. Typically, a large suite of programs might have thousands or millions of possible inputs, and so could be in many millions or even billions of states. Exhaustive testing cannot be possible. If a computer system is to be used in the well-funded and high-profile military field to control a space craft, aeroplane, or a nuclear power station, it is highly desirable if the system can be actually *proved* to be correct, secure, and reliable. Since testing, although vital, can never prove the system’s correctness, more mathematical methods involving the notion of proof became of great interest in the late 1960s and have remained so ever since.

In fact the history of the verification of computer systems echoes that of mathematical proof, with basically the same two approaches: those who support the rigour of formal methods and those who believe that the purely formal, mechanised proof lacks the crucial element of human understanding (Tierney, 1993). In a paper to an ACM Symposium, DeMillo et al. (1977) argued that the two types of proof were completely different in nature, and that only the persuasive rigorous argument proof with its strong social aspect will ultimately be believable and capable of earning *trust*.

COMPUTER-MEDIATED TRUST

In ethical terms, trust is a complex phenomenon and is essentially a human relationship (Nissenbaum, 1999; Stahl, 2006). We think of trust in terms of a trustor who does the trusting and a trustee who is trusted. The trustee does not of course have to be human, but Nissenbaum (1999) suggests that the trustee should be a being to whom we ascribe human qualities such as intentions and reasons, what might be termed an ‘agent.’ Trust allows meaningful relationships and a vast range of intuitions to work. Nissenbaum (1999) argues that when we are guaranteed safety trust is not needed: ‘What we have is certainty, security, safety – not trust. The evidence, the signs, the cues and clues that ground the formation of trust must always fall short of certainty; trust is an attitude without guarantees, without a complete warrant.’ Intrusive regulation and surveillance are attempts at control and bad for building trust.

This generalised definition of trust clearly maps onto our description of mathematicians trusting proofs. They may not have complete certainty over the correctness of a mathematical proof, but they have good reason to trust a competent member of the community of expert mathematicians. Therefore they can trust the proof supplied by such a person.

Understandably, there has been much interest in trust in the online world, both in terms of online security and trust in e-commerce transactions. Nissenbaum (1999) suggests that excessive safety controls, say in e-commerce, may encourage participation but they limit experience: ‘Through security we may create a safer world, inhospitable to trust not because there is distrust, but because trust cannot be nourished in environments where risk and vulnerability are, for practical purposes, eradicated.’

Stahl’s (2006) take on trust in e-commerce shows another example of the intangible human nature of trust, which has become reified and commodified, so that it can be measured and

exchanged in machine transactions. Like Nissenbaum (1999), Stahl points to the way that a trustor does not have complete control over a trustee; vulnerability and uncertainty must be accepted in a trusting relationship. This of course includes business transactions, and is especially important in e-commerce as many of the traditional ways of developing trust are absent from online transactions. Trust becomes a way of generating profit; small wonder that trust, including technological ways of creating trust and maintaining it, has been of so much interest in e-commerce. In the world of e-commerce research, trusts lose its relational aspects and becomes a form of social control. ‘If trust is limited to calculations of utility maximisation in commercial exchange, then most of the moral underpinnings of the mechanisms of trust become redundant. Trust changes its nature and loses the binding moral quality that it has in face-to-face interaction.’ (Stahl, 2006, p. 31)

Although, on the face of it, Nissenbaum’s and Stahl’s arguments on the problems of online trust in e-commerce are not the same as the issue of trust described in the body of this article, there are important congruencies which are very directly applicable to our characterisation of trust. Whether it is a human trusting another human or an expert mathematician trusting another expert mathematician to supply an accurate proof, the same relationship between trustor and trustee obtains.

For Nissenbaum and Stahl, the issue is what happens to trust when it is commodified within an online relationship. In other words, what happens when the human-trusting-human relationship is mediated by technology? In this article we also consider what happens when the human-trusting-human relationship—in terms of a human trusting another human’s mathematical proof, or computer program—is replaced by a human having to trust a machine. Of course, in this trustor-trustee relationship, the trustee, that is, the machine, cannot be understood in the way that another person can be.

The pressure to create computer-mediated trust is completely bound up with commercial pressures. The maximisation of profit drives the reification of trust in e-commerce. Similarly in the world of military avionics we describe, it is the commercial pressure of building systems more cheaply and faster which provides the impetus to turn over proofs, testing of programs, and automatic generation of code to a machine. A third aspect of similarity between Stahl's and Nissenbaum's view of computer-mediated trust and ours relates to the tension between trust and control. This is clearly present in the debate over trust in e-commerce. But it is also present in software quality discourse as we discuss below.

In the following section we briefly discuss some of the ways in which human trust has traditionally been built into procedures designed to verify program correctness, and how this can be seen to mirror an ideal group of mathematicians agreeing upon a mathematical proof.

BUILDING TRUST INTO A COMPUTER SYSTEM

We argue that, historically, much of the development of the software engineering discipline can be understood in terms of the development of procedures, through which we can convince ourselves to trust, and control, the development of information systems and the production of software. For instance, Myers' (1979) classic book on software testing explores the topic of human testing in detail, justifying methods such as formal *code inspections* and *code walkthroughs*. The differences between the two methods depend on different usages of the terms 'inspection' and 'walkthrough,' but the important point is that both involve a small group of professionals carefully reading through code together. We argue that this can be viewed as an imitation of the social (persuasive rigorous argument) form of proof described earlier where 'mathematicians talk to each other'

in symposia and colloquia and so on (DeMillo et al., 1977). The original programmer should be in the group, analogous to the mathematician demonstrating a proof or principle to expert colleagues. The aim (as originally suggested by Weinberg [1971]—an 'egoless' approach) is to discover as many errors as possible rather than to try to demonstrate that there are none. So the team is to act as an idealised group of 'Popperian' scientists looking for 'refutations' (Popper, 1963). Under such an approach, one can never be entirely sure that the code is correct. But, as the walkthrough proceeds, the original programmer and the code inspection team can gradually come to trust the code as bugs are weeded out and fixed.

Myers claims positive advantages of code inspections and walkthroughs, including the value of the original programmer talking through the design (and thus spotting the errors). He also notes the ability of human testers to see the causes and likely importance of errors (where a machine might simply identify symptoms) and also the likelihood that a batch of errors will be identified simultaneously. Also the team is able to empathise with and understand the thought processes of the original programmer in a way which a machine arguably cannot. Importantly, the team can be *creative* in its approach. In working together they also, inevitably, form something of a sharing and trusting community (even if it is disbanded after a day or two).

The lesson gleaned from human verification techniques, such as walkthroughs and code inspections, is that these have been regarded, for some time, as reliable, if not exhaustive, ways of ensuring reliability of software.

SOFTWARE QUALITY ASSURANCE AND MILITARY STANDARDS FOR SOFTWARE

The software verification techniques of code walkthroughs and inspections are important parts

of the armoury SQA. Effectively, we argue that SQA is a branch of software engineering which formalises and standardises the very human methods of trust, and ultimately control outlined above, which we need to build into software engineering procedures. The SQA movement is an important part of the story of the growth of software engineering because of its quest for rigour and control of potentially unruly programs and programmers.

First of all, SQA offers a promise of rational control over software, the software development process, and those who produce software. Software quality criteria include features for directing, controlling, and importantly, measuring the quality of software (Gillies, 1997). ‘Qualification’ is achieved when a piece of software can be demonstrated to meet the criteria specified in these quality procedures. An important aspect of SQA involves demonstrating that software meets certain defined independent standards.

The development and adherence to software standards is a very important part of the story of SQA. Generic industry standards are available, but also of much interest—particularly for the case study set out later in the article—are military standards. Indeed, the defence industry is so influential that Tierney (1993) argues that military standards influence software engineering far beyond applications in defence. Hence military standards are a very important part of SQA, and ultimately are important in formalising ways in which designers of computer systems can come to trust the systems and the production of correct software.

A number of military standards have been developed to regulate and control the use of software in defence applications. For instance, US standards DOD-STD-2167A (1988), MIL-STD-498 (1994), and ISO/IEC 12207 (1995) respectively established the requirements for software development and documentation in all equipment to be used by the US military (and effectively that of all Western armed forces),

introduced object oriented development (OOD) and rapid application development (RAD), then broadened the scope of international standards to include acquisition and maintenance. (DSDM Consortium, 2006).

The relevant UK standard 00-55, (MoD, 1997) *Requirements for Safety Related Software in Defence Equipment*, was published in 1997 and echoes much of MIL-STD-498, but moves the discussion on provably correct software in a particular direction. At first sight, this seems highly significant to the current argument, because it clearly expressed a preference for *formal* methods, in other words mathematical procedures whereby the software is proved to be correct by a machine (MacKenzie, 2001).

Tierney (1993) argues that the release of UK Defence Standard 00-55 in draft in 1989 had the effect of intensifying the debate over formal methods in the UK software engineering community. It devoted as much space to regulating and managing software development labour processes as the techniques and practices to be used for formal designs. This reinforces our argument that SQA is concerned with control of work processes and those who perform them, the software developers. On the one hand, many argued that mathematical techniques for software development and verification could only ever be used sparingly, as there simply was not enough suitable mathematical expertise in most organisations and it increased software quality at the expense of programmer productivity. On the other side, those from a more mathematical camp argued that there was commercial advantage in proving software correctness as errors could be trapped earlier in the software development cycle (Tierney, 1993, p. 116).

Designed into the MoD (UK Ministry of Defence) standard was a view of safety-critical software as an important area of regulation and control. Some of the reason for this was a change in its own organisation from the 1980s. The UK government sought to open up work traditionally

done in-house by the MoD in its own research establishments to private contractors (Tierney, 1993, p. 118). Given that it had to offer its software development to the private sector, it built in ways of controlling it within its defence standards (Tierney, 1993, p. 118). Further political impetus was offered by the introduction of consumer protection legislation in the UK in the late 1980s which required software developers to demonstrate that their software had not contributed, in the event of an accident enquiry, and that they had demonstrably attended to safety. Thus we can see that in Def Stan 00-55, politics, in the shape of the MoD's need to open up software development to the private sector and also to avoid being held responsible for inadequate software in the event of an accident, played an important role.

However, more significantly, this document has itself been superseded in 2004 by (draft) standard 00-56 (MoD, 2004). Def Stan 00-55 has now become obsolete. The changes involved in Def Stan 00-56 are of great interest, in that the preference for formal method is lessened. In the new standard, it is accepted that provably correct software is not possible in most cases and that we are inevitably involved in a human operation when we attempt to show that code is reliable in a safety-critical environment. Without a more detailed consideration of the history of formal methods in the UK over the last decade, which is beyond the scope of the present article, a strong claim that the move back to more human methods of verification might be difficult to sustain. Nevertheless it is interesting to note the way that Def Stan 00-5, with its emphasis on formal approaches and attendant onerous work practices, has been consigned to the history books with a clear move back to human verification.

CASE STUDY CONTEXT

The case study relates to a large European military aircraft company (MAC) with which one

of the authors was engaged as a researcher in a joint research project, lasting around three years, during the mid to late 1990s. A high proportion of the senior management were men and its culture was masculine in style, particularly emphasising an interest in engineering and technical mastery (Faulkner, 2000). Indeed there was much interest, pleasure, and admiration for elegant products of engineering (Hacker, 1991). When one of their fighter planes flew over (an event difficult to ignore on account of the engine noise), offices would clear as employees went outside to admire the display of a beautiful machine. A certain amount of military terminology was used, sometimes ironically, in day-to-day work. A number of employees had links with the armed forces. MAC was exclusively involved in the defence industry, with the UK's MoD being its largest customer and other approved governments buying its products.

As a manufacturing company in an economy where manufacturing was in steep decline and with its ties to the defence industry, if a major defence contract went elsewhere, jobs would be on the line. Despite the 'hi-tech' nature of its work, MAC had a traditional feel to it. The company had existed, under one name or another, right from the beginning of the avionics industry. The defence industry, and within that the defence aerospace industry, faced uncertain times as the UK government was redefining its expectations of the defence industry in post-Cold War times. It quickly came to expect much clearer demonstrations of value for money (Trim, 2001). Therefore, the 'peace dividend' brought about by the end of the Cold War meant uncertain times for the defence aerospace industry as military spending was reduced significantly (Sillers & Kleiner, 1997). Yet, as an industry contributing huge amounts to the UK economy (around £5 billion per annum in export earnings Trim (2001, p. 227)), the defence industry is hugely important in terms of revenue and employment. Defence industries have civil wings (which was the case with MAC) and it was seen as important that the

defence side of the business did not interfere with civil businesses. For instance, BAE Systems is a partner in a European consortium and was pledged £530 million as a government loan to develop the A3XXX aircraft to rival the USA's Boeing 747 (Trim, 2001, p. 228).

Although not strictly a public sector organisation itself, its location in the defence industry put MAC's business in the public sector. However, in the UK, views of public sector management were undergoing rapid change in the mid 1990s and it was seen as no longer acceptable that the taxpayer should underwrite investment (Trim, 2001). Such firms were required to be more competitive and to be held more accountable financially. Hence, quality management and value for money were becoming key concepts in the management repertoire of the UK defence industry from the mid 1990s onwards. As we discuss in the preceding section, this was at the height of the UK MoD's interest in formal approaches to the production of software. In a climate where post-Cold War defence projects were likely to demand a shorter lead time, there was considerable interest in speeding up the software development process.

Computer technology and related activity clearly played a central role in MAC. One division of MAC, the Technical Directorate (TD), developed most of the airborne software (much of it real-time). This software clearly has a central role in ensuring aircraft performance and safety. Around 100 people were involved in developing systems computing software. It was in this division that Software Development System (SDS), a safety-critical airborne software system for flying military aircraft, was developed.

Research Methodology

The methodological approach of the research was based on action research (Myers & Avison, 2002). As several successful participant observation studies in technology based organisations have been reported in the literature (Forsythe, 2001; Low

& Woolgar, 1993; Latour & Woolgar, 1979), an ethnographic approach holds much appeal. However, a strict ethnographic approach was neither feasible nor desirable in this study. As someone with technical expertise, the researcher could not claim to be the sociologist or anthropologist, more typical of reported ethnographic studies of technological systems (Low & Woolgar, 1993; Forsythe, 2001). This also meant that he was not 'fobbed off' by being directed into areas that the participants thought he wanted to look at or where they thought he should be interested in as happened in the Low and Woolgar (1993) case study. Based in the Quality Assurance Division (QAD) in the SQA team, early in his research, the researcher proved his technical credentials by helping run a workshop on software metrics and this helped to gain him full inclusion in the technical work. Although as a technical researcher, rather than a social researcher, it was arguably difficult for him to maintain the 'anthropological strangeness' which ethnographers look for in explaining the common sense and every day logistics of working life. In any case, he had been invited, through this research, to make a contribution to the improvement of SQA procedures. Therefore the research can be characterised as a form of action research (Baskerville & Wood-Harper, 1996), where potential improvements to SQA were to be seen as the learning part of the action research cycle.

Although action research receives a mixed press from the IS research community (Baskerville & Wood-Harper, 1996; Lau, 1999), it is nevertheless seen as a way of coming to grips with complex social settings where interactions with information technologies must be understood within the context of the whole organisation. Baskerville (1999) notes the growing interest in action research methods in information systems research. Two key assumptions are that complex social settings cannot be reduced for meaningful study and that action brings understanding (Baskerville, 1999). The culture of MAC was extremely complex, as we characterise above and

discuss again in what follows. Arguably, key elements would be lost were the researcher to have adopted a more distant role, relying on interviews and questionnaires rather than becoming fully immersed and contributing to the detail of the project. The researcher adopted an interpretivist approach, looking to the interpretations of the other participants of the research. But by allowing for social intervention he became part of the study, producing shared subjective meanings between researcher and subjects as coparticipants in the research (Baskerville, 1999).

For a period of over one year out of the three that the whole project lasted, the researcher spent, on average, one day per week working with MAC staff with access to a variety of staff across the organisation, and was therefore able to participate in a range of meetings and workshops and to gain a familiarity with the individuals concerned. This could not easily have been gained from interviews or surveys. These events included meetings where software quality staff considered quality policy, such as the implication of international standards, to broader meetings where technical staff were considering development methods in detail. Free access was allowed to relevant policy and development documents. This permitted an overview of the detailed practices and culture of this large and complex organisation.

Analysis of Case Study Findings

The initial remit of the researcher was to work with staff to optimise the use of software quality assurance within the organisation. The use of cost benefit analysis was originally suggested by senior management. Given our characterisation of the UK defence industry's particular focus on management of quality and value for money, as described above, it is entirely in keeping with the industry's changing needs that the researcher was initially directed into these areas. The researcher viewed it as problematic to assign monetary cost to SQA activities, and even harder to assign

monetary benefits. However, these concerns were never addressed directly in the project as it soon emerged that there was greater interest in a new approach to software development being pioneered by MAC.

Ince (1994, p. 2-3) tells the story of a junior programmer's first day in a new job. A senior programmer shows him around, advising him where to buy the best sandwiches at lunchtime, where to find the best beer after work, and other similarly important matters. Then the senior colleague points to a door. 'Whatever you do don't go through that door, the people there have been given the job of stifling our creativity.' The door, of course, led to the quality assurance department.

The staff of MAC's Quality Assurance Division expressed some similar feelings, albeit less dramatically. They wanted to act as consultants, offering a measure of creativity to the technical development process, although safely wrapped in appropriate quality assurance processes, but all too often they felt like the police. The strong awareness of the safety-critical nature of software development, and the related fairly advanced organisation of quality assurance in MAC, thanks in no small measure to the necessity to adhere to MoD standards, meant that SQA was never going to get quite the negative press that it attracted in Ince's (1994) anecdote. Nevertheless, there was still some feeling that the Quality Assurance Division could be brought on board in a project some time after the Technical Division had time to do the creative part.

Hence, TD had been prototyping the new SDS system for about a year when they decided to bring in Quality Assurance Division. As we explain below, the newness of the style of development in SDS made it unclear how it was to be quality assured. Unsure of how to proceed, the SQA manager turned to the researcher for suggestions. The researcher now became involved in investigating the use of the new software development approach, which would involve the inclusion of

computer generated program code ('auto-code') in safety-critical airborne software systems, leading to the approval of the new approach and its incorporation into MAC's software quality assurance systems.

Although there has been a long tradition of using computers to aid the process of software engineering itself, such CASE tools (Pressman, 2005) have not generally been used to generate safety-critical code (this was always written by human programmers). The new MAC SDS was an ambitious system whose targets were principally to reduce avionics systems development time by 40% and the cost by 30%, whilst maintaining the very high quality standards necessary for computer-based system which fly—and therefore can crash—military aircraft.

A key aspect of SDS was process integration using an integrated modeling environment. There was consequentially a heavy reliance on automated methods. A specification was developed in a formal modeling language and this generated programming code automatically. In particular, automatic code generation was eventually to lead to aircraft flying 'auto-code' in safety-critical systems. Two aspects of SDS stand out in the climate of defence spending of the mid 1990s. First, there was pressure to reduce costs and show value for money. Second, the use of formal methods in computer programming received a huge boost in the mid-1990s through the Defence standard DEF Stan 00-55 which mandated the use of formal methods base approaches in safety-critical software. It is not surprising that there was considerable interest in a system which offered the promise of considerably reduced software production times.

MAC invested a great deal of money and time in SDS in the hope that the improved time-scales which SDS promised, together with reduced costs, could keep major current aircraft developments on course. This was particularly important in an environment of political intervention and considerable public interest and concern over escalating costs

and delivery times in the public sector, including the defence industry. These benefits could only accrue to MAC if the quality, that is, correctness of the software, could be assured.

SDS was heavily dependent on software (CASE) tools. MAC had used these for many years, and had procedures in place for their qualification (i.e., acceptance) in certain circumstances. However, these applied to mission-critical rather than safety-critical systems. Furthermore, the movement towards auto-generated code led to a different environment than one where tools improved and speeded up the design process, but where failure would show up and be merely time-wasting. There was seen to be a need for a major improvement/update of these procedures, a quantum change, before they would be acceptable for safety-critical applications.

Some tools being used had major world-wide user communities, associated academic conferences, and came from supposedly secure and reliable suppliers. Others might not be so well supported, both intellectually and commercially. (For instance, it might be no use having an ideal tool if the supplier was small and unlikely to survive for many years.) Methods already existed for supplier qualification. These methods were undertaken by software quality staff. However, the qualification of these suppliers could be a crucial issue in the qualification of the tool and ultimately the integrity of the avionics system. The issue was not merely one of qualification, it was also one of *demonstration* of qualification to customers. Ultimately, the need in some sense to *prove* the new methods became paramount. Hence we can see that quality procedures did not just involve procedures, such as code walkthroughs through which software teams could persuade themselves to trust program code, they also applied to the question of choosing and trusting suppliers.

A number of meetings took place with members of the SDS team. This discussion was very useful for an understanding of SDS and gave the researcher a richer understanding of the SQA

needs. It soon became apparent that the necessary fundamental problems with SQA in SDS were going to be difficult to answer.

The difficulties were centred around two conflicting ideas. The first of these was that for the *persuasive rational argument* approach to be successful there would be a need for a group of professionals to participate in code walkthroughs, with consequent discussion and persuasion. On the face of it, this was simply not possible, since the computer which wrote the auto-code could not take part in such a discussion. Alternative approaches were considered. Clearly there would be a stage before the auto-code (at the requirements specification level) where human agents were involved, but this was found to be too high level to meet the relevant military standards (the US MIL-STD-498 [1994] and the UK standard 00-55 [MoD, 1997]). Both standards are very specific about the exact conduct of the necessary walkthrough. It had to be a *code* walkthrough.

On the other hand, for the *formal proof* approach method to work, there would first need to be such a formal proof. This did not seem within the capability of the QAD itself, despite the division being quite well resourced. MAC referred back to the auto-code tools suppliers, but once again there was no such proof and no realistic possibility of achieving such a proof. Although MAC was an important customer for the auto-code tool suppliers, they were not prepared to expend the necessary resources. Furthermore, a 'weakest link' argument demonstrates a fundamental flaw with the formal approach in computer systems. If the auto-code tool itself could be formally verified, it would then become necessary also to consider the operating system on which the tool would run and the hardware systems involved. Potentially this could involve a seemingly infinite regression of hardware and software systems having to be proved correct, where the system is only as good as its weakest link. Frustration grew as no solution was forthcoming and ultimately SDS was shelved indefinitely.

We have argued that mathematical proof is essentially a human achievement between members of the expert mathematical community who are persuaded of the correctness of mathematical proofs because they trust each other. These processes of trust are replicated in the procedures that have been developed in software engineering, and within that, software quality assurance. As part of the defence industry, developing safety-critical systems, MAC had highly developed SQA procedures which were obliged to follow international military standards. Their code walkthroughs, which are analogous to the ways mathematicians achieve trust in a proof, were an important part of such quality procedures. Formal methods offer the promise of an attractive certainty and control over software production and hence control over the work processes of human programmers. They also offer the promise of automatic verification of software systems which, potentially, could be much cheaper than traditional human based approaches to the verification of software through traditional SQA procedures.

SDS achieved very little despite the huge efforts put into it by the many people working for MAC. Although it was not, at the time, formulated in such stark terms, success was elusive because an attempt was being made to achieve the impossible: namely using auto-code whilst being held to quality assurance procedures which demanded code walkthroughs which could not possibly be achieved in an auto-code system. Attempts were made to consider formally proving the correctness of the auto-code. In addition to supplier reluctance, this raised the spectre of the infinite regress. If one looks to proving the auto-code correct, then the operating system must be proved correct, the hardware platform and so on.

This was at the height of interest in formal methods for safety-critical systems for defence, a view embodied in Def Stan 00-55. The rise of formal methods is crucially linked to the defence industry. The interest in formal methods and automated approaches arrived as pressure

mounted on Western governments to prove cost effectiveness due to the changing nature of defence developments after the end of the Cold War and the need to avoid litigation for software that might be implicated in an accident. Yet the difficulties of applying formal methods in systems of any level of complexity and the need to trust the program code acted as a spur to maintain complex human centred software quality assurance procedures.

CONCLUSION: TRUSTING COMPUTERS

There is much evidence that we already *do* trust computers in many walks of life without formal proof or other formal demonstration, even to the extent of trusting safety-critical systems such as the ‘fly by wire’ software in the Boeing 777 airliner, two million lines of code which have not been fully proved (Lytz, 1995). Expert mathematicians have begun to accept computer generated proofs, albeit in qualified ways (Chang, 2004). As MacKenzie (2001, p. 301) argues, ‘moral entrepreneurs’ of computerised risk ensure that warnings about computerised risk are heeded so that safety-critical software is avoided and, where it is unavoidable, much care is taken over its development. Military standards, so detailed about the use of formal methods in software design and attendant work processes in the 1990s, have moved a decade later to be much less prescriptive about the work methods of ensuring software quality, thereby allowing for the crucial element of human inspection in order that the software may be trusted. As Collins (1990) notes, we are remarkably accommodating to computers, making sense of them and involving them in our social networks, and will continue to find imaginative ways of doing so. This echoes Nissenbaum’s (1999) view that we may trust computers if we can treat them as ‘agents.’ We may meaningfully ascribe intentions and reasons to them.

In this article we have sought to tell a story of trust, in particular how software may be trusted when it is not produced by a human programmer. This involves consideration of a complex set of discourses including the question of mathematical proof and how proof is achieved within mathematical communities. We see a similar need to replicate such human processes of trust in trusting computer systems. We have argued that the making of standards to be applied within software quality assurance procedures shows ways in which mechanisms of trust are inscribed in software standards. Our case study, an action research project in a military aircraft company, demonstrates the difficulties which occur when quality assurance procedures involving code walkthroughs—procedures with built-in human trust mechanisms—are incommensurable with a system which relies on auto-code. The climate of defence research and spending was a major influence, both on our case study and the wider development of standards. There is a continued tension between needing to trust and trying to control: trusting the software and controlling its production. The story which we tell here is one of continuing human ingenuity in finding ways of trusting computer software.

Chapter 7.14

Propagating the Ideal: The Mobile Communication Paradox

Imar de Vries

Utrecht University, The Netherlands

ABSTRACT

In this chapter, visions of mobile communication are explored by focussing on idealised concepts surrounding wireless technology. By examining sources on the development, marketing, and use of wireless technology, I contextualise these visions within earlier accounts of ideal communication found in media history and isolate the regularities that are part of these accounts. On close examination, a paradox reveals itself in these regularities, one that can be described as resulting from an uneasiness in the human communication psyche: an unfulfilled desire for divine togetherness that clashes with individual communication needs. While the exact nature of this paradox—innate and hardwired into our brains, or culturally fostered—remains unknown, however, I assert that the paradox will continue to fuel idealised ideas about future communication technology. I conclude with the observation that not all use of mobile technology can immediately be interpreted as transcendental, and that built-in locational awareness balances the mobile communication act.

INTRODUCTION

In October 2003, two British climbers were caught in a blizzard on a Swiss mountain. Rachel Kelsey and her partner Jeremy Colenso, both experienced climbers, were forced to stop behind a large rock at 3000 meters up and wait for the weather to clear. They soon realised that their chances of finding the abseil points in heavy snow were very slim, which meant they were stuck. They texted five friends, one of whom received the message in London at 5 a.m. and immediately notified the rescue services in Geneva. After having to wait another 36 hours because the conditions were too severe for the rescue team to pick them up, the two climbers were finally rescued (Allison, 2003).

The idea that Earth is becoming entirely networked is not new,¹ but the characteristics of mobile communication media have—just as with the first wireless revolution in the beginning of the 20th century²—fiercely fuelled the Western notion that through better communication technology all problems of communication will—finally—be solved (Peters, 1999). The “anywhere, anytime, anyhow, anyone” slogan, subliminally attached

to every mobile apparatus, opens up a vision of a universally accessible communication space, in which the exchange of information comes to stand for the single most important condition of human progress. More than at any other time in history, this human progress is thought to depend on technological progress.

Rescue stories as those described in the opening paragraph play their part in keeping the idea alive that improvement through technological progress can be measured. The conventional wisdom is that human lives are the single most valuable things we can think of, and if new technology can help save them, it must be treasured. Moreover, if new technology such as mobile telephony makes possible a way of life that is never forsaken of human contact—which therefore is taken as safe because there will always be someone who can help—this technology is surely poised to be seamlessly adapted to and integrated in our being (Katz, 2003). Through the remediation of older dominant forms of communication and entertainment technology, the mobile device (or personal digital assistant (PDA) or smart phone, as it is increasingly being called by mobile phone operators and providers) does seem to try to provide an ultimate extension of the natural balance of our sense organs (Levinson, 1997, 2004). Future visions of mobile communication strive for setting up globally accessible meeting points that cater bodiless but perfect interaction, and ultimately for opening up a communication space in which everyone is represented.

This is the inherently human dream of reaching an ideal state, which is cunningly exploited by advertisements, telecom operators, service providers, and the like. We know it is a dream, and we know that we are confronted by it day after day. It will probably haunt us for centuries to come. However, just as “our desire for each other [is] a poor substitute for the primary Eros—and therefore doomed to fail” (Campe, 2000), so are our telecommunication media substitutes for the primary closeness—and bound to fail (Vries,

2005). The end result of this is a tragic search for ideal communication through a continuous so-called improvement of communication technologies, a search that will never end.

This chapter will investigate the paradox of this eternal futile quest that we seem to keep embarking on, and will do so by looking at how mobile discourse is framed within quest-ending narratives. By analysing texts from influential scholars such as Pierre Lévy, Howard Rheingold, and Paul Levinson, we will get a grasp of how idealised ideas of the power of new communication technology have pervaded the mobile realm. From there, an attempt is made to single out the recurrent elements in those ideas, whose pervasiveness in our culture will then be examined. Finally, we will look at a few current trends in mobile cooperation techniques that potentially realise certain ideals of communication, albeit in a more pragmatic sense than a sublime one.

UNWIRING THE KNOWLEDGE SPACE

So far, it has mainly been cyberspace and its accompanying access points in the form of personal computers and laptops that are associated with potentially establishing the universally accessible communication realm. However, with the amount of mobile phones growing at an enormous pace,³ the mobile device has with stunning speed become an essential tool to establish and maintain social networks, as well as managing all kinds of data flows. In this capacity, the device seems perfectly poised to morph itself into the logical choice of medium when accessing the ever-expanding Über network, the Internet.⁴ Wherever, whenever, whatever: downloading or uploading information on the move, sharing news events as they happen with your carefully filtered online friends, checking in on your favourite weblog while lying on the beach; it is already possible and will be even more so when the devices grow into always-on

mode. It is at this point where Pierre Lévy’s (1997) imaginative collective intelligence, located in what he calls the knowledge space, starts to come into its own on an immense scale.

Lévy describes the evolution of earthbound living as being immersed in a succession of four types of space, in which man’s identity is determined by the tools and symbols predominantly available in that space (see Table 1). The knowledge space is the fourth—and final—space in which we have come to live, and can best be seen as an informational cloud, a “space of living-in-knowledge and collective thought” (Lévy, 1997, p. 140). An important premise for its existence, growth, and preservation is that people interact with the informational cloud by adding, changing, and retrieving data in whatever way possible.⁵ It is to “unfold and grow to cover an increasingly vast and diverse world” (Lévy, 1997, pp. 111-112), ultimately creating a universally accessible information realm. Already, we can recognise this vision in descriptions of the multiple thrusts behind both the Internet and the mobile revolutions, such as those found in marketing publicity and open source movements’ manifests alike.

Lévy’s hierarchical description of the four levels of space invoke Borgmann’s (1999) distinction between information about (“my shed can be found next to the willow tree”), for (“this is how you build a cathedral”), and as reality (“hi, I am Imar’s avatar, shall we start exchanging data?”). Both Lévy and Borgmann show us historical

shifts that expose a dematerialising transition of the dominant form of information. Although—as is conspicuously evident from the title of his book *Holding on to Reality*—Borgmann warns us for a Baudrillard-like potentially dangerous split between information about/for reality and information as reality, Lévy is not so much concerned about the danger of leaving reality behind, as he frames the knowledge space firmly within the other three spaces: “[It is n]ot exactly an earthly paradise, since the other spaces, with their limitations, will continue to exist. The intention of collective intellect is not to destroy the earth, or the territory, or the market economy” (Lévy, 1997, p. 141).

Paradise or not, Lévy cannot help but describe the knowledge space in terms of “a u-topia ... waiting to be born,” “a cosmopolitan and borderless space,” “an electronic storm,” and “a sphere of artifice shot through with streaks of light and mutating signs” (Lévy, 1997, pp. 138-141), thereby mimicking the eccentric cyberpunk style of William Gibson’s *Neuromancer*. There is undeniably a religious element visible in the way Lévy writes about the knowledge space, in which information is to be uncoupled from its static base. This dematerialising movement fits perfectly with the transcendental nature of going wireless: liberating things by releasing them from their carriers (be it wires, paper, or the brain) promises more opportunities to interconnect those liberated entities, as they form free-floating nodes in a dynamic

Table 1. Succession of spaces according to Lévy (1997)

Space	Identity
Nomadic Space of Earth	totems, lineage
Territorial Space	territorial inscription
Commodity Space	position within the domains of production and consumption
Knowledge Space	skill, nomadic cooperation, continuous hybridization

network. In the end, in its most radical form, the idea is that every node can be connected to all others, providing instant and perfect transferral of whatever form of data.

As asserted previously, although the knowledge space is self-regulated and its transcendental nature gives rise to the supposition that it might leave the other spaces behind, Lévy holds that it cannot be entirely separated from the three preceding spaces. Moreover, in a circular movement—“a return of the earth to itself,” as Lévy (1997, p. 141) calls it—the knowledge space connects back to the first space through the recurrence of the nomadic identity. Again, this is a characteristic that is typically found in the mobile device, as has been shown by scholars in recent literature (Gergen, 2003; Kopomaa, 2000; Meyrowitz, 2003). The multiple social roles we possess are called upon in increasingly diverse geographical and social environments when a mobile device is carried along: we can perform parental tasks while at work, we can keep in touch with friends while on vacation, and we can consume entertainment while sitting in classrooms. Slowly, urban design is responding to the diminishing need to build strict and fixed divisions between sites for work, leisure, and family, creating heterogeneous zones in which the individual’s social status is defined by the type of communication he or she engages with. The use of mobile technology therefore does not entail a full-circle return to the nomadic in the sense that it forces us to change location in order to find more fertile ground, as was the case in Lévy’s first earthly space, but it forces our locations to adapt to our dynamic modes of being.

The transcendental and nomadic nature of the knowledge space calls for an intricate investigation of the points where it meets other spaces, and of the materiality of these meeting points. Considering the ease with which the mobile device has found its place as the essential data tool, such meeting points, which according to Rheingold (2002) seem to call for a “marriage of bits and atoms” (p. 100) or for us to be able to “click on reality,” (p. 95)

are set to be facilitated by the smart phones of the future. Or, as we will see in the next section, this is how it is envisioned in idealised ideas of communication.

THE LURE OF THE IDEAL

Although he admits to being utopian, and has subsequently tried to capture the dynamics of the collective intelligence in a formal language in order to make it more visible and tangible, Lévy has been criticised for painting an exaggeratedly pretty picture, ignoring the tough reality of political, economic, social, and other factors that influence the way communication technology is developed, produced, distributed, and used. In the fourth chapter of their book *Times of the Technoculture: From the Information Society to the Virtual Life*, Robins and Webster (1999) accuse Lévy of “promot[ing] and legitim[izing] the prevailing corporate ideology of globalization,” and hold that “there is a desperate need for a richer debate of knowledges in contemporary societies — in place of the shallow, progressivist marketing that attaches itself to the cyberculture slogan (and reflects the hegemony of corporate interests)” (Robins & Webster, 1999, pp. 225, 227). In the same chapter, the aforementioned Rheingold receives similar flak for his—supposedly uncritical—belief in the Internet as a means of restoring communities.

However, Lévy and Rheingold are influential writers and are certainly not alone in taking an optimistic and idealised view on the possible contributions new communication technology can make to finally bring people together in an intelligent collective—nor will they be the last. If the years between the launch of the world’s first graphic Internet browser in March 1993 and the crash of the dotcom boom in early 2000 marked the building up of the cyberspace hype, then the subsequent years can be characterised as having been labelled the new and improved mobile or

wireless era: countless press releases, research papers, news articles, advertisements, books, radio shows, and television programmes have heralded mobile technology as the ideal solution to many communication problems. Two books I would like to bring to the fore in this respect are *Smart Mobs: The Next Social Revolution* by Howard Rheingold (2002) and *Cellphone* by Paul Levinson (2004), as their structures show interesting similarities with Lévy's (1997) approach—and with it, the same dangerous tendency to overestimate communication technology's power to fulfill longtime ideals of communication.

Comprised of a large series of anecdotal, interview, and travel journal material, *Smart Mobs* intends to uncover the characteristics of the “next social revolution,” which is to be cranked up by the new mobile devices that “put the power of instant and ubiquitous communication — literally—within everyone's grasp” (Rheingold, 2002, back cover). Describing an impressive amount of trends, experiments, news reports, and commercial projects within the global realm of mobile telephony and computing, Rheingold shows how “technologies of cooperation” have an inherent tendency to group people together—and where there is a group, there are opportunities to learn, create, or topple over. The well-known (albeit somewhat overused) example of the protest demonstration in the Philippines in 2001, in which more than 1 million people were rallied by text messages to oppose Joseph Estrada's regime, is used by Rheingold as a key argument in describing a pivotal cultural and political moment: the power of mobile, ad hoc social networks is not to be underestimated; it can even influence politics on a momentous scale! To be fair, Rheingold's argument does not hinge upon this example alone; next to three other activist movements, he also mentions the squads of demonstrators that, thanks to mobile coordination, won the “Battle of Seattle” during a World Trade Organization meeting in 1999. These movements, however, have been minor in impact and longevity, and

do not appeal to the imagination as much as the Philippine regime change does. It is therefore that *Smart Mobs* focuses mainly on events and projects that contain a clearly visible potential to change things; after all, what better way is there to show that the social impact of mobile technology is not only measurable, but can also be described in terms of setting in motion an unstoppable voyage towards a better future?

Other examples of what the consequences of ubiquitous mobile communication might be are equally carefully chosen for their provocative nature. Among the phenomena that await us, Rheingold (2002) names WiFi neighbourhoods; wearable computing that makes our environment aware of our presence and can react accordingly; RFID tags that provide contextual information on any object; and swarm intelligence that makes possible useful emergent behaviour. He does his best to convince us of the inherent potential of these things to fundamentally change the way we are living—and does so with an obligatory nod to the possibility that some of those changes might not be as pleasurable as we would like—but fails to go much further beyond stating the mantra together is good. The majority of Rheingold's examples, however tangible and useful they may be within their own context, are used to construct a vision of a futuristic world in which the possibility to connect things (people and machines) is most highly rated. To connect is to solve, to evolve, to come closer to the ideal of sublime togetherness.

Levinson's *Cellphone*⁷ is another very good example of how opportunistic ideas found in much cyberculture literature have been transferred to the mobile realm. Not wasting any time, the book's subtitle, which is as subtle as it is provocative, already promises to tell us “[t]he story of the world's most mobile medium and how it has transformed everything” (bold in original). Working from within his Darwinian approach to media evolution—only the fittest media persist in the human environment—Levinson holds that “the cellphone has survived a human test,”

and that the human need it satisfies is “as old as the human species — the need to talk and walk, to communicate and move, at the same time” (Levinson, 2004, p. 13). This need, which “even defines the human species” (Levinson, 2004, p. 13), is satisfied by the mobile device to such an extent that Levinson foresees the end of the digital divide; the rise of new and more honest forms of news gathering and dispersal; and the birth of a smart world.

The most important (and obvious) characteristic Levinson stresses is that the mobile device blurs the boundary between inside and outside, rendering it unnecessary to confine ourselves to brick and mortar rooms when we want to call someone or find information. The consequence of this blurring is that it will enable us to “do more of what we want to do, be it business or pleasure, pursuit of knowledge, details, companionship, love,” and that it will make “every place in the world in which a human may choose to thread ... well-read, or ‘intelligent’” (Levinson, 2004, pp. 60-61). Dubbing this intelligent world a “telepathic society”—accompanied by the obligatory but hollow disclaimers that “our progress ... will be tough going at times” (Levinson, 2004, pp. 60-61) and that the mobile device not only solves things but generates new problems of privacy as well—Levinson sides with previous visions of emerging all-encompassing intelligence that have proved to be vulnerable to easy critique, including the Noosphere of Teilhard de Chardin (1959), the morphic fields of Sheldrake (1989) and the global brain of Bloom (2000). As we will see in the next section, the recurrence of these ideas is not coincidental.

RESEARCHING REGULARITIES

Clearly, optimistic visions of new futures are often met with scepticism, but this does not stop them from reoccurring through time; especially when new information and communication me-

dia find the limelight. To understand why this “almost willful, historical amnesia,” as Mosco (2004, p. 118) calls it, occurs, it is necessary to investigate the underlying regularities of such idealised claims, and to map the basic elements that make up those regular elements. By focusing not on a new medium itself—nor on what it is that makes it unique—but on the path that lies before that medium, we can get a detailed view of the moments in time that mark significant contributions to the medium’s earlier discourse. This can best be achieved using the so-called media archaeology approach, which aims to prevent historical amnesia by “(re)placing [the histories of media technologies] into their cultural and discursive contexts” (Huhtamo, 1994). Doing so, the emphasis is shifted “[f]rom a predominantly chronological and positivistic ordering of things, centered on the artefact, ... into treating history as a multi-layered construct, a dynamic system of relationships” (Huhtamo, 1994). It is these relationships that can clarify the intricate ways in which idealised regularities in the dynamic communication media discourse may have changed face, but not their core.

Huhtamo proposes to call the regularities *topoi*, or topics, which he defines as “formulas, ranging from stylistic to allegorical, that make up the ‘building blocks’ of cultural traditions.” He stresses that these *topoi* are dynamic themselves: “they are activated and de-activated in turn; new *topoi* are created along the way and old ones (at least seemingly) vanish” (Huhtamo, 1994). In other words, *topoi* are highly political and ideologically motivated. As an example of a *topos* found in media history, Huhtamo considers the recurrent “panicky reactions” of public being exposed to visual spectacles, and finds these in illustrations of the *Fantasmagorie* shows at the end of the 18th century, in reports of the showing of the arriving train in the Lumière brother’s *L’Arrivée d’un train à La Ciotat* (1895) and in the stereoscopic movie spectacle *Captain EO* in Disneyland. There is, of course, a danger

of over-interpreting historical sources that may well have served another function than to give an accurate account of what actually happened, but this is exactly Huhtamo's point: "unrealized 'dream machines,' or discursive inventions (inventions that exist only as discourses), can be just as revealing as realized artefacts" (Huhtamo, 1994). The Lumière showing may well not have created any panic at all, but it still remains a poignant reference, a media myth that is repeatedly used in numerous books, articles, and essays in which the reception and impact of new media is discussed. Media archaeology tries to expose these dubious but persistent stories, to collect and dust off forgotten elements of a medium's history by looking at discursive connections, however weak those connections may be. By looking at the many levels on which the discursive construction of a communication technology presents itself, media archaeology bridges the revolutionary gaps that are often found in teleological historiographies of that technology.

This archaeological approach has been put to practice by several scholars in recent years,⁸ and has so far been successful in revealing and critically analysing media topoi such as the desires for immediacy, presence, liveness, and simultaneity. The most powerful (or overarching) topos, however, is the gnostic longing to transcend earthly life by improving technology, and to create a Universal Brotherhood of Universal Man. This ultimate topos unites every imaginable description of fulfillment, perfection, pureness, and harmony, and can be found in accounts of every communication medium, in every stage of its development, production, distribution, and use. The dream to finally fulfill the ultimate topos through improvement of communication technology can be comprehensively traced through media history, as many scholars (Mattelart, 2000; Mosco, 2004; Peters, 1999) have already shown. As I have written elsewhere, "[w]ireless telegraphy was seen as 'the means to instantaneous free communication'; telephony seemed to promise banishment of dis-

tance, isolation and prejudice; radio would pave the way for contact with the dead and television would transform its viewers into eyewitnesses of everything that went on in the world" (Vries, 2005, p. 11). With every development, be it technological, political, economical, or social, the regularities in discursive accounts of older media have been passed on to newer versions, thereby changing form but not essence.

The argument here is that mobile technology fits into a long line of media in which a limited set of regularly used modes of reflection determines the discursive domain of media reception. By analysing the discursive construction of mobile technology and comparing it to that of previous communication media, we can get a grasp of the topoi that have flourished or been revived—be it essentially unchanged or in disguised form—and of those that have floundered or been abandoned. Some of the most interesting indicators of these topoi are to be found in rationalisation techniques people use when explaining why they buy mobile phones, or what they are mainly going to use them for. On the surface, these explanations mostly point to very pragmatic reasons. Field study has shown that common justifications for acquiring a mobile phone are business, safety, and security (Palen, Salzman, & Youngs, 2000). On a deeper psychological level, however, these pragmatic reasons can be tied to fears of solipsism, a desire to increase the amount and strength of communication channels in the social network, and a wish for greater control over one's overall connectivity and availability. Just as we have seen in Rheingold's *Smart Mobs*, a need for the potential to increase togetherness is expressed in the mobile discourse, reflecting the ultimate topos of ideal communication.

The hints of religious elements present in these uncovered communication ideals is not surprising; just as Ludwig Andreas von Feuerbach stated in the middle of the 19th century that God is the projection of the human essence onto an ideal, so is an ultimate communicative Being

One a projection of a human essence onto communication ideals. The religious motifs continue to exist today: authors such as Erik Davis (1998) and David Noble (1997) have written elaborate accounts of how contemporary technological discourses are still undeniably intertwined with religious beliefs, despite the widely held notion that since the Enlightenment these categories have slowly but surely separated. Such is the case with the topos of ultimate togetherness: the fears and desires disseminated by that topos are exponents of a mixture of the autonomous behaviour of the liberated Cartesian subject on the one hand, and a dream of a bodiless sharing of minds, described by Peters (1999) as angelic communication, on the other. This is a deeply paradoxical mixture, however. Angelic communication shows all the hallmarks of a divine togetherness: with no physical borders and direct one-on-one mappings of minds, every entity will ultimately know and be the same. This loss of individuality collides with the search for more control over one's individual connectivity found in the modern subject's autonomous behaviour. Both angelic communication and complete autonomy are idealised opposite poles on the same scale, and will therefore remain forever out of reach.

THINKING THROUGH PARADOX

The crux of the communication paradox can be described as an uneasiness in the human communication psyche, born out of the tension between the desire for ideal communication and the knowledge of never being able to reach that goal. This is not to say that every individual always wants to strive for perfection. Moreover, reaching perfection may not be what would actually be beneficial for human kind, as many dystopian answers to utopian projects, proposals, and literature have shown; there is no room for individuals or deviations in a society that can only function perfectly if every citizen is synchronised in the

grand scheme.⁹ Still, the paradox holds, as even in dystopian visions the utopian looms; in the end, Armageddon, the ultimate dystopian event, does nothing more than to destroy old structures in order to lay the foundation for a new, perfect one. A similar argument can be made for a dominant part of the communication media discourse: New media strive for the abolishment of old media in order to provide improved togetherness (Bolter & Grusin, 1999).

As we have seen in the previous section, the successive observations that the development phase and subsequent promotion of communication media are almost always framed within idealised expectations, that these are always accompanied by dystopian rebuttals, and that this process of touting and dismissing keeps reoccurring through time, give rise to the assumption that there is a steady undercurrent present, a topos that can be described as an idea of ideal communication that drives humankind to keep searching despite guaranteed failure. The objection to this assumption might be that this process is merely a marketing mechanism, but such a mechanism can only work if it addresses a human longing, one that is sensitive to promises of solving the communication tension.¹⁰ The question, then, is whether the paradoxical attitude towards communication technology is innate, or if it is just a temporary, culturally sustained concept of progress left over from the Enlightenment, which, at some time in the future, is to be replaced by another concept. If it is innate, we will not be able to escape it; if it is not, we might be able to understand how to change or manipulate the structures in which the paradox resides.

To ask the question of innateness is to enter the realm of epistemology, the study of how we can know the world around us. Until the middle of the 18th century, this field had known two fairly opposed visions: the rationalist and the empiricist view. The rationalist Innate Concept thesis holds that there are some concepts that are already in our minds when we are born, as part of

our rational nature. The notion that we can have a priori knowledge, that we have some innate awareness of things we know to be true that is not provided by experience, rests on the premise that the concepts used to construct that knowledge are also innate. Empiricists, however, argue that there are no innate concepts, and that experience alone accounts for the raw material we use to gain knowledge. The most well-known proponent of empiricism, John Locke, wrote that humans are born with a blank mind, a *tabula rasa*, which is written onto by experience. Knowledge, therefore, is not brought to consciousness by experience, but is provided by that experience itself.

This distinction largely disappeared toward the end of the 18th century when the two views were brought together by Emmanuel Kant, who divided reality into the phenomenal world (in which things are what they appear to us to be, and can empirically be known) and the noumenal world (in which things are what they are in themselves, and where rationalism rules). According to Kant's transcendental idealism, innate concepts do exist, but only in the noumenal world, where they remain empirically unknowable. Arguably, these innate concepts are philosophical in nature and therefore proof of their existence remains hard to formulate, but this does not mean innateness is always metaphysical. For instance, genetic theory, a late 20th century science, claims to provide empirical evidence for the existence of innate mechanisms in cognitive evolution: Human brains are not *tabula rasa*, but prestructured in specific ways so that they can learn things other organisms can not. While some elements of evolutionary psychology (EP) are highly controversial,¹¹ it is increasingly accepted that we all come wired with what Chomsky (1957) has called a Language Acquisition Device (LAD): Not only do we possess an innate capacity to learn, but also an innate set of universal language structures. This means that, independent of our social, cultural, or ethnic environment, we already know how language works before we even speak it. It is on this

level that we have to look for the communication paradox if we believe it to be innate: Are we in some way hard-wired to have a tendency to long for goals that are impossible to reach, to be fascinated by things that are and yet are not? Is there some sense of divine togetherness that we come programmed with, that is at some point in time to be fulfilled but keeps slipping away when we think we come close? The long history of trying to overcome distance and time through the use of media makes a strong argument for such a claim, especially when looking at the positivist discourse this search is usually framed in.

Seen this way, the topos of increased togetherness through idealised communication is but one manifestation of a central paradoxical tendency generated by our brains, albeit one of the most dominant. An imaginative account of how this paradoxical core pervades all aspects of life is found in Hofstadter's (1979/1999) *Gödel, Escher, Bach: An Eternal Golden Braid*. In the new preface in the 20th anniversary edition Hofstadter stresses the paradoxical motive for writing the book by stating that he had set out to "say how it is that animate beings can come out of inanimate matter" (Hofstadter, 1979/1999, p. xx). Introducing so-called strange loops, instances of self-reference that can often lead to paradoxical situations, Hofstadter shows that these loops can not only be found in math, perspective drawings, and music, but also—and this is his main argument—in the very essence of conscious existence itself. Without paradoxes, it seems, life as we know it could not exist. A similar argument is made by Seife (2000), who explores our uneasy relationship with zero and infinity in *Zero: The Biography of a Dangerous Idea*. Innocent as they might seem, in many situations in many times the notions of zero and infinity have been difficult to grasp, use, and explain; to such an extent even that people have equated them with the work of God and ignored them as not allowed by God at the same time. It was through the use of zero and the infinite that Zeno could create his paradoxical race, in which

Achilles never overtakes the tortoise, and it is zero and the infinite that plague contemporary physicists' current understanding of our universe. Opposite poles that invoke as well as fight the paradoxical will always be with us, because we are born out of a paradox, Seife concludes.

EP is a relatively young field, and as such has not yet found very stable ground. The argument that there is a universally active module in our brain that triggers—or is even responsible for—a life with paradoxes is therefore to be very cautiously approached. As asserted previously, it may well be that our paradoxical attitude towards communication is not the manifestation of an innate concept, but of a culturally constructed one. A helpful nongenetic argument for the paradoxical inclination is found in existentialist theories, especially in Heidegger's treatment of *Gelassenheit* (releasement) and Sartre's description of *mauvaise foi* (bad faith). Whereas the former concept deals with fully accepting one's Being-in-the-world as something that has no intrinsic goal or pre-given content, as something that can only receive its significance through the meaning one chooses to give to it, the latter is the result of not accepting the open-ended nature of our existence, of continuously asking "why"? and trying to find the answer outside of one's own will. Such a denial of things-as-they-are and things-as-they-happen actively feeds and sustains a two-pole system, in which paradoxes reside: There is no coincidence when everything happens for a reason, and there is no sense when everything is contingent. People with bad faith—and there are a lot, according to Sartre—often face and cannot accept the most fundamental paradox: Sometimes things are just what they are, even when they are not.

Now all these observations may seem a far cry from our day-to-day experience of using mobile phones, but whenever we transfer any information in any way we are positioned as a node in a communication network, one that exists foremost because we as humans seek contact. We hope

and strive for this contact to be instantaneous, clear, under control, and ideal, even when we want to mislead or deceive the other person; if we manage to use the medium and channel in such a way that it serves our intent, the contact has been ideal for its purpose. The desire is for a technologically induced complete fulfillment, which is omnipresent in mobile discourse. There is never any certainty about having reached this ideal state, however, as we have seen. The communication paradox makes sure that something always gets in the way of pure experience.

THE RETURN OF LOCATION

In light of this knowledge, the best way we can act, as Peters (1999) also argues, is to embrace the impossibility of ideal communication and make do with what forms of communication we can realise. The transcendental nature of wireless technology may at times lure us into thinking we have come close and need just a little push in the right direction, but this would be like chasing a mirage. What then are the elements of more appropriate pragmatic approaches to using new communication technology, ones that defy the urge to hand out idealised promises? Some interesting trends in recent innovative wireless concepts show that the independency of locality, the characteristic that seemingly constitutes the essence of mobile telephony, can be turned on its head. Where the most pure form of communication is equated with a bodiless presence and is therefore situated in a nondescriptive anywhere, part of the current crop of wireless projects inject exactly this sense of locality into the mobile communicative act. The resulting location based services (LBS) are put to use in a variety of ways: backseat games that merge road context with virtual content (Brunnberg & Juhlin, 2003), portable devices that support the tourist experience by supplying on the spot information (Brown & Chalmers,

2003), systems that provide virtual annotation of physical objects (Persson, Espinoza, Fagerberg, Sandin, & Cöster, 2002), and mobile phone applications that can sense the proximity of people on your buddy list (Smith, Consolvo, Lamarca, Hightower, Scott, Sohn, et al., 2005). Of course, all these projects in some way reflect a drive towards making things easier, quicker, better, or simply more enjoyable, and therefore do not completely escape paradoxical idealised thinking, but they do not ostentatiously try to transcend our present experience of communication by denying its inherent grounding in lived space and time.

Another area where mobile phones are undeniably making a difference without having to resort to metaphysical musings is in developing countries. By leapfrogging older communication technology—in most cases this concerns landlines that had been too expensive to be installed nationwide—mobile technology is used to quickly set up cheap networks, thereby facilitating measurable boosts to local economies and communities. The mobile networks do not instantly connect all parts of a country, but remain localised in existing urban or rural environments. This localisation is further strengthened by the fact that, less tempted to use the mobile device to mix different social locales into one heterogeneous zone, as is more the case in Western metropolitan areas, people in these developing countries tend to see the mobile more as a landline that happens to be wireless. If there would have been a landline the impact would have largely been the same, something communication theorist Jonathan Donner (2003) concurs with. He conducted several field studies in Rwanda, and found that the use of mobile phones by Rwandan entrepreneurs enhanced their ability to do business, but also to satisfy their emotional and intrinsic needs. This is mostly due to the mere presence of a communication channel, and not to the mobile's intrinsic essence. Again, the underlying idealised implication is that appointments, deals, and transactions can occur faster and more streamlined when people are increasingly

brought together in whatever way, but in cases such as those in Rwanda the results of introducing wireless technology are clearly visible and do not remain mostly theoretical.

CONCLUSION

With the global proliferation of mobile communication devices, a reinvigorated sense of ubiquitous connection possibilities has emerged. Covering large parts of the Earth, a networked informational skin seems set to revolutionise our way of living. The key new paradigm that is stressed in this “mobilisation” of the world is the ability to tap into an all-encompassing knowledge space, thereby making information addition, retrieval, and communication virtually instantaneous. The fundamental driving force behind this endeavour can be ascribed to a desire for establishing connections to everyone or everything in whatever way possible, a bodiless omnipresence. The radical consequences of this—almost angelic—desire are affecting traditional modes of interaction such as dialogue and dissemination.

This dream of idealised communication is subconsciously stressed by the dominant image of wireless communication that is found in advertisements, press releases, books on social change, government policies, and the like. Promises that things will get better, fuel our impatience when contemporary technology fails to deliver. In other words, the desire for ideal communication itself is part of a paradoxical system found in all layers of our existence. The dream can never be realised, and will therefore continue to recur through time. Whether we will be able to change our attitude towards this strange loop depends on its nature: If it is hard-wired into our brains, we will have to live with the paradox forever. If it is not, who knows, we might come to see mobile communication for exactly what it is, a specific but not definitive “Being” of communication.

Chapter 7.15

A De–Construction of Wireless Device Usage

Mary R. Lind

North Carolina A&T State University, USA

ABSTRACT

In this article, wireless technology use is addressed with a focus on the factors that underlie wireless interaction. A de-construction of the information processing theories of user/technology interaction is presented. While commercial and useful applications of wireless devices are numerous, wireless interaction is emerging as a means of social interaction—an extension of the user’s personal image—and as an object of amusement and play. The technology/user interaction theories that have driven the discussions of computer assisted communication media are information richness, communicative action, and social influence modeling. This article will extend this theoretical view of wireless devices by using flow theory to address elements of fun, control, and focus. Then, these technology/user interaction theories are used with respect to wireless devices to propose areas for future research.

INTRODUCTION

Within the United States, wireless devices have become ubiquitous communication devices. Yet, in Europe and the Far East, these devices are not only widely used as communication devices, but as vehicles of commerce and of entertainment. It is widely known that the GSM telecommunications standard is not fully implemented in the United States, inhibiting the development of wireless applications by firms to support their mobile customers. Yet, there seems to be more to this than telecommunication standards. This article will examine social behavioral issues that affect wireless usage and propose a model to better understand this usage.

Wireless devices, serving as transmitters of information at a reasonable cost from point to point without being tethered to a wired line, are profoundly impacting how we communicate and perform work (Rudy, 1996). Little research exists on how to design wireless technologies to better

support wireless communications and applications (Te'eni et al., 2001). Research on information technology design finds that the technology should be fit to the user's task needs (Senn, 1998, Swanson, 1988). Since wireless devices provide a tool for convergence of voice, text, audio, photos, videos, and data (Yager, 2003), it is critical that the design of these wireless devices fits the multiple modes of data exchange and usage supported by the wireless devices.

Models to explain information technology design and adoption are rooted in the assumptions of the usefulness and usability afforded by the technology (Davis, 1989, Swanson, 1988), where the context for these technology design and adoption models is the workplace. As information technologies have become pervasive throughout the culture (Gaver, 2005), these technologies, while still an instrument to perform work more efficiently, have become a means of social networking, diversion, and entertainment for the homo luden (Huizinga, 1950). Yet along with this play aspect, the homo luden also gains control of his/her personal space. These aspects of mobile information technologies, usefulness, usability, play, and control will be explored in this article to determine how these dimensions of mobile information technology interaction can enable flow (Csikszentmihalyi, 1975) and enable homo ludens (Huizinga, 1950) to seamlessly process information for work and for play. Huizinga (1950) notes that play influences the culture of the players as well as Gaver (2005) observes that pervasive, "ambient" technologies also shape the culture in which the technologies are used. In this article, the discussion focuses on the use of these wireless technologies that have become artifacts representative of work, social, and play activities in our everyday cultural contexts, and how these same cultural contexts, in turn, are shaped by the wireless artifacts, and through this interaction, the enactment of additional uses for the wireless devices.

THEORETICAL FOUNDATION FOR WIRELESS MEDIA USAGE

Two theoretical approaches will be examined. First, the view of wireless devices as communication media based in information richness theory is presented, followed by the theoretical view of wireless devices using the social networking theory perspective. Secondly, wireless media will be addressed as objects of play and of control. Finally, a model is developed showing the bidirectional impact of wireless devices as artifacts that influence culture and the resulting culture that in turn impacts perceptions of the wireless artifacts.

Media Richness Theory

The rational choice model contends that users select the most effective medium for data exchange. Media richness theory (Daft & Lengel, 1984; Lind & Zmud, 1991) proposed that managers will use richer media in ambiguous contexts and the leaner media for more structured tasks. For example, face-to-face media that permit the transmission of nonverbal clues and immediate feedback will be used in contexts that are unclear and need to be sorted through in order to reduce the ambiguity of the context. In information richness theory (Daft & Macintosh, 1981; Daft & Weick, 1984; Daft & Lengel, 1984), it was proposed that communication channels vary in their ability to convey information and meaning. This theory suggests a continuum where the richest channels are those that provide for more face-to-face interaction and feedback, allowing for the communication of nuances, often unspoken, in adding meaning to communication. The leanest channels are those written or printed. Since research into information richness theory has met with conflicting results, especially in the area of e-mail studies, other theories and theory extensions have been explored. Neither voice mail nor e-mail allow for

face-to-face interaction, but voice mail records the actual voice of the speaker while e-mail provides much quicker feedback than printed media. Thus, the underlying media richness theory is the assumption that individuals seek to be efficient communicators and make rational decisions, selecting a communication medium that fits the nature of the information being communicated.

Other theories have addressed the use of media as a social construct (El-Shinnawy & Markus, 1997). Using the social influence model of technology use, Fulk, Schmitz, and Steinfield (1990) proposed that perceptions of communication media, such as richness, are socially constructed. They found that individuals were more influenced in communication channel use and perceptions by their co-workers than by their supervisors. Also, they found that keyboard skill and computer experience were important predictors of perceptions of electronic mail richness. The communication medium became viewed as an artifact that reflects the social circumstances of the communicating partners that in turn impacts the social context for their social network, thus becoming an influence on the culture of that social group.

Ngwenyama and Lee (1997) proposed a critical social theory perspective for communication channel richness using the work of Weick (1969) and Habermas (1984), they posit that the richness of a communication channel is determined by how the person using that channel enacts the channel. Thus, critical social theory advocates the notion that the interpretation of the information conveyed through a channel is in the mind of the receiver. Some may filter complex, rich information and seek to simplify it to fit their simplistic view of the organization. While others may embrace complex, rich information and revel in trying to interpret the many dimensions of often ambiguous but rich information. It cannot be assumed that greater usage means a richer channel. It may just mean that the channel is more accessible or easier to use for short messages than the telephone or

face-to-face media. Thus, critical social theory shows that the enactment of the communication artifact is determined by that individual's context and the individual's perception of that context and as the use of the communication artifact becomes widespread then the culture will develop shared perceptions of its attributes, which can then have a broad impact on the culture.

Communicative Action Theory

The object of most communication is to convey information so that the communicating partners reach a mutual understanding, regarding the topic at hand. Habermas (1984), in his theory of communicative action, addresses the concept of communicative rationality, where a mutual understanding is reached through processes that signal commonalities in culture that promote understanding. Thus, the goal of communication is to reach a common understanding between the communicating parties. However, according to Habermas, different cultural groups may interpret different signals for enacting this mutual understanding. Hence, channel richness for one such group may differ from another group. Thus, communication action theory recognizes that the media are enacted differently in different cultural contexts, but the rational goal is to achieve a common understanding using the medium for communication.

Communication Channel Enactment

Addressing this issue of enacted meaning, Carlson and Zmud (1992) proposed communication channel extension theory and showed that one's past communication experiences, both in terms of the communication channels and the person with whom one is communicating via the channel, will in turn shape one's perception of a communication channel. Thus, different levels of experience with a computer mediated chan-

nel in an organizational context will shape one's perceptions, and use of such computer mediated channels, just as one's past experiences in engaging in face-to-face communication will influence face-to-face communication. This view of channel enactment then shows the circular impact of the channel on the communication content, within a cultural context where the perceptions of the communication partners influence future expectations of that channel.

Flow Theory

A different explanation has been proposed with little relationship to richness theory—flow theory (Trevino & Webster, 1992; Ghani & Deshpande, 1994). In flow theory, the channel is enacted as an article of amusement. Flow theory (Csikszentmihalyi, 1975; Miller, 1973) suggests that a flow state is a playful, exploratory experience where flow is a continuous variable from none to intense. Thus, some communication channels, particularly the computer mediated ones, may enact such playful behavior. Trevino and Webster (1992) proposed that, through flow, the individual has a sense of control of the interaction and thus finds it more interesting. This seems particularly true as the communication medium becomes a tool of commerce and work activity. Thus, control of the interaction engages the attention of the person using that medium. Csikszentmihalyi (1990, p. 4) developed the theory of optimal flow as, "the state in which people are so intensely involved in an activity that nothing else seems to matter; the experience itself is so enjoyable that people will do it even at great cost, for the sheer sake of doing it." Here, the context, rather than individual differences, is used to explain human motivation (Maehr, 1989; Weiner, 1990), and the focus is on the total concentration on an activity and the enjoyment resulting from that activity (Ghani, 1991; Malone & Lepper, 1987). Wireless devices serve as artifacts of communication and entertainment for many. When not talking on the

wireless device, people are observed looking at the screen for text messages, browsing the Web, playing games, and so forth. These artifacts of our culture have become a source of time absorption for many, as they wait for the next meeting or walk to their destinations.

Further, Csikszentmihalyi (1990, p. 25) characterized flow theory as, "A phenomenological model of consciousness based on information theory." Consciousness deals with the flow ordering of information regarding intended actions and goals (Parr and Montgomery, 1998). One of the dimensions of flow is the challenge of the experience (Ghani and Deshpande, 1994). Csikszentmihalyi (1990, p. 3) said, "The best moments usually occur when a person's body or mind is stretched to its limits in a voluntary effort to accomplish something difficult or worthwhile." Ghani and Deshpande (1994) state that a second dimension of flow is control by the users. Csikszentmihalyi (1994, p. 3) states, "We have all experienced times when, instead of being buffeted by anonymous forces, we do feel in control of our actions (on such occasions) we feel a sense of exhilaration, a deep sense of enjoyment." Turkle (1984) discussed how a computer user may work because of the fun of the interaction, not necessarily to achieve a specific goal. In flow, Csikszentmihalyi (1990) discussed how a person loses their sense of time. So flow enables a person to process information best when the effort expended by the individual is within that individual's control and when the challenge of the experience meets the skills of the person. The interaction with the wireless artifact must match the skill level of the user. The communication and Web browsing aspect of these wireless artifacts are compatible with already learned skills, using wireless artifacts for other activities, such as entertainment or games, requires skills interaction that match those the user will have to insure concentration on the activity. In any case, the control of the wireless artifact is in the hands of the user where this accessibility encourages increased usage.

Psychic-entropy is a counter force to flow in which there is disorder in consciousness. This occurs whenever, “Information...conflicts with extreme intentions or distracts us—from carrying them out.” (Csikszentmihalyi, 1990, p. 36) Anxiety, fear, jealousy, or rage describes disordered experiences. Entropy drains our psychic energy, fragmenting attention. Attention is the process for collecting, storing, and retrieving information. Flow is an experience in which attention is freely invested in the accomplishment of goals allowing the self to develop, increasing complexity (Csikszentmihalyi, 1990). The control afforded by the wireless artifact helps to counter the force of psychic-entropy, giving the user more control over their environment (communication, schedules, messaging), where adjustments can be made in schedules easily, without the user being tethered to land based devices. Parr and Montgomery (1998, p. 27) state “Flow experiences have been characterized as the following, merging of action and awareness; centering of attention on a limited stimulus field; letting go of self-consciousness (transcendence of ego); a feeling of competence and control; having unambiguous goals and receiving immediate, specific feedback; and being intrinsically motivated.” Thus, this aspect of flow looks for balance between one’s goals and one’s skills in achieving those goals. Flow is more closely associated with positive emotions, greater concentration, and a greater sense of control. A person must see that there is something worthwhile to do and that he/she has the ability to do it (Csikszentmihalyi, 1990). As one increases his/her skill level, she/he is motivated to seek out increasingly challenging activities (Mandigo & Thompson, 1998). Csikszentmihalyi (1990) indicates that the flow state is so enjoyable that the participant will want to continue with the activity for the sake of participation.

The communication, enabled by the wireless artifacts, creates a sense of flow for the wireless communities. These communities can achieve collaborative action (Crane, 1972) using the

wirelessly connected communities. The wireless communities are not bounded by space and can connect easily to take action so that the communities are empowered by the collective strength and ability to influence actions in their space. So another aspect of flow enabled by the wireless artifacts is control over collective action.

Flow is about optimizing the happiness that occurs from the everyday immersion in life’s activities, “It is by being fully involved with every detail of our lives whether good or bad, that we find happiness, not by trying to look for it directly.” (Csikszentmihalyi, 1990, p. 2) A key component to the flow experience is participation or active involvement in something. It comes when an individual is participating in an activity that makes a difference in the person’s life. “The concept of flow—the state in which people are so involved in an activity that nothing else seems to matter; the experience itself is so enjoyable that people will do it even at great cost, for the sheer sake of doing it.” (Csikszentmihalyi, 1990, p. 4) This connectedness to communities can become an absorbing aspect of the wireless artifact. Yet paradoxically, the wireless artifact absorption can be with music, games, or Internet browsing afforded by the wireless artifact, which is largely a nonsocial activity. However, games are increasingly played via online networks, creating online gaming communities.

Much of the experience of finding flow is about order and goals. “When goals are clear, feedback relevant, and challenges and skills are in balance, attention becomes ordered and fully invested.” (Csikszentmihalyi, 1990, p. 31) Here, a defining factor within a flow experience is the ability to recognize and accept clear boundaries in terms of the goals and acceptable behavior. This means that a flow activity must be ordered to some extent by conforming to cultural or social boundaries. “Athletes, mystics, and artists do very different things when they reach flow, yet their descriptions of the experience are remarkably similar.” (Csikszentmihalyi, 1997b, p. 29) Although one person’s

experience with flow may be solitary and pertain simply to their specific circumstances, chances are that the flow is experienced as a member of a social network.

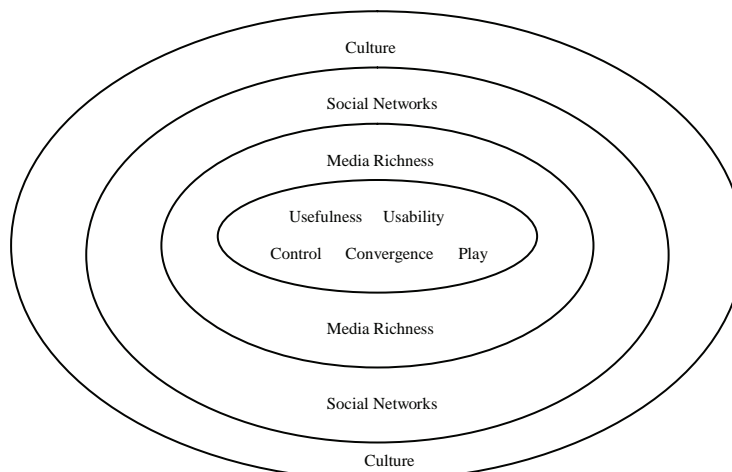

Therefore, within any given flow experience and particularly with usage of the wireless artifact, it is important to pinpoint the organizational frameworks or structural boundaries to which the participants adhere. It is within this willing submission to structural boundaries that highlights an important dimension for understanding the flow experience. What needs do these boundaries fulfill? And if the flow experience is a group activity, how is this mutual submission to ordered rules enhancing the flow experience and leading paradoxically to a freer, happier existence? Submission to overarching rules is found often within games, sports, social networks, and organizations. Membership in these groups brings meaning to its members, whereby meaning is imbued in the artifacts that provide the linkages for these groups. It is through these wireless artifacts, and the resulting linkages within the communities, that trust in the social network develops. While the wireless devices enable multiple modes of

communication between and within the communities, their interactions can be shared using common codes and symbols in text messaging and in gaming communities.

Csikszentmihalyi lays out three main qualities of a flow experience. These are: first, when there is a clear set of goals; second, when immediate feedback is provided; and third when all of a person's skills are being used to overcome challenges. (Csikszentmihalyi, 1997b, p. 29-30)

Because of the total demand on psychic energy, a person in flow is completely focused. There is no space in consciousness for distracting thoughts, irrelevant feelings. Self-consciousness disappears, yet one feels stronger than usual. The sense of time is distorted: hours seem to pass by in minutes. When a person's entire being is stretched in the full functioning of body and mind, whatever one does becomes worth doing for its own sake; living becomes its own justification. In the harmonious focusing of physical and psychic energy, life finally comes into its own. (Csikszentmihalyi , 1997b, p. 31-32)

Figure 1. Wireless artifact

It seems that, during the flow experience, the participant is able to forget about any larger problem and completely focus for the span of time while they are completing their activity. Absorption with games, online chats, blogging, and so forth, all provide clear rules and immediate feedback. In the context where the user's skills match the demands of the interface, the result can be total immersion.

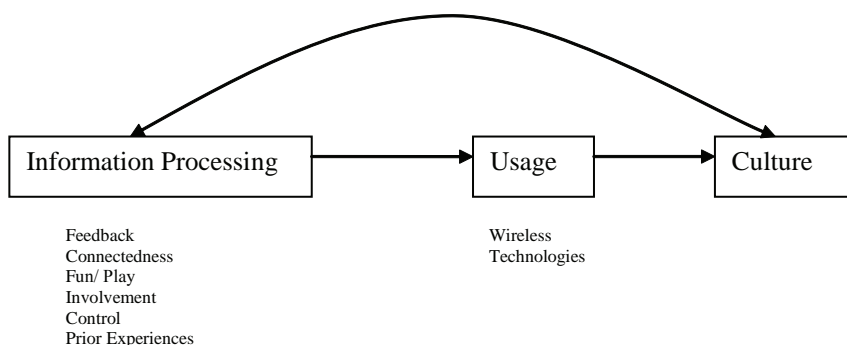

From this discussion of the development of the theory for communications technology interaction and specifically wireless devices based in media richness theory and social network theory, the concept of flow was introduced, providing a multilayer perspective on wireless artifacts. So, in addition to the convergence achieved via the communication media, the media also engage the user by providing means for play and for control over, not only the play and communications activities enabled by the wireless device, but work activities as well. An assumption built into these wireless devices is that they are both useful and useable. The theoretical layers of wireless devices discussed in this section are shown in Figure 1.

Culture and Phratria—Wireless Artifact Interaction

Shiller (1979, p. 29) defines culture as a way of life in which our life's activities shape our culture.

As technologies are adopted within society, these technologies shape our culture. For example, Tomlinson (1991) states, "The relationship implied in this is the constant mediation of one aspect of culture experienced by another: what we make of a television programme or a novel or a newspaper article is constantly influenced and shaped by whatever else is going on in our lives. But, equally, our lives are lived as representations to ourselves in terms of the representations present in our culture." Thus, the wireless technologies as artifacts enable communication, play, scheduling tasks, information search, and so forth, but the artifact itself shapes the culture and the expectations of those in the culture using these wireless devices. Huizinga (1950, p. 12) observed that play affects culture, "It would be rash to explain all the associations which the anthropologist calls "phratria"—for example, clans, brotherhoods, and so forth—simply as play-communities. Nevertheless, it has been shown again and again how difficult it is to draw the line between, on the one hand, permanent social groupings—particularly in archaic cultures with their extremely important, solemn, indeed sacred customs—and the sphere of play on the other." As discussed, these wireless artifacts enable social groupings. In some contexts, these phratria are for work purposes, but in many contexts, these groupings are social and for pleasure. Thus, the play is evidenced in

Figure 2. Model of wireless usage

the form of the type of phratia as well as the type of diversion, such as games or Internet browsing enabled by wireless devices.

Thus, flow applications are those that accomplish a repetitive activity, but do it in a way that makes doing the activity enjoyable, almost effortless with security. Flow applications blend in with our daily lives, causing little disruption. As the widely accepted technology acceptance model (TAM) has shown (Davis, 1989), the user must perceive both usefulness and ease of use, while the flow model adds the dimensions of

enjoyment and control. Table 1 shows the items for assessing usefulness and ease of use. Added to the TAM dimensions are the proposed flow dimensions of enjoyment and control.

Davis (1989) showed that task usefulness and ease of use of the technology are key components of technology acceptance. In flow theory, it is advocated that technology enables a carefree approach to doing a task that is effortless and fun, while enabling greater control. Two other factors affecting use of a specific communication channel are accessibility of the channel (Zmud,

Table 1. Technology acceptance model and flow

Usefulness
Using technology x enabled me to accomplish tasks more quickly.
Using technology x improved my task performance.
Using technology x increased my task productivity.
Using technology x enhanced my effectiveness while performing the task.
Using technology x made it easier to do my task.
Technology x is useful in my task.
Ease of Use
Learning to use technology x is easy for me.
I find it easy to get technology x to do what I want to do.
My interaction with technology x is clear and understandable.
I find technology x flexible to interact with.
It is easy for me to become skillful at using technology x.
I find technology x easy to use.
Proposed Flow Dimension
Using technology x was a fun experience for me.
While using technology x I felt in control.
Using technology x gave me more control over my work activities.
Using technology x was a challenge that used my skills.
Using technology x was a pleasant adventure.

Lind, & Young, 1991) and the degree to which the channel affords rapid feedback (Zmud, Lind, & Young, 1991). Few things are more accessible than a wireless device that can be carried in a person's pocket and these devices enable rapid feedback. So, the richness dimension of feedback, identified by Zmud et al. (1991), is an inherent factor discussed by Csikszentmihalyi (1997a) in flow theory.

FURTHER RESEARCH NEEDED

To move beyond using the devices as voice communication devices, applications that enable the dimension of flow are needed. These are applications for the user that enable them to carry out routine activities easily and with a great degree of control and applications that enable the connectedness with phatria. These applications will enable rich transaction exchanges within the phatria, whether the exchange is for social networking, collaborative action, gaming, or for mobile commerce. Applications enable the flow immersion, giving the user control over work activities and play activities. These applications should provide seamless intergration as the user moves from the work space to the play space to the social network space.

From a broad communication perspective, it has been shown that there are systematic differences in communication by gender. Women have a tendency to work harder at maintaining conversation in face to face situations (Fishman, 1983; Meyers et al., 1997). It has been shown that women value connection and cooperation more than men (Meyers et al., 1997), suggesting that this tendency to maintain the conversation level is evidence of insecurity. Both Allen and Griffeth (1977) and Gefen and Straub (1997) have examined the relationship between gender and information processing. Allen and Griffeth (1997), counter to their hypothesis, found that women did not experience information under load as

compared to their male coworkers in a study of 666 workers at a Midwestern telephone company. In the study, roughly 40% were female and about half the workers were hourly employees. Gefen and Straub (1997) found that women perceived electronic mail differently, but in practice, did not use it differently in a study of 392 respondents with three different airlines in three countries. The Gefen and Straub (1997) study showed that the women respondents perceived e-mail to be of higher social presence and more useful than men; however, these same women did not find e-mail easier to use than men and did not, in fact, make greater use of e-mail when measured through self report. Research is needed to determine if gender differences exist in wireless media use.

Certainly gender, culture, and age differences may influence acceptance of wireless media. Examination of these factors, in terms of the expanded TAM model, is needed. Is the greater acceptance of wireless media in Europe and Asia due to technological or cultural factors? Looking at the applications that drive usage of these wireless media, applications are needed that not only simplify work transactions, but are fun to use and not labor intensive in terms of data entry. A new paradigm for wireless applications may be instrumental in promoting flow. A paradigm that recognizes the need for work, play, and control by the user, which in turn, can change the culture of work and play, which through the interconnectedness of the phatria, leads to new uses in terms of work, play, and control for these wireless devices.

Wuppertal Institute, Germany

ABSTRACT

This chapter concentrates on the environmental impacts of the increasing use of the Internet. It highlights that the Internet and Internet applications are far from being purely virtual, but are clearly linked to the use of natural resources. With the growth of the Internet's infrastructure there is a seemingly inevitable increase in the resource consumption for the production of electronic equipment and its electricity consumption. A number of conclusions can be made regarding the minimisation of environmental risks and maximisation of e-business' potential to dematerialise. The presented findings are mainly based

on findings derived from research within the Digital Europe project, which was conducted as the first pan-European study of the social and environmental impacts and opportunities of e-commerce and information communication technologies. Supported by the European Commission, the project has been led by the research organisations Fondazione Eni Enrico Mattei in Italy, Forum for the Future in UK and the Wuppertal Institute in Germany.

INTRODUCTION

The transition from an industrial society to a service society proceeding in many countries

Virtual Networking without a Backpack?

of the world is supported by information and communication technology (ICT) and ICT applications. The industrial society was primarily about large-scale production and distribution of goods. Within the service society, added value is increasingly generated from immaterial production factors such as information and know-how, and a large number of functional areas such as the economy, politics, legislation, culture or health depend to an increasing degree on knowledge. Adoption of this knowledge is supported by ICT. Thus ICT can be accounted as a key technology within the service society.

The diffusion of ICT within societies can be illustrated by the adoption of the Internet. Even if only experts knew the medium “Internet” at the beginning of the 90s, it became mass media in the middle of last decade. About 600 million people have gone online in the last 15 years – this is about 10% of the world population. And there are forecasts that there will be 710 million users of the Internet in the year 2004 (e.g., Cyber Atlas, 2003). On average, 81% of EU enterprises accessed the Internet in 2002, and a majority of them had their own Web site or homepage (European Commission, 2003). Even if the initial euphoria about the new technology is subsiding, every day we hear news about large ICT investments, technology innovation and new areas of ICT applications.

As ICT and ICT applications increasingly spread, so do also the ecological problems of this trend appear to become more relevant. For example, increasing Internet use is linked with increasing electricity use. However, ICT is generally not seen to be associated with significant environmental problems. In fact, the opinion predominates that new communication media are just as virtual as their contents. Sometimes it is even seen as an innovation, which would make possible a sustainable and resource-efficient way of life per se.

This chapter highlights the environmental impacts of the increasing use of the Internet.

The following section provides insights into the physical elements of the ICT infrastructure with a specific focus on the Internet, and provides a classification of environmental effects caused by ICT. The subsequent sections discuss the direct and indirect effects as well as the systemic effects on the consumption of natural resources. Finally, conclusions are drawn on how to develop a more resource-efficient information society.

This book contribution is based mainly on findings derived from research within the Digital Europe project. The project was conducted as the first pan-European study of the social and environmental impacts and opportunities of e-commerce and information communication technologies. Supported by the European Commission, the project has been led by the research organisations Fondazione Eni Enrico Mattei in Italy, Forum for the Future in UK and the Wuppertal Institute in Germany. Twelve corporate and regional partners have been involved: AOL Europe, Barclays Bank, EMI, Finmatica, the Global eSustainability Initiative (GeSI), Hewlett-Packard, Welsh Assembly Government, Netscalibur, Projekt Ruhr, Sun Microsystems, Vitaminic and Vodafone. Information on environmental effects of ICT are described by Kuhndt et al. (2003). Further information, for example, specific case study reports on mobile computing, digital music and e-banking can be found on www.digital-eu.org.

ICT INFRASTRUCTURE AND ENVIRONMENTAL EFFECTS

Electronic information processing (e.g., by computers) and telecommunication (telephone, radio, TV) have been separate technologies in the past. However, these two technologies have merged and spread increasingly by means of the digitalisation of previously analogue media (telephones, music, pictures, faxes, etc.) and an increase in digital communication. Among the different technologies connecting digital devices, the Internet is currently

the main ICT infrastructure and seems likely to remain that throughout the near future (e.g., Office of Technology Assessment at the German Parliament, 2002). According to a survey by the Internet Software Consortium (2002), the number of Internet hosts grew worldwide from 30 million at the beginning of 1998 to over 172 million in January 2003, corresponding to a growth of more than 25 million per year.

The growth of the Internet goes hand in hand with an increase in ICT infrastructure, which can be illustrated by some examples. Worldwide more than 410 million people have access to the Internet through a personal computer at home (Cyber Atlas, 2003b). It is estimated that there were 117 million PCs in the EU in 2001, 31 per 100 inhabitants (European Commission, 2003). A study by Intel concluded that in 2001 only 4% of the servers were in place that will be needed in 2005 (VDI Nachrichten, 2001). Figure 1 illustrated the spread of “information appliances” in Western Europe, a trend highlighted by EITO as easy-to-use, low-cost tools to access the Internet (EITO, 2000).

The physical infrastructure forming the Internet can, with a certain level of abstraction and

simplification, be broken down into four different categories:

- Network access devices (client side) are used by clients (users) to access the services provided by Internet service and content providers. These services are based on files and programmes stored on servers. PCs and laptops account for the overwhelming majority of devices used to access the Internet. A forecast for the near future sees many more devices such as mobiles, set-top boxes (located on top of a television set as interface between the home television and the cable TV company enabling Internet access, video-on-demand, video games, educational services, database searches, and home shopping), cars and household appliances as forthcoming connection devices.
- Content providing devices: This category basically covers servers. In general, a server is a computer programme that provides services to other programmes on the same or other computers. The computer on which a server programme runs is also frequently referred to as a server, though it may contain

Figure 1. Web access devices by type, installed base, Western Europe, 1997-2002 (EITO 2000)

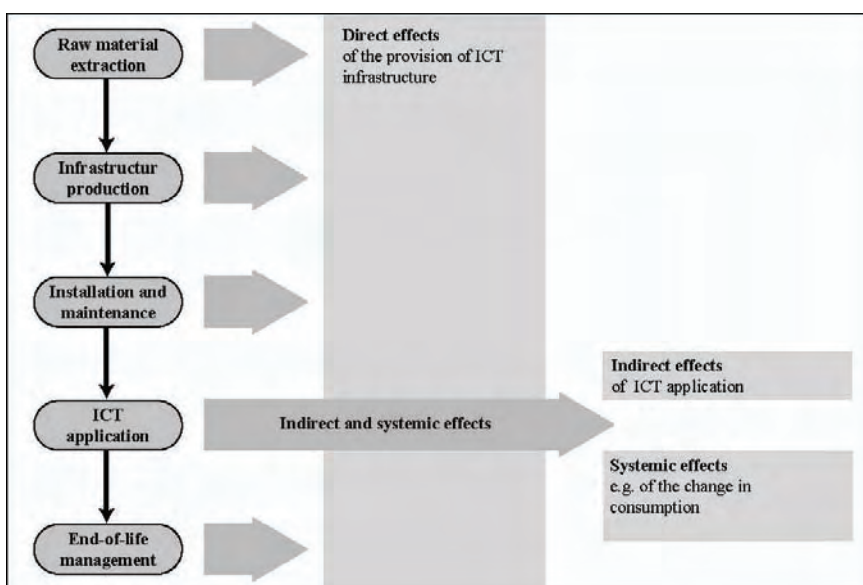

Virtual Networking without a Backpack?

a number of servers and other programmes. Specific to the Web, a Web server is a programme (running on a computer) that serves the files that form Web pages, using the client-server model and the World Wide Web's HTTP protocol (Hypertext Transfer Protocol, defining the rules for transferring files on the World Wide Web). Several other types of servers exist, such as FTP servers, e-mail servers and news servers.

- Intermediate devices include several different devices that enable communication on the net. "Routers," "switches" or "gateways" switch or route traffic on the network – for example from a long-distance network to a local exchange point. "Bridges" connect different networks, "repeaters" receive, amplify and retransmit signals and "firewalls" are programmes located at network gateways or servers that protect the resources from other users and programmes. Until the mid-90s all national Internet traffic in Germany was routed via the US. In 1995 the Deutscher Commercial Internet Exchange (DE-CIX)
- started operating and presently connects all but one major national and many international ISPs. 85% of German and 35% of European Internet traffic is routed over the DE-CIX. The advantage of such a centralised peering point is that traffic within Germany is routed within the country, leading to much faster and less costly data exchange (Deutscher Commercial Internet Exchange, 2001).
- Data transfer media are the "highways" (or sometimes just "country lanes") that transfer the data. Most common are "cables," traditionally made of copper; the newer and much faster ones are made of optic fibre. They range from old-style telephone networks with transfer rates up to 56,000 bps to inter-continental "backbones" with a bandwidth above 1 GBps. A backbone is a large transmission line that carries data gathered from lines that interconnect with it. The Internet is a wide area network (WAN) comprised of a number of backbones – regional networks that carry long-distance traffic. At the local

Figure 2. Environmental effects of ICT

level a backbone is a line or a set of lines that connects local area networks (LANs) to a WAN. On the national level, directional radio is used as well.

Looking more at the environmental effects of ICT, the associated resource consumption can be classified into direct, indirect and systemic effects (see Figure 2).

The direct effects refer to the effects caused by ICT infrastructure and equipment, for example the material consumption for producing PCs and Internet servers or from energy consumption. The reduced need for travelling or office space as a result of telework or the increase in just-in-time deliveries thanks to B2B applications are examples of indirect effects which are caused by the application of ICT. Indirect effects derive from existing desires or habits that are fulfilled through new, ICT-based applications. In contrast, systemic effects stem from new habits or consumption patterns that arise through the use of ICTs, such as the increase in transatlantic freight shipments as a result of online auctions in the US. This contribution highlights the fact that ICT infrastructure and the application of ICT are leading to both positive and negative environmental impacts and represent a recommendation of how to develop

an information society which does not induce an increase in resource consumption.

DIRECT EFFECTS OF ICT INFRASTRUCTURE ON RESOURCE CONSUMPTION

Backpack of ICT Production

While no studies quantifying the material intensity required to build the entire Internet system are known of, we do have some case study research within Digital Europe which highlighted specific components of the communication infrastructure (Geibler et al., 2003). Related studies are from Loerincik, Jolliet and Norris (2002) (on energy consumption and selected emissions) and from US EPA (2001), Atlantic Consulting (1998) or Behrendt et al. (1998) (for life cycle assessment of electronic products).

Regarding the resource consumption for the end appliances a comparative analysis of a handheld and a notebook's production has been conducted (Geibler et al., 2003). The analysis is based on the MIPS methodology (Schmidt-Bleek, 1995). MIPS provides indicators (e.g., abiotic raw material, biotic raw material and water consump-

Table 1. Results of material intensity analysis for production

Product	Components	Weight (kg)	Abiotic raw materials (kg)	Material intensity of component (kg/kg)
Notebook	Device	3.0	398	133
	Support items (cables, power adapter)	0.4	31	78
	Packaging	1.3	5	4
Handheld	Device (incl. modem)	0.2	58	290
	Support items (cables, power adapter)	0.6	19	32
	Packaging	0.7	5	7
Personal Organiser	Paper-based device	0.4	4	10

Virtual Networking without a Backpack?

tion) to assess the systemwide resource consumption from the cradle to the grave taking in the total mass of material flows at all product stages, from raw material extraction to disposal. By associating the material fluxes connected to energy generation, the MIPS methodology integrates also the energy intensity. A traditional personal organiser has also been analysed to provide a base for comparison with non-electronic tools for mobile communication. The following table shows that the handheld's resource consumption lies between both other products.

As these results show, the efficiency gains from the shift to the handheld are not proportional to the difference in weight. The handheld device (excluding packaging and support items) weighs 200 grams, but its production consumes 58 kg of abiotic, non-renewable raw materials. This yields a factor of 290. For the notebook, this factor is lower: at 133 comprising less than half of it. The high material intensity of the handheld device is a result of the large share of functional materials included in the handheld and the modem. These functional materials have intensive upstream processing demands for components such as PWBs, LCDs, chips and precious metals. Additionally, most of the materials in the electronic devices used arise from abiotic, non-renewable sources. Generally, it can be observed that the production of the paper-based personal organiser consumes by far the smallest amount of resources. The accumulative effects of these material-intensive appliances are visible at the macro-economic level.

A first and very rough estimate by the Wuppertal Institute of the material intensity necessary for producing just the servers installed in Germany came to about 1.7 million tons of abiotic raw materials or 0.2 kg if allocated per hour of Internet use. While this figure can only be regarded as an initial trace of what is to come, it might serve as an indication of the volume of resource flows still to be included if the entire infrastructure were considered.

Transporting ICT has Low Relevance

Transportation from ICT manufacturing to the consumer contributes little to the entire resource consumption caused within the device's life cycle. In the case study for the handheld it accounted for less than 1% of the abiotic raw materials. However, if the transport of components and subcomponents before assembly, possibly by air, were to be considered, transport's contribution to resource consumption would probably be higher. In addition, the consumer habits (transport mode and distance traveled to sales point) constitute an influential factor of the transport related effects.

More Electricity for the Net

In the use phase all Internet infrastructure parts are associated with energy demand, which is an important factor to include when calculating the overall resource consumption of the Internet. Researchers at the Wuppertal Institute and other researchers working on the electricity consumption of Internet infrastructure have highlighted its dimension.

The electricity consumption of the end appliances in the use phase contributes significantly to the resource consumption of the infrastructure (Loerincik, Jolliet & Norris, 2002; Türk, 2001; Türk et al., 2002). The electricity consumption of a single device is determined by the user behaviour (the time spent in active, standby, sleep and charging modes) as well as the device's and charger efficiency. Also the energy source (e.g., coal, oil, hydro, wind) and the technology used for electricity production determine the material use of the device. Within the Digital Europe case study (based on the European electricity mix and on specific assumptions regarding consumer behaviour) the use phase accounts for a resource consumption up to 1.5 times higher than the one of the production phase. The respective figures for a handheld are only a third or half; that is, the

handheld is relatively energy efficient in the use phase. Regarding the service of “mobile information processing” that both products provide, there are differences in the convenience and handling of the information processing. There are mainly “mobility-related” advantages on the handheld’s side, whereas there are “information processing-related” advantages for the notebook. But still, as the users of mobile computing devices do not need (and cannot use) all the functions at one time, the concept of a shared use of the electronic equipment is coming into the picture as an interesting improvement option. Regarding shared use of electronic devices, the question is what raw material savings could be achieved if for example a company provided handhelds to all of its salespeople and promoted sharing of notebooks. This could be compared to a situation where each employee uses an individual notebook (see Figure 3).

The shared use of notebooks and individual use of handheld devices can increase overall efficiency. Starting from the material intensity analysis of the notebook and its assumptions, the

use intensities of the notebooks and the handhelds would increase with each increase in the number of persons sharing a notebook. However, with respect to the related use of abiotic raw materials, the saving attained with notebooks (and paper based personal organisers) is offset by the increasing use intensities illustrated in the figure.

These savings seem to be high. However in practice there are a number of obstacles to the shared use of notebooks and related material saving. For example, in a company where salespeople share electronic equipment, some salespeople will need a notebook when they are travelling. The shared use of notebooks might force other salespeople to come back to the workplace when they need the notebook’s processing capacities. Also, there are a number of changes needed to create shared working places (e.g., additional office equipment), which might be related to additional material intensities. As most of the handhelds are currently used in combination with notebooks, the handheld today is more an add-on device than a substitution for the notebook. As long as consumers demand a notebook or a PC in

Figure 3. Abiotic raw material intensity for sharing notebooks and additional use of handhelds

Virtual Networking without a Backpack?

addition to the handheld, no increase in resource efficiency can take place. But still, the concept of sharing seems to be an opportunity for increased resource efficiency.

On the national level the Internet's electricity consumption is considerable. For example, in Germany the life cycle electricity consumption of the entire Internet infrastructure is estimated to account for almost 2% of national electricity consumption (Thomas, 2002). The future energy demand of the Internet is most likely to increase. Initial estimates of future energy consumption indicate that the electricity demand from the Internet in Germany could increase to 5% of total electricity consumption by 2010. Also, research conducted by Romm in the US and by Aebischer and Huser in Switzerland points to an increase in the demand for energy caused by the entire Internet infrastructure, despite the energy efficiency improvements of individual Internet-enabled activities (Aebischer & Huser, 2000; Thomas, 2002).

The resource consumption associated with the Internet's energy use depends on how the electricity is produced, as shown by research done at the Wuppertal Institute (e.g., by Liedtke et al., 1998 or Manstein, 1996). It is the specific energy mix of a country that determines the associated resource consumption. In Germany, the material flows associated with electricity consumption during the use phase currently account for about 0.5% of nationwide material consumption (Türk, 2001). However, with increasing electricity demand by the Internet, the related resource consumption is most likely to rise.

End-of-Life Aspects of ICT

In the year 1998, 6 million tons of electronic waste had to be disposed of at the European level. The growth rate is at least 3% to 5% per year (European Commission, 2000). In Germany more than 2 million used computers, printers and so forth

accumulate every year. These cause large amounts of waste to be processed, which will be tripled over the middle term. If the electronic waste is disposed of in domestic waste, either it will end up untreated on a dumpsite (thus ensuring that contaminated waste will develop in the future), or will be fed into a "thermal utilization" type of waste incineration plant, the cleaning technologies of which are not designed for this kind of contaminated waste, or they will be transported to developing countries.

Considering the large amount of resources used to produce individual end-user appliances, reuse and recycling as well as the extension of the use phase are important improvement options from a life-cycle perspective. However, the actual number of recycled devices is low. The basis of an efficient recycling scheme includes both a good motivation for the end-user to return products and efficient logistics (take-back and recycling). As the material value of smaller products is reduced and the smaller size of devices allows them to be discarded with household waste, the take-back and recycling systems face major challenges. It is not yet clear what impact the WEEE directive will have on this matter. More practical data and research are needed for reliable evaluation of recycling schemes.

INDIRECT AND SYSTEMIC EFFECTS OF INTERNET APPLICATIONS ON RESOURCE CONSUMPTION

As highlighted in Figure 2, Internet applications have indirect effects as well as systemic effects. Both need to be considered for evaluation of the environmental effects of the broad system of the Internet. This section will highlight the resource consumption with a focus on the e-commerce applications of online banking and the digital provision of music.

Online = Virtual?

The analysis of the indirect environmental effects of e-commerce within the Digital Europe project highlights that the object of the economic transaction (the product or service) is an influential factor for the overall dematerialisation potential of e-commerce. This means that the material intensity of the transaction's object as such determines substantially the influence that e-commerce has on resource efficiency. Thus, e-commerce activities can be divided into product-based and information-based e-commerce, depending on the amount of physical material used to provide the specific service delivered by the product.

Information-based e-commerce, as one important application of ICT, can – under specific circumstances – provide significant resource efficiency potentials. Information-based e-commerce is not based on a physical product forming the object of the economic transaction. Online banking is one example where resource efficiency gains can be achieved by e-business, as illustrated in Figure 4 (Türk et al., 2003).

Based on the assumptions made in the online banking case study, a traditional payment causes resource flows in the order of 2.7 kg abiotic raw materials, whereas online payment only for 1.1

kg. Comparing these amounts with the amounts of raw materials needed to produce, e.g., beverage cans, we see that the traditional payment uses as much raw materials as the production of 10 cans requires. If the payment is conducted online, the equivalent of only four cans is needed. Assuming that from all 20 million online accounts in Germany (estimations of the number of online accounts are given for example by NUA Internet Surveys (2003)) annually 20 previously traditional payments would be replaced by online transactions, this would account for annual savings of 640 thousand tons of abiotic raw materials, that is, non-renewable resources.

Another example of information-based e-commerce is a music server that can provide a tremendous number of song units to many consumers (see Digital Europe case study on digital music by Türk et al., 2003b). The case study showed that downloading 56 minutes of music over the Internet is more than two and a half times less resource intensive than buying a CD with an equivalent amount of music at a shop. Savings are made at different stages in the process. For a start, a physical CD is replaced by a digital file. The resources needed to produce a CD are associated with an ecological backpack seven times their actual weight. Additionally,

Figure 4. Abiotic resource consumption of banking: Comparing a traditional payment with an online payment

Virtual Networking without a Backpack?

resource flows associated with the production and retail infrastructure as well as with transportation are made redundant. Moreover, resource savings associated with the reduced need for building infrastructure appear to be relevant. Other examples of dematerialised products are centralised voice mailing servers (Reichling & Otto, 2002) or news servers (Reichart et al., 2000).

With virtual products and services, consumers have a far greater influence on life-cycle-wide resource intensity because material intensity is no longer concentrated on the production and delivery phase of the product life cycle. Figure 5 shows how the overall material intensity is distributed among the producer, retailer and consumer when a CD is purchased in a music store (physical shopping), online (online shopping) or an equivalent number of compressed music files are downloaded over the Internet (digital distribution). There is a clear sign of a shift in material intensity down the value chain, making consumers the guardians of the environmental potential of virtual products and services.

In the case of product-based e-commerce, the physical production and delivery of a product takes place in a way similar to traditional shopping. Thus, the related resource consumption can be only partly influenced by ICT, as the production of the product and most of the logistical efforts remain. The resource savings due to e-commerce for products that have a high resource intensity during production are small anyway, since pro-

duction will likely dominate the material intensity along the life cycle. Additionally, there is an important difference compared to digitised products: digitised products can be shared by an unlimited number of users if not restricted by any kind of software protection. This means that one “product” can serve many users, adding a functionality that does not exist for traditional products even if they are sold by e-commerce.

Taking a Broader Perspective

Regarding systemic effects, influential factors for the resource consumption are the businesses and consumer habits or rebound effects. As with many other technical applications and services, these factors are important to consider in order to evaluate the full picture of the environmental effects of ICT and e-business. While on a case study level they might not turn out to be of relevance, on a macro level they are likely to be. A few examples are:

- The Internet will reframe markets, enabling companies and consumers to buy globally, which potentially increases transport demand;
- Flat rate internet access might reduce the (economic) incentives for Web users to disconnect from the Internet between sessions, resulting in an increasing energy demand, even if the PC itself is in sleep mode;

Figure 5. Environmental potential of virtual products and services in the case of digital music

- Fast Internet connections might change consumer behaviour and increase overall material intensity, as consumers with a fast Internet connection are more likely to stay online or to download more files.
- Consumers tend to re-materialise digital information. Examples are music files burned on CDs or the tendency to print out most digital documents.

In particular, people's habit to re-materialise is a good illustration of how consumer habits can be rooted in a non-digital world. Information stored only on a remote server or hard-drive is burned onto a CD or printed out on a regular basis. The reasons for this can be manifold, including issues such as trust (Is the information safe? Is a back-up needed?), traditions (important information needs to be filed as a printout) or habits (working with long documents requires a printout). The case study on digital music has highlighted the fact that this habit might offset the savings obtained from digital distribution.

In summary, information-based e-commerce has the potential to decouple economic growth from resource consumption. However, larger savings on a macro scale are not expected at the present situation or in the near future for various reasons (Kuhndt et al., 2003). First, e-commerce is a sales channel built up and maintained in parallel with traditional channels. Second, the number of products that can be reduced to an "informational core" seems to be limited. In the resource intensive sectors such as building, food, clothing and community as well as large parts of health and leisure there are a number of products that are not likely to be digitised. This leaves a fraction of total material consumption in which information-based e-commerce could potentially contribute to a decoupling. Third, under the current framework influencing resource consumption, consumer habits and rebound effects might have a counterbalancing influence. Whether with

changed framework conditions the benefits could outweigh the risks remains an open question.

CONCLUSIONS

The Internet and Internet applications are far from being purely virtual, but are clearly linked to the use of natural resources. It seems that a seemingly inevitable increase in the resource consumption for the production of electronic equipment and its electricity consumption comes with the growth of the Internet's infrastructure. Based on existing research, a number of conclusions can be made regarding the minimisation of environmental risks and maximisation of e-business' potential to dematerialise.

Monitoring Environmental Impacts of Internet and Internet Applications

The quantification of environmental effects caused by ICT technologies is still a major challenge. Having knowledge about environmental effects along the entire product chain is a necessary precondition for the identification of efficient improvement options. Efforts are required to improve macro-level statistical classification systems for ICT infrastructure and applications to provide adequate statistical information. At the company level, opportunities can be the combination of cost accounting systems with internal material flow data (material flow accounting) as well as improved supply chain communication covering the ecological costs of preliminary production and transport.

Greening ICT Hardware

The research within Digital Europe pointed out the importance of ICT infrastructure as a main factor for resource consumption of e-business and e-government. Often, the early manufacturing

Virtual Networking without a Backpack?

stages and the use phase are neglected within evaluations. However, these turn out to be of high relevance for a large share of ICT products and services. Improvement opportunities can be derived from the extension of ICT's lifetime, the promotion of the shared use of ICT equipment, extended warranties or design for environment, as initiated by proactive ICT companies.

Shifting to E-Services

E-commerce can – under specific circumstances – provide significant resource efficiency potentials, especially if physical products are shifted to e-services. Public administration and businesses can be a forerunner in offering e-services as part of their e-government strategies. As well as being a provider of e-services (push-strategy), these organisations could request services instead of products from their suppliers wherever possible (pull-strategy). Societal and technological framework conditions can be enhanced for the uptake of e-service applications. Fast, affordable and reliable Internet connections are a prerequisite, as is the trust in the confidentiality of data transferred via the Net. Besides this, large parts of the population still lack basic e-society literacy. Empowering these groups is a key for a wider uptake of e-services. Scientific assessments should be carried out to determine in which sectors of traditional industry with high resource consumption the use of ICT could enable a dematerialisation noticeable at the macro scale. Such an assessment could help to answer the question as to where it is worthwhile to promote e-services on a larger scale.

Raising Awareness and Changing Habits

The habits of ICT users and their awareness are to an increasing extent decisive for total material intensity. Efficiency gains may even be offset. Examples are re-materialisation of digitised in-

formation or building up of e-channels without reducing traditional ones. E-society literacy is needed, allowing users to handle digital information without re-materialisation. While the younger generation will hopefully grow up with a mindset allowing them to deal with this, training and empowerment might be needed for other population groups. A better understanding of the size and potential impact of rebound effects is urgently needed. Of particular importance is the early integration of information on potential rebound effects in the design phase of products and services, as the main effects are determined there. With the growth of the Internet, global and national framework conditions become more important as a means of limiting undesired rebound effects, such as additional resource or energy consumption.

Chapter 7.17

Cultural Factors and Collective Identity of Women in ICT

Phyl Webb

University of Tasmania, Australia

Judy Young

University of Tasmania, Australia

INTRODUCTION

There is a considerable body of research to support the longstanding problem of a gender imbalance in the ICT industry (Ahuja, 2002; Baroudi & Igbaria, 1994; Cukier, Shortt, & Devine, 2002; D'agostini, 2003; Frenkel, 1991; Moody, Beise, Woszczynski, & Myers, 2003; Nielsen, von Hellens, & Wong, 2000; Nielsen, von Hellens, & Wong, 2001). However it appears there has been little attempt to draw it together to inform the influences and impacts that many women face when employed in the industry. The objective of this article is to examine research focussing on two factors that have impacted on the experiences of women who have established careers in the ICT industry.

GENDER IMBALANCE IN THE ICT INDUSTRY

The authors conducted a search of the literature related to gender imbalance in the ICT industry. From this, it became apparent that the existing body of literature consistently identified a number of elements as representing the existing state of ICT workplaces. It is possible and perhaps probable that some of these elements are conspiring to influence the:

1. Cultural factors typically encountered in ICT workplaces
2. Collective identity of women employed in ICT workplaces

Cultural Factors

In reviewing the gender related ICT literature, an image of the tensions that are at work and could influence and impact on women working within the industry emerges. These factors are, in general, subtle. However, they do make a contribution to enhancing understanding by highlighting potential relationships between social pressures to identify reasons and solutions relevant to the current situation within the industry.

Dominant Male Culture

The idea of ICT as a male dominated industry characterised by masculine language and modes of operation is evident from the literature (Pringle, Nielsen, von Hellens, Greenhill, & Parfitt, 2000; The Women in Science Engineering and Technology Advisory Group 1995). A sense of a shared masculine ownership of the science and technology sector as a whole pervades with the result women can feel marginalised and isolated. One outcome of this is a perception that senior men in industry favour males coming in and regard females almost with suspicion and even derision.

The notion of the IT sector as a male domain has conspired to perpetuate a culture of long working hours and masculine language. von Hellens, Nielsen and Trauth (2001) found that while many women did not see IT as an inherently male domain, they reported situations where they had been challenged as a consequence of their sex. In addition, it was noted that many women do leave IT workplaces if they are unable to deal satisfactorily with male domination. Those who remain can be subjected to inappropriate language, advances and stereotyping within the workplace (Teague, 2000; O'Neill & Walker, 2001).

Competitive Atmosphere

Women working in ICT are constantly confronted by the competitiveness of men in presenting themselves and promoting themselves. The preference of women for connections rather than competition may contribute to the levels of discomfort generated within the competitive environment (Lind, 2000). Men can be aggressive and arrogant in the way they compete and reluctant to admit making mistakes or not knowing something. Women tend to find this approach confronting and a challenge to their self-confidence. In general, they tend to have less confidence in their abilities and may be less likely to attempt new activities or activities that are considered challenging. This can have a detrimental effect as it often precludes women from opportunities to demonstrate themselves in a positive light in the work situation. Since these characteristics are valued within the male culture women are disadvantaged as a consequence (Teague, 2000; Cuny & Aspray, 2000).

Demographics of Women in IT within Organizations

As a group women working in ICT workplaces have less organizational tenure, less job tenure and are younger than their male colleagues. Few women hold senior management positions in the sector (Ahuja & Rodlain, 2000; Baroudi & Igbaria, 1994; O'Neill & Walker, 2001; Pringle et al., 2000; Trauth, Nielsen, & von Hellens, 2000). Results from the Association of Professional Engineers, Scientists, and Managers, Australia (APESMA, 2002) survey showed that in the Australian computer profession women outnumbered men in levels 1 and 2 of responsibility and that their representation began to decrease at levels 3 and 4 of responsibility. Further at the higher levels of responsibility (5 and above) men outnumbered

bered women almost to the extent of two to one (APESMA, 2002). In addition often when women achieve seniority in job title this is not reflected in the opportunity to participate in critical IT decision making in the organization and team leadership (Panteli, Stack, & Ramsay, 1991). The exclusion of women from IT management ranks has implications for their career options and probability of better remuneration (Truman & Baroudi, 1994). The distribution of women throughout middle and lower levels in the industry is significant. Panteli, Stack, and Ramsay (1999) reported that even though they might share the same positional role and title as men, women are not engaged in the same projects. Women are more likely to be engaged in administrative functions (O'Neill & Walker, 2001) or in low status specialities such as merging and tidying databases (Pringle et al., 2000).

Effect of Gender Traits

From the literature, it has become apparent that some researchers have concluded that there are specific gender traits and that the existence of these traits impact on the manner in which women assimilate into ICT workplaces. Venkatesh and Morris (2000) explored gender traits in ICT and suggested that men were interested in how useful technology was while women were interested in how easy it was to use. Another gender trait they identified was that women, more so than men, are influenced by peers and others when making decisions to use technology. Women also have a greater need to belong to a group, a greater interest in personal goals and were more responsive to the needs and feelings of others.

For those women who have already chosen to work in ICT workplaces Holmes (1998) found that while men and women do not differ appreciably in relation to many of their work goals, men consider high earnings, variety and advancement as

more important than women. Ahuja (2002) has suggested women make choices that see them placed in positions and professions considered female friendly and offers that this may be occurring because of the diversity of roles that women fulfil during their lives. Generally, women prefer a greater balance in their lives.

Balancing Work and Family Commitments

Many women successful in the ICT industry appear to have sacrificed family for work. Even where arrangements exist for women to access flexible working arrangements there is a tendency not to do so. Dowse and Underwood (2001) depicted a negative image for the future of the ICT industry for balancing work and family for both men and women. Historically ICT as an industry has not been sufficiently cognitive of the needs of employees trying to balance paid employment with raising a family (Pearl, Pollack, Riskin, Thomas, Wolf, & Wu, 1990; Truman & Baroudi, 1994). The image of the culture of ICT workplaces is one of long hours often worked outside of normal business hours. So enduring and pervasive has this view become that both men and women have come to expect this regime within ICT workplaces to the point where managers have been reported as rebuffing staff complaints about hours worked because that is just the way it is in IT (Nielsen, von Hellens & Wong, 2001, O'Neill & Walker, 2001). However, the long hours are biased against women (O'Neill & Walker, 2001). Women do shoulder a greater share of the parenting responsibility in most families (Dowse & Underwood, 2001) and because of this expectation it is likely to be a severely limiting factor for females in the ICT industry. To be successful in the industry, women typically need to prioritise work over family (Pringle et al., 2000) while others delay having children until later in life (APESMA, 2002).

ICT as a Solitary and Isolating Career

The image of ICT as a solitary and isolating career still endures. Women tend to favor personal interaction and communication and as a consequence a career that conjures up images of isolation and boredom may be perceived as unattractive (Nielsen, von Hellens & Wong, 2001, Trauth, 2002). The dominant image of the computer nerd is that he is incapable of interacting with people (von Hellens, Pringle, Nielsen, & Greenhill, 2000). Interviews conducted by Trauth (2002) with women working in the IT industry revealed that in order for them to be successful they needed to work alone. This is contrary to the need of women to openly communicate and engage in collaborative approaches (Panteli, Stack, & Ramsay, 1991).

Collective Identity

The second major category identified in the literature is based on examples of literature dealing specifically with the characteristics of women employed in ICT workplaces.

Exhibiting Masculine Tendencies

There is a strong sense within the existing literature that women who are successful working within ICT workplaces have a picture of themselves as being different to most women and more like men in some ways (von Hellens, Nielsen, & Trauth, 2001, Webb, 2002). The women interviewed by Trauth, Nielsen, and von Hellens (2000) who had achieved management positions agreed they have personality traits described as masculine. This happened to the extent that a women professor intentionally aligned herself with the sexist males in order to achieve a “shining career” (von Hellens, Nielsen, & Trauth, 2001).

Further, the women who have achieved in ICT workplaces tend to be more competitive and

perhaps as a consequence they do not embrace stereotypical gender roles (APESMA, 2002; von Hellens, Nielsen & Trauth, 2001). They have described themselves as being logical, assertive and task-focussed (Nielsen, von Hellens & Wong, 2001). As one women recounted, to obtain a position in a particular IT organization she felt it necessary to prove that she could ‘drink as many beers as the men’ (Pringle et. al., 2000, p. 4).

Women Who Use Mentors Tend to be More Successful

There is a lack of mentors and mentoring opportunities for women. As a result many women coming into the industry are denied appropriate role models and the support from other women to whom they can relate (Sumner & Neiderman, 2004; Teague, 2000; von Hellens, Nielsen, & Beekhuyzen, 2004). The shortage of mentors is problematic as this support is crucial to provide positive work experiences in the IT industry and an ability to achieve career success (Pearl et al., 1990).

Ahuja and Rodlain (2000) found a likely connection between the success of women in IT, their intention to remain and advance within the field and the effectiveness of mentoring relationships. von Hellens et al. (2002) cited the example of a young IT professional who was fortunate to have a female team leader. This mentor supported her appointment as a project leader that enabled her to demonstrate her capability in the role and gain acceptance in the organization.

Capacity and Willingness to Adopt Adaptive Behaviours

In the ICT work environment, male personnel are established as the benchmark and women are often forced to adopt masculine behaviours to participate let alone succeed (O’Neill & Walker, 2001). From a constructivist viewpoint, Trauth

(2002) states that while women are subject to different social influences, to succeed in the IT environment they need to adjust to work in a male dominated workplace.

From the literature there is an impression that adaptive behaviour may disadvantage a woman in the workplace (Nielsen, von Hellens, & Wong, 2000; Pringle et al., 2000). Pringle et al. (2000) have argued that it should be unnecessary for women to adapt because their organizational and communication skills can challenge the link between technology and masculinity in an IT environment. While this view may have merit the current literature lends little support for the success of women who cannot or will not adapt to the current ICT workplace paradigms.

DISCUSSION

The issues discussed in this article are not claimed to be representative of all actual situations in ICT workplaces. While these have emerged from the literature, it is acknowledged that examples of gender equality cultures do exist in the industry. However, there is ample evidence in the literature to support that generally there is a male dominated culture in the ICT industry.

Gender imbalance is a complex issue and often belies simple explanation and resolution. With respect to the ICT work environment it may be that this domination was established at the very origin of the industry, a time when technology was seen solely as a male activity. Potentially this set a foundation where the notion of homosocial reproduction has perpetuated the situation. Homosocial reproduction implies the politics of the dominant group in the organization will largely drive decisions and actions. While it is possible to change the male domination in the ICT work environment it will be a slow process and to be effective must be embraced by those within the industry. The major barrier is that change will

not happen unless there are a sufficient number of women succeeding in ICT workplaces.

If the dominance of the male culture is not challenged, it is unlikely that change will occur. As long as male dominance remains it is central to maintaining the inequitable demographics of women in IT organizations, the competitive atmosphere, the problems of balancing work and family commitments and the solitary and isolating nature of careers in the industry. While there is evidence to support that gender traits can affect the work experiences of women, a change in culture may be more accommodating to the different attitudes and approaches between the sexes.

From a perspective of collective identity it becomes clear that women who do succeed in ICT are those who are willing to be adaptive and get on with their careers. While this tends to involve the adoption of masculine tendencies as a minority group it is probably the only way they can compete on an equal level.

CONCLUSION

The aim of this article was to present an examination of the literature that reports the impact of cultural factors and the influence of collective identity on women who have established careers in the ICT profession. In so doing, it has highlighted some of the issues that have confronted some of the women who have forged successful careers in ICT.

The benefit of this approach is that it offers information to enable women to be better prepared and informed when contemplating a career in the ICT industry. Perhaps this could prove instrumental in reducing the number of women leaving the industry because they are ill equipped to cope in a male dominated work environment. Potentially this may reduce the negative image of the industry. As such it may attract more women to consider

careers in ICT and, at the same time, stem the high attrition of women from the industry.

KEY TERMS

Collective Identity: Implies the characteristics exhibited by any group of people in specific circumstances.

Gender: The biological division of the sexes. This division does not consider psychological or other facets of the construct gender.

Gender Imbalance in ICT: The state in which there exists a significant difference between the percentage of male and female participation within the ICT industry. This imbalance extends across most levels of appointment within ICT workplaces.

Homosocial Reproduction: A process in which the politics of the dominant group in the organization will largely control decisions and actions.

ICT Careers: A general term associated with the ICT industry that covers a diversity of roles involving technology, information processing and people issues.

ICT Industry: A business sector focussed on supporting computer infrastructure, people, and information processes within and between organizations.

Cultural Factors and Collective Identity of Women in ICT

Organizational Culture: This refers to the shared values, characteristics and rules that govern behavior and attitudes in specific work-place environments. These may be formally or informally applied depending on the nature of the organization.

Chapter 7.18

A Cultural Studies Approach to Gender and ICT

Merete Lie

Norwegian University of Science and Technology (NTNU), Norway

INTRODUCTION

This article introduces a cultural studies approach to the field of gender and ICT. This implies an emphasis on the symbolic aspects of technology. Technologies are approached as cultural phenomena to which meaning is attached, but in the sense that they are open to various interpretations. Technology holds a position as a key symbol in Western societies. A key symbol is, in Sherry B. Ortner's terms, a symbol that helps us to sort out experiences and put them into place within cultural categories, and even help us think about "how it all hangs together" (Ortner, 1973, p. 1341). This key symbol has gone through a radical transformation from mechanical machines to ICTs as the leading technologies. An important question is how changing technologies are linked to another key symbol, namely that of gender. Moreover, following from that question, how can you study the relationship of gender and ICTs when both are continually changing?

THEORETICAL KNOTS

My own background is from a Norwegian network of researchers who have been studying gender and technology for the last 25 years. The differences between two Norwegian collected volumes may indicate a changing direction in the understanding of gender and ICT from the 1980s until today. The volume from the 1980s depicts technology as a tool of power in the hands of men (Lie et al., 1988). This provided a clear line of analysis as well as a direction for action to change the imbalance between men and women's access to technology. A volume from the 2000s, however, depicts a cybernetic pattern with threads and knots and loose ends—and may serve as an illustration of a seamless web with neither one distinct pattern nor one direction for change (Lie, 2003).

In our research during the 1980s, we analyzed technology as a means of power within a gendered division of labor. Technology was analyzed as the result of social constructions with in-built gender

divisions, or in David Noble's terms, "frozen culture" (Noble, 1985). At the same time, however, technologies are also messengers, telling us who and what belongs where. During the 1990s, my focus shifted towards the symbolic dimensions of technology and the strong connections between technology and masculinity. As a symbol of masculinity, technology strengthens bonds between men and offers a way of "doing" or "performing" gender. To prove one's competence with technology is to prove one's place as a man among men. This perspective tends however, to be too static and has therefore spurred a search for new perspectives that include changing technologies as well as varying and constantly changing understandings of femininities and masculinities.

Within the field of gender and ICT, most attention has been accorded to women and how one might change their attitudes to technology. Feminists have tried to move away from this one-sided perspective towards regarding it in relational terms, thus drawing attention to technology as the other side of the gender-technology relationship. Instead of changing women, it was argued, one should change technology and the culture of technical institutions. In this way, however, both the concept of gender and that of technology may appear to be given and stable, thus in need of conscious strategies if they were to change. However, what we actually observe is that both are constantly changing. Suffice to mention how computers as calculating machines have been transformed into information and communication devices (Turkle, 1995) and continuing debates about what gender means and proper gender conducts. The challenge is that when we try to find out why gender still matters in relation to ICT, the themes we are dealing with tend to change their shape: gender relations are re-negotiated and new technologies appear. Thus, once we have identified a strategy to include women into the field of ICTs, the whole field is re-configured. Change is therefore obviously, what theories of gender and technology have to include.

Moreover, ICT is no longer an exotic item with the prefix cyber-, alluding to something that is virtual, out of the real world, and exclusively for a minority with access to a cyber society. Today, ICT indicates rather familiar items that are included in the everyday routines of many people, at work, for entertainment, and for social activities. ICT is part of a variety of activities related to different aspects of people's lives. However, we still tend to talk about ICT as if it were one thing.

As mentioned, the studies of gender and ICT have mainly directed the attention at women, and they are often focused on education (cf., Gansmo, 2004; Lagesen 2004). Women's attitudes and relationships to ICT have been studied empirically. It has been said that women's performances are measured against a norm that is set by men, and consequently women are considered to do computing in an inferior way and not up to standards (Corneliussen, 2003; Rasmussen & Håpnes, 1991). The difference is conceptualized in terms of men's more technical approach vs. women's more communicative approach; that is, men are deemed to be interested in and competent at technical matters whereas women are deemed to be interested in chatting and e-mail (Stuedahl, 1998). We may ask, however, whether this feature of "men as norm" does not actually refer to "real men," with varying user patterns, but rather to an abstract "ghost feature" of masculine gender symbolism.

Studies from working life have shown that when masculinity is symbolically linked to different technologies and to technical competence, it is the result of cultural practices (Cockburn, 1983, 1985; Faulkner, 2000; Lie, 1998; Mellström, 2003; Wajcman, 1991). The symbolic association of technology and masculinity is, in other words, not self-evident but must be produced and confirmed continually. This also tells us that gender symbolism is open to change, holding that matters do not "have" meaning but are accorded meaning by actors and within particular contexts (Geertz, 1973). My concern is how gender functions as a

cultural distinction that literally “gives” meaning to technical artefacts and practices.

TECHNOLOGY AS CULTURE

A cultural studies approach to the knot of gender and ICT implies that not only gender but also technology is analyzed as a cultural phenomenon. Technology and culture are conceptualized as interwoven in mutual shaping processes. This mutual shaping can be studied in design and also during the cultural consumption of a new technology. In Norway, a user perspective and focus on cultural appropriation of technology have been prominent in gender and technology research (Berg, 1996; Lie & Sørensen, 1996). This is an approach following the traditions of social shaping or social construction of technology (Bijker & Law, 1992; MacKenzie & Wajcman, 1985;), the point being that a technical device could always have been otherwise. There is no technical necessity that leads to a certain end product, and culture is integrated, literally in-built, in the technical products. Moreover, the concepts of gender and ICT cannot be explored separately because they are intricately interwoven. This implies leaning on the metaphor of a seamless web of technology, culture, and society (Hughes, 1988) and on cyborgian and hybrid conceptualizations that blur the otherwise clear boundaries between nature-culture, both in the sense of sex-gender and human-technical (Haraway, 1991, 1997).

The connection of technology to masculinity has implied that tools are more easily identified as technologies when they belong to the masculine realm, whereas tools associated with women are more ambiguous and may be categorized otherwise, as with kitchenware or sewing-kits for instance. In this way, preconceptions regarding gender are constitutive for what is recognized as technology. Likewise, with technical competence as a characteristic of masculinity, technology has functioned as a device for sorting out gender.

Although we recognize a variety of masculinities, meaning that there are many ways to be identified as “masculine”, a close relationship to technology still remains one of them. However, whereas steel, cogs, and mechanical machinery produced masculine connotations related to muscles and strength, computers are more ambiguous. This ambiguity refers not only to the design of machinery but also to the varied social contexts of ICT use. Thus, the new ICTs could have meant a re- or de-gendering of technology, but the social processes taking place have directed ICTs towards traditionally masculine realms. One example is the linking of computer science to technical institutions; another is the production of software for “boys’ games” (Cassell & Jenkins, 1998). But—it might have been otherwise. The rapid introduction of computers into a wide variety of contexts is contributing to the opposite effect of de-gendering ICTs.

GENDER AS “PRODUCER OF MEANING”

Here, gender is considered as cultural distinctions that are activated to literally “give” meaning to technical artefacts and practices related to them (and vice versa). The cultural categories of masculine and feminine may or may not be in accordance with what particular men and women look like and act like. Since the notions of femininity and masculinity are basic categories of distinction, though culturally specific, gender is a relevant category when technologies are designed, advertised, talked about—in other words, during all stages of a technology’s “life cycle.”

The design of technical artefacts is based upon imagined users and it may make a difference whether the projected users are imagined as men or women. The visions of designers are inscribed in the products, in the sense that “like a film script, technical objects define a framework of action together with the actors and the space

in which they are supposed to act” (Akrich, 1992, p. 208). Such scripts can be deduced from the technical products, and differences that habitually are recognized as feminine and masculine may be identified in the design (Berg & Lie, 1995; Oudshoorn, Sætnan, & Lie, 2001; Rommes, 2002). Designing computer games, for instance, the imagined user is generally a young man, and designers emphasize that what they are after is “a good story”—but not reflecting on the combination of the two statements (Gansmo, Nordli, & Sørensen, forthcoming). Still, the combat heroines like Lara Croft are not only men’s “perfect fantasy girl” but also an ambiguous mixture of male and female.

The design of technologies is, however, only one step in the process of its cultural construction. Even after a piece of technology has assumed a particular form, it still retains interpretive flexibility. Through the media, we get information on what this particular technology is meant to be, why it is important, and what it is useful for. We get other versions via product marketing and through education and information materials. These are ways in which technologies are domesticated within a particular cultural context. Users contribute to the process of domestication when they are adjusting technologies to their own needs and lifestyles; in other words “taming” them when bringing them home (Lie & Sørensen, 1996; Oudshoorn & Pinch, 2003). This is because technologies have to be enculturated in order to function, thus users must accord them meaning and fit them into their lives. Through domestication processes, new technologies are fashioned to users’ daily lives and routines, which in turn are adjusted in relation to the new technologies. Domestication also involves the discussion and demonstration of technologies amongst users. An obvious example is how mobile telephones and PCs have become so visible in our daily lives, and how widely and enthusiastically the use of these objects is discussed and interpreted in everyday conversations.

In the cultural process of defining what ICT is, how it should be used, what ICT skills are, or in other words what “counts” as valuable knowledge and skills, gender functions as a cultural category in sorting things out. In this process of negotiating boundaries, gender is a marker that still functions to sort out high tech from low tech or no tech. The mobile phone, for instance, changed rapidly from a rather exclusive high-tech gadget to being for everyone. We might reason that the gender of the users affected the image of the artifact, as did the young age of the users, in the sense that when women and youngsters were identified as users, it became trivial. With PCs, chatting is often designated as a girlish activity, even if many boys, as well as adults, are active chatters; whereas gaming is held as “a boy thing”, thus making girl gamers invisible (Nordli, 2003). In such ways, new technologies spur processes of boundary work and renegotiations of what is to be considered masculine and feminine.

The concepts applied and the examples given, serve to illustrate the point that neither technology nor gender should be taken for granted. Rather technologies should be studied as artefacts and types of knowledge that are shaped by cultural processes, not only while the technology is being developed and produced, but also by its subsequent use and reputation. Whether a particular technology is considered interesting and accessible or not, is dependent not only on how it is designed, but also on how it is presented to users and interpreted by them. At the same time, gender and gender relations are designed as relational to the different designs of technologies. So gender is not “given” in the sense that it consists of respectively male and female capacities and fields of interest that do or do not fit with technical artefacts and technical skills. What we need to study are processes of gendering (i.e. how gender transfers meaning to artefacts, practices, and places); the negotiations taking place when ICTs are introduced into new contexts or for new audiences; and the flexible

interpretations of gender and technology in such cases.

To take an example: when young teenage girls together talk about computers as something nerdy (Håpnes & Rasmussen, 2003), they tell each other that this is something that we do not need to know anything about: we can ignore it, or, if we want to use it, we should under-communicate the use of it. Accordingly, ICT has a masculine label with negative connotations in a particular age group within which strong gender dichotomies prevail. Still, if a girl is good at it, she may be admired and not considered “nerdy” or masculine because of this interest. The nerd image is available but does not have to be used in a particular context. Moreover, such notions are flexible. Nerd may be used as a negative label, but at the same time some people like to use it, meaning to express that they actually spend a lot of time at computers and therefore possess wide expertise within the field. Likewise, the notion of the hacker has a double meaning, or maybe even triple: a “person without a life,” super expert, or burglar/outcast. Again, several meanings are available as a repertoire one can draw upon. The nerd image is one, but that does not mean that the computer and its users are pinned down once and for all, as nerdy and only that, because there is always interpretative flexibility in cultural matters.

FUTURE PERSPECTIVES

One important change of gendered relations to ICTs is that women are increasingly participating as users. In this sense, ICTs are not linked to masculinity as an exclusive male domain. This trend also contributes to a de-mystification of the field—it is not only for nerdy insiders; rather, it is a technology for everybody. When it comes to developments within the ICT branch, however, this is still dominated by men, and we should therefore be aware of new “divisions within.”

Lagesen (2003) has studied campaigns to attract more women students to computer science whereby one tries to redefine it as a “feminine subject” by stressing the aspect of communication. Lagesen points out that there may be a new trend not simply identifying ICT with masculinity, but towards a division whereby one tries to attract men by emphasizing the T, and detached from I&C, which are advertised as interesting for women.

We may be aware of such cases of re-gendering based on gender dichotomies. Still, I would like to draw attention to how cultural processes of gendering new matters also can take different and unexpected paths. There are a wide variety of possible cultural interpretations. Thus, it is not a good idea to take as a point of departure, that ICT is a masculine matter and ask how we can change that, but rather to seek out other issues from the wider cultural repertoire that can be associated with ICTs.

CONCLUSION

Is it possible to modify the cultural associations of gender and ICT?

Firstly, gender is more than differences between women and men. Gender is also a cultural distinction that provides us with categories that are applied to produce meaning. We literally use gender as a tool to identify ourselves, to identify people we relate to, but also to identify practices, events, and new artefacts. To “give” things gender is to put them into place, like when talking about computers as for instance nerdy/masculine or useful/feminine. We may instead talk about them as exciting and eventful and stress that they are multi-faceted—in other words, strive to attach to them a wider repertoire of meaning that is not one-sidedly gendered.

Secondly, this leads to the question of change in relation to cultural matters. The problem with

culture is that it is the very material we are thinking with. Therefore, it is difficult to deliberately make a change and think differently. Still, there is some variety in the cultural images connected to ICT. What we should be aiming for is to utilize this variety and also to expand the repertoire. We may acknowledge and speak about ICT as a field that includes much more than male nerds and hackers. More attention should be directed at cases where women are active users and designers and where women use ICTs in unexpected ways. Even if these are not the “majority cases,” they are important within a strategy for developing new perspectives on gender and ICT.

KEY TERMS

Boundary Work: Intentional and unintentional efforts to maintain gender divisions.

Domestication: The cultural appropriation of technology.

Gender Dichotomies: Feminine/femininity is defined in terms of being the opposite of masculine/masculinity and vice versa.

Gender Script: Gendered connotations are in-built in the design of a technology.

Gender Symbolism: Cultural associations of masculinity and femininity.

Key Symbol: A symbol that summarises main features of a certain time within a particular cultural context.

Script: Directions for use integrated within the design of a technology.

This work was previously published in Encyclopedia of Gender and Information Technology, edited by E. Trauth, pp. 166-171, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 7.19

Who's Talking Online?

A Descriptive Analysis of Gender & Online Communication

Taralynn Hartsell

The University of Southern Mississippi, USA

ABSTRACT

This preliminary descriptive study investigated the association between gender and online communication and involved participants from an online graduate course. The study implemented a descriptive model in that “student involvement” was assessed by tabulating and recording the quantity and quality of student activity in the discussion threads. Quantity was recorded by the amount of times students posted online comments and the number of words that women and men used to make their responses. In addition, quality was examined by reviewing the content that women and men made concerning topics under discussion. In the end, a difference between the genders was found in that the amount (quantity) women contributed to the discussions exceeded that contributed by the men. Women were also more inclined to give supportive or encouraging remarks than men, and addressed their classmates by name to promote a sense of online community, all which support previous studies.

INTRODUCTION

Delivering courses through the World Wide Web in higher education is a growing trend that has taken precedence at many colleges and universities. As the population of non-traditional students increases and the pervasiveness of computer technology has reached an all-time high in education, delivering online courses has become an alternative medium to offering coursework and degree programs to remote students who are not physically present on campus (Simonson, Smaldino, Albright & Zvacek, 2003). The push for educators to offer more new online courses or adapt existing courses to an online medium will not disappear. In fact, more online courses will be offered to students as an alternative mode for completing their educational degree programs, a circumstance that was incomprehensible 15 years ago (Picciano, 2001).

This trend for promoting online courses in higher education also creates concerns for both the teacher and student. Some of these concerns

include factors such as management, communication, interaction, discipline, and retention (Moore & Kearsley, 1996). Communication is one of these key factors for student success. Studies have looked at student isolation and disillusionment as contributory factors toward impairing student retention and effective learning. Communication between student-teacher and student-student is important toward alleviating the feelings of isolation. Another aspect of communication is participation. There is an assumption that more a student participates in an online course, the better success that he/she will find in acquiring and learning the material related to the course (Picciano, 2001b).

One question that arises concerning online communication is whether gender of the student is a contributing factor toward learning success. Although research has shown that females and males differ in terms of their attitudes toward computer use and computer aptitude, women and men are still both users of computer technology — a direct opposite to the notion that females are not as technologically-inclined as males (Whitley, 1996). In addition, many have voiced that the Internet is a more neutral playing field for both men and women to enjoy. In a sense, the Internet has been claimed to lead toward greater gender equity because of its communication interface (Gorritz & Medina, 2000; Herring, 2001). Furthermore, scholars say that the Internet should be taken seriously to help create opportunities for less powerful individuals to participate with members who are more vocal, especially in asynchronous environments (Balka, 1993; Selfe & Meyer, 1991; We, 1993).

Because research on Web-based instruction is relatively new, particularly in the aspect of communication effectiveness in relation to gender, there is a paucity of research that investigates how women and men communicate online. There are few studies that investigate the use and integration of online communication in reference to gender, but more research needs to be performed

that examines the amount of communication that occurs between men and women (Arbaugh, 2000; Shaw & Gant, 2002; Sullivan, 2001). The old assumption that women are more verbal, and thus more inclined to communicate in online discussions and e-mail needs to be analyzed more closely (Shaw & Gant, 2002; Waldeck, Kearney & Plax, 2001).

This article reports upon a pilot study that investigated gender differences in a distance-learning course on the use of online communication tools. The article is divided into three sections. First, an overview of the study is discussed in addition to providing a summary of the literature. The literature is primarily based upon the area of technology and gender differences in education to help build a theoretical base toward analyzing the influence of gender in online communication activities. Second, the article will explain the results of the study with the gender perspective in mind. Finally, the third section will discuss the implications and recommendations for online instructors who are teaching diversified student populations, particularly those courses that have an even or odd distribution of women and men.

REVIEW OF THE LITERATURE

There are many factors that influence how women and men use computer technology. It has been assumed that women and men differ in their attitudes toward, comfort with, and anxiety levels concerning computer technology (Weiser, 2000). Research has suggested that women and men like to use computers to gain information and complete tasks. The disparities, if any, exist in their interactions with computer technology and how women and men use the tool (McCoy, Heafner, Burdick & Nagle, 2001).

Level of anxiety may contribute toward the use and attitude toward computer technology. According to Whitley (1996), college women exhibited low levels of anxiety when it came to

Who's Talking Online?

computers, but not as low as men. Among these subjects, Whitley found that less anxious men and women were more likely to take computer courses and spend more time on a computer. Namlu (2003) examined whether learning strategies (LS) were factors in controlling the levels of computer anxiety (CA). She concluded that learning strategies, categorized into simple, advanced, and derived LS, seemed to play an important role in handling computer anxiety in that those who had a solid foundation in monitoring their learning progress had lower computer anxiety. Hence, anxiety toward computers in association with learning styles can be contributing factors toward how women and men view computers and how they handle technical troubleshooting.

Differences in how the genders perceive technology also contribute toward varying computer usage. Women tend to view the computer as a tool to achieve and complete tasks (Fiore, 1999). They tend to see computer technology, particularly the Internet, as a way to gather information and to communicate with others or to promote human interaction. In other words, females see the computer as a "tool" to be used for what it can perform. Males, on the other hand, have viewed the computer more as a recreational toy (Shashaani, 1994). According to the Commission on Technology, Gender, and Teacher Education (2000), males tend to view the computer as a "toy" or an extension of the self. For males, computer technology has been predominantly used for entertainment. In a study conducted by McCoy, Heafner, Burdick, and Nagle (2001) that looked at the assimilation of IBM ThinkPads on a university campus, individual computer use was examined through the following categories: tool, communication, resources, entertainment, and total use. These categories were compared between the genders using independent t-tests. What the researchers discovered was that the males were more frequent users in the categories of resources, entertainment, and total use. There was no significant difference for tool use

or communication, meaning that women used the technology for these purposes more than for entertainment. This supports the previous finding that women, more than men, tend to use computer technology as a way to reach out and complete tasks rather than just "playing" with the technology to see what it can do and retrieve information/programs for personal use.

In regard to distance learning technology and Internet access, any gap that may have been in place between the genders seems to have narrowed (Novak & Hoffman, 1998). In fact, recent research has indicated that more females are enrolling in Web-based online courses and programs, with comparable success to males (Ory, Bullock & Burnaska, 1997). In a study investigating the use and attitudes toward asynchronous learning networks (ALN) in a university setting, Ory, Bullock, and Burnaska (1997) discovered that both males and females made equivalent use of ALN and had similar positive attitudes about their experiences. Women also shared a common desire to take more courses that used computers as a result of their experiences with ALN in this situation.

The Internet has been said to be inherently democratic, and thus, leveling traditional distinctions of social status. This, in turn, would create opportunities for those who are often silent to speak out and participate with members of the more powerful group. It has been said that text-based computer-mediated communication allows men and women to participate equally in contrast to traditional patterns of face-to-face conversations. With the absence of physical and auditory cues, the gender of online communicators is irrelevant or invisible (Danet, 1998). This situation could help facilitate free communication between women and men in that gender roles have somewhat been removed.

With the rise of the Internet, researchers have begun to investigate whether gender disparities exist with Internet technology (Shaw & Gant, 2002). Researchers have predicted that males and females will differ in the ways they view and

interact with the Internet, hypothesizing that males will be less anxious and more comfortable using the medium compared to females. This proposition supports the idea that women are more “technophobic” than men in that women are more afraid of technology, and therefore slower to adapt to technological advances (Shaw & Gant, 2002). Although studies have found that males report more experience using the Internet and score higher in areas of comfort, innovativeness, and Internet self-efficacy, this does not explain the growing numbers of women accessing the Internet (Shaw & Gant, 2002). Women are accessing the Internet just as much as men. The explanation could be attributed to how the women may be using the Internet as compared to males. Communication is a motivating factor for women to seek out social interaction online. Men tend to seek information and entertainment through the Internet, which supports earlier studies on gender and computer usage (Hamburger & Ben-Artzi, 2000).

Based on studies of gender differences in communication and technology usage, the encouragement of collaboration in online courses can be quite favorable toward women. Because previous studies in communication patterns have revealed that men tend to communicate on the basis of social hierarchy, and women are more network-oriented and collaborative, a collaborative Web-based environment may help to reverse this process (Kilbourne & Weeks, 1997). Thus, in a setting that is absent of competition, the playing field can be leveled between the genders.

There have been studies that look at the way men and women communicate in terms of online communication. The use of language and tone are primary areas of difference in that men tend to use more aggressive language to assert their point in the discussion as opposed to women (Rossetti, 1998). In addition, women tend to contribute more overt expressions of agreement, appreciation, and support. They also present their assertions indirectly as suggestions (Kuntjara, 2002). Gender differences in online communication suggest that

women prefer a “rapport” style, while men generally speak in the tone of a “report” in that their postings sound as if they are simply providing information (Kuntjara, 2002).

In short, the literature supports the notion that women and men are almost equally equivalent in terms of computer and Internet usage, even though a difference exists in terms of the motives behind the use. Because the literature tends to sustain that communication is the main motive for women to use the Internet, this is an area that needs to be investigated further. The primary question is whether women participate more in online communication than men. In addition, do women’s participation exceed in terms of the quality in that women explain their perspectives/ideas more thoroughly than men? It has been found that the tone and presence of women and men in their conversation styles differ, and thus should be looked at more closely.

STATEMENT OF THE PROBLEM

The goal of this preliminary study was to examine whether online communication differed between the women and men enrolled in a distance-learning course through the use of discussion threads. Discussion threads were the primary communication tool used between students in this study as opposed to e-mail, and thus became the instrument of data collection. Discussion threads allow students and teachers to see the “trail” of thought among individuals, as postings to the discussion threads are made in response to previous postings. The research questions investigated in this preliminary descriptive study included whether women more than men: (a) participated or made postings to discussion threads, (b) supplied more explanation in their responses to support the topic under discussion, (c) provided more informal responses than formal, and (d) tended to provide more supportive/encouraging comments.

METHODOLOGY

Participants

The course under study was a graduate-level instructional technology course in which 15 students were involved. There were seven females and eight males who participated in this study. Of these 15 participants, seven were doctoral level students majoring in educational leadership, six were Master's level students majoring in instructional technology, one in nursing, and one majoring in foreign languages. Other than the six students majoring in instructional technology, the particular course used for this study was considered as an elective or for fulfilling minor requirements. All students were required to interact in discussion threads over a 10-week period that involved topics stemming from the course readings. Each week, two of the participants were responsible for facilitating the discussions and providing opening questions to initiate weekly discussion. Participants were required to contribute at least four postings each week in response to the course material. However, a number of participants posted more than what was required.

Design & Measures

The research design was primarily descriptive in nature and the instrument for data collection was the documentation of the actual discussions that took place across the semester between the men and women. The pilot study implemented a descriptive model in that "student involvement" was assessed by tabulating and recording the quantity and quality of student interactivity in the discussion threads. The intention of the study was not to make generalizations to a larger population, but to report upon the findings discovered in this particular sample. Therefore, the study examined raw data collected from the transcriptions of discussion threads that used a method of calculation rather than employing thick-descrip-

tions to explain the setting. The main purpose of this preliminary study was to help the researcher establish the framework for future explorations on gender differences and online instruction/learning. The intention of this pilot study was not to construct broad generalizations, but to help generate research questions and methodologies that could be used in forthcoming research.

The research design was not qualitative in that it did not go in-depth or describe the meaning of the findings from the perspective of the research participants. Instead, the data were analyzed by simply counting the words or the number of times a participant posted a response. Quantity was recorded by the amount of times that students posted responses to the threads as well as the number of words that women and men used to make their responses. Quality was examined by reviewing the content that women and men made concerning topics under discussion. Tone was also studied because this had been a common factor in the literature in terms of how men used online communication tools as opposed to women. In short, quality of the postings was studied further in detail by looking at who responded to whom, the tone of the posting, and whether the response contributed toward the discussion and was not just a simple, informal comment made to someone.

Procedures

During the fall semester, the online graduate-level instructional technology course was offered through the WebCT medium in which the university had a license. The fall term was the third time in which the course instructor taught the course, although this was the second time in which the instructor decided to use discussion threads. The first time that the instructor used discussion threads as a requirement, the students enjoyed speaking to one another online even though they found the number of postings to be overwhelming at times. Nonetheless, the online students, both women and men, seemed to take

pleasure in the opportunity to socialize with one another through the online discussions.

The discussion thread requirement occurred over a 10-week period. Students in the online course were required to make at least four postings to the weekly discussions, although the opportunity to contribute more was available and optional. Two of the participants were responsible for facilitating the discussion thread each week, and therefore these two individuals would either contribute more to the weekly discussion or they would not. Nonetheless, this was a variable that had to be considered in the findings. The weekly discussion covered topics stemming from the course reading materials. For two of these 10 weeks, the course instructor was the facilitator and offered the initiating questions.

The discussions progressed in an organized manner and occurred through the WebCT's discussion tool feature. Each week, the students had to read two to three chapters within the textbook or from online articles. Based upon the readings, the selected facilitator(s) had to generate questions to open the discussion. After that, the rest of the participants contributed postings of their own in reply to previous messages. The weekly discussions began each Monday and concluded the following Monday, at which point the instructor closed or locked the discussion thread to prevent miscellaneous postings made to the thread.

The discussion threads that occurred each week were then compiled into a text file that displayed who said what and to whom. With these text files of the discussion threads, the postings were broken down by individual participants to help in the calculation of how many times males, as opposed to females, made postings and the number of words made in each posting. The text file was also used to determine whether the postings were in response to someone else's reactions or if a new topic/concern was initiated by the participant. Furthermore, the discussion threads were examined to assess the "quality" aspect of the postings that focused upon two areas: (1) tone

of the posting and (2) the value of information given. Discussions were coded for ascertaining the quality aspect. The coding scheme used the following classifications: (a) I being informal in tone, more like a discussion or rapport style, (b) F being formal in tone, somewhat like a report of the facts, (c) S including supportive/encouraging comments and reacting to personal matters, (d) B including short replies of one to four sentences long or not really addressing content material, and (e) R for postings that directly made reference to course materials. Each discussion posting was coded and some postings had two or more codes ascribed to them because they crossed classifications.

FINDINGS

Results of the study are summarized and organized in terms of the original research questions. Table 1 shows the patterns for the genders are presented by the aggregate of individual weeks as well as the minimum, maximum, and mean scores separated by gender for all 10 weeks of discussion. As predicted, the women participated more in the discussion threads, as can be seen by the number of postings. Overall, the women posted 51 more responses than their male counterparts. In addition, when one examines the minimum, maximum, and mean scores, the women again surpassed their male counterparts in the collective 10-week period. Even for the week that the women did not contribute much toward the discussion, they still made 13 more responses than the men (MIN). These numbers are interesting in that the women composed the minority group in this study, with seven individuals, as opposed to eight men. One would expect to see more postings from the majority group of men because they have an additional member. However, this was not the case.

An independent-samples t-test was conducted to evaluate whether gender did play a role in the number of postings made by the participants. The

Who's Talking Online?

Table 1. Class participation patterns by gender

Gender	Class postings per week										Total	Min	Max	Mean
	2	3	4	5	6	7	8	9	1	0				
Women (n=7)	53	49	68	44	40	52	98	42	43	61	550	34	136	78.6
Men (n=8)	36	57	62	50	42	41	59	52	39	61	499	21	118	62.4

results were not significant, $t(13) = 1.059$, $p = .05$, and most likely represented a chance occurrence. However, on average, the women did produce more postings to the discussion threads than men. A reason to account for this lack of significance could be to the small sample size, and thus more participants are required to be included in future studies to help validate the t-tests.

Findings from the data also demonstrated that women incorporated more explanation into their postings to support their ideas and opinions. Men tended to get “straight-to-the-point” in their responses, while women wanted to expand and augment what they said through illustrations, experiences, and examples. The results show that women did use more words to explain their responses or defend their ideas as opposed to their male counterparts. In all, the women surpassed the men by over 10,000 words during the 10-week period. Curiously, the men exceeded the women in weeks eight and nine, but not by a great deal in terms of numbers.

For examining the quality of the responses, the discussion postings were coded into five classifications as addressed in the procedures section. The results indicated that women were more outspoken, whether formally or informally. This contradicts previous findings that women tend to be more informal in their responses, because in this sample the women also made more formal

comments as opposed to their male colleagues. In addition, women tend to give more supportive comments. The men did give more brief comments than women. This finding supported the literature that suggests men, more than women, are more direct in their responses.

When the discussion postings were coded, the S code was broken down into several other classifications. The S code had been separated into different categories as (a) E for offering support or encouragement, (b) N for referring to people directly by name, (c) A as making a personal apology, (d) P as reacting to personal matters or responding to incidences not really related to class, and (e) D to indicate disagreement. This stratification helps in understanding what type of support was made by the participants. The results show that women offered more comments that were encouraging and thoughtful. They also directed their comments toward other colleagues by name. Males, on the other hand, exceeded in the area of disagreement, although this was not by a considerable number.

Results for the study show that women, more than men, participated in the discussions. In this case, women made more postings to the discussion threads than males and with greater explanation. In the area of quality, the women also excelled in their responses in terms of content matter and tone. Women also gave more encouraging remarks

to others' comments and addressed individuals by name, indicating a sense of intimacy and amiability. In this area, external variables such as students' majors could have influenced the results, in that majors in instructional technology would offer more comments in response to the issues addressed. However, this was not the case because more males than females happened to be majors in instructional technology. The women were diverse in their concentration fields, which included two instructional technology majors, two educational leadership majors, one foreign languages and one nursing major. Thus, the assumption that instructional technology majors would contribute more because of their familiarity with the subject matter was non-existent in this sample in that the diverse group of women articulated more in terms of depth.

CONCLUSIONS

Before addressing the conclusions to this initial study, limitations need to be discussed. First, the study is not generalizable because of the small sample size. In addition, the participants were part of a convenience sampling and not a true random sample. However, this sample could lead to larger studies because it provided the preliminary basis for identifying exclusive variables to be studied further. Second, this study did not collect the perspectives and reactions from the participants themselves concerning the effectiveness of online communication. A more qualitative approach could be used to obtain such in-depth information to obtain the participants' perception toward online communication, behavior, and learning. Coding of the discussion threads was also a limitation in that an inter-rater reliability test was not performed. Thus, coding conducted by the researcher could be biased. Fourth, participants also served as facilitators in the discussion and this could have skewed the numbers in that some participants contributed more or less

when they were the facilitators. In this particular sample, the facilitators did not differ that much in their contributions, although a few exceeded their normal expectations. Finally, because the participants were required to make four or more postings a week, this could affect the number of postings made across the 10 weeks, in that participation was not always voluntary. If students were concerned with their grades, they would have opted to make more postings than normal. Although limitations existed in this study, this should not discount the findings exposed but be used as questions for further analysis.

This preliminary descriptive study investigated whether online communication differed between the women and men enrolled in a distance-learning course through the use of discussion threads. Four research questions were introduced and answered in this study. The first question asked whether women more than men made postings to the discussion threads. As a result, the female participants made over 50 more postings during the 10-week period than males. Although the independent samples t-test did not indicate this direction, the raw data implied that women in this particular course preferred and enjoyed communicating online. For online courses, instructors should seriously consider integrating online communication tools to help women and men share their ideas to others. This may prevent social isolation that commonly occurs in distance-learning courses.

The second question examined whether women supplied more explanation in their responses to support the topic under discussion. The women did surpass the men by over 10,000 words. This implies that women in the course valued the opportunity to elaborate upon their ideas, opinions, and experiences without the restraint upon length. The finding may also suggest that women enjoy the impartial environment of online communication because they are not obligated to remain within social norms of face-to-face interactions. In short, women can "speak" all they desire because they

Who's Talking Online?

have a closed audience who will not silence them. For online course instructors, communication tools should be used to promote interaction among students from diverse backgrounds. Without the physical and auditory cues, women may feel more inclined to participate. Thus, online participation should be encouraged by the instructor to offer individuals from non-dominant groups the chance to discuss freely their ideas and opinions without the fear of repercussions.

The third question investigated whether women, more than men, used more informal expressions in their responses. When viewing the findings, this was not the case. Women made as many informal responses as they did formal, compared to the men. Women did use the “reporting” format that had been normally reserved for men (Kuntjara, 2002). Men did make briefer statements that supported the literature about men’s use of language. However, the important finding was that the women used both. This implies that the women in the course were not afraid to use the more formal tone to prove their point. They were also adaptable in switching between the tones depending upon the topic under discussion. Online instructors should take this into account. Incorporating online debates should not be shied away if course enrollment has more females than males. If these courses have online students who are similar to the participants in this study, women will not have any difficulty taking a more formal approach in defending their ideas.

The last question examined was whether women provided more supportive/encouraging comments than their male counterparts. This was true in that the women contributed more encouraging comments than men. The women also addressed their colleagues by name, which promotes a sense of familiarity and collaboration, something that had been discovered in previous studies (Kilbourne & Weeks, 1997). This implies that the women searched for collaboration and friendship online, and needed the sense of community more than men (Shaw & Gant, 2002). For

online course instructors, communication tools should be used to promote collaboration, such as assigning group activities, discussing reading materials, deliberating over case studies, and so forth. If women feel that they are part of the online community, their learning will be enhanced.

This study only provided the basic foundation of investigating gender differences in online communication. Some findings discovered in this study supported previous literature/studies, while others did not. Future studies should look into these areas that countered previous research because they could illuminate the external variables that may have caused these effects to occur. Further studies should also be conducted to validate and support the findings of this initial study. Investigating a larger sample, using courses that have both undergraduate and graduate students, studying students from various disciplines, and performing more in-depth, qualitative studies should be performed to help support the findings addressed in this pilot study. This study is only the beginning and many more can be performed to investigate the variables in question. With additional support from other investigations, the relationship between gender and online communication can be exposed and pondered.

EDITOR'S NOTE

The author provided additional tables documenting the results of the study. For copies of this supplementary information, please contact the author via e-mail.

Chapter 7.20

Who's Talking Online II: Revisiting Gender and Online Communications

Taralynn Hartsell

University of Southern Mississippi, USA

ABSTRACT

This descriptive study investigated the association between gender and online communication that involved participants from two online graduate courses. The study implemented a descriptive model in that “student involvement” was assessed by tabulating and recording the quantity and quality of student activity in the discussion threads. Quantity was recorded by the amount of times students posted online comments and the number of words that women and men used to make their responses. In addition, quality was examined by reviewing the content that women and men made concerning topics under discussion. A difference between the genders was found in that the quantity women contributed to the discussions exceeded the men. Women were also more inclined to give supportive or encouraging remarks than men, and addressed their classmates by name to promote a sense of online community, all of which support previous studies.

INTRODUCTION

Delivering courses through the World Wide Web in higher education is a growing trend that has taken precedence at many colleges and universities. As the population of non-traditional students increase and the pervasiveness of computer technology reaches an all-time high in education, delivering online courses has become an alternative medium to offering coursework and degree programs to remote students who are not physically present on campus (Simonson, Smaldino, Albright, & Zvacek, 2003). The push for educators to offer more online courses or adapt existing courses to an online medium will not disappear. In fact, more online courses will be offered to students as an alternative mode for completing educational degree programs, an occurrence that was inconceivable 15 years ago (Picciano, 2001).

This trend for promoting online courses in higher education also creates concerns for both

the teacher and student. Some of these concerns include factors such as management, communication, interaction, discipline and retention (Moore & Kearsley, 1996). Communication is one of these key factors for student success. Studies have looked at student isolation and disillusionment as contributory factors toward impairing student retention and effective learning. Communication between student-teacher and student-student is important toward alleviating feelings of isolation. Another aspect of communication is participation. There is an assumption that the more a student participates in an online course, the better success that student will find in acquiring and learning the material related to the course (Picciano, 2001b).

One question that arises concerning online communication is whether gender of the student is a contributing factor toward learning success. Although research has shown that females and males differ in terms of their attitudes toward computer use and computer aptitude, women and men are still both users of computer technology—a direct opposite to the notion that females are not as technologically inclined as males (Whitley, 1996). In addition, many have voiced that the Internet is a more neutral playing field for both men and women to enjoy. In a sense, the Internet has been claimed to lead toward greater gender equity because of its communication interface (Herring, 2001; Gorris & Medina, 2000). Furthermore, scholars say that the Internet should be taken seriously to help create opportunities for less powerful individuals to participate with members who are more vocal, especially in asynchronous environments (Balka, 1993; Selfe & Meyer, 1991; We, 1993).

Because research on Web-based instruction is relatively new, particularly in the aspect of communication effectiveness in relation to gender, there is a paucity of research that investigates how women and men communicate online. Few studies investigate the use and integration of online communication in reference to gender, but more research needs to be performed that examines the

amount of communication that occurs between men and women (Arbaugh, 2000; Shaw & Gant, 2002; Sullivan, 2001). The old assumption that women are more verbal and, thus, more inclined to communicate in online discussions and e-mail needs to be analyzed more closely (Shaw & Gant, 2002; Waldeck, Kearney, & Plax, 2001).

This report describes a study that investigated gender differences in two distance learning courses on the use of online communication tools. The chapter is divided into three sections. First, an overview of the study is discussed in addition to providing a summary of the literature. The literature is primarily based on the area of technology and gender differences in education to help build a theoretical base toward analyzing the influence of gender in online communication activities. Second, the report explains the results of the study, with the gender perspective in mind. The third section discusses the implications and recommendations for online instructors who are teaching diversified student populations, particularly those courses that have an even or odd distribution of women and men.

OVERVIEW OF THE LITERATURE

Many factors influence how women and men use computer technology. It has been assumed that women and men differ in their attitudes toward, comfort with and anxiety levels concerning computer technology (Weiser, 2000). Research has suggested that women and men like to use computers to gain information and complete tasks. The disparities, if any, exist in their interactions toward computer technology and how women and men use the tool (McCoy, Heafner, Burdick, & Nagle, 2001).

Level of anxiety may contribute toward the use of and attitude towards computer technology. According to Whitley (1996), college women exhibited low levels of anxiety when it came to computers, but not as low as men. Among these

subjects, Whitley found that less anxious men and women were more likely to take computer courses and spend more time on a computer. Namlu (2003) examined whether learning strategies (LS) were factors in controlling the levels of computer anxiety (CA). She concluded that LS, categorized into simple, advanced and derived, seemed to play an important role in handling CA in that those who had a solid foundation in monitoring their learning progress had lower CA. Hence, anxiety toward computers in association with learning styles can be contributing factors toward how women and men view computers and how they handle technical troubleshooting.

Differences in how the genders perceive technology also contribute toward varying computer usage. Women tend to view the computer as a tool to achieve and complete tasks (Fiore, 1999). They tend to see computer technology, particularly the Internet, as a way to gather information and communicate with others or to promote human interaction. In other words, females see the computer as a "tool" to be used for what it can perform. Males, on the other hand, have viewed the computer more as a recreational toy (Shashaani, 1994). According to the Commission on Technology, Gender, and Teacher Education (2000), males tend to view the computer as a "toy" or an extension of the self. For males, computer technology has been predominantly used for entertainment. In a study conducted by McCoy, Heafner, Burdick and Nagle (2001) that looked at the assimilation of IBM ThinkPads on a university campus, individual computer use was examined through the following categories: tool, communication, resources, entertainment and total use. These categories were compared between the genders using independent t-tests. The researchers discovered that males were more frequent users in the categories of resources, entertainment and total use. There was no significant difference for tool use or communication, meaning that women used the technology for these purposes more than for entertainment. This supports the previ-

ous finding that women, more than men, tend to use computer technology as a way to reach out and complete tasks than just "playing" with the technology to see what it can do and retrieve information/programs for personal use.

In regard to distance learning technology and Internet access, any gap that may have been in place between the genders seems to have narrowed (Novak & Hoffman, 1998). In fact, recent research has indicated that more females are enrolling in Web-based online courses and programs with comparable success to males (Ory, Bullock, & Burnaska, 1997). In a study investigating the use and attitudes toward asynchronous learning networks (ALN) in a university setting, Ory, Bullock and Burnaska (1997) discovered that both males and females made equivalent use of ALN and had similar positive attitudes about their experiences. Women also shared a common desire to take more courses that used computers as a result of their experiences with ALN in this situation.

The Internet has been said to be inherently democratic and, thus, leveling traditional distinctions of social status. This, in turn, would create opportunities for those who are often silent to speak out and participate with members of the more powerful group. It has been said that text-based computer-mediated communication allows men and women to participate equally in contrast to traditional patterns of face-to-face conversations. With the absence of physical and auditory cues, the gender of online communicators is irrelevant or invisible (Danet, 1998). This situation could help facilitate free communication between women and men in that gender roles have somewhat been removed.

With the rise of the Internet, researchers have begun to investigate whether gender disparities exist with Internet technology (Shaw & Gant, 2002). Researchers have predicted that males and females will differ in the ways they view and interact with the Internet, hypothesizing that males will be less anxious and more comfortable using the medium compared to females. This

proposition supports the idea that women are more “technophobic” than men in that women are more afraid of technology and, therefore, slower to adapt technological advances (Shaw & Gant, 2002). Although studies have found that males report more experience using the Internet and score higher in areas of comfort, innovativeness and Internet self-efficacy, this does not explain the growing numbers of women accessing the Internet (Shaw & Gant, 2002). Women are accessing the Internet just as much as men. The explanation could be attributed to how the women may be using the Internet as compared to males. Communication is a motivating factor for women to seek out social interaction online. Men tend to seek information and entertainment through the Internet, which supports earlier studies on gender and computer usage (Hamburger & Ben-Artzi, 2000).

Based on studies of gender differences in communication and technology usage, the encouragement of collaboration in online courses can be quite favorable toward women. Because previous studies in communication patterns have revealed that men tend to communicate on the basis of social hierarchy, and women are more network-oriented and collaborative, a collaborative Web-based environment may help reverse this process (Kilbourne & Weeks, 1997). Thus, in a setting absent of competition, the playing field can be leveled between the genders.

There have been studies that look at the way men and women communicate in terms of online communication. The use of language and tone are primary areas of difference in that men tend to use more aggressive language to assert their point in the discussion as opposed to women (Herring, 1993; Rossetti, 1998). In addition, women tend to contribute more overt expressions of agreement, appreciation and support. They also present their assertions indirectly as suggestions (Kuntjara, 2002). Gender differences in online communication suggest that women prefer a “rapport” style while men generally speak in the tone of a “report”

in that their postings sound as if they are simply providing information (Kuntjara, 2002). Susan Herring (1993) has been investigating gender rhetoric in online communications for quite some time and discovered that the topics of discussion influence the amount and type of participation that women and men contribute. Women tend to participate in discussions that are more associated to the real world than on the abstract and theoretical. Men, on the other hand, tend to be more concerned with receiving information from others and less interested in personal discussion.

Nonetheless, some studies do show the opposite in terms of gender differences in online communication. Kirsteen Monteith (2002) found in her study that women did not hesitate to take control over discussions and were participating equally among themselves. In addition, the women, at times, were dominating the discussions while retaining a collaborative environment. In fact, Monteith discovered that male participants were not the more formal, antisocial and controlling participants. Instead, the men tended to shift toward the collaborative approach by sharing information with others, responding to their female counterparts, and keeping a polite and courteous manner (traditionally a female characteristic). With this gender shift in mind, the Web-based medium does have implications for leveling the ground for all users.

In short, the literature supports the notion that women and men are almost equally equivalent in terms of computer and Internet usage, even though a difference exists in terms of the motives behind the use. Because the literature tends to sustain that communication is the main motive for women to use the Internet, this is an area that needs to be investigated further. The primary question is whether women participate more in online communication than men. In addition, do women's participation exceed men's in terms of quality, in that women explain their perspectives/ideas more thoroughly than men? It has been found

that the tone and presence of women and men in their conversation styles differ and, thus, should be looked at more closely.

PURPOSE OF THE STUDY

The goal of this study was to examine whether online communication differed between the women and men enrolled in two distance learning courses. This particular study has been augmented from an earlier preliminary study published by the researcher (Hartsell, 2005). Discussion threads were the primary communication tool used between student-student in this study as opposed to e-mail, and thus, became the instrument of data collection. Discussion threads allow students and teachers to see the “trail of thought” among individuals, as postings to the discussion threads are made in response to previous postings. The research questions investigated in this descriptive study included whether women more than men: (a) participated or made postings to discussion threads, (b) supplied more explanation in their responses to support the topic under discussion, (c) provided more informal responses than formal, and (d) tended to provide more supportive/encouraging comments.

METHODOLOGY

Participants

The courses under study were graduate-level instructional technology courses in which 25 students were involved. Twelve females and 13 males participated in this study as participants. Of these 25 participants, 12 were doctoral-level students majoring in educational leadership, communications or mathematics; 10 were master's-level students majoring in instructional technology, and one was majoring in nursing, foreign languages

and technology education. Other than for the 10 students majoring in instructional technology, one course used for this study was considered as an elective and/or for fulfilling minor requirements. The other course in this study was an elective for all participants involved. All students were required to interact in discussion threads over a 10-week period that involved topics stemming from course readings. Participants were expected to contribute at least four postings each week in response to the course material. However, a number of participants posted more than what was required.

Design and Measures

The research design was primarily descriptive in nature and the instrument for data collection was the documentation of the actual discussions that took place across the semester between the men and women. The study implemented a descriptive model in that “student involvement” was assessed by tabulating and recording the quantity and quality of student interactivity in the discussion threads. Raw data collected from the transcriptions of discussion threads were examined using a method of calculation rather than employing thick descriptions to explain the setting as in qualitative research.

The research design was not qualitative in that it did not go in-depth or describe the meaning of the findings from the perspective of the research participants. Instead, the data was analyzed by simply counting the words or the number of times a participant posted a response. Quantity was recorded by the amount of times students posted responses to the threads as well as the number of words that women and men used to make their responses. Quality was examined by reviewing the content that women and men made concerning topics under discussion. Tone was also studied, because the literature review indicated that this was a contributing factor in terms of

how men used online communication tools as opposed to women. In short, quality of the postings were studied further in detail by looking at who responded to whom, the tone of the posting and whether the response contributed toward the discussion and not just a simple, informal comment made to someone.

Procedures

Data collection occurred during two different semesters. The discussion thread requirement for each course occurred over a 10-week period. Students in the online courses were required to make at least four postings to the weekly discussions, although the opportunity to contribute more was available and optional. The weekly discussion covered topics stemming from the course's reading materials.

The discussions progressed in an organized manner and occurred through WebCT's discussion tool feature. Each week, the students had to read two to three chapters within the textbook or from online articles. Either a facilitator or the instructor posted questions to the discussion threads each week. The weekly discussions began each Monday and concluded the following Monday, in which the instructor closed or locked the discussion thread to prevent miscellaneous postings made to the thread.

The discussion threads that occurred each week were then compiled into a text file that displayed who said what and to whom. With these text files, the postings were broken down by individual participants to help in the calculation of how many times males, as opposed to females, made postings and the number of words made in each posting. The text file was also used to determine whether the postings were in response to someone else's reactions or if a new topic/concern was initiated by the participant. Furthermore, the discussion threads were examined to assess the "quality" aspect of the postings that focused upon two areas: (1) tone of the posting and (2)

the value of information given. Discussions were coded for ascertaining the quality aspect. The coding scheme used the following classifications: (a) *I* being informal in tone, more like a discussion or rapport style, (b) *F* being formal in tone, somewhat like a report of the facts, (c) *S* including supportive/encouraging comments and reacting to personal matters, (d) *B* including short replies of one to three sentences long or not really addressing content material, and (e) *R* for postings that directly made reference to course materials. Each discussion posting was coded; some postings had two or more codes ascribed to them because they crossed classifications.

RESULTS

Results of the study are summarized and organized in terms of the original research questions. First, participation patterns for the genders are presented by the aggregate of individual weeks in Table 1. Table 2 shows the minimum, maximum, mean and standard deviation scores separated by gender for all 10 weeks of discussion. As predicted, the women participated more in the discussion threads, as can be seen by the number of postings. Overall, the women posted 91 more responses than their male counterparts. In addition, when one examines the minimum, maximum and mean scores, the women again surpassed their male counterparts in the collective 10-week period. Even for the week that the women did not contribute much toward the discussion, they still made 6 more responses than the men (MIN). These numbers are interesting in that the women comprised the minority group in this study, with 12 individuals as opposed to 13 men. One would expect to see more postings from the majority group of men because they have an additional member. However, this was not the case.

An independent-samples *t*-test using the total number of postings as the test variable was conducted to evaluate whether gender played a role.

Table 1. Class participation patterns by gender

Gender	Class postings per week										Total
	1	2	3	4	5	6	7	8	9	10	
Women (<i>n</i> = 12)	69	73	88	84	62	81	116	56	68	79	776
Men (<i>n</i> = 13)	54	77	84	77	63	63	81	61	50	75	685

Table 2. Frequency of postings by gender for all 10 weeks

Gender	Frequency of postings			
	Min	Max	Mean	SD
Women (<i>n</i> = 12)	56	116	77.6	16.78
Men (<i>n</i> = 13)	50	84	68.5	11.79

The test was not significant, $t(18) = 1.403$, $p = .05$, and most likely represented a chance occurrence. However, on average, the women did produce more postings to the discussion threads than men. A reason to account for this lack of significance could be due to the small sample size; thus, more participants are required to be included in future studies to help validate the *t*-tests.

A factorial ANOVA was also conducted to evaluate the effects of class (the two courses) and gender on the number of postings made to the discussion threads. The factorial ANOVA indicated no significant interaction between class and gender, $F(1, 21) = .182$, $p = .674$, $\eta^2 = .009$, nor was there a significant effect for gender, $F(1, 21) = 1.585$, $p = .222$, $\eta^2 = .070$. However, there was a significant effect for class, $F(1, 21) = 9.279$, $p = .006$, $\eta^2 = .306$. The difference between the classes could be attributed to the uneven number of participants in each course and that one course had less discussion activity than the other. Be-

cause there were fewer than three groups for the fixed factors, post hoc tests were not conducted in this ANOVA.

Findings from the data also demonstrated that women incorporated more explanation into their postings to support their ideas and opinions. Men tended to get "straight to the point" in their responses, while women wanted to expand and augment what they said through illustrations, experiences and examples. Table 3 presents the number of words used by the women and men in their postings. The results show that women used more words to explain their responses or defend their ideas as opposed to their male counterparts. In all, the women surpassed the men by more than 8,000 words during the 10-week period. Curiously, the men exceeded the women in weeks 1 and 3, but not by a great deal in terms of numbers.

For examining the quality of the responses, the discussion postings were coded into five classifications, as addressed in the procedures section. The

Table 3. Number of words used in postings by gender

Gender	Number of words per week										Total
	1	2	3	4	5	6	7	8	9	10	
Women (<i>n</i> = 12)	5,662	10,920	9,342	10,274	8,471	8,119	8,688	8,765	8,509	7,810	86,560
Men (<i>n</i> = 13)	6,142	10,089	9,396	8,688	6,884	7,398	8,339	7,276	6,326	7,679	78,217

Table 4. Coding of discussion postings by gender

Gender	Codes				
	Informal	Formal	Support	Brief	Report
Women (<i>n</i> = 12)	576	97	305	223	90
Men (<i>n</i> = 13)	471	90	162	223	51

distribution of responses according to the codes across the entire 10 weeks can be found in Table 4. The results indicated that women were more outspoken, whether formally or informally. This contradicts previous findings in that women tend to be more informal in their responses, because in this sample the women also made more formal comments as opposed to their male colleagues. In addition, women tend to give more supportive comments, which are broken down in Table 5. Both women and men were equal in terms of posting brief comments.

When the discussion postings were coded, the *S* code was broken down into several other classifications. Table 5 depicts the results in terms of the number of responses that have been coded with an *S*. The *S* code had been separated into different categories as (a) *E* for offering support or encouragement; (b) *N* for referring to people

directly by name; (c) *A* as making a personal apology; (d) *P* as reacting to personal matters or responding to incidences not really related to class; and (e) *D* to indicate disagreement. This stratification helped determine what type of support was made by the participants. The results show that women offered more comments that were encouraging and thoughtful. They also directed their comments toward other colleagues by name. Males, on the other hand, exceeded in the area of disagreement, although this was not by a considerable number.

Results for the study show that women, more than men, participated in the discussions. In this case, women made more postings to the discussion threads than males and with greater explanation. In the area of quality, the women also excelled in their responses in terms of content matter and tone. Women also gave more encouraging remarks

Table 5. Number of postings classified as "S"

Gender	Support Classifications				
	<i>E</i>	<i>N</i>	<i>A</i>	<i>P</i>	<i>D</i>
Women (<i>n</i> = 12)	145	290	12	57	4
Men (<i>n</i> = 13)	78	134	7	19	8

to others' comments and addressed individuals by name, indicating a sense of intimacy and amiability. In this area, external variables such as students' majors could have influenced the results in that majors in instructional technology would offer more comments in response to the issues addressed. However, this was not the case, because more males than females happened to be majors in instructional technology. The women were diverse in their concentration fields, which included instructional technology majors (6), educational leadership majors (3) and a foreign languages major (1), nursing major (1) and communications major (1). Thus, the assumption that instructional technology majors would have contributed more because of their familiarity with the subject matter was non-existent in this sample.

CONCLUSION AND IMPLICATIONS

Before addressing the conclusions to this initial study, limitations need to be discussed. First, the study is not generalizable because of the small sample size. In addition, the participants were part of a convenience sampling and not a true random sample. However, this sample could lead to larger studies, because it provided the preliminary basis

for identifying exclusive variables to be studied further. Second, this study did not collect the perspectives and reactions from the participants themselves concerning the effectiveness of online communication. A more qualitative approach could be used to obtain such in-depth information as participants' perceptions toward online communication, behavior and learning. Coding of the discussion threads was also a limitation in that an inter-rater reliability test was not performed. Thus, coding conducted by the researcher could be biased. Finally, because the participants were required to make four or more postings a week, this could affect the number of postings made across the 10 weeks in that participation was not always voluntary. If students were concerned about their grades, they would have opted to make more postings than normal. Although limitations existed in this study, this should not discount the findings but be used as questions for further analysis.

This descriptive study investigated whether online communication differed between the women and men enrolled in two distance learning courses through the use of discussion threads. Four research questions were introduced and answered in this study. The first question asked whether women more than men made postings to the discussion threads. As a result, the female

participants made more than 90 more postings during the 10-week period than males. Although the independent samples t-test and ANOVA did not indicate this direction, the raw data implied that women in these courses preferred and enjoyed to communicate online. For online courses, instructors should seriously consider integrating online communication tools to help women and men share their ideas with others. This may prevent social isolation that commonly occurs in distance learning courses.

The second question examined whether women supplied more explanation in their responses to support the topic under discussion. The women did surpass the men by more than 8,000 words. This implies that women in the course valued the opportunity to elaborate on their ideas, opinions and experiences without the restraint on length. The finding may also suggest that women enjoy the impartial environment of online communication because they are not obligated to remain within social norms of face-to-face interactions. In short, women can “speak” all they desire because they have a closed audience who will not silence them. For online course instructors, communication tools should be used to promote interaction among students from diverse backgrounds. Without the traditional physical and auditory cues, women may feel more inclined to participate. Thus, online participation should be encouraged by the instructor to offer individuals from non-dominant groups to discuss freely their ideas and opinions without fear of repercussions.

The third question investigated whether women, more than men, used more informal expressions in their responses. When viewing the findings, this was not the case. Women made as many informal responses as they did formal compared to the men. Women did use the “reporting” format that had been normally reserved for men (Kuntjara, 2002). This implies that the women in the courses were not afraid to use the more formal tone to prove their point. They were also adaptable in switching between tones depending

on the topic under discussion. Online instructors should take this into account. Incorporating online debates should not be shied away from if course enrollment has more females than males. If these courses have online students who are similar to the participants in this study, women will not have any difficulty taking a more formal approach in defending their ideas.

The last question examined whether women provided more supportive/encouraging comments than their male counterparts. This was true in that the women contributed more encouraging comments than men. The women also addressed their colleagues by name that promoted a sense of familiarity and collaboration, something discovered in previous studies (Kilbourne & Weeks, 1997). This implies that the women searched for collaboration and friendship online, and needed the sense of community more than the men (Shaw & Gant, 2002). For online course instructors, communication tools should be used to promote collaboration, such as assigning group activities, discussing reading materials, deliberating over case studies and so forth. If women feel that they are part of the online community, their learning will be enhanced.

This study only provided the foundation of investigating gender differences in online communication. Some findings discovered in this study supported previous literature/studies, while others did not. Future studies should look into these areas that countered previous research because they could clarify the external variables that may have caused these effects to occur. Further studies should also be conducted to validate and support the findings of this initial study. Investigating a larger sample; using courses that have both undergraduate and graduate students; studying students from various disciplines; and performing more in-depth, qualitative studies should be performed to help support the findings addressed. This study is only the beginning, and many more should be performed to investigate the variables in question. With additional support from other

investigations, the relationship between gender and online communication could be exposed and integrated effectively into distance learning activities.

Chapter 7.21

Cultivating Greater Acceptance of Women in Technology: A Pilot Study

Mara H. Wasburn
Purdue University, USA

ABSTRACT

Many Western nations face a critical shortage of skilled professionals in science, technology, engineering and mathematics (STEM). However, despite abundant opportunities, few women prepare themselves for careers in these fields. Several of those concerned with the problem have proposed that new media programming, such as television dramas with women engineers, computer professionals and/or engineers in leading roles, might help attract more women to STEM fields. This article identifies a theoretical rationale for a media-centered strategy, and describes a pilot study whose data suggest that a media-centered approach might have some success in producing greater interest among women in pursuing STEM careers, particularly information technology (IT) careers.

INTRODUCTION

“It is still news whenever women tackle any job American society traditionally has seen as male” (Vavrus, 2002, p. 11). In July 2005, 15 major American business groups, led by the Business Roundtable, issued a joint statement decrying the declining prominence of the United States (US) in STEM, and calling for the nation to double the number of college graduates in those fields by 2015. The statement cited data indicating that more than 50% of the current US science and engineering workforce is approaching retirement age and that by 2010, if present trends continue, the vast majority of all scientists and engineers in the world will be living in Asia. The report claimed that the scientific and technical capacity of the US has already begun to atrophy, threatening America’s standard of living at home and leadership in the world (Business Roundtable, 2005).

Corresponding concerns for their nation's welfare and standing in the global political economy have been expressed in many countries throughout Western Europe (Femtec, 2002).

It is widely understood that part of the solution to the escalating problem of the shortage of well-trained technical personnel in all advanced industrial nations involves attracting considerably more women to careers in STEM disciplines. In the US, there is substantial occupational segregation by sex. Although women constitute 46% of the labor force, less than one-quarter of the scientists and engineers in the country are women (Mervis, 2000). Precise international comparisons of occupational segregation are difficult, because nations seldom use comparable detailed occupational coding systems (Jacobs, 1993, p. 133). However, available data indicate not only the existence of such a gendered division of labor throughout Western Europe, but also the likelihood of its persistence. For example, while half of all university students in Germany are women, women represent only 34% of all students in the natural sciences and 19% of all students in engineering (Femtec, 2002, p. 2). Similarly, men were found to be over-represented among computer science graduates in all 21 industrial nations considered in a recent study. In the US, the "male over-representation factor" is 2.10; United Kingdom, 3.10; France, 4.57; and Germany, 5.58 (Charles & Bradley, 2005).

Approximately half the potential STEM talent pool consists of women. Therefore, in 2000, a US government commission was charged with developing strategies to attract more women and minorities in STEM careers. The commission reported to the Committee on Science of the House of Representatives that significant barriers to these goals persist (Committee on Science, 2000). Such deterrents range from differing male/female attitudes toward science and technology that begin to diverge as early as elementary and middle school to the absence of women faculty, mentors and fellow students in college and university classrooms

that create a "chilly climate for women" in these areas (AAUW, 2000; Seymour, 1999).

In the field of IT, career opportunities for women abound. Yet despite the obvious advantage of entering this area, there has been a steady decline in the number of computer science bachelors degrees awarded, particularly to women (Camp, 1997). In 1983-'84, more than 37% of the bachelors degrees in computer science were awarded to women. Ten years later, the percentage had fallen to 28%, and it has held relatively steady through the new millennium (Camp, 2002).

An examination of research on women in computer science revealed that emphasis at the post-secondary level is on the social psychological factors that prevent women's inclusion (Dryburgh, 2000). Margolis and Fisher (2002) used the metaphor of a "clubhouse" to describe the extent to which women are excluded from the male purview of computing, and "dreaming in code" as "emblematic of a male standard of behavior in this computer-oriented world." The authors no longer want to try to fit women into this male culture. They issued a call to arms for a revolution in the culture and curriculum of computer science that will encompass and respect the contributions women can make to the discipline.

As young women grow older, fewer of them express interest in studying STEM subjects. The literature refers to a "leaky" pipeline of women from elementary school through graduate studies and employment, eventually leading to their under-representation in the STEM professions. (Freeman, 2004; Jones, Howe, & Rua, 2000.)

A 2003 US National Science Foundation publication described 211 ongoing projects in the country designed to attract and retain women in STEM courses. More than \$90 million had already been poured into these projects. Given the proliferation of such efforts, some measurable effect on the entry and persistence of women in these professions should be expected. However, studies indicate no substantial gains (Freeman, 2004; Huang, Tadolese & Walter, 2000). In fact,

much of the progress that women have made in these areas has stalled or eroded (National Council for Research on Women, 2001). Such findings indicate the importance of developing additional new strategies for attracting more women into STEM programs. One such approach, which is the focus of this article, involves using the mass media to create a more positive understanding of women in these professions.

The approach was the topic of a seminar entitled “Women in Science and Engineering, and TV Drama: Sex, Lives and Videotape” held in November 2004 in London’s Institution of Electrical Engineers. The event was organized by the Public Awareness of Science and Engineering (PAWS) Drama Fund and was supported by six of the United Kingdom’s leading science, engineering and technology organizations. The seminar brought together scientists, engineers, and television drama producers and writers. Its goal was to offer recommendations for helping and encouraging the media to present more well-rounded, up-to-date and attractive images of women in STEM careers through the development of new programming, such as science-based television dramas with women in leading roles.

THEORETICAL RATIONALE FOR A MEDIA STRATEGY

In the 1960s, the international feminist movement helped advance the idea that cultural understandings of gender roles are socially constructed and have to do with ideology and power rather than being “natural.” Feminist scholars began directing attention to the media’s role in making women’s minority status experienced as part of the “natural order of things.” Numerous content analyses found that women were under-represented in the media and portrayed in ways that tended to sexualize, commodify and trivialize them. Such presentation supported an inequalitarian status quo in which women played marginal roles in political,

economic and intellectual life (Brunsdon, D’Acci, & Spigel, 1995; Gunter, 1995; McQueen, 1998; Tuchman, 1978).

The basic theoretical insight that our understanding and experience of the world of everyday life is socially constructed was first fully articulated in the early 1930s by German philosopher Alfred Schutz (1932), who sought to develop a sociological variant of phenomenology. The work gained considerable influence in the US when it appeared in English in 1967. This was one year after Peter Berger and Thomas Luckmann’s theoretically similar study, “The Social Construction of Reality” (1966), had gained the attention of American social scientists. The publication of the two studies corresponded with the height of feminist activity. For example, the National Organization of Women was founded in 1966.

In Schutz’s view, all of us carry in our minds a “stock of knowledge of physical things and fellow citizens, of social collections and artifacts, including cultural objects” (Schutz, 1932/1967, p. 81). This stock of knowledge provides a frame of reference or orientation with which we can interpret objects and events as we conduct our everyday lives. Moreover, the objects and events of the world have no inherent or universal meaning apart from this imposed framework.

For Schutz, our stock of knowledge *is* our reality. It is experienced as the objective world existing “out there,” independent of our will and confronting us as fact. This stock of knowledge has a taken-for-granted character and is seldom the object of conscious reflection. It is understood by us in a common-sense fashion as reality itself. Although we can doubt this reality, we rarely do so, and we cannot do so when we are engaged in our routine activities. This perspective suggests that most of us might feel too busy to attend seriously to the fact that boys monopolize classroom computers or to the low probability that one of the attractive female characters in the enormously popular American television series *Sex and the City* might be a physical scientist,

engineer, mathematician or systems analyst. We would be unlikely to react to the fact that the brilliant, crime-solving mathematician on the series *Numb3rs* could just have easily been cast as a woman without disturbing the plot, or to the fact that *Friends*, one of the all-time most popular television programs of all time, had three prominent female characters: a masseuse, a restaurant owner and a member of the fashion industry. Not one of them was an engineer or a computer scientist. Even the female leads on *CSI, Crime Scene Investigation*, who are forensic scientists using the most advanced scientific and technical methods to apprehend criminals, came to their jobs by chance, rather than by completing formal programs of scientific education.

Schutz contends that we assume other members of our society generally share our stock of knowledge and will experience the world in the same way we do. We assume that others will see the world as being made up of the same types of objects and events, that these objects and events will have the same meaning for them, and that they will respond to them in ways they themselves have learned are appropriate. After all, even today, how many people really believe that being a chemical engineer is just as suitable a career for a woman as being a teacher or nurse?

According to Schutz, we rely on typifications, or “recipes” for action that exist in our culture. These typifications, which are part of our stock knowledge, provide us with ready-made courses of action, solutions to problems and interpretations of the social world. Although the typifications constitute a cultural framework experienced as requiring no further analysis, problematic situations can arise that call the typifications into question. For example, frequently encountering mass media images of reasonably attractive women successful doing “men’s work” might, over time, encourage people to reconsider their views about how “natural” is the traditional gendered division of labor.

In a manner similar to that of Schutz, Peter Berger and Thomas Luckmann (1966) discuss the process by which we create the realities of our everyday lives. They observed that social institutions appear to have an objective reality of their own as given, self-evident aspects of the world. The social world, which is a human product, confronts its producer as an external reality, as something other than a human product. New generations learn about this reality through the process of socialization, just as they learn about other things that make up the world they encounter.

New generations also learn meanings of the social order, which bestows on that order not only cognitive validity but normative legitimacy as well. Socialization involves the simultaneous transmission of knowledge and values. All understandings of the social world carry with them evaluations. Berger and Luckmann’s position rejects the standard distinction between the explanation and evaluation of the social world. Presentation of traditional images, such as those of a gendered division of labor, legitimates that institutional order.

By the time Schutz’s study was published, the power of radio and motion pictures as agents of socialization that could be used to legitimate or challenge social institutions was well recognized worldwide by those in the media industry, as well as by social scientists and national governments (see Blumer, 1933; Cantril & Allport, 1935; Furhammer & Isaksson, 1971; Lacey, 1996). Nevertheless, Schutz fails to discuss the media’s role as a major source of our “stock of knowledge” and as a creator of the typifications on which we rely as we go about our everyday lives. More than three decades later, Berger and Luckmann also ignore the importance of the mass media in legitimating or changing social orders. This is remarkable in light of the vast literature on the influence of television that was produced in the 1960s by cultural critics and feminist theorists, as well as social scientists.

A major constructionist theory focusing on the influence of mediated reality on social behavior was introduced by George Gerbner and his associates in the 1970s and subsequently elaborated on (Genuter, 1995; Gerbner, 1976; Gerbner, et al., 1994; Signorielli & Morgan, 1990). Initial concern was with how the vast amount of violence portrayed on American television exaggerated the fears people have about encountering violence in their own neighborhoods. Later developed as cultivation theory, the approach asserts that, at least among heavy users, television produces a “mainstreaming” effect whereby differences in beliefs in otherwise heterogeneous populations are muted. Heavy television viewers internalize many of the perspectives on the social world presented by television. Such influence occurs as a result of continual and lengthy exposure to television in general, not just exposure to individual programs or genres.

In terms of the works of Schutz (1932/1967), Berger and Luckmann (1966) discussed earlier, television presents typifications which, after prolonged repetitious exposure, the viewing public accepts as accurate representations of social reality. Ubiquitous images come to represent not only the social order but the normative order as well. Viewers use typifications to negotiate the social world by understanding “the natural order of things.” If girls, compared to boys, are never or almost never represented as interested in STEM disciplines in youth-oriented television programming, or seen as enrolled in advanced physics, chemistry, calculus or computer classes, that is the way things are – just natural. Change in the social order is not called for. If women, compared to men, are never or almost never portrayed as scientists, technical experts or engineers on television programs, that, too, is a reflection of “the way things are.” The likely viewer reaction to such under-representation is not dissatisfaction with the apparent inequality, but simple acceptance of the consequences of how “natural” interests and abilities are distributed by sex.

Taken together, social constructionism and cultivation theory clearly suggest an approach to attracting more women to STEM careers. The strategy is to vastly increase media representation of women in these occupations. This should be undertaken in all varieties of programming, including children’s shows, dramas, situation comedies, talk shows, soap operas and even commercials. The goal is to cultivate a social understanding of middle and high school girls enrolled in STEM classes, of women scientists, engineers and technical experts as simply part of the natural social order — as nothing unusual. STEM education and careers can be presented as legitimate spheres of participation for women — areas of professional activity in which women not only *do* but *should* participate.

Positive images of women technology professionals are not necessarily images of bright, articulate, personable, physically attractive people. While, quite obviously, they should not be less attractive than the other characters with whom they interact or others who appear regularly on other programs, the important point is that women technology professionals appear frequently in the full variety of television programs. Young women should be commonly encountered as characters enrolled in technology-rich classes rebuilding computers.

It is important to note that women are not a monolithic group and, consequently, no one approach will work for attracting women to STEM disciplines. In addition to gender, other factors such as race, class, ethnicity and sexual orientation influence education and career choices (Rosser, 1998). This suggests that if a media strategy is to be helpful, it must involve diverse programming appealing to audiences composed of women with diverse demographic characteristics.

Women should be commonly encountered as characters competently doing technologically sophisticated work that is just as legitimately “woman’s work” as it is “man’s work.” This proposal is consistent with research concluding that,

at least in the US, media routinely ignore and/or trivialize women's participation in STEM, and thereby discourage their career aspirations in scientific and technical fields (Potts & Martinez, 1994; Steinke, 1997).

PILOT STUDY

The preceding suggests the hypothesis that television viewers who have encountered images of women technical professionals are more likely to believe that STEM careers are acceptable (legitimate) careers for women than are those who have not seen such presentations. An opportunity presented itself to conduct a pilot study that, though limited in several ways, does shed some new light on the tenability of this suggestion.

Between April 1 and May 15, 2004, the Survey Research Institute at Purdue University conducted as a graduate student training exercise one of its periodic social surveys of the entire continental US via computer assisted telephone-interviewing (CATI) system. In the system, telephone numbers are selected randomly from a list of random digit-dialing telephone numbers that include all area codes and telephone prefixes throughout the US. The CATI system allows graduate student interviewers to record responses into a database while conducting the interview. CATI software prevents a researcher from calling anywhere in the US before 9 a.m. or after 9 p.m. in each time zone.

For each potential interview, the respondent is first asked whether or not he or she is 18. If the respondent is not 18 or older, the researcher asks if anyone in the house is at least 18 years of age. Once an 18-year-old is contacted, the respondent is asked if he or she has enough time to answer the survey. As long as the respondent agrees, the survey is administered. Should a respondent show an interest in taking the survey but state that he or she does not have the time to take the survey, a better time is scheduled in the CATI system and

the respondent is called back at the rescheduled time. Upon completion of the interview, the researcher records the sex of each respondent. In the case that a respondent prematurely terminates the interview, all of the responses up to that point are saved and a callback is scheduled in an attempt to complete the interview.

Four hundred interviews were initiated, of which 284 were completed, for a response rate of 71%. The social survey allocated 30 minutes for questions of the pilot study investigating media images of women technology professionals. Three categories of STEM careers were selected to represent a broad range of specific professions: engineer, research scientist and computer technician. The analysis dealt with the proportion of the sample that had seen actresses playing these occupational roles, an indirect measure of the relative attractiveness of those occupations, and the differences in attitudes toward the acceptability (legitimacy) of various careers for women between those who had and those who had not seen actresses playing those occupational roles on television.

Limitations

Although the sample did randomly include individuals representing a wide range of demographic characteristics, it cannot be considered representative of the entire population of the continental US. Women, in particular, were over-represented: 210 (70.7%), as opposed to 83 (29.2%) male respondents. Since use of the CATI system prevented interviewing young women and men below the age of 18, students are not represented in the sample. Also, due to the necessary brevity and other characteristics of telephone surveys, respondents were asked short questions, some of which were only proxy measures of central concepts, such as the relative attractiveness of women in various STEM occupations, and the terms for those occupations such as "computer technician," which was used to represent a variety of computing-focused careers.

The cumulative effect of encountering numerous positive images over time, central to cultivation theory, could not be explored.

FINDINGS

Data in Table 1 show that more than 90% of the sample had seen actresses portray nurses, medical doctors, lawyers and secretaries. This is not surprising in light of the long-term popularity of medical and legal dramas on US prime-time television. Female secretaries are likely to appear in work contexts in most varieties of television programming.

There is a considerable gap between the frequency with which respondents report seeing actresses portraying those roles and the frequency with which they report seeing actresses portraying other occupational roles, including the three technology roles selected to represent a large cluster of related occupations. Research scientists are seen much more frequently than are computer technicians and engineers. This probably reflects their appearances on several types of television

dramas, including crime, law, mystery and science fiction. The only two occupational roles in which the majority of respondents had not seen actresses were computer technician and engineer. This is certainly due, at least in part, to the comparative rarity that such roles appear in any variety of programming. When decisions are being made as to the careers to assign female characters in television comedies, dramas, soap operas and even commercials, having those characters portrayed as engineers or computer technicians would take advantage of a particular opportunity to establish women in technology as a part of the natural order of things.

How attractive are women technology professionals compared to women in other occupations? The elementary school teacher was selected as the profession for comparison. This is one of the most traditional middle-class occupations, and has had a long history of being gender stereotyped as appropriate for women. Data in Table 2 indicate that the relative attractiveness of women in technology generally is a reflection of the standing of their occupation in the occupational prestige hierarchy. However, there are exceptions. When comparing

Table 1. Question: Would you tell me if you have ever seen actresses on television playing characters with the following professions?

	Yes (In %)	No (In %)
Nurse	96.1	3.9
Medical Doctor	93.0	7.0
Lawyer	91.2	8.8
Secretary	90.1	9.9
Research Scientist	78.2	21.8
Factory Worker	65.8	34.2
Elementary School Teacher	63.7	36.3
Engineer	50.6	49.4
Computer Technician	44.7	55.3

n=284

Table 2. Question: I would like you to tell me which of two women, described by their careers, do you think most men would prefer as a spouse or partner?

	(In %)	Elementary School Teacher (In %)
Medical Doctor	64.4	35.6
Nurse	61.3	38.7
Lawyer	49.6	50.4
Engineer	44.2	55.8
Research Scientist	39.1	60.9
Computer Technician	28.2	71.8
Secretary	24.6	75.3
Factory Worker	14.1	85.9

n=284

respondent perceptions of the attractiveness of a woman who is an engineer or a research scientist with that of a woman who is an elementary school teacher, the latter is more frequently judged more attractive. Generally, engineers and research scientists have more education, higher income and higher occupational prestige than elementary school teachers. Yet, data show that respondents believed most men would prefer an elementary school teacher as a spouse or partner. Such a finding indicates the need to improve the image of women in technology-rich professions.

Are those who have seen actresses in a STEM occupation significantly more likely than others to believe it is an acceptable (legitimate) occupation for a woman? The answer to this question bears directly on the tenability of the theoretical assumption central to this article: Media images of social reality come to be regarded not only as the empirical but also as the normative “natural order of things.”

Respondents were asked the extent to which they agreed with the statement that each of several STEM careers (research scientist, engineer, com-

puter technician) was an “acceptable career for a woman.” The theoretical expectation is that those respondents who had seen an actress on television playing the role of a technology professional would more frequently report that the role is legitimate for a woman than those who indicated they had never seen such a representation. Because attitudes of men and women toward women in technology might be quite different, their responses also were analyzed separately.

In the case of each of the three careers, five comparisons were made: overall between the attitudes of those who had and those who had not seen a representation of a woman in that occupational role on television, between men who had seen and men who had not seen such a portrayal, between women who had seen and women who had not seen such a portrayal, between men who had and women who had seen such a portrayal, and between men who had not seen and women who had not seen such a portrayal.

Data in Table 3 were used to calculate the magnitude of difference in the distribution of attitudes for the overall sample. Chi-square tests

were used to assess the probability that the magnitude of each of the observed differences was due to chance. Due to space limitations, data

used to calculate additional chi-square values are not presented here. However, they are available. Chi-square tests require row and column totals

Table 3. Question: Do you agree or disagree: Is it acceptable for a woman to be a research scientist?

Cultivating Greater Acceptance of Women in Technology

greater than zero. Consequently, in some tables, strongly disagree and even disagree responses were eliminated in the calculation.

None of the comparisons using the data in Table 3 reveals a statistically significant difference between the attitudes of those who had and those who had not seen an actress portray a research scientist on television. In the case of research scientists, data do not conform to the theoretical expectation.

Data in Table 4 present similar results. None of the five comparisons reveals a statistically significant difference. In the case of engineers, as in the case of research scientists, data do not conform to the theoretical expectations.

Data in Table 5, however, tell a different story. Table 1 showed that fewer viewers had seen an actress on television playing a computer technician than playing any one of the eight other professional roles considered in this study. Table 2

indicated that overall, women who are computer technicians are much less frequently viewed as attractive than women who are engineers or research scientists. Table 5 shows that of the 284 respondents, the majority (53.2%) disagreed with the statement that it is acceptable for a woman to be a computer technician. This is an impressive statistic when contrasted with the corresponding 4.6% for research scientist and 2.5% for engineer. If there is a need to create a more positive view of women technology professionals, computer technicians would appear to be among those in greatest need.

Consistent with theoretical expectations, overall differences in the attitudes of those who saw an actress portray a computer technician and those who did not are statistically significant. Corresponding differences also were found for women but not for men. Significant differences were found between the attitudes of men and

women, all of whom had seen a portrayal; and between men and women, all of whom had not seen a portrayal. These results indicate the existence of gender differences in attitudes toward computer technicians (and perhaps toward other STEM occupations as well) and in the apparent ability of media representations to influence perceptions of and attitudes toward women in certain STEM careers. If more women are to be attracted to STEM occupations, it would seem important to influence the perceptions and attitudes of men as well as those of women. It is primarily men who teach classes in STEM disciplines in high schools and colleges; make admission decisions to college and university science, engineering and technology programs; hire scientists, engineers and other technology professionals; and constitute the majority of colleagues with whom women work in these professions.

DISCUSSION AND CONCLUSION

Part of the solution to the shortage of trained scientists, engineers and computer professionals in advanced industrial societies is to attract more women to careers in these areas. One widely discussed strategy for accomplishing this goal is to make such careers more attractive through the use of the media, particularly television. While this proposal makes common sense, several questions have yet to be addressed. These are the concerns of this article. Are there sound reasons to believe that a media-centered approach will achieve some success? That is, what is the theoretical basis for the hypothesis that exposure to positive television images of women as technology professionals will attract more of them to STEM careers? What causal mechanism is involved? Understanding causal dynamics can inform actions taken to produce desired results. What will empirical data suggest about the tenability of the hypothesis? Can we move beyond common sense and anecdotal evidence in evaluating the hypothesis?

The works of social theorists Schutz, Berger and communication researcher Gerbner provide an explanation for our understanding, evaluation and reaction to the social world. Commonly encountered representations of actors, conditions and events in the “real world” come to be understood, correctly or not, as the nature of reality itself. Furthermore, this understanding of the “natural order of things” comes to be accepted as the proper or legitimate structure. Such an understanding provides a guide for social behavior. The theory suggests that if children seldom or never encounter, directly or indirectly through the media, girls in laboratory classes or solving difficult mathematics problems, they are likely to believe that such educational pursuits are naturally the purview of boys. Similarly, if adults seldom or never encounter, directly or indirectly through the media, women scientists, engineers or technicians, they are likely to believe that such careers are “naturally” careers for men.

The social construction of reality perspective and cultivation theory suggest a strategy for attracting more women to STEM careers: Use media to present the public continuously with images of women in a wide variety of technology-rich educational programs and occupations. The object is to cultivate the view of women scientists, engineers, mathematicians and technology professionals, and of young women preparing for those careers, as nothing exceptional. The goal is to construct the socially shared perspective that it is just as “natural” for a woman to be a STEM professional as it is for her to be a medical doctor or a lawyer.

Social constructionism and cultivation theory call attention to the importance of the frequency with which audiences encounter positive media images of women technology professionals. To reach large and diverse audiences, representations must appear in a wide range of television program formats, including soap operas, situation comedies, talk shows, dramas, commercials and arguably, most important of all, programs that

appeal to teenage girls. It is helpful to produce programs that feature strong, competent and otherwise attractive female characters in the role of technology professionals. However, for the most part, positive images of women in technology need not be glamorous. Primarily producing such images might actually discourage women whose self-assessments are not nearly so glamorous from pursuing STEM careers.

This pilot study investigated the tenability of one of two hypotheses derived from social theory and communication research. The first hypothesis states that those who have been exposed to positive media images of women technology professionals are more likely to believe that STEM careers are legitimate careers for women than those who have not been exposed to such images. The second hypothesis states that widespread belief that STEM careers are legitimate careers for women will actually move more women to those careers. Investigating this second hypothesis is beyond the scope of this pilot study.

As noted earlier, although data were drawn randomly from the entire population of the continental US, the sample was too small to be considered representative of the entire country. It certainly cannot be taken as representative of the views of those in other nations. Also, as previously noted, the necessary brevity and other characteristics of telephone surveys imposed further limitations. The cumulative effect of encountering numerous positive images over time, central to cultivation theory, could not be explored. However, while findings are tentative, they are suggestive. Among these are:

1. There may be vast differences in the frequency with which television audiences have encountered representations of women in different STEM occupations.
2. There may be vast differences in public perceptions of the relative attractiveness of various technology-rich occupations.
3. In each of the cases of research scientist, engineer and computer technician, men were more likely than women to agree that the profession is an acceptable career for a woman. This is encouraging since, as noted, those hiring women into these positions and serving as faculty in university courses are more likely to be men than women.
4. Exposure to positive images of women in technology may increase the likelihood that viewers will believe these are acceptable careers for women in the case of some STEM careers (e.g., computer technician) but not others (e.g., research scientist and engineer.)
5. Significantly fewer women than men believe that the computing category of STEM careers, represented by computer technician, is acceptable for women. It might be more profitable to invest more effort in creating positive media images of women in computer-focused careers.

Computer technician emerged from the pilot study as the career category deemed least acceptable to both men and women as being appropriate for a women. Fewer viewers surveyed had seen an actress on television playing a computer technician than playing any one of the eight other professional roles considered in this study. Women who are computer technicians were viewed as less attractive than women in other STEM careers.

Additional research, using a representative sample of the US, more rigorously defined concepts and more sensitive measures is needed to determine whether or not these findings of the pilot study — tentatively suggesting that the media strategy most likely to be effective is one targeting young women likely to be interested in becoming computer technicians — are, in fact, valid. Future research should also include respondents younger than age 18, because it can be useful to know the views of students preparing to select their future

professions. The impact of variables such as age, race and class would also be instructive.

Similar international data are needed to determine whether or not the findings would apply in other countries as well. The findings can be understood as suggesting patterns of beliefs, values and sources likely to be found in the country as a whole. If the findings hold, it would appear that the majority of both men and women find other STEM careers appropriate for women, suggesting that a media strategy would be less effective in raising those numbers, and that other explanations and strategies should be explored.

Chapter 7.22

Are Cross–Gender Conversations in Threaded Discussions Reminiscent of Communicating Across Cultural Boundaries?

ABSTRACT

At the core of sociolinguistic theory is the recognition that men and women when engaging in an open conversation communicate differently because of their different respective social objectives in communication. Oral conversations are, according to sociolinguists, akin to cross cultural conversations and hence the tendency toward same-gender conversations. Extrapolating to the realm of threaded discussions in online courses,

these gender differences, it is hypothesized, should translate into mild gender segregation in the threaded discussions as well as men showing a greater proclivity to dominate the discussion. Data from 233 students in 27 courses support these hypotheses and allow a significant identification of the gender of the student based on whom they reference in the threaded discussion and the way they reference others. Implications on managing threaded discussions are discussed.

INTRODUCTION

Conversation is more than an exchange of words and the meaning they convey. A central part of conversation is to carry a social message and the relating social segregation this creates. Unconsciously, both men and women insert into their conversations a rich social message. The trouble is that men and women communicate with very different social objectives. So different can these objectives be that men and women may totally misunderstand the underlying meaning an opposite gender member is making. Typically, men, more than women, communicate with an objective of establishing and maintaining their social status, while women, more than men, communicate to broadcast rapport. The result is often a cross-cultural misunderstanding (Tannen, 1994). Often a direct consequence of these differing social objectives and cross-cultural misunderstandings is gender-segregated discussions, both in underlying meaning and in who talks to whom. In gender-segregated discussions, men prefer to talk to other men and women prefer to talk to other women. This is the basic premise of sociolinguistics (Yates, 2001).

The applicability of this idea, originally conceived in the socially rich context of oral conversations, to the Internet with its more lean social context has received some verification in recent years (Gefen & Ridings, 2005). Virtual communities in which people freely interact online as though they were interacting face to face in a social club exhibit much of the same gender-related behavior predicted by sociolinguistics. Men join these communities to gather and share information, while women do so to give and share social support. Moreover, although many virtual communities are voluntarily mostly single-gender communities, when men seek social support in virtual communities, they go to mixed-gender communities, supporting the typically stereotyped tendency of women to center their communica-

tion on the social side of things. Likewise, when women seek information, they go to mixed-gender communities, supporting the typically stereotyped tendency of men to center their communication on information exchange (Gefen & Ridings, 2005). These cross-gender boundary preferences portray the characteristic gender behavior observed in oral communication (Hannah & Murachver, 1999). And, across cultures, business-related e-mail messages, although generally not there to serve a social purpose, are perceived differently by men than by women, with women significantly sensing more social presence in these e-mails and as a result perceiving them as a more useful medium in their work (Gefen & Straub, 1997).

But whether and how this applies to online class settings remain open questions. These are important questions to answer because threaded discussions are among the most valuable activities in online classes (Levy, 2006). On the face of it, in the controlled social environment of an online class, threaded discussion and the limited power play available in these settings should make these gender tendencies, especially the need for social dominance by men and the voluntary gender segregation, rather mute. On the other hand, if these are indeed ingrained gender-based characteristics, as opposed to being socially and context oriented, then these gender tendencies should come through even in these very lean social settings. Moreover, and relating to the second part of the research question, the very controlled online class environment, with its dictated rules of conduct, makes many of the typical gender-related behaviors inapplicable. Nonetheless, how these behaviors may come through is the other open-ended question. The objective of this study is to empirically examine this and, in doing so, to raise the need to consider these gender differences in threaded discussion in online courses.

These issues are important. Although online learning has gained considerable growth in recent years, there are many student dropouts making

student retention a major concern (Rovai, 2002). One facet of the online threaded discussions is to replace of face-to-face class discussions and enhance learning. The other facet is overcoming the “loneliness of the long-distance learner” (Eastmond, 1995). Online discussions are aimed at solving this problem and increasing retention (Guri-Rosenblit, 2005). Hence, it is crucial to conduct these discussions effectively by creating the appropriate social atmosphere to support the online learning process.

The data, which examines some prominent gender differences in communication style embedded in the online discussions, show that men and women do generally communicate differently, and there is some preference for same-gender communication within the shared class threaded discussion, even in the socially lean and rigid environment of online course discussions. While there was no support to the hypothesis that women would show more empathy than men would, there was support for the hypothesis that men would show more socially dominating behavior. These effects while weak in the entire data became strong when examining only students who took advantage of the online conversations to engage with other students.

The contributions of this study are twofold, practically and theoretically. Practically, the study highlights the different conversational behavior men and women have also in online courses, giving instructors some idea of what to expect, hence how to better manage online courses. Theoretically, the study introduces sociolinguistics to the hitherto unstudied context of conversations in online courses, with their relative lean and controlled social environment, showing that while the empathy of women may not have extended to this context, men’s tendency to control the conversation as a way of showing social standing does. The paper discusses the implications of these findings on online learning and suggests directions for further research.

THEORY AND HYPOTHESES

Gender Communication Style Differences

Although communication is about the exchange of information, there almost always is also a strong social aspect that permeates conversation and that carries meaning beyond the actual words spoken and the direct meaning they convey. The social meaning embedded in conversation and the way it is understood, according to sociolinguists, are both to a large extent gender dependent. Men and women may speak what on the surface may be the same language, but the underlying social message is often very different. So different, in fact, that some sociolinguistics claim that cross-gender conversations are almost bound to be misunderstood. For example, when a woman says she wants to buy something, there often is a social message of inclusion and rapport permeating this statement. This social message may actually be at the core of the message, being more important than the information conveyed itself. It is a message of come share this idea with me and talk to me about it. But, many men might understand this message either as a matter of informing them of this purchase intention or as requesting permission, although neither of which were initially intended. Tannen (1994) exasperatedly and famously caught this cross-gender misunderstanding it in her best-selling book with the telling title *You Just Don’t Understand*.

According to sociolinguistic theory, the basic gender difference in communication is that men communicate with the social objective of attaining and maintaining social status, while women communicate more to create rapport. Consequently, men try to control the conversation and are more critical of others, while women try to be inclusive and supportive (Kilbourne & Weeks, 1997; Mulac, Erlandson, Farrar, & Hallett, 1998; Tannen, 1994, 1995). This holds true across

cultures (Costa, Terracciano, & McCrae, 2001; Hofstede, 1980). These differences originally observed in oral conversations apply also to the Internet, to listservs (Herring, 1996b; Stewart, Shields, & Sen, 2001), to electronic commerce (Gefen, 2000), to the reason people join virtual communities (Gefen & Ridings, 2005), to their assessment of e-mail (Gefen & Straub, 1997), to why people use the Internet (Fallows, 2005), and to how they take computer training (Venkatesh & Morris, 2000). Supporting these conclusions, women, more than men, utilize email and the Internet to maintain social ties (Boneva, Kraut, & Frohlich, 2001; Parks & Floyd, 1995).

A second consequence of these gender differences is the preference, in some cases, to have same-gender conversations. Men generally prefer to talk to other men and women to other women. Considering the cross-cultural communication aspects of cross-gender communications, this is no surprise (Tannen, 1994). This preference can easily be seen in cocktail parties, but it also applies to virtual communities. This applicability to virtual communities is important because people can hide or masquerade their gender in these communities; nonetheless, some expected gender differences and the preference for same-gender conversations come through. Perhaps even more telling is that when people prefer cross-gender communications, it is in accordance with the stereotypical gender behavior. Men go to mixed communities because they want social support, a known female communication attribute, while women go to mixed communities when they want to concentrate on obtaining information, a known male communication attribute (Gefen & Ridings, 2005).

Online Course Discussions

These social segregations and misunderstandings in communication may seem rather amusing, and, indeed, Tannen's book (1994) was a best seller, but their repercussions are far reaching. Tannen

(1995) demonstrates how differences in conversational style may undermine women in the workplace by making them seem less competent and confident. A similar phenomenon was observed in classroom discussions (Tannen, 1991). These gender-related discourse differences also affect some aspects of the way people learn online. Notably men use online resources more often to obtain information, while women do so more often to communicate personal issues (Herring, 1993, 1996a; Yates, 2001). Unknown to them and with no bad intentions, students may bring these gender-related social messages into their class conversations, as people generally do into many of their conversations. The result of all this may be misunderstandings, which may impair the learning process. That is why it is imperative for online instructors to recognize these differences and realize their cross-gender differences.

One place where these misunderstandings may come about and have unintended consequences are in online courses. Online courses are courses taught through the Internet, where students download course materials online, send in their assignments electronically, and even take quizzes and exams online. An integral part of many of these online courses is the threaded discussion section. In the threaded discussion, the professor posts a question or topic for discussion, and the students are then expected, and are often graded on, to take part in an asynchronous discussion of this topic. As an integral part of this discussion, the students are expected not only to bring up their own ideas but also to discuss the ideas brought up in the postings of the other students. In the university where the data were collected, these conversations were weekly units with a new topic started once a week. These weekly topics would evolve during the week, much as a guided discussion in a face-to-face setting would, with new questions being posted to the students as older ones were discussed in full. Typically, there were around 20 students participating in each online class. Participation was graded.

HYPOTHESES

If these gender differences and segregation tendencies in communication, so highlighted in oral discourse (Crawford, 1995; Gray, 1992), are a matter of gender differences, rather than dependent on the type of media involved (Gefen & Straub, 1997), then some of these differences should also be evident in online courses. Specifically, in the case of the type of online course discussions that goes on in a threaded discussion, we would expect, extrapolating from sociolinguistics, to find that women will be more supportive of other threaded discussion participants, while men will be more critical. This is in accordance with women's reputed tendency to be inclusive and men's tendency to be controlling in conversation. Moreover, men do tend to try and control the conversation more than women do (Edelsky, 1993) and are more prone to try to create their superior social standing through the conversation (Tannen, 1994, 1995). Women, on the other hand, tend to encourage more participation by all involved and are less forceful toward other participants (Weatherall, 1998), encourage cooperation (Coates, 1986), and are more complementary (Coates, 1986; Yates, 2001). Moreover, men tend to be more aggressive and competitive in their speech (Kilbourne & Weeks, 1997) and to interrupt others more (Anderson & Leaper, 1998; West & Zimmerman, 1983; Zimmerman & West, 1975) in an attempt to be dominant in the conversation (Herring, 1993; Holmes, 1992).

Taken together, this should translate to women being more supportive of others in the conversation as a way of being inclusive, paying complements, and being encouraging, while men should be more critical of others as a way of showing their domination, higher social standing, and generally being more competitive, especially as this could downplay the importance of others (Tannen, 1994).

H1: Women will be more supportive of others in the threaded discussions.

H2: Men will be more critical of others in the threaded discussions.

In the context of these gender-related communication characteristics, the reputed same-gender congregation tendency should also be evident in threaded discussions. In oral conversations cross-gender conversations are akin to cross-cultural conversations, hence, there is a tendency toward same-gender conversations (Tannen, 1994). If this applies also to online courses, then this tendency should carry over also to threaded discussions. Practically, this means that there should be more references by men to previous postings by men and more references by women to previous postings by women. Indeed, in virtual communities there is such a preference with many communities being almost all men or all women (Gefen & Ridings, 2005).

H3: There will be more references to previous postings by same-gender students in the threaded discussion, than to posting by members of the other gender.

If these tendencies are as pronounced in threaded discussions as they are in oral discourse, then just as in oral discourse where conversation styles could be a predictor of the person's gender (Hannah & Murachver, 1999), styles should be a predictor of gender in a threaded discussion too.

H4: Student gender can be identified by the supportiveness and criticism in the posting.

RESEARCH METHODOLOGY

Examining threaded discussion postings in online courses, this study answers these two questions.

A large number of courses and their online discussion components were examined. The content of the threaded discussion in these courses was copied and then classified. In all, 1,335 postings in 27 courses by 233 individuals were classified. Each posting was initially classified based on whether it referred to previous postings by other students. If the posting did refer to a previous posting, then it was recorded as to whether the posting agreed or disagreed with the postings to which it referred and whether it related to the person who posted the referred to posting by name. The data were classified by two raters with a 100% agreement between them during the training period on the actual data.

DATA ANALYSIS

Hypotheses H1, H2 and H3 were examined with T tests. These are shown in Table 1, together with general statistics. There is no significant difference in the percent of supportive, agreeing, or disagreeing messages. Neither H1 nor H2 are supported, although men did post more and longer messages, possibly related to an attempt attributed to men in the literature to try and dominate the conversation (Edelsky, 1993).

A more detailed analysis of Table 1, however, shows a more complex picture. Men refer back more often to men and women more often to other women. In doing so, the women agree more with other women, and the men are more supportive of other men. This supports H3. Practically then, while the anticipated typical gender behaviors were not evident in the data, what was evident was a gender-oriented group boundary of the kind one typically comes across at a cocktail party. Women communicate more with other women and men more with other men. Interestingly, Gefen and Ridings (2005) came to much the same conclusion when analyzing voluntary participation in virtual communities.

Hypothesis 4 was examined by verifying whether the gender of the poster could be significantly classified based on the nature of the reference to previous posters. Based on these 1,335 postings the logistic regression did significantly ($\chi^2_8=8.951$, $p=.346$)¹, albeit weakly (Nagelkerke $R^2=3.8\%$) identify 56% of the students' gender correctly. This weak result is not surprising. Many students in online courses do not refer back to postings by other students, so identifying the gender of the student by typical gender communication style with others should be mostly weak. Nonetheless, the data did show some characteristic communication behavior, even in these data. Men were significantly identified by having longer postings ($\beta=.002$, $p<.001$) and referring to women by name significantly less than women did ($\beta=-.372$, $p=.002$). Trying to control the conversations by speaking longer is a typical male trait (Herring, 1993, 1996b), and men do tend to interrupt others (Anderson & Leaper, 1998; Coates, 1986). In this case, since the conversation is asynchronous, the equivalent of interruption is downplaying the contribution of others.

The data was then reanalyzed but only including those postings where students referred back to postings by others. Since this type of posting corresponds more readily to the equivalent of a discussion, rather than a monologue, we expected the results to be much stronger in this case, as indeed they were. Based on the 401 postings of students who did refer back to other students at least once in their posting, the results of the logistic regression did significantly ($\chi^2_8=9.043$, $p=.339$), albeit still rather weakly (Nagelkerke $R^2=7.4\%$) identify 58% of the respondents' gender correctly. Again, the data showed some characteristic communication behavior but in a more pronounced manner. Men significantly referred more to postings by other men by name ($\beta=.550$, $p<.001$) and agreed less often with them ($\beta=-.362$, $p=.032$). This tendency to prefer to communicate with same-gender others resembles findings about virtual

Cross-Gender Conversations in Threaded Discussions

Table 1. Group statistics

		All the data (1,335 postings)			Those who referred back to others at least twice (162 postings)		
		Mean	Std.	T-statistic	Mean	Std.	T-statistic

How many postings relate to postings by men by name	Women	0.31	0.65	-1.91	1.42	0.96	-3.74**
	Men	0.40	0.86		2.12	1.24	
How many postings relate to postings by women by name	Women	0.21	0.58	2.08*	1.02	1.11	1.78
	Men	0.15	0.47		0.73	0.94	
How many of these postings to men are supportive in tone	Women	0.08	0.31	-.198*	0.42	0.65	-2.33*
	Men	0.13	0.47		0.76	1.00	
How many of these postings to women are supportive in tone	Women	0.05	0.22	1.26	0.23	0.46	2.42*
	Men	0.03	0.21		0.08	0.33	
How many of these postings to men agree with others	Women	0.20	0.56	0.13	1.02	1.08	0.20
	Men	0.20	0.55		0.98	1.08	

Table 1. continued

How many of these postings to women agree with others	Women	0.13	0.40	1.97*	0.51	0.76	0.27
	Men	0.09	0.37		0.47	0.84	
How many of these postings disagree with men	Women	0.04	0.19	-1.32	0.21	0.41	-1.20
	Men	0.06	0.30		0.33	0.71	
How many of these postings disagree with women	Women	0.02	0.14	-0.99	0.11	0.31	-1.24
	Men	0.03	0.21		0.19	0.50	

communities where men and women tend mostly to congregate in same-gender communities (Gefen & Ridings, 2005), as in H3. This tendency of men to agree less with other men is also in agreement with theory about oral discourse, where men are supposed to be more motivated to compete with other men for social dominance (Tannen, 1994, 1995) and downplay the contribution of others in an attempt to bolster their own social standing (Kilbourne & Weeks, 1997).

This pattern is even stronger once the analysis was limited to only those who referred back to others at least twice. Here the results became much stronger. Limiting the analysis to these 162 postings, the logistic regression did significantly ($\chi^2_8=6.819, p=.556$) and rather strongly (Nagelkerke $R^2=25\%$) identify 66% of the respondents' gender correctly. As before, the data showed some characteristic communication behavior but in a more pronounced manner. Men significantly referred more to postings by other men by name ($\beta=.837, p<.001$) and agreed less often with them ($\beta=-.470, p=.022$). H4 was supported.

DISCUSSION

Summary of Results

Men and women also communicate differently in threaded discussions. Apparently, the dictated nature of the conversation in an online course does not support the typical gender behaviors, which are so evident in oral discourse and virtual communities. But, nonetheless, the conversational behavior of men and women is still sufficiently different, primarily in preferring same-gender references, that the gender of a student can be identified based on this behavior. Also, men tend to refer more to postings by other men and are more supportive of other men, while women refer more to postings by other women and are more supportive of other women. These tendencies are evident especially when the analysis focuses on those students who refer more to others. Although it would be an exaggeration to say there are two separate discussions going on, men-to-men and women-to-women, there are some signs of a slight tendency in this direction. This is interesting

because overall men and women are on average about as supportive, agreeing, and disagreeing with other students if the gender of the other student is not included in the analyses. In other words, even in the pedagogically controlled setting of online courses, there are gender effects.

Limitations

Online courses and the way they are taught are not cast in a mold. As courses generally do, online courses differ in the way they are taught and are influenced by the personality of the online instructors. Thus, the results and conclusions of this exploratory study with its convenience sample should be understood as such. The data raise the need to consider these interesting implications and warrant additional research. Whether the results can be generalized to other online course environments depends on additional research and many more samples.

Implications to Theory

The theoretical contribution of this study is in its initial validation of the need to consider the gender mix of classes, even when they are online, and by bringing in sociolinguistics theory, which explains this in online course threaded discussion settings. Much more research is needed to establish exactly how sociolinguistics applies to this setting, to better understand how the gender mix affects online classes, and exactly what online instructors and course designers need to do to make the online threaded discussion more successful. But this study does verify this need. Gender implications also apply in an online course environment.

The following discussion presents some questions that arise from our findings and suggests directions for further research. The first question is does the gender mix in an online class matter? More specifically, now that this study has shown that the gender mix does make a difference in

how students participate in online discussions, the question becomes how does this gender mix affect the quality of student learning and student satisfaction with online courses? This question then ties into the next crucial question: What impact does this have on student retention? Considering what the gender mix does in regular classroom settings (Felder, Felder, Mauney, Hamrin, & Dietz, 1995), it is quite possible that this gender mix effect might negatively affect students, therefore, it should be recognized at least. This study takes the first step in that direction by showing that there is such a gender effect and by suggesting a possible theory base which, in part, explains it.

The role of the course instructor in shaping the social atmosphere in online discussions and its influence on the conversational style of students is another important question that requires further research. As Salmon (2004, p.4) explains, students' experience is central to knowledge construction, and the electronic moderator (e-moderator) is essential in promoting constructive communication. She also encourages e-moderators to pay attention to cultural differences, regarding styles of address, hierarchy, and authority; attitudes towards gender, criticism; the proper ways of asking and answering questions; personal disclosure; and even the names that students use (Salmon, 2004, p.157-159). It is still an open question exactly how this can be done in an online course, but some ideas can be borrowed from other settings. As Tannen (1991) reports regarding nononline class settings, women respond differently to challenges during class discussions and are relatively silent, but they can be encouraged to participate with open-ended questions. Whether this applies to online discussions requires more research.

Implications to Practice

Men and women do communicate differently, therefore, in certain cases, they prefer gender-segregated communications (Tannen, 1994). The same applies with online virtual communities

(Gefen & Ridings, 2005). As this study shows, to some extent, this tendency also applies to online courses with threaded discussions. Being aware of this could help instructors facilitate better threaded discussions. While this preference by students to relate more to same gender students may not interfere with their or with others' learning experiences, it might spoil the online course social atmosphere, if a student feels relatively ignored or not supported enough by his or her cohorts. After all, communication is of paramount importance in learning.

Understanding this student proclivity to cluster in their threaded discussions in same-gender subgroups should be considered when managing these discussions, especially because one of the main advantages of online courses is in the way that they allow reticent students to actively participate in the course discussions. However, as this study findings show, even in the lean environment of threaded discussions, there are conversational-style gender differences that may imperil this advantage.

This actually is not so surprising, apparently, even the perceived gender of the computer itself, manifested by its sound being based on a male or a female narrator, is enough to elicit typical responses associated with this artificial gender manipulation (Nass, Moon, & Green, 1997). Likewise, associating a computer-generated message with a cartoon representation of a man or a woman elicited the same type of gender response. People are more inclined to accept the answer given by the computer when the gender of the computer-generated cartoon giving this answer matches gender stereotypes: people were more accepting of answers about sports when given by a male cartoon and more accepting of answers about fashion when given by a female cartoon (Lee, 2003).

Being aware of the student and his or her unique needs is a hallmark of good teaching. Although arguably this is much harder in an online course than in a regular classroom, nonetheless, at least

this gender aspect is something online instructors can and should consider. Controlling the online conversation and discreetly, but directly, focusing the positive discussion on a student who might otherwise have been relatively ignored because of these same gender preferences is one way of doing so. Creating smaller and mixed-gender teams is another method instructors in online courses can apply. Such a method directly utilizes one of the great advantages of online courses and may make the online environment more conducive to overcoming these same-gender preferences than other teaching environments.

CONCLUSION

Sociolinguists typify cross-gender communication as almost a cross-cultural experience. Our data do not quite support such a view but do show certain patterns of online communication in threaded discussion of which instructors should be aware. The expression birds of a feather flock together applies when it concerns the gender of online students. Students prefer to relate to other students of their own gender. Instructors should seek ways to use the flexibility and unique capabilities of online courses to better serve their students, recognizing these gender preferences.

Chapter 7.23

The Paleolithic Stone Age Effect?

Gender Differences Performing Specific Computer-Generated Spatial Tasks

Geoffrey S. Hubona

Georgia State University, USA

Gregory W. Shirah

National Aeronautics and Space Administration, USA

ABSTRACT

Most computer applications feature visual user interfaces that assume that all users have equivalent propensities to perceive, interpret, and understand the multidimensional spatial properties and relationships of the objects presented. However, the hunter-gatherer theory (Silverman & Eals, 1992) suggests that there are modern-day differences between the genders in spatial and cognitive abilities that stem from differentiated prehistoric sex roles. If true, there may be discrepancies in how males and females differentially utilize particular spatial visual cues and interface features. We report three experiments in which participants engage in visual spatial tasks using 2D and 3D virtual worlds: (1) matching object shapes; (2) positioning objects; and (3) resizing objects.

Female subjects under-perform male subjects in the matching and positioning experiments, but they outperform male subjects in the resizing experiment. Moreover, male subjects make more use of motion cues. Implications for the design of gender-effective user interfaces and virtual environments are considered.

INTRODUCTION

A perennial trend in the evolution of computer technology relates to the ever-increasing power of hardware and the resulting burgeoning possibilities to develop more complex software. These trends have enabled the proliferation of more specialized and powerful computer applications that support users in a wide variety of personal

The Paleolithic Stone Age Effect?

and professional tasks. Associated with these trends are multiple challenges: (1) to make the presentation of geometrically increasing amounts of data ever more concise; and (2) to condense, convey, and present larger and larger volumes of useful information using smaller and smaller spaces. To meet these challenges, new and creative approaches to the design of visual user interfaces have emerged, many that present complex, multidimensional data sets and relationships into condensed visual forms and spaces.

Unfortunately, an implicit assumption in the design of commonplace visual user interfaces is that preponderant portions of the existing user population have similar abilities to cognitively perceive, process, interpret, and ultimately understand the intended visual and spatial properties of the objects presented. Yet, it is known that certain measures of spatial cognition are correlated with performance in user interface tasks (Cockburn, 2004). As an example of how individual perceptual differences can affect user interface design, professional Web designers are aware of color blindness patterns¹ in the general population that affect the ability to correctly perceive color-encoded information. As a result, professional designers of high-traffic Internet Web sites avoid these color blindness traps in order to enhance the universal usability of the sites.

Clearly, the assumption of equivalent user capabilities runs the risk of impairing the usability of visual interfaces that ignore broad, existing population anomalies in spatial cognitive and task performance abilities. Through the process of evolutionary natural selection, the hunter-gatherer theory (Silverman & Eals, 1992) ties modern-day, gender-based differences in certain cognitive, spatial abilities back to sharply differentiated sex roles from prehistoric times. Also, it is recognized in behavioral research communities that there are innate differences between the male and female genders related to cognitive spatial abilities (Kimura, 2000; Linn & Petersen, 1985; Voyer, Voyer, & Bryden, 1995). These gender differences

may directly impact the ability to perceive, interpret, and cognitively process spatial properties and spatial relationships of multiple visual objects presented on a computer screen. Thus, there may be fundamental differences between the genders with respect to the ability to use certain visual user interface features, particularly when these features relate to the perception of depth and to the spatial relationships of objects and scenes presented at varying levels of intended depth.

In this article, we review theory and empirical studies relating to (1) gender and human computer interaction and (2) gender differences in innate spatial cognitive and task performance abilities. We then describe three experiments that examine gender-based performance differences in object matching, positioning, and size estimation tasks using two-dimensional (2D) and three-dimensional (3D) virtual worlds. The observed gender performance differences are discussed with respect to applicable theory and with respect to the design of gender-neutral user interfaces and virtual environments.

THEORY AND BACKGROUND

Gender and Human-Computer Interaction

Researchers long have acknowledged the relevance of gender as impacting human computer interaction. Gender has been noted as a broad issue affecting computer skills and computer design issues (Balka, 1996). Gender has been recognized as an important consideration for the design of user interfaces (Leventhal, Teasley, & Stone, 1994) and display techniques (Shneiderman, 1990) and as an issue relevant to achieving universal usability among diverse users of Web-based computer services (Shneiderman, 2000). Gender has been related to the process of decision making, to preferences for investment models, and consequently, as an important consideration

in the design of financial (Palma-dos-Reis & Zahedi, 1999) and organizational decision support systems (Powell & Johnson, 1995) for men and women. It has been shown that there are different perceptions and preferences between men and women with respect to the use and satisfaction with different features of electronic commerce Web sites (Simon, 2001).

Numerous researchers have noted differences between the genders while interacting with computers. For example, it has been shown that boys and girls think differently about computers (Hall & Cooper, 1991; Wilder, Mackie, & Cooper, 1985), and that boys and girls have different motivations for using computers (Inkpen et al., 1994; Upitis & Koch, 1996). Moreover, gender-specific preferences for computer interface features and usage styles also have been documented (Lockheed, 1985). Hinckley, Pausch, Proffitt, and Kassell (1998) reported that females were faster than males performing a two-handed, 3D neurosurgical visualization (manipulation) task, and it has been suggested that females outperform males at certain dexterity tasks (Halpern, 1986; Hinckley, Pausch, Proffitt, Patten, & Kassell, 1997).

However, some studies have found no gender differences while interacting with computers. For example, Inkpen (2001) found no boy-girl differences in children's interaction styles with point-and-click as compared to drag-and-drop interfaces. In addition, Rieman (1996) found no significant gender impact on the number of reported exploratory learning discoveries using new systems.

One area of HCI that has examined closely the gender performance differences is with respect to the exploration, use, and navigation of virtual reality (VR) and virtual environment (VE) applications. Investigating gestural input techniques for multimodal and virtual environment applications, Wexelblat (1995) reported that gender was not a reliable predictor of gesture frequency for subjects describing movie scenes. Basdogan, Ho, Srinivasan, and Slater (2000) found that female

subjects engaged in haptic communication in shared virtual environments (SVEs) reported higher levels of sense of togetherness in performing a collaborative task with an unseen partner than did male subjects. Kauppinen, Kivimaki, Era, and Robinson (1998) argued that gender differences in interacting with others in Collaborative Virtual Environments (CVEs) can be traced to broader, societal-driven, gender-specific, identity distinctions that are also witnessed in natural, non-computer-mediated interactions.

Waller, Hunt, and Knapp (1998) suggested that the transfer of spatial knowledge in virtual environment training is responsible for males outperforming females in computer-generated environments. Similarly, other studies have reported men outperforming women (Astur, Ortiz, & Sutherland, 1998) and making use of different cues than women (Sandstrom, Kaufman, & Huettel, 1998) in navigating virtual worlds. Tan, Robertson, and Czerwinski (2001) reported that men completed 3D virtual environment navigation tasks more quickly than women while using smaller, 15-inch displays, but that this male performance advantage disappeared when using larger, 39-inch displays. Subsequently, Czerwinski, Tan, and Robertson (2002) extended this work with two navigation studies. The first study replicated their findings that a wider field of view combined with a large display reduces gender performance biases. Their second study demonstrated that wider fields of view assist females' performances in navigating virtual worlds that are densely populated with objects.

Gender Differences in Spatial Abilities

Innate gender differences in mental spatial abilities generally are identified as the basis for gender disparities in performing spatial tasks (Kimura, 2000; Linn & Petersen, 1985; Voyer et al., 1995). Certain meta-analytic studies (Linn & Petersen, 1985; Voyer et al., 1995) do indicate a male ad-

vantage on particular cognitive spatial tests, but individual studies' results are inconsistent in this regard. Further, the different studies often use varying test instruments to measure spatial abilities. Linn and Petersen (1985) categorized the various instruments reported in the literature into three distinct groups: those that measure (1) spatial perception, (2) mental rotation, and (3) spatial visualization. Spatial perception is described as the ability to determine spatial relations despite distracting information. Mental rotation refers to the ability to rotate quickly and accurately two- or three-dimensional figures in imagination. Spatial visualization is the ability to manipulate complex spatial information when several stages are needed to produce the correct solution. These meta-analyses (Linn & Petersen, 1985; Voyer et al., 1995) conclude that men score higher than women on spatial perception and mental rotation cognitive tests, but that neither gender has higher scores on spatial visualization cognitive tests.

The hunter-gatherer theory of the origin of sex-specific spatial attributes (Silverman & Eals, 1992) is one prominent theory that offers an evolutionary perspective on gender differences in modern-day spatial abilities. This theory suggests that men and women have different present-day cognitive skill predispositions that relate to handling differentiated sex role aspects from prehistoric times. Prehistoric females, or gatherers, who could effectively forage for food, and who were successful at keeping track of relationships, activities, objects, locations, and landmarks near their habitats, were superior at acquiring resources for bearing and raising offspring. On the other hand, prehistoric males, or hunters, who could travel better in unfamiliar territory, estimate distance, and navigate with a bird's-eye view orientation, were, as a consequence, more successful at hunting, competing with other males, finding mates, and, thus, fathering offspring.

The hunter-gatherer theory suggests that these male-female cognitive predispositions persist today through the process of natural evolutionary

selection. As evidence supporting this theory, it has been shown that contemporary females outperform men on spatial tasks related to foraging-related activities, such as remembering the location of objects (e.g., landmarks) in their environment (Dabbs, Chang, Strong, & Milun, 1998). Moreover, it has been demonstrated that women outperform men at keeping track of objects and in finding objects that are lost (Eals & Silverman, 1994; Silverman & Eals, 1992). In addition, studies have shown that women remember the locations of previously viewed items better than men (McBurney, Gaulin, Devineni, & Adams, 1997), and that women outperform men remembering the locations of specific objects (James & Kimura, 1997). In contrast, men typically outperform women at spatial tasks manipulating objects in space (Collins & Kimura, 1997; Goldstein, Haldane, & Mitchell, 1990; Kimura, 1983; Kolb & Wishaw, 1990; Linn & Petersen, 1985; Lohman, 1986; Maccoby & Jacklin, 1974). Other studies have demonstrated that men have more adept mental rotation spatial abilities than women (Dabbs et al., 1998; Silverman, Choi, Mackewn, Fisher, Moro, & Olshansky, 2000), purportedly as an evolutionary artifact of the ability to pursue an animal through unfamiliar terrain and then expeditiously find their way home.

METHOD

Hypotheses and Experimental Tasks

We report three experiments performing spatial tasks using 2D and 3D virtual worlds: object matching, object-positioning, and object resizing. The object-matching experiment was designed largely to tap mental rotation abilities (Linn & Petersen, 1985). The object-positioning and resizing experiments were designed to tap spatial visualization abilities (Linn & Petersen, 1985). Commensurate with the spatial abilities literature, we expect men to outperform women

in the object-matching task, but there should be no male-female performance differences in the object-positioning/resizing tasks. Consequently, we propose the following two hypotheses:

- H1: Male subjects will outperform female subjects matching objects using a mental rotation paradigm.
- H2: Male and female subjects will exhibit equivalent performances positioning and resizing objects.

Object-Matching Experiment. The object-matching experiment was based on the mental rotation paradigm first developed by Shepard and Metzler (1971). Viewing successive pairs of object images presented from different angles, the task was to judge as accurately and as quickly as possible whether the two images represented identical or different objects. For example, Figure 1 shows a typical object-matching image pair. As quickly as the subject could judge whether the split-screen image pair represented the same or different objects, she or he clicked a corresponding same or different button on the interface, causing the next image pair trial to be presented. Exactly

one-half of the 208 randomly presented image pairs represented identical objects, and the other half showed non-identical objects in the pair.

One-half of all trials were viewed by the men and women subjects in stereo, using 3D Crystal-Eyes™ glasses. The remaining trials were viewed in 2D (monoscopically). The left object image in each trial was always stationary, while the right image was always capable of motion and, specifically, two kinds of motion: (1) in one-half of the trials, subjects could control the motion of the right object image by rotating it in any direction for 360 degrees around the center; and (2) in the remaining trials, the right object always rotated automatically in a fixed and random direction about the center point, rotating at a constant speed of approximately 18 degrees per second. The measured performance variables included error rate, the percentage of incorrect matching responses, and response time, measured in milliseconds.

Seventeen males and 14 female subjects volunteered to participate in the object-matching experiment. All subjects were employees or contractors of the Goddard Space Flight Center in Greenbelt, Maryland. Subjects with corrected vision wore

Figure 1. Object-matching image pair

The Paleolithic Stone Age Effect?

their eyeglasses underneath the stereoscopic viewing glasses. All subjects had professional occupations and included engineers, computer programmers, and computer scientists. The mean age of the subjects was 34.97 years with 4.48 mean years of education beyond high school, 17.03 mean years of computer experience, and 12.65 mean years of professional work experience.

Object-Positioning Experiment. The object-positioning task consisted of subjects viewing computer-generated virtual worlds containing three identically sized spherical objects suspended in 3D space (see Figures 2 and 3). As quickly and accurately as possible, subjects were asked to reposition a target object in order to complete a straight line vector configuration defined by three spheres positioned at equal distances from each other. For example, Figure 2 shows a typical initial scene presented at the beginning of a positioning trial. Subjects would fly the object to be repositioned within the virtual world using a (six-degrees-of-freedom) spaceball input device. When satisfied that they had correctly positioned the misplaced object, they pressed a button on the spaceball that recorded their performance data in an output file and caused the next world to appear

immediately. Figure 3 shows the correct (solution) placement of the spheres for the initial trial scene presented as Figure 2. Note that correctly performing the positioning task required subjects to locate the displaced object in three dimensions: x (left and right); y (up and down); and z (toward and away from the viewer). One hundred and forty-four unique worlds were presented to each subject in random order.

Thirty volunteer subjects, 14 female and 16 male, participated. All had professional occupations as computer programmers, analysts, and scientists at the Goddard Space Flight Center. The subjects' mean age was 35.03 years, with 5.53 mean years of education beyond high school, 17.07 mean years of computer experience, and 13.12 mean years of professional work experience.

One-half of all positioning trials was viewed stereoscopically using 3D CrystalEyes™ glasses, while the remaining trials were viewed in 2D (monoscopically) without wearing the glasses. Because subjects wore the glasses to view scenes in 3D, the stereo and mono trials were presented in cohesive blocks of 72 scenes each. The starting order for presenting the stereo and mono blocks was alternated between subjects.

Figure 2. Initial positioning scene trial

Figure 3. Completed positioning scene trial

The measured performance variables included distance error magnitude, response time, and rotational distance magnitude. Distance error magnitude was defined as the Euclidean summation of the three directional errors in the x, y, and z dimensions, or $((e^2x + e^2y + e^2z)^{1/2})$. Thus, this metric measured the exact absolute distance of the repositioned target object from its correct location in three-dimensional space. Response time again was measured in milliseconds. Also, subjects were able to voluntarily rotate the world left or right a total of 45 degrees from the center in either direction, using the left and right arrow keys on the keyboard. The total number of degrees in which the world was rotated in both the left and right directions was captured as a performance rotational distance metric. In addition to positioning distance accuracy and response latency, we were particularly interested in observing mean variances in rotational distance as a function of gender. We introduced the ability for the subjects to rotate the worlds for two predominant reasons: (1) to extract another dependent variable performance measure in addition to standard accuracy and response time measures; and (2) to provide an additional motion-related cue and to see if

the male and female subjects would use this cue differentially.

Object-Resizing Experiment. The object-resizing task consisted of subjects viewing virtual worlds containing two differently sized spherical objects suspended in 3D space and displaced at different depths from the viewer (see Figures 4 and 5). Unlike the positioning task, the resizing objects were fixed in position. The task was to adjust the size of a target object in order to correspond with the apparent size of a referent object. Figures 4 and 5 show a typical set of starting and correctly resized ending virtual worlds. One hundred forty-four unique worlds again were displayed in random order to each subject within alternating blocks, consisting of 72 2D (monoscopic) or 3D (stereoscopic) scenes. Each subject viewed the same 144 worlds (although in a random order); thus, the average target and referent ball sizes across all scenes were equivalent and, therefore, the same for all males and females.

The same 30 subjects from the object-positioning experiment participated in the object-resizing experiment. The measured performance variables included radius error percentage in addition to

Figure 4. Initial resizing scene trial

Figure 5. Completed resizing scene trial

The Paleolithic Stone Age Effect?

response time and rotational distance magnitude. Specifically, radius error percentage was defined as the absolute value of the difference between the correct (e.g., referent sphere) radius length and the final resized (e.g., target sphere) radius length divided by the radius length of the referent sphere, or $\frac{|(\text{correctRL} - \text{finalRL})|}{\text{correctRL}}$. An accuracy measure relative to the size of the referent object was used, because the referent objects randomly varied in size from large to very small. The response time and rotational distance performance metrics were identical to those used in the positioning experiment.

Assessing Gender Differences in Cognitive Spatial Abilities

Gender-based differences in subjects' mental (cognitive) spatial abilities were assessed using the factor-referenced cognitive tests (Ekstrom, French, Harman, & Dermen, 1976) developed by the Office of Naval Research (ONR) and licensed for research use through the Educational Testing Service (ETS). In all three experiments, subjects were administered the cube comparisons and paper-folding cognitive tests. The ETS cube comparisons test assesses mental rotation cognitive ability. In this timed test, subjects were presented with image pairs of wooden cubes, or blocks. Each cube had a different letter, number, or symbol on each of the six faces (i.e., top, bottom, four sides) of the cube. However, in each pair of cubes presented, only three (of the six) sides of the cube were visible. The task was to determine whether the pair represented identical (e.g., the same) or different cubes.

Unlike cube comparisons, which assess mental rotation ability, the ETS paper-folding test assesses spatial visualization ability. In the timed paper-folding test, subjects had to imagine correctly the folding and unfolding of pieces of paper with holes punched through them. According to ETS, cube comparisons require only the mental rotation of the cube configurations, whereas paper

folding requires both rotation and visualization, defined as performing serial operations on the configuration. Since both cube comparisons and object-matching task performances are based on the mental rotation process, as described by Shepard and Metzler (1971), cube comparison ability should correspond with object-matching task performances. Similarly, paper-folding skill should correspond to task performances in the object-positioning and resizing experiments, since all are based on spatial visualization ability.

Results

Cognitive Abilities Test Scores. Tables 1 and 2 reflect the mean scores of the male and female subjects by experiment on the cube comparisons and paper-folding cognitive abilities tests. According to Dr. Ruth Ekstrom (by personal correspondence), the appropriate approach to assess these test results is to consider separately for each test the total number of items answered correctly, the number answered incorrectly, and the number omitted, or unanswered. As indicated in Table 1 (and after checking for equal variances in the male-female scores populations²), t-test comparisons of male-female scores on each test indicated that for the object-matching subjects, female subjects answered incorrectly significantly more cube comparison items than males. However, there were no male-female differences in the number of cube comparison items answered correctly or in the number omitted. Moreover, for the paper-folding test, there were no significant male-female differences in the number of items answered correctly, answered incorrectly, or omitted. By answering significantly fewer cube comparison items incorrectly, there is at least some evidence that the male subjects in the object-matching experiment had an advantage over the females in innate mental rotation cognitive ability. However, the paper-folding test scores indicate no significant male-female differences in innate spatial visualization cognitive abilities.

Table 1. Mean cube comparisons and paper folding test scores by gender for subjects in the object-matching experiment

Object Matching Subjects	Cube Comparisons Test (Mental Rotation)		Paper Folding Test (Spatial Visualization)	
	Males	Females	Males	Females
Number of Test Items:				
Answered Correctly	26.65	26.00	13.29	13.57
Answered Incorrectly	3.47*	6.07*	2.71	2.57
Omitted (Unanswered)	11.29	9.93	4.00	3.93

* *Bolded test scores indicate significantly different (at $p < 0.05$) male-female scores.*

Table 2. Mean cube comparisons and paper-folding test scores by gender for subjects in the object-positioning and resizing experiments

Object Positioning/Resizing Subjects	Cube Comparisons Test (Mental Rotation)		Paper Folding Test (Spatial Visualization)	
	Males	Females	Males	Females
Number of Test Items:				
Answered Correctly	28.25*	21.43*	13.06	10.36
Answered Incorrectly	2.38*	5.79*	2.31	4.00
Omitted (Unanswered)	11.38	14.64	4.63	5.64

* *Bolded test scores indicate significantly different (at $p < 0.05$) male-female scores.*

As indicated in Table 2, t-test comparisons of male-female cube comparison test scores for subjects in the object-positioning and resizing experiments indicate that male subjects answered (1) significantly more items correctly than females and (2) significantly fewer items incorrectly than females. However, there were no significant male-female differences in the number of items omitted in the cube comparisons test. Moreover, there were no significant male-female differences in the number of paper-folding test items answered correctly, answered incorrectly, or omitted. Thus, in the object-positioning and resizing experiments, there again is evidence that males compared to females had superior innate mental rotation cognitive abilities. However, similar to

the cognitive test data for subjects in the object-matching experiment, there again is no evidence of significant male-female differences in innate spatial visualization cognitive abilities.

Object-Matching Experiment Results. The object-matching data were fitted to a repeated measures multivariate analysis of variance model (MANOVA). There were significant differences in both error rate ($p < 0.0001$) and response time ($p < 0.0001$) as a function of gender. Males were more accurate at judging whether the objects were identical or different (see Figures 6 and 7). The overall mean male error rate was 9.39%, whereas the overall mean female error rate was 13.05%. Furthermore, the male subjects were faster at

The Paleolithic Stone Age Effect?

Table 3. Mean object-matching error rates and response times by gender for the viewing and motion conditions*

Object Matching Conditions:	Error Rate (%)		Response Time (seconds)	
	Males	Females	Males	Females
Stereo Viewing	6.79	10.10	11.75	12.88
Mono Viewing	11.99	16.00	13.32	14.28
Controlled Motion	7.07	11.95	12.87	13.98
Uncontrolled Motion	11.71	14.15	12.20	13.18

* The minimum significant performance differences (at $p < 0.05$) between the genders for the object-matching task are (1) mean error rate: 1.51%; (2) mean response time: 0.43 seconds.

making these object comparisons (see Figures 8 and 9). Males exhibited an overall mean response time of 12.53 seconds, whereas females responded in an overall mean time of 13.58 seconds.

To further investigate the gender-based impact of the viewing and motion conditions on object-matching performances, the sample then was split by gender and tested for the effects of viewing

mode and type of motion on the object-matching error rates and response times for each gender. The data are presented in tabular form in Table 3. Figures 6, 7, 8, and 9 present these data using line graphs that indicate the minimum significant differences (at $p < 0.05$) between the genders for object-matching error rate and response time (noted in Table 3).

Figure 6. Object-matching error rate by gender by viewing mode

Figure 7. Object-matching error rate by gender by type of motion

Figure 8. Object-matching response time by gender by viewing mode

Figure 9. Object-matching response time by gender by type of motion

Both male and female subjects were more accurate and faster at matching objects when viewing the object pairs in stereo (see Figures 6 and 8). When the males controlled the motion of the right-hand object image, also called the comparison object (recall that the left image was always stationary), they were more accurate than when they did not control this motion (see Figure 7). For females, there was no significant difference in object-matching accuracy whether they controlled the motion of the comparison object or not (see Figure 7). However, both males and females took longer to judge whether the objects were identical or different when they were controlling this motion (see Figure 9).

Object-Positioning Experiment Results. The positioning data were also fitted to a MANOVA model. There were significant differences in distance error magnitude ($p < 0.0001$) and in

rotational distance magnitude ($p < 0.0001$) as a function of gender. The male subjects were more accurate in the positioning task (see Figure 10). The overall mean male distance error was 0.573 units, whereas the overall mean female distance error was 0.851 units. Furthermore, the male subjects rotated the positioning scenes to a greater extent than did the females (see Figure 12). The overall mean male rotational distance was 171.99 degrees, whereas the overall mean female rotational distance was 150.78 degrees. The difference in positioning response time as a function of gender was not significant ($p = 0.97$). Both males and females exhibited a mean positioning response time of 20.1 seconds (see Figure 11).

To further investigate the gender-based impact of the viewing conditions on object-positioning performances, the sample again was split by gender and tested for the effects of mono and stereo viewing on positioning accuracies, response

times, and rotational distances for each gender. The data are presented in tabular format in Table 4. Figures 10, 11, and 12 present these data using line graphs that indicate the minimum significant differences (at $p < 0.05$) between the genders for object-positioning radius error, response time,

and rotational distance (noted in Table 4). Both males and females were more accurate and faster at positioning objects in stereo (see Figures 10 and 11). Stereo viewing particularly improved the positioning response time for males more than for females (see Figure 11). Furthermore, both

Table 4. Mean object-positioning distance errors, response times, and rotational distances by gender* for the viewing conditions

Viewing Conditions:	Object Positioning Performance Measures					
	Distance Error (Euclidean distance)		Response Time (seconds)		Rotational Distance Magnitude (degrees)	
	Males	Females	Males	Females	Males	Females
Stereo Viewing	0.515	0.745	17.71	19.44	140.63	142.43
Mono Viewing	0.631	0.957	22.49	20.80	203.36	159.13

* The minimum significant performance differences (at $p < 0.05$) between the genders for the object-positioning task are (1) mean Euclidean distance error: 0.0377 units; (2) mean response time: 0.78 seconds; and (3) mean rotational distance: 9.62 degrees.

Figure 10. Object-positioning distance error by gender by viewing mode

The Paleolithic Stone Age Effect?

Figure 12. Object-positioning rotational distance by gender by viewing mode

males and females used less rotational distance positioning objects when viewing the objects in stereo, although males exhibited more of this effect than did the females (see Figure 12).

Object Resizing Experiment Results. In the resizing task, there were significant differ-

ences in radius error percentages ($p < 0.027$) and rotational distance magnitudes ($p < 0.006$) as a function of gender. The male subjects were less accurate resizing the objects than were the females (see Figure 13). The overall mean male radius error percentage was 15.14%, whereas the overall mean female radius error percentage was

Table 5. Mean object resizing radius error percentages, response times, and rotational distances by gender* for the viewing conditions

	Object Resizing Performance Measures					
	Radius Error (%)		Response Time (seconds)		Rotational Distance Magnitude (degrees)	
Viewing Conditions:	Males	Females	Males	Females	Males	Females
Stereo Viewing	14.61	13.53	9.87	10.05	100.05	98.46
Mono Viewing	15.66	14.57	11.49	11.90	125.32	112.39

* The minimum significant performance differences (at $p < 0.05$) between the genders for the object resizing task are (1) mean radius error percentage: 0.96%; (2) mean response time: 0.64 seconds; and (3) mean rotational distance: 5.20 degrees.

Figure 13. Object resizing radius error by gender by viewing mode

The Paleolithic Stone Age Effect?

Figure 14. Object resizing response time by gender by viewing mode

Figure 15. Object resizing rotational distance by gender by viewing mode

14.05%. However, the male subjects rotated the resizing scenes to a greater extent than did the females (see Figure 15). The overall mean male rotational distance was 112.68 degrees, whereas the overall mean female rotational distance was 105.43 degrees. Furthermore, males and females were equally fast at performing the resizing task (see Figure 14). The difference in resizing response time as a function of gender was not significant ($p = 0.37$). The mean male response time was 10.68 seconds, and the mean female response time was 10.98 seconds.

The resizing data sample also were split by gender and tested for the effects of mono and stereo viewing on resizing accuracies, response times, and rotational distances for each gender. The data are presented in tabular format in Table 5. Figures 13, 14, and 15 present these data using line graphs that indicate the minimum significant differences (at $p < 0.05$) between the genders for object resizing radius error, response time, and rotational distance (noted in Table 5). Viewing the worlds in stereo compared to mono had no significant effect on the mean resizing accuracy for either gender (see Figure 13), although it did reduce mean response times for both genders (see Figure 14). Similar to the results from the positioning task, both males and females rotated the scenes less while resizing objects viewed in stereo compared to mono viewing, although the males

reduced this stereo-viewed rotational distance more than the females (see Figure 15).

SUMMARY OF FINDINGS

Table 6 summarizes relative task performance differences by gender with each experiment. The spatial abilities literature indicates a robust male performance advantage in mental rotation tasks but no clear advantage for either gender in spatial visualization tasks. Indeed, the ETS factor-referenced cognitive tests administered to our subjects generally corroborate the existing literature. The male subjects answered significantly fewer cube comparisons (mental rotation) test items incorrectly than the females, but there were no differences in male-female paper folding (spatial visualization) test scores.

We hypothesized a male performance advantage in the (mental rotation) object-matching experiment (H1) but no advantage for either gender in the (spatial visualization) object-positioning and resizing experiments (H2). Consistent with the prediction of hypothesis H1, males did exhibit more accurate and faster performances than females in the object-matching experiment. As this task was based on a mental rotation paradigm (Shepard & Metzler, 1971) and coupled with spatial literature meta-analyses indicating male

Table 6. Summary of gender-based differences in accuracy, response time, and rotational distance performances for object matching, positioning, and resizing experiments

Experiment:	Accuracy/Gender:	RT/Gender:	Rot. Dist./Gender
Object Matching	Males more accurate	Males faster	Not Applicable*
Object Positioning	Males more accurate	No M/F difference	Males use more
Object Resizing	Females more accurate	No M/F difference	Males use more

* There was no formal rotational distance dependent variable performance measure in the object-matching experiment. However, when males controlled the motion of the comparison object, they were more accurate (unlike the females) in their object-matching performances.

The Paleolithic Stone Age Effect?

advantages in mental rotation tasks and cognitive tests, it is not surprising that the male subjects outperformed the female subjects in the accuracy and speed of matching objects. Moreover, controlling the motion of the right-hand comparison object image significantly improved (i.e., reduced) male object-matching error rates but had no effect on female error rates. Since controlling the motion facilitated the mental rotation task in general, and since males typically outperform females at mental rotation tasks (Dabbs et al., 1998; Silverman et al., 2000), this could explain why males made more effective use of this motion cue.

However, contrary to the prediction of hypothesis H2, in the object-positioning and resizing (spatial visualization) experiments, the relative gender performances were mixed; males were more accurate at positioning objects, whereas females were more accurate at resizing objects. Moreover, the male subjects made more use of the rotational distance feature in both the positioning and resizing tasks. Note that the rotational distance feature, by nature, is a type of motion cue. That is, by rotating the virtual world left or right, the viewer is able to adjust the locations and displacements of the objects in relation to the other objects and in relation to the viewer. The males evidently found this rotating feature to be more useful than females in attempting to position and resize objects in the virtual worlds.

To understand why males were more accurate at positioning objects and why females were more accurate at resizing objects, it is worthwhile to scrutinize the elements of each task. In this regard, object motion was a critical attribute for successfully positioning objects but not for resizing objects. Accurately positioning the target object in a straight line segment required flying the object around the visual space. This essential motion attribute may have contributed to a male performance advantage at positioning objects and is consistent with previous findings that men typically outperform women in tasks manipulating objects in space (Collins & Kimura, 1997;

Goldstein et al., 1990; Kimura, 1983; Kolb & Whishaw, 1990; Linn & Petersen, 1985; Lohman, 1986; Maccoby & Jacklin, 1974).

However, the females were more accurate than the males at resizing the target object to match the apparent size of the referent object. The females evidently had a better sense of the relative comparative sizes of the two objects that were displaced in distance but otherwise fixed in position. It has been demonstrated that females, compared to men, rely more on landmarks for way finding (McGuinness & Sparks, 1983; Miller & Santoni, 1986) and refer to landmarks when giving directions (Miller & Santoni, 1986). The literature also indicates that females outperform males in remembering the location of objects that are fixed in space (Dabbs et al., 1998; McBurney et al., 1997). Accurately resizing the target object required the cognitive calibration of the relative apparent sizes of two objects that were displaced in distance from the viewer but otherwise fixed in position. We speculate that the female resizing accuracy advantage could be related to a female propensity to recognize better the locations of landmark objects that are fixed in position (Eals & Silverman, 1994; Silverman & Eals, 1992).

CONCLUSION AND DISCUSSION

In general, the results of these experiments indicate the following:

1. Males outperform females at matching abstract, visual objects using mental rotation in computer-generated virtual worlds.
2. Males make more use of certain motion-related cues in performing visual tasks in computer-generated virtual worlds.
3. Males are more accurate at moving and positioning objects in computer-generated virtual worlds.
4. Females are more accurate at estimating the relative sizes of objects displaced in depth

but fixed in position in computer-generated virtual worlds.

How do these findings suggest approaches to developing gender-neutral visual interfaces? The ideal goal in this regard is to move toward the design of user interfaces that will improve usability for both genders and, particularly, to mitigate the postulated female handicap with mental rotation and motion cues. Simply adding a third dimension to an otherwise 2D display does not guarantee improved task performances (Cockburn & McKenzie, 2002). One suggestion is to add meaningful landmarks and to decrease user reliance on mental rotation ability. For example, visual interfaces that allow the stationary user to look right or look left (or up, down, backward, etc.) for familiar landmarks may prove to be an effective, gender-neutral alternative to the use of typical motion cues such as flying around virtual spaces. Our research suggests that the reliance on motion cues, in particular, to extract information can be especially problematic and can lead to a male performance advantage.

An evolving area of visual computing technology to which these findings are relevant is computer-generated virtual environments (VEs). The spatial structure of a VE and the objects that are visible sometimes are used to represent information. According to Vinson (1999), "a VE could contain objects whose spatial properties (e.g. shape, position, size) represent data values on different dimensions. Here, it is necessary for the navigator to quickly develop accurate representations of those spatial properties in order to understand the relationships in the data" (p. 279). These spatial properties (i.e., shape, position, and size) correspond with the three spatial task manipulations analyzed in our studies. To the extent that there are gender biases when cognitively processing and understanding these spatial properties, then these biases likely would extend to understanding the corresponding data relationships in VEs.

Although the tasks analyzed in our studies are not navigation tasks per se, the findings, nevertheless, have implications for the design of navigable VEs, since recognizing object shape and estimating the size and distance of objects are intrinsic activities of successful VE navigation (Vinson, 1999). Navigation is a process of tracking one's position in an environment in order to arrive at a desired destination. Doing so requires knowledge about positional, velocity, and acceleration attributes, which are derived from location, depth, and motion cues (Cutmore et al., 2000). Location information comes from landmarks and other fixed, distant features in the environment. The ability to recognize object shapes and to estimate their relative distances (or positions) is necessary in order to acquire basic location information that is a foundation of successful navigation. Moreover, correctly estimating the relative size of a landmark directly relates to understanding its distance and also promotes successful navigation.

Previous studies have indicated male performance advantages when navigating virtual worlds (Astur et al., 1998; Sandstrom et al., 1998; Waller et al., 1998). However, other researchers have noted that the apparent male navigation superiority is mitigated when the virtual worlds are presented to users with wider fields of view and larger display screens (Czerwinski et al., 2002; Tan et al., 2001). Indeed, both genders benefit under these conditions. Tan, Gergle, Scupelli, and Pausch (2003) reported that using larger displays improved both male and female performances in a static, 2D, mental rotation task³, but there was no corresponding performance benefit in a reading comprehension task. Subsequently, Tan, Gergle, Scupelli, and Pausch (2004) also demonstrated that users are more effective when performing 3D virtual navigation tasks on larger displays. They noted that when navigating, users continually update their mental sense of position and orientation within the environment (termed spatial updating) using two basic strategies: (1) piloting, or using external landmarks to position

themselves within the environment; and (2) path integration, or sensing self-velocity and acceleration to determine their position relative to some starting point. There is evidence that women rely more heavily on the piloting strategy (Czerwinski et al., 2002; Golledge, 1999).

Cockburn (2004) suggested that human spatial capabilities could be leveraged while interacting with computer-generated 3D scenes if the scenes were presented in ways “that better reflect the way we perceive our natural environment” (p. 25). We submit that user interface technology will best support all users to effectively navigate virtual worlds when those worlds are presented to user groups in ways that most closely mirror how users typically and best navigate in natural environments. Flying around over terrain that is visually presented on a limited 2D display screen is not a natural approach for ordinary human navigation. Extending the wider field of view and wider display arguments of Czerwinski et al. (2002), we suggest that the total immersion of users navigating a pedestrian and, apparently, terrestrial virtual world can better support individual human navigation in those worlds. Spatial navigation is improved with an increased sense of presence, or being in the virtual environment, which is a direct outcome of immersion (Tan et al., 2003). For women, these worlds perhaps would be designed best using highly visible and easily recognizable landmarks⁴ that are stationary in position and visible within a 360° field of view. That is, women users should be able to look around the virtual landscapes in all directions. Furthermore, the mode of navigating, or movement, should be along the surface of the virtual landscape, especially with alignment and orientation to and from those salient landmarks. For men, cues that further suggest Euclidean distance and direction also should be helpful. Virtual worlds that support both genders’ existing propensities to navigate would be most effective for the majority of users.

Limitations

The results of this study should not be interpreted as suggesting that either gender is superior in terms of spatial abilities. Rather, the study suggests (and the reported findings confirm) that there are differences in relative male and female performances on particular spatial processing tasks. Some of these differences are explored in this study. Many others are well-documented in the gender-specific mental abilities literature. In point of fact, both males and females have performance advantages in particular cognitive tasks.

The domain of this study is limited. It focuses on the gender-effective use of abstract visualizations and visual tasks that may relate to particular attributes of visual user interfaces. For example, visual user interface domains that involve the mental rotation of objects or the user-controlled motion, orientation, or resizing of objects, particularly in scenes representing three-dimensional space, are germane. However, domains relating to typical two-dimensional point-and-click activities or to the user interpretation of textual information are not addressed in this study.

In terms of methodology, a limitation of this study is that there was a separate set of subjects in the mental rotation experiment compared to the positioning and resizing experiments. As a result, there was a combination of within- and between-subject comparisons pertinent to the findings and related discussions. However, because these experiments were conducted over a period of time, the attrition of some subjects was unavoidable.

Further, in generalizing these findings, we note that these subjects likely have heightened spatial abilities relative to the general population. They were all working professionals in a premier scientific governmental organization, many holding advanced degrees. Therefore, whether these findings generalize to the population at large is debatable. However, one could argue that any

performance effects fostered by the spatial cues would be more pronounced within this group than within the general population. That is to say, if there were no observable effects with these select subjects, then there likely would be no effect within the general population.

Finally, we mention one additional limitation. Egocentric motion tasks, for example, physically walking through a 3D environment, and finding one's way along a route and/or to and from landmarks have additional perceptual dimensions than do the tasks in our study. However, some elements of egocentric way-finding are embedded in our tasks, such as recognizing the relative shapes, orientations, distances, and sizes of objects in the visual field. Additionally, we did incorporate aspects of egocentric motion skills by enabling the rotation of objects and the rotation of the scenes left and right. However, these tasks do not capture completely all of the perceptual cues and sensory elements inherent in egocentric motion tasks.

Considerations for Future Research

There are large segments of the general population that are characterized by differing opportunities, propensities, and abilities to access and make effective use of computer technologies. For example, the very young, the elderly, and the handicapped all have particular impediments to using computer technologies that most people take for granted. As computer applications become increasingly prevalent in everyday life, it is a worthwhile goal to try to mitigate intrinsic barriers and to equalize access and opportunities in order to make effective use of computer technologies.

In terms of gender differences in using visual interfaces, this research is an attempt to identify and highlight broad categories of disparities in male-female abilities to interpret and to manipulate visual abstractions. The intent is to work toward the development of gender-neutral guidelines for effective visual user interfaces and virtual

environments. Future research should explore the relative efficacies of different approaches of augmenting computer-generated visualizations so as to promote equal understanding and effective interfaces for different user groups. To this end, investigating approaches that do not rely strictly on abstract visualizations to convey information is warranted. Although it has been demonstrated that visual abstractions effectively can condense and convey large volumes of tabular, multi-dimensional (2D and 3D) data, the combination of visual with, in some cases, textual as well as multi-modal approaches likely will lead to more effective user interfaces across a larger number of user groups. Furthermore, investigating the design of virtual worlds that most closely mimic how men and women navigate real worlds likely would benefit the largest share of all users.

Section 8

Emerging Trends in Information Communication Technologies

This section highlights research potential within the field of ICT while exploring uncharted areas of study for the advancement of the discipline. Introducing this section are chapters that set the stage for future research directions and topical suggestions for continued debate. Discussions exploring RFID, virtual religion in the 21st century, and new ICTs for conflict management provide insight into forthcoming issues in ICT study. Authors within this section look past the digital divide to a time when ICT is ubiquitous and divisions no longer exist. These contributions, which conclude this exhaustive, multi-volume set provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Chapter 8.1

Bringing the Next Billion Online: Cooperative Strategies to Create Internet Demand in Emerging Markets

Karen Coppock
Stanford University, USA

ABSTRACT

This chapter classifies the types of partnerships employed to increase Internet demand in emerging markets. This classification system, or taxonomy, is based on more than 60 in-depth interviews, about 32 partnerships, designed to create Internet demand in Mexico. The taxonomy first classifies the partnerships into three broad categories based on the number of barriers to Internet usage the partnership was designed to overcome: one, two, or three. The partnerships are then classified into six subcategories based on the specific barrier or combination of barriers to Internet usage the partnership sought to overcome. The six subcategories of the taxonomy are: (1) lack of funds; (2) lack of awareness; (3) lack of uses; (4) lack of funds and lack of uses; (5) lack of funds and lack of infrastructure; and (6) lack of funds, lack of uses, and lack of infrastructure. This taxonomy gives empirical meaning and enables further analysis of this unique and increasingly popular type of partnership.

INTRODUCTION

... it may sound altruistic and it may sound philanthropic, but let me tell you, it is very concrete ... if we do not invest, if we do not take the time ... we will never close the digital divide ... and we will never grow these markets ... and we can never do it alone ... not the government alone, not universities alone, not even businesses alone, we absolutely have to do it together. (Omar Villarreal, President, Latin America and the Caribbean, Motorola)¹

The focal point of the Internet is rapidly shifting toward emerging markets. The sale of personal computers (PCs) and Internet access is stabilizing in industrialized countries and profit margins are eroding (International Telecommunications Union [ITU], 2001; Smith, 2001). Market research firms predict that the growth rates of information and communications technologies (ICTs) such as the Internet will not return to their previous levels in industrialized markets, but that future revenue

opportunities lie in the developing world countries of China, India, Russia, Brazil, and Mexico (De Marcillac, 2003). The sheer size of the population of these five economies, coupled with their low Internet usage rates, make them extremely attractive markets for multinational corporations. The Internet is also seen as a powerful tool for socioeconomic development and therefore, governments, nongovernmental organizations (NGOs), and universities are also intent on increasing their usage in these emerging markets.

The opportunity is clear, yet elusive. In 2001, from 33-50% of the population of industrialized economies had Internet access, whereas a scant 1% or less of emerging market citizens were online (ITU, 2002). Billions of people, therefore, have never surfed the Web nor used e-mail. The reasons for the discrepancy in Internet proliferation have been widely studied. On the demand side, education and skill levels, Internet access costs, per capital gross domestic product, and a lack of access facilities (telephone lines) are all statistically significant determinants of Internet usage rates in emerging markets (Cukor & McKnight, 2001; Kiiski & Pohjola, 2002). On the supply side, the absence of an independent regulator and credible regulatory frameworks lead to under investment in ICT infrastructure, which hinders Internet access rates (Gutierrez & Berg, 2000).

A wide range of initiatives sponsored by a diverse set of organizations have been launched to increase Internet usage in emerging markets. The Digital Dividends Project Clearinghouse (<http://wriwsl.digitaldividend.org/wri/app/index.jsp>) created by the World Resources Institute lists nearly 1,000 initiatives designed to increase Internet usage. At least one half of these initiatives are being implemented through the cooperative effort of two or more organizations. These include both “traditional” partnerships, or those between two or more private sector firms, and cross sector partnerships, or those between firms (private sector) and organizations from the public (government) and/or nonprofit sectors (including universities).

The purpose of this chapter is to classify the types of partnerships being used to increase Internet demand in emerging markets. A classification system, or taxonomy, will enable further analysis of this unique type of partnership and is the first step in any new line of social science research.

The chapter is organized as follows. First, I define the concept of market creation and outline the discrepancy between the practice and theory of market creation partnerships. Secondly, I present and explain the Internet market creation partnership taxonomy and provide definitions for each of its six categories. In the third, fourth, and fifth sections of this chapter, each of the three main categories of the taxonomy are explained in detail and examples are provided for each of the partnership configurations. The sixth section provides a high level overview of the methodology used to develop the taxonomy. The chapter ends with a brief conclusion.

MARKET CREATION PARTNERSHIPS

This chapter focuses on partnerships formed to create new markets, not simply access existing markets. A partnership in this chapter is defined as two or more organizations (i.e., firms, government agencies, NGOs, and universities) that agree (implicit or explicit contract) to share risk, responsibility, resources, competencies, and benefits to achieve a specific objective—in this case, to increase Internet usage rates in Mexico (Nelson 2002).²

According to Kotler and Armstrong (2001), one way a firm can expand the size of its market is to develop new users: either by extending into new geographic segments (market access) or by converting nonusers of a good or service into users (market creation). Market access, therefore, refers to market-share expansion, or increasing a firm’s proportion of the total sales of a particular good or service on a global level. Conversely, market

creation, or converting nonusers to users, is defined as increasing the total sales of a particular good or service on a global level. Because the vast majority of emerging-market citizens do not currently use the Internet or Internet-related goods and services, the focus of this chapter is on market creation partnerships or those designed to convert Internet nonusers into users.

There is a discrepancy, however, between the practice and theory of market creation partnerships. In practice, firms are drawing upon a wide range of entities—firms, universities, government organizations, and nonprofit organizations—for their market creation partnerships. Scholars such as Kanter (1998) and Prahalad and Hart (2002) all agree that market creation efforts in emerging markets require partnerships of diverse configurations. In theory, however, the conceptual foundations for partnership are largely separated into two categories: traditional (between two or more private sector firms) and cross-sector (between public, private, and nonprofit organizations) partnerships (Gray, 2000; Huxham & Vangen, 2001). Not only is this scholarship compartmentalized, but Nelson (2002) also contends that there is a bias toward the study of traditional interfirm partnerships.

This research project contributes to academic theory by simultaneously analyzing both traditional and cross-sector partnerships. Specifically, the focus is on partnerships with a market creation objective. As a first step in this new line of inquiry, this chapter will classify the partnerships to give them empirical meaning.

INTERNET MARKET CREATION PARTNERSHIP TAXONOMY

Classification is arguably one of the most central and generic of all of our conceptual exercises ... Without classification, there could be no advanced conceptualization, reasoning, language,

data analysis or, for that matter, social science research. (Bailey, 1994, p. 1)

High-tech firms are partnering with a wide array of organizations to overcome the barriers to Internet usage in Mexico and stimulate its demand. These strategies can be categorized according to the barrier(s) to Internet usage they were designed to overcome. This classification system, or taxonomy, is based on a total of 32 Internet market creation partnerships in Mexico. The Internet market creation partnership taxonomy (taxonomy) is shown in Table 1.

The taxonomy classifies the market creation partnerships into three broad categories and six subcategories. The three broad categories are the number of barriers to Internet usage, in Mexico, the partnership was designed to overcome. The majority of partnerships in this study set out to tackle a single barrier to Internet usage. Slightly less than one third of the partners set out to simultaneously tackle two barriers to Internet usage. Very few partnerships set out to simultaneously tackle three barriers to Internet usage. None of the partnerships included in this study simultaneously tackled all four barriers to Internet usage. This is because two of the barriers (lack of awareness and lack of uses) are mutually exclusive.

The six subcategories of the taxonomy are the specific barrier, or combination of barriers, to Internet usage the partnership set out to overcome. These are as follows:

Single Barrier Partnerships

- Lack of funds: The potential user does not have the economic resources to afford Internet access or to acquire the technology or services required to facilitate this access.
- Lack of awareness: The potential user is unaware of the value of the technology.
- Lack of uses: The technology is not “accessible” to the potential user or does not have value for the potential user due to its current

Table 1. Internet market creation partnership taxonomy

INTERNET MARKET CREATION PARTNERSHIP TAXONOMY						
Number of Barriers Tackled by the Partners	SINGLE BARRIER			DUAL BARRIER		TRIPLE BARRIER
Type of Barrier(s) to Internet Usage Tackled by the Partners	Lack of Funds	Lack of Awareness	Lack of Uses	Lack of Funds + Lack of Infrastructure	Lack of Funds + Lack of Uses	Lack of Funds + Lack of Uses + Lack of Infrastructure

form or the user’s profile (education rates, etc.) (Gándara, 2003).³

have value for the potential user due to its current form or the user’s profile (education rates, etc.)

Dual Barrier Partnerships

- Lack of funds + lack of infrastructure: The potential user does not have the economic resources to afford Internet access or to acquire the technology or services required to facilitate this access; and the potential user does not have a telephone line to use to access the Internet.
- Lack of funds + Lack of uses: The potential user does not have the economic resources to afford Internet access or to acquire the technology or services required to facilitate this access; and the technology is not “accessible” to the potential user or does not

Triple Barrier Partnerships

- Lack of funds + lack of infrastructure + lack of uses: The potential user does not have the economic resources to afford Internet access or to acquire the technology or services required to facilitate this access; the potential user does not have a telephone line to use to access the Internet; and the technology is not “accessible” to the potential user or does not have value for the potential user due to its current form or the user’s profile (education rates, etc.)

The underlying assumption behind the lack of awareness, lack of funds, and lack of infrastructure barriers to Internet usage is that the technology, in its current form, does offer value, but the potential user is simply unaware of this value (lack of awareness) or unable to tap into this value due to economic (lack of funds) or telephone line (lack of infrastructure) constraints. The lack of infrastructure barrier always went hand-in-hand with the lack of funds barrier in the partnerships cited by the high-tech firms in the sample.

Examples of single-, dual-, and triple-barrier partnership strategies are presented in the next three sections of this chapter. This serves to clarify and further describe the taxonomy and categories.

SINGLE BARRIER PARTNERSHIPS

Approximately two thirds of the 32 partnerships analyzed to develop the taxonomy fall within one of the three single barrier categories of the taxonomy: lack of funds, lack of uses, and lack of awareness. More than half of the single barrier partnerships were between two or more firms, often high-tech multinational firms. The other half of the partnerships consisted of a diverse array of partner configurations (i.e., a private sector firm and a government agency; a private sector firm and a university; and a private sector firm and a nonprofit organization). In the balance of this section, each of the single barrier category types is explained and an actual example of a partnership in this subcategory is provided.

Lack of Awareness

After the double-digit growth of the ICT industry in the late 1990s, spending on ICT-related goods and services plummeted after the turn of the century. The dot com bubble burst, coupled with the overall downturn in the global economy, led ICT investment proposals to be scrutinized as never

before. This is particularly true of small- and medium-sized enterprises (SMEs), an extremely large and important market segment in Mexico, and late adopter of Internet-related technologies. Most high-tech executives interviewed for this study believe that the Internet has intrinsic value for both SMEs and larger organizations and many have formed partnerships to build the business case or educate the market on the value of this technology. These partnerships tended to be, but were not exclusively, between two high-tech firms.

Example: Making the Business Case

Partnership: Cisco Systems and the Mexican Ministry of Health

Cisco Systems (Cisco), a \$19 billion dollar company, is the “worldwide leader in networking for the Internet” (Cisco, n.d.). Until recently Cisco was the darling of the new economy. Within 10 years of its creation, Cisco had experienced growth rates of up to 50% and at one point had one of the highest market capitalizations in the world. After the turn of the century and with the burst of the dot com bubble, however, Cisco’s stock plummeted and for the first time ever it announced layoffs.

Cisco’s lackluster performance after the turn of the century, coupled with an overall downturn in the global economy, forced the firm to revisit its sales strategies. In this more austere environment, technology investment proposals were being scrutinized as never before and traditional financial measurements, such as return on investment, were now required to justify these purchases. Cisco equipment would no longer sell by itself, the firm now needed to proactively create new markets for its products.

Cisco relied heavily on the Internet to facilitate the exponential growth it experienced in the 1990s and has incorporated this technology into all facets of its business operations. Cisco has

been meticulous in documenting the cost and productivity advantages that resulted from its internal use of Internet technology. Cisco created the Internet Business Solutions Group (IBSG) to share these Internet “best practices” with its key customers.

IBSG provides pro bono consulting services to Cisco’s most strategic customers. These services revolve around demonstrating the business case for using Internet technology to solve tangible business problems. Cisco’s objective is to help potential customers justify Internet-related investments. Each solution generally involves products and services from multiple providers, including Cisco. Partnerships, therefore, are a large part of the equation and Cisco has a stable set of solid technology partners it knows it can depend on for high quality, integrated solutions.

In Mexico, the IBSG group proactively approached the leaders of e-Mexico, the national connectivity program, and offered them its trusted advisor services. E-Mexico is the Mexican government’s strategy to exploit the power of the Internet technology for the delivery of health, education, commercial, and government services across the country. Specifically, Cisco has worked with the Ministry of Health on a medical training project. As in most emerging markets, the public sector is a major technology consumer and therefore a key target for Cisco. By forming strong relations with the e-Mexico team, Cisco hoped to improve its overall positioning within Mexico’s federal government.

In a tribute to Cisco’s Mexican IBSG team, a representative from the e-Mexico Committee of the U.S. Chamber of Commerce commented that the Ministry of Health’s e-Mexico plan is one of the most realistic and feasible of all of the e-Mexico projects. The quality of the actual plan, however, is not Cisco’s primary objective. By becoming a trusted advisor to, and partner of, the Mexican government and providing them with Internet-

based solutions to concrete business problems, Cisco is attempting to expand the overall market for its Internet equipment.

Example: Educating the Market

Partnership: Alestra and Cisco’s Public Forum for Technological Diffusion

Alestra, which markets its services under the AT&T brand name, is a telecommunications provider and the fourth largest Internet service provider (ISP) in Mexico.⁴ Since competition was introduced into the Mexican marketplace in 1996, prices for Alestra’s core offering—long distance telephone service—decreased by over 60% (Alestra, 2002). Alestra believes that the Internet and data services are key to its survival, but fears that the low number of high-usage Internet customers in the country could hinder its success (Alestra, 2002).

Almost 80% of all of Mexican corporations have less than 15 employees (Osterroth, 2004). These firms are leading the growth of the Mexican economy and are expected to contribute to more than half of the new jobs created in 2004 (“SMEs generate 70% of new jobs”, 2004). Alestra’s Internet business development director noticed that SMEs were not aware of the capabilities or value of Internet technology. In late 2001 he decided to work on educating this market segment on the value of Internet technology in order to generate new demand in this fast growing and underserved market.

Alestra invited Cisco to partner with it on its SME education initiative. Alestra’s parent company, AT&T, has a close relationship with Cisco in the United States and Alestra itself uses Cisco equipment exclusively for its Internet network in Mexico. The relationship was mutually beneficial because as Alestra sells more Internet services, it will need additional networking equipment. Suc-

Bringing the Next Billion Online

cess in this initiative, therefore, would translate into increased demand for both firms. Furthermore, by partnering, the two firms would become solutions providers and not stand-alone hardware or communications service vendors.

The solution was the Public Forum for Technological Diffusion for SMEs. Alestra and Cisco sporadically hosted these sessions in the six principal cities in Mexico. The objective was to educate SMEs on the value of Internet technology, not sell products. No price lists or sales-oriented literature was shown. In the forum events, Alestra and Cisco presented economical alternatives for exploiting the Internet for business gain, and SMEs gave testimonials on their successes in implementing this powerful business tool.

Although these forum events are not sales seminars, Alestra measures success based on the number of leads generated at each session and how many of these led to new sales of virtual private networks. Based on these two indicators, the forum has had very good results. The relationship between the two firms is also very solid.

Lack of Funds

According to World Bank (2004) statistics, Mexico's per capita income was \$6,230 in 2003. The vast majority of potential Internet users in Mexico, therefore, do not have the economic resources to afford Internet access or to acquire the technology or services required to facilitate this access. High-tech firms have partnered amongst themselves to decrease the costs of Internet access to create new demand for this service. These partners have employed three main tactics: (1) decrease upfront costs (bundle and finance model), (2) decrease recurring costs (prepaid model), and (3) increase operational efficiency (efficiency model). One firm took an alternative approach and focused on increasing income levels rather than decreasing costs.

Example: Decreasing Upfront Costs (Bundle and Finance Model)

Partnership: Teléfonos de México's Prodigy Internet Plus

Teléfonos de México (Telmex) is the leading communications provider in Mexico and a part of the Carso Group, the largest conglomerate in Latin America ("Latin Trade 100", 2002; Telmex, 2002). Carlos Slim, Chairman of the Carso Group, believes because of the commoditization of long distance telecommunications services, Telmex's primary source of revenues, "we have to move into other areas...the key is the Internet" (Business-Week Online, 2001). Telmex launched Mexico's first commercial Internet access service, Direct Personal Internet (DPI), in 1997 and although the number of DPI subscribers increased 400% in a single year, this still represented less than 2% of Telmex's customer base (Telmex, 2000). Telmex estimated that it should easily have five times that number of subscribers and set out to accelerate Internet usage in Mexico.

Telmex's Vice President, Internet Platform realized that "to sell the Internet and use the Internet you need a device," or PC. This was an obstacle to Internet growth in Mexico as there were less than 4 million PCs in the entire country in 1998 (ITU, 2000). Many of Telmex's customers could not afford the upfront expense of a PC and consumer credit was severely limited due to the significant defaults associated with the 1994 Peso crisis. Telmex decided to "lower the barriers to entry" by bundling a PC with its Internet service and finance this bundle over a several year period. This is a model telecommunications carriers have used with their commercial customers for years: personal branch exchange (PBX) equipment was bundled with telecommunications services and the telecom company charged the corporate customer a fixed monthly fee. Telmex simply extended

this model to the consumer mass market and the Internet arena.

In mid-1999, Telmex introduced Prodigy Internet Plus (PIP) in Mexico. Telmex partnered with a wide array of firms to assemble and distribute this package. The PIP service included a PC loaded with Microsoft's Office suite of products, 2 years of unlimited Internet access, an e-mail account, and an individual Web page. Subscribers were charged a small down payment upon signing up for the service and the balance was paid via fixed monthly fees charged to their Telmex phone bill. At first, Telmex sold PIP services via a call center, but subsequently it extended this offering to the retailers in the Carso Group of companies (e.g., Sears and Sanborns) for wider distribution.

Telmex and its partners have had to adjust its PIP program various times to stimulate demand. When PIP sales began to level off in 2000, Telmex revised the PIP package and replaced Microsoft's Office for Microsoft's less expensive (and functional) Works suite of products. Telmex passed this cost savings on to its customers and decreased the PIP fixed monthly fee. PIP subscriptions surged as a result. In 2002, PIP sales once again stalled. As before, Telmex adjusted the package, this time replacing Intel processors with a less expensive processor and charging a per-minute fee for Internet access during peak hours. This new offering was called PIP-Home and was designed for students, which would likely use the Internet on nonpeak hours. PIP sales again spiked as a result.

Several of Telmex's competitors state that Telmex's PIP offering has been the most successful program in increasing Internet demand in Mexico and credit it with single handedly doubling Internet usage rates in the country. An anonymous senior executive at Telmex, however, acknowledges that the PIP program has limits, "today we finance computers ... in order to facilitate the purchase of PCs ... it is a method of attacking the lack of purchasing power ... but even this has a limit,

when you reach a point when even with this people can't use a computer..."

Example: Decrease Recurring Costs (Pre-Paid Model)

Partnership: Todito and Adatel's Pre-Paid Internet Card

Todito is an Internet portal, electronic commerce (e-commerce) site, and ISP in Mexico (Todito, n.d.). Todito is part of Salinas Group, a large Mexican conglomerate led by Ricardo Salinas, which focuses primarily on the mass market in Mexico. During the dot com boom of the late 1990s, the group's companies became interested in exploiting the Internet and e-commerce. Instead of creating a new Internet company, the Salinas Group acquired a 50% stake in Todito, which was owned by Salinas' brother's Dataflux Group.

Todito's chief executive officer (CEO) recognized that his Internet portal and e-commerce services would be worthless if people could not access the Internet. He believed that one significant barrier to Internet usage in Mexico was the lack of affordable ISP access. Adatel, a small high-tech firm, had approached Todito with a pre-paid Internet solution. Todito's CEO thought that this would be a particularly appropriate solution for Mexico. He notes that pre-paid programs proliferate in the country because the economic uncertainty makes the idea of having a long-term obligation unappealing to most Mexicans. Furthermore, he claims that the average Internet user in Mexico connects to the Internet only 8 hours a month, thus he believed the flat-fee Internet services made hourly rates cost prohibitive for the mass market. A pre-paid Internet card would allow consumers to both control their costs and only pay for the time they are actually online.

Todito and Adatel worked together to develop a "Todito card" prepaid Internet product, which was launched in the spring of 2001. At first, Todito

Bringing the Next Billion Online

marketed and distributed the Todito card and Adatel provided the actual service. Over time, Todito licensed the technology from Adatel and assumed the service delivery responsibilities. The partnership subsequently ended, but Todito continued with the Todito card product on its own.

The Todito card catapulted Todito from relative obscurity to being the third ranking ISP in the Mexican marketplace in less than 2 years. The profit margins on the card are generous and it is now a profitable business for Todito.

Example: Increasing Operational Efficiency (Operational Efficiency Model)

Partnership: IBM and Telecommunications Providers in Mexico

IBM is the “worlds largest” information technology (IT) solutions and services provider (IBM, 2004). When Gerstner joined the firm as CEO in the early 1990s, IBM was a decentralized, technology-centric firm that was losing billions of dollars a year (Gerstner, 1998). In less than a decade, IBM was once again a highly profitable IT powerhouse and Gerstner a widely acclaimed business guru (Teresko, 1999). Gerstner claims that this successful turnaround is due to IBM’s singular focus on developing integrated solutions that will provide its customers with a competitive advantage. The Internet is at the core of IBM’s solution-centric strategy, and early on IBM focused on the “transformative power” of the Internet and “ways individuals and institutions derive value” from the Net (Gerstner, 1998).

IBM was the sole firm in the sample that took an indirect approach to tackling the lack of funds barrier to Internet usage in Mexico. Specifically, IBM focused on increasing the operational efficiency of telecommunications providers in Mexico. It realizes that the productivity of telecommunications’ infrastructure investments greatly decreases

once outside of high-density urban areas. IBM believes that its technology can help increase the efficiency of telecommunications providers, enabling them to offer more services at more economical rates in lower density populations and subsequently lead to increased Internet demand in the country. IBM therefore collaborates with its customers—telecom providers—to assist them with systems integration, processes optimization, and creating and provisioning new services to this client base.

Specific information was not made available on the success of this approach, but it is an innovative way of tackling the supply side of the lack-of-funds barrier to Internet usage.

Example: Increase Income Levels

Partnership: Motorola=educ@Mexico

Motorola has a long tradition of supporting education and viewing investments in education as imperative to achieving its long-term, market creation objectives. Motorola’s executive team in Mexico believes that improved education levels lead to enhanced employment opportunities and thus, higher earning potential. As disposable incomes increase, so does the overall market for Motorola’s products and services. Additionally, they believe that education can be used to overcome people’s fear of technology, again leading to increased demand. Education-related activities, therefore, are a core component of Motorola’s long-term expansion strategy in emerging markets, such as Mexico.

In 1999, Motorola launched the Motorola=educ@Mexico initiative. Motorola had been actively engaged with educational institutions since its entry into the Mexican market over 40 years ago, and this program simply organized these efforts under a single umbrella initiative. Motorola has partnered with a diverse range of firms, NGOs, universities, and government agen-

cies to improve education under the auspices of the Motorola=educ@Mexico program.

One specific Motorola=educ@Mexico partnership was between Motorola and the Universidad del Valle de Mexico (UVM). UVM is a large, national, private university in Mexico with a predominantly middle-class student body. Motorola provided UVM with \$25,000 to assist it with equipping two computer laboratories on its Lomas Verdes campus, and high-ranking Motorola executives participated in educational-related events at UVM (Romano, 1997). UVM believes that its students must have access to state-of-the-art technology for their laboratory experiments and workshops. The Motorola partnership has enabled UVM to achieve this objective, and the laboratory on its Lomas Verdes campus is the most sophisticated of its 16 campuses.

Motorola's university partners interviewed in this study unanimously agreed that Motorola made great strides in enhancing educational activities in their institutions and they believe this is largely due to the firm's pro-education corporate culture and executive team in Mexico. In an industry where the very survival of a firm depends on its ability to effectively compete for a limited pool of highly trained personnel, Motorola's direct link to the source of this talent could also be a significant competitive advantage.

Lack of Uses

Many potential Internet customers in Mexico are unable to use the technology because of language, literacy, training, and cultural barriers. Lack of Uses could be the single most difficult barrier to overcome, as resolving it requires rethinking the value proposition of the technology and partnering with nontraditional players (educational institutions, government agencies, and/or NGOs). The most common approach to tackling this barrier to Internet usage was to develop new applications and uses for the technology.

Example: Developing New Uses for the Technology

Partnership: IBM's Reinventing Education

High-tech firms have a long history of partnering with educational institutions. These partnerships have traditionally revolved around product donations, which are seen as a method of building brand awareness and future consumers. IBM has taken a distinct approach—it has focused on providing educators and educational institutions with compelling reasons to use its technology. IBM's Director of the Public Sector in Mexico, Lorenzo Valle, states, "it isn't a question of simply implementing Internet services, it is a much more complex problem...the most important thing is that people know how to use it and have a reason to use it" (personal communication, 2004, emphasis added).

IBM believes that it is capable of developing technological solutions, but it needed experts in education to help identify and develop value-added uses for Internet technology in academic institutions. The result was IBM's Reinventing Education Program. IBM partnered with a small set of schools to identify systemic problems in education and educational institutions. It then worked hand-in-hand with these schools to develop technological solutions for these problems. These solutions were pilot tested in a school, refined and then, ideally, converted into commercial offerings for the educational marketplace.

One specific result of the Reinventing Education Program was the development of Learning Village software. This software connects schools, libraries, professors, students, teachers, and parents to encourage greater collaboration, communication, and learning. The software was initially developed and refined in conjunction with a school in the United States and in 2004 was introduced to Mexico and Brazil. In Mexico, the Learning Village software will be piloted in the Mexican

state of Hidalgo. IBM believes that Hidalgo is an ideal test bed for this software as there are just a handful of advanced firms and universities, a moderate-sized, middle-class population, and a large marginalized and poor community in this state. These characteristics—small upper and middle classes and a large lower class—are representative of Mexico as a whole.

It is too early to evaluate the success of IBM's Learning Village pilot project in Mexico. An evaluation conducted by the Center for Children and Technology, however, reports that IBM's overall Reinventing Education Program has had very positive results on education and educational administration in the United States (Spielvogel, 2001). This program has also helped IBM begin to make a profit in the K-12 education market—a market where IBM had traditionally recorded a loss (Kanter, 2001).

DUAL BARRIER PARTNERSHIPS

Slightly less than one third of the partnerships analyzed to develop the taxonomy fall within one of the two dual barrier categories of the taxonomy: lack of funds + lack of uses and lack of funds + lack of infrastructure. Approximately half of these partnerships were formed between a high-tech firm and a university, one quarter were between two high-tech firms, and one quarter involved the participation of high-tech firms and NGOs. In the balance of this section, each of the dual barrier category types is explained and an actual example of a partnership in this subcategory is provided.

Lack of Funds and Lack of Infrastructure

The vast majority of Mexico's Internet subscribers rely on the traditional wire-line telephone network for Internet access. According to the ITU (2002),

14 out of 100 Mexicans, or approximately 45% of households, have a phone line. The number of telephone lines is therefore an artificial ceiling for Internet usage rates in Mexico. This is particularly true for potential users in lower economic levels in Mexico, which tend to live in infrastructure-poor areas (no telephone lines). High-tech firms partnered with a diverse set of entities to simultaneously overcome both the financial (lack of funds) and infrastructure (lack of telephone lines) barriers to Internet usage in Mexico. Todito, for example, was particularly active with dual barrier partnerships and employed two main approaches: providing low-cost, shared-access sites (cybercafe model) and developing alternative, less expensive, access and payment technologies (wireless and prepaid model).

Example: Cybercafe Model

Partnership: Todito and Oxxo's Digicentro Todito

Todito's CEO believes that there are three barriers to Internet usage in Mexico: a phone line, a computer, and an affordable ISP. The Todito prepaid Internet card addressed the last issue—the affordable ISP. The remaining two barriers still prevented large segments of the Mexican population from using the Internet. Todito, therefore, decided to simultaneously leverage the success of its Todito card and tackle the income and infrastructure barriers to Internet usage in Mexico via a new initiative: Digicentro Todito.

Todito partnered with one of Mexico's largest chain of convenience stores, Oxxo, which was also one of the primary distributors of its Todito card. These two parties created cybercafes or Digicentros Todito. Customers would use their Todito prepaid Internet cards in the Digicentro Todito to access the Internet from one of the half dozen computers located in the Oxxo store. Oxxo provided the physical and communications

infrastructure (telephone lines and space in the Oxxo stores) and Todito provided an affordable method of accessing the Internet (Todito prepaid Internet cards and PCs).

It was envisioned that Todito would benefit by having an additional outlet for its Todito cards and by solidifying its relationship with a key distributor. Oxxo would benefit by selling additional units of a high-volume product (Todito card) and by upgrading its stores and image in line with its “Oxxo of the Future” campaign. To bias the likelihood of success, the first Digicentro Todito was launched in late 2003 in Cancun, a hot spot for foreign tourists. If this launch is a success, Digicentro Todito cybercafes will be rolled out in the major cities in Mexico and ideally, to all 2,000 Oxxo stores across the country.

Example: Wireless and Pre-Paid Model

Partnership: Todito and Biper’s Movilaccess

Todito executives believe that e-mail is the number one application on the Internet in Mexico. In the mid-1990s, Grupo Salinas established a company—Biper—to provide paging services in the Mexico market. The cost of acquiring a pager and Biper’s monthly fees were relatively expensive for the mass market for which the Grupo Salinas’ companies traditionally catered. Todito’s executives believed that if they could lower the price of the device and enable customers to send and receive e-mails paid for by Todito prepaid Internet cards, they could enable an entire new segment of the Mexican market access to the most popular application of the Internet and increase aggregate Internet demand. This solution would overcome both the income (low cost device and prepaid Internet access) and infrastructure (low levels of telephone lines) barriers to Internet usage.

Todito’s business plan was based on three elements: a device priced at less than \$50, affordable access fees, and wide-scale distribution.

The access fees could be made affordable by using Todito’s prepaid Internet access card, which would allow Mexicans Internet access without having to sign a long-term contract. Distribution channels had already been secured for the Todito card and could now be used for this new product. The critical factor was decreasing the device cost from approximately \$160 to less than \$50.

At the time, the usage of two-way paging technology was declining in industrialized countries. Todito hoped to exploit this mature technology for a few years in Mexico until the country was ready for more sophisticated technology. Todito sought a partnership with a two-way paging technology company. These companies, however, were diverting their resources and energies away from this declining technology and toward more cutting-edge solutions. Todito quickly found that as the technology fades in industrialized countries, the number of firms that offer it decreases, as do investments in the technology.

Todito and Biper were still negotiating with paging manufacturers at the end of this study and it was unclear as to if they could reach the targeted \$50 price for these devices. This case is interesting, however, as it demonstrates the limitations of firms and countries in repurposing existing technology for the needs of emerging markets. Leapfrogging, or bypassing mature technologies in favor of cutting-edge technologies, may be the only option in some cases.

Lack of Funds and Lack of Uses

Low income levels often go hand-in-hand with low educational attainment rates. If individuals do not learn computers, IT, and English language skills in school, they may not be able or interested in using the Internet. Firms have partnered with educational institutions and NGOs to simultaneously tackle the income and uses barriers to Internet demand in Mexico. These partnerships generally attempted to increase income levels and

to develop new uses for this technology (education and content development model).

Example: Education and Content Development Model

Partnership: Sun Microsystems and UNITEC's E-Business Technology Incubator

Sun Microsystems (Sun) is a “leading provider” of hardware, software, and services that power the Internet (Sun, n.d.). Sun strongly believes in ubiquitous connectivity and its mission is to link “every man, woman, and child on the planet” to the Internet (Sun, n.d.). Sun executives in Mexico perceive that there are at least two primary barriers impeding Sun from achieving this mission in their country: lack of funds and lack of uses. Sun's collaborations with universities are designed to overcome these obstacles and in the long run, create Internet demand in this market.

Since the turn of the century, Sun has executed a variety of strategies directed toward expanding its business around the world and in Mexico. Given Sun's long tradition of collaborating with universities, many of these market creation initiatives were implemented in conjunction with the educational sector. Specifically, these strategies focus on creating employment opportunities, improving education, and diffusing Sun's network-centric technology vision. In the long run, higher educational achievement and increased employment opportunities will lead to improved income levels and people's ability to afford the Internet and Sun's goods and services. Furthermore, Sun focuses many of its university collaborations on developing applications designed to make the Internet “simpler” and less expensive. Sun's Java technology can be used to connect less expensive devices—such as cell phones and personal digital assistants (PDAs)—to the network, decreasing the lack of funds and lack of uses barriers to Internet diffusion.

One specific partnership was the Sun—Universidad Tecnológica de México (UNITEC) electronic business technology incubator (Incubator). In September of 2001, Sun invited UNITEC to participate in its elite Campus Incubator Program. UNITEC is the second largest, private university in Mexico and has a predominantly middle-class student body (UNITEC, n.d.). These two organizations jointly established an Incubator on UNITEC's Atizapán campus outside of Mexico City.

The UNITEC Incubator is equipped with an extensive array of Sun products, so that the students can develop their Java-based business concepts on state-of-the-art technology. Students that enter the Incubator are required to take a significant number of courses on Sun's Java technology. In order to facilitate the technical training, Sun taught and certified three UNITEC professors on Java and has authorized UNITEC to impart Java courses to the students in the Incubator free of charge. The students also received business training and individualized assistance on their business plans.

In late 2003, UNITEC announced its sixth business plan competition for entry into the Incubator. Over 300 business plans have been submitted thus far and 20 have been selected for development in the Incubator. The first businesses were slated to exit the Incubator in early 2004. The Incubator Director's top priority in late 2004 was to find venture capital for these nascent companies, an extremely difficult task with the significant decreases in capital being invested in IT solutions and in Latin America after the dot com bubble burst.

TRIPLE BARRIER PARTNERSHIPS

Less than 10% of the partnerships analyzed to develop the taxonomy fall under the triple barrier category of the taxonomy: lack of funds + lack of

uses + lack of infrastructure. Very few high-tech firms had the financial capacity and reach to initiate these partnerships and the Mexican government took the lead on the primary initiative in this category—e-Mexico, a national connectivity program. The one exception was a multi-sector relationship between a high-tech firm, a university in the United States, local government agencies, and NGOs.

Lack of Funds, Lack of Uses, and Lack of Infrastructure

Many Mexican high-tech firms segment their market according to socioeconomic level (education, housing, and income levels). The scale ranges from A to E, with A being the highest socioeconomic level and E the lowest. A Mexican newspaper, reported that from 2000 through 2002 the number of Internet users in the highest (A and B+) and lowest (D- and E) socioeconomic levels in Mexico remained relatively constant (Reforma, 2004). This suggests that the majority of programs designed to increase Internet usage in Mexico have attracted new customers primarily from middle socioeconomic tiers. These customers may have faced one or two barriers to using the Internet. The lower on the socioeconomic pyramid an individual is, however, the more barriers to Internet usage he/she likely faces. In rural communities and marginalized sections of urban areas, Mexicans may lack the funds, required infrastructure (telephone lines), and ability to use the Internet. In Mexico, the government and private sector are collaborating to simultaneously tackle these three barriers to Internet usage. The programs extend telephone infrastructure (both wireline and wireless—satellite), developing relevant content, and subsidizing usage fees. In the balance of this section, the only triple barrier category type is explained and an actual example of a partnership in this subcategory is provided.

Example: Subsidized Internet Access, Infrastructure Deployment, and Content Development Model

Partnership: e-Mexico

In December of 2000, Mexico's newly elected President, Vicente Fox, announced a national Internet connectivity program, e-Mexico. By the end of Fox's 6-year presidency, the e-Mexico system would consist of 10,000 digital community centers, which provided free (or highly subsidized) access to computers, the Internet, and newly developed content in the areas of health, education, electronic government (e-government), and e-commerce-related content. These centers would be placed in public facilities (i.e., schools, government offices) and would connect over 95% of Mexico's population to the digital economy.

President Fox made it clear that he was counting on private sector support for this multi-billion dollar initiative because the federal government did not have the budget, nor technical expertise, to complete it on its own. Shortly after e-Mexico was announced executives from Telmex, Hewlett Packard, IBM, Intel, Microsoft, Sun Microsystems, and other firms all expressed an interest in partnering with the federal government on this ambitious program. Some partnerships simply extended existing global programs to Mexico (i.e., Intel committed to training Mexican teachers via its global Teach for the Future initiative). Other partnerships created new initiatives to contribute to the Mexican government's objectives for e-Mexico (Telmex created eTelmex, an initiative designed to connect 2,445 targeted e-Mexico villages to the Internet).

By mid-2003, President Fox announced that he had connected 3,200 digital community centers to the Internet and created the e-Mexico portal with content in the areas of education, health, e-commerce, and e-government (Fox, 2003). What was not reported, and is not being monitored by the

Mexican government, is the actual number of new Internet users on the e-Mexico platform. Access to the technology does not necessarily translate into its usage; particularly if training is not included with the newly deployed access. Furthermore, although the Mexican government pronounced an interest in “partnering” with the private sector to achieve the e-Mexico objectives, it has worked in a more traditional vendor-customer fashion and has submitted requests for proposals and selected its “partners” largely based on price.

METHODOLOGY

Four main steps were taken to develop the taxonomy. The first step was to select the partnership population: 25 leading high-tech firms in Mexico. The second step was data collection: data were gathered via more than 60 personal interviews with executives and managers of leading high-tech firms, nonprofit leaders, academic, government representatives, and external experts in Mexico. The third step was data analysis: an iterative process of data reduction, categorization, and testing. The fourth, and last step, was testing: the integrity and exhaustiveness of the taxonomy was tested through a second round of data collection and analysis, and external validation.

Step 1: Select the Partnership Population

A relatively broad population was drawn upon to develop the taxonomy. This population consisted of 25 leading high-tech firms in Mexico and was selected based on three dimensions: (1) market characteristics (industry growth potential, income and population levels, and regulatory framework), (2) industry characteristics (high-tech firms in Mexico), and (3) firm characteristics (firm’s market position and physical presence in Mexico). Mexico was selected for analysis because it represents upper-middle income, densely populated countries

with substantial competition in the Internet arena. The 25 firms included in the taxonomy population are: Alestra, AMD, AOL, Apache, Avantel, Cisco, Dell, EsMas, Hewlett Packard, IBM, Intel, Juniper, Maxcom, Microsoft, MSN, PanAmSat, Prodigy, RedUno/Uninet, Satmex, Sun, TIMSN, Telmex, Terra Lycos, Todito, and Yahoo.

Step 2: Data Collection

After the population was selected, data were gathered. Two pieces of information were required from the firms to construct the taxonomy: (1) high-tech executives’ and managers’ perceptions of the barriers to Internet diffusion in Mexico; and (2) the partnerships these firms have created, or participated in, to overcome these barriers and grow the market. Interviews were also conducted with the firms’ partners and external experts to determine the effectiveness and nature of the partnerships included in the taxonomy.

Before interviews were conducted, both primary and secondary archival records were consulted. These were used to construct a preliminary sketch of the high-tech firms market in Mexico and to develop a list of potential interview candidates.

A total of 13 of the targeted 25 firms agreed to be included in this study. Personal interviews were conducted with a total of 63 individuals: 38 representatives of high-tech firms, 14 of the high-tech firms’ partners, and 10 external experts in Mexico. Most of these interviews were conducted during four field research trips to Mexico City: February 2003, May 2003, October 2003, and January 2004. The interviews were semi-structured, face-to-face sessions that ranged from 20-240 minutes.

Step 3: Data Analysis

Vast amounts of data were generated from the interviews. Miles and Huberman’s (1994) process of data reduction, data display, conclusion drawing,

and verification were used to analyze these data. The first step in the data analysis process was to reduce the data, or to identify and select specific portions of data for analysis. The data in this case were the interview transcript sheets. A coding scheme was developed to enable data reduction. Once the data were reduced, they were displayed in Excel spreadsheets. The data in these spreadsheets were reviewed and labels given to the individual barriers to diffusion. Subsequently, these labels were analyzed to see if there was consistency, or a pattern, in the barriers cited. A great deal of consistency was found and 10 major themes emerged. These themes were further examined and grouped into more concise and overarching categories. The final result of this process was the creation of four categories of the perceived barriers to Internet diffusion in Mexico (lack of awareness, lack of funds, lack of infrastructure, and lack of uses).

Once the perceived barriers to Internet diffusion had been identified and classified, they needed to be associated with the partnerships. Specifically, each of the 32 partnerships was categorized by the specific barrier(s) to Internet diffusion it was designed to overcome. The draft taxonomy was then completed.

Step 4: Validity Assessment

Two primary verification mechanisms were used to increase the validity of the taxonomy: external validation and a second round of data collection and analysis. After the first round of interviews and data analysis, an external expert in the field cross validated the coding of the interview transcripts. This individual coded a representative sample of approximately 20% of the senior executive, interview transcript sheets. The coding results were compared against those of the author of this study and any inconsistencies were reviewed and discussed until agreement was reached. The coding definitions were also rewritten to make them more concise and clear.

Secondly, after completing the first draft of taxonomy, an additional 19 interviews were conducted. The data from these interviews were used to further test the validity of the taxonomy. This additional data suggested that these conclusions are valid and the taxonomy was exhaustive.

CONCLUSION

This chapter shed light on innovative market creation strategies being implemented by leading high-tech firms in Mexico. The objective was to develop a taxonomy of Internet market creation partnerships. This taxonomy classified the types of partnerships high-tech firms were using to create Internet demand in Mexico. The classification was based on the number and type of barrier(s) to Internet usage the partnership was designed to overcome.

As markets become more saturated in industrialized countries and multinational firms seek additional growth opportunities, market creation partnerships will increase in number and importance. This chapter advances scholarship by developing a classification system for market-creation partnerships. Practitioners can use this tool to identify and understand the diverse models being employed to increase Internet usage and emerging markets. Academics can use this tool as the basis for further empirical analysis of partnerships of this nature. Both society and business will benefit from a greater understanding of market creation partnerships as the barriers to Internet usage have both social and commercial underpinnings.

APPENDIX A: INTERVIEWS USED TO DEVELOP THIS CHAPTER

Personal interviews were conducted with a total of 63 individuals: 38 representatives of high-tech firms, 14 of the high-tech firms' partners, and 10 external experts in Mexico. Most of these interviews were conducted during four field research trips to Mexico City: February 2003, May 2003, October 2003, and January 2004. These interviews were used to develop this chapter and taxonomy. Almost half of those interviewed requested anonymity. Those that agreed to be identified are listed here by name and/or title and organization.

Representatives from High-Tech Firms

- Carlos Baradello, Vice President and General Manager of Latin America and the Caribbean, 1996-2002 (retired), Motorola of Mexico
- Gerardo Barragan, Director of Business Development, Alestra

Chapter 8.2

ICT and the Efficient Markets Hypothesis

Andrea J. A. Roofe

Florida International University, USA

INTRODUCTION

This article represents a preliminary attempt to identify the variables influencing the relationship between technological development and efficiency in the financial markets of a Caribbean economy. The analysis uses qualitative methods only. From the late 1980s, Kitchen (1988) observed, "... the major inefficiency in the capital market is the lack of information..." (p. 48). Two characteristics that differentiate the financial markets of developing countries from those of developed economies, and have an impact on their efficiency are:

1. A small number of investors;
2. Few types of investors;
3. The limited range of financial instruments.

The above render the financial markets inefficient, from the perspective of the Efficient Markets Hypothesis, compared with those of developing countries. As the ICT infrastructure among developing countries varies, the article is

limited to one country—Jamaica. The Jamaican financial market was considered a top performer among emerging markets in 1992, based on movements in its stock prices. Following the collapse of the island's financial sector in 1993, the market remained in the doldrums for several years..

The government and the key players in the financial services sector recognized the need to upgrade the technological infrastructure of the financial markets to attract international players and render its operations more efficient and transparent. The technology permits trading in real time, across borders among the three major exchanges in the Caribbean-Trinidad, Jamaica and Barbados.

In the last 12-15 years, in addition to attracting international institutional investors, the Jamaican financial services industry has been actively educating the local individual investor to attract his participation in the financial markets as an individual investor – whether as a holder of a Unit Trust/Mutual Fund, Treasury Bills, Local Registered Stock or as a minority stockholder in a listed company. The Jamaican market, therefore,

provides an example of an institution that recognized the importance of the role of ICT (especially Internet-based technologies) in its re-emergence from relative obscurity and as it attempts to facilitate economic development.

The outline of the article is as follows:

1. The role of the financial sector in the development process in an economy and in wealth-creation.
2. The structure of the Jamaican financial market.
3. The underlying theoretical framework—the efficient markets hypothesis and the contribution of 21st century technology to the improved efficiency in the Jamaican financial markets. It assesses measures of the technological development of the country—tele-density and infrastructure development and legal considerations. These are considered important issues for local development as, in addition to international institutional investors, the key players have been actively trying, in recent years, to attract the participation of local individual investors into the market to facilitate a more diverse basis of local wealth creation. In addition, international investors can serve as an invaluable source of capital during a public offer of shares.
4. Issues in customer relationship (client account management) and operations management (back office operations) in the financial services sector that have been, or can be addressed by enhanced technology. These are the key areas of management of financial services that impact directly on market efficiency.
5. Opportunities for new technology product development, training and marketing that may reasonably be considered by software developers, infrastructure providers, and providers of technology training services, with the intention of attracting skilled

persons into the field of technology and/or improving the technological infrastructure and applied knowledge of the key players in the financial markets.

BACKGROUND

Martin Sewell, owner of the Web site, <http://www.e-m-h.org>, states that “...The origins of the Efficient Markets Hypothesis (EMH) can be traced back at least as far as the pioneering theoretical contribution of Bachelier (1900) and the empirical research of Cowles (1933). The modern literature in economics begins with Samuelson (1965), whose contribution is neatly summarized by the title of his article: ‘Proof that Properly Anticipated Prices Fluctuate Randomly’...” Solnik and McLeavy (2004) argue that “the notion of an efficient market is central to finance theory. In an efficient market, any new information would be immediately and fully reflected in prices. Because all current information is already impounded in the asset price, only news—that is, unanticipated information—could cause a change in price in the future” (p. 24).

The central concept of this article is that technology facilitates efficient financial markets by making information available to existing and prospective investors on a timely basis. It assumes greater relevance in light of the global nature of financial transactions. An efficient financial market is required to attract global institutional investors to an emerging economy. In addition, it facilitates the wealth creation process among the local populace. The author is unaware of any recent scholarly work that considers the Jamaican financial markets, from the perspective of the Efficient Markets Hypothesis. In the last five years, several governments and international bodies have sponsored conferences and working groups to help developing nations consider the impact of technology on key sectors of the economy. It was argued that technological infrastructure and legal

ICT and the Efficient Markets Hypothesis

and audit concerns ranked highest in their priorities to develop the national economies. Bridges.org (2001), Digital Opportunity Initiative (2001), Grant (2001), COMNET-IT (2002) and UNCTAD Secretariat (2002) offer similar opinions.

Grant (2001) refers to the work of the E-Commerce working group, a sub-committee of the E-Commerce Committee of Jamaica that identified a number of requirements for the successful implementation of e-commerce in the island. He cites the following:

- i. Human resources skills:
 - “Education across all parts of the society in ICT is needed. This is in fact a cross-cutting issue and should be given the highest priority and resources allocated. Some important areas of development for the private and public sector are:
 - The establishment of Life Long Learning facilities to facilitate technology training by older users who may be intimidated by technology.
 - To inculcate a vision of ICT usefulness through training of senior management in IT skills rather than creating an environment where they are forced to use technology” (p. 24).
- ii. Improved ICT infrastructure:
 - “Electricity should be available to all persons in reliable supply.
 - Telecommunications to every home and business place and at low cost (VSAT, Fibre, Wireless, dial-up).
 - Database Security, Dependable backup, redundancy, disaster mitigation, and when all else fails, adequate consequential loss insurance” (p. 24).

The financial sector was not mentioned in this discussion, possibly because the financial markets were well underway, with the process of upgrading

their technological base. In Jamaica, the thrust toward improved technological infrastructure was largely driven by the private sector (viz. the Stock Exchange, stockbrokers and investment bankers), which felt the need to meet international standards to attract the international investment community. The Caribbean and international academic communities appear not to have carried out significant research on this topic. Hopefully, this article will stimulate further discussion and writings on this issue within the development, academic and professional communities.

FINANCIAL MARKETS AND ECONOMIC DEVELOPMENT: THE EFFICIENT MARKETS HYPOTHESIS

The Efficient Markets Hypothesis

Reilly and Brown (2000) state that the most basic form of the efficient markets hypothesis—the weak form—“...assumes that current stock prices reflect all security-market information, including the historical sequence of prices, rates of return, trading volume data, and other market-generated information such as odd-lot transactions, block trades, and transactions by exchange specialists or other unique groups” (p. 215). An efficient market, therefore, has few opportunities for arbitrage, as imbalances are immediately corrected by the immediate dissemination of information using ICT.

The Role of Financial Markets in the Development Process

Finance is considered the “lubricant” of the wheels of the productive sector. ICT have dramatically transformed the manner in which the financial services sector of developing economies operates. As with other industries, ICT help financial markets become more effective, customer-oriented and

transparent in their operations. ICT facilitate the investment decision-making process as follows:

1. The delivery of investment information on a timely basis, using computerized investment information systems and investment research tools.
2. Verification and delivery of client transaction information for prompt settlement of transactions, and authentication, using automated trading, settlement and depository systems.

Efficiency and transparency are necessary to attract foreign investors to participate in an emerging financial market. They ensure the survival of such markets, as the local investors lack the resources to support the market, especially during times of economic downturn. Sometimes, the size of a public offer may be reduced, because of the limited capacity of the local market. The economy benefits from the positive impact on individual and corporate wealth enhancement.

How the Jamaican Financial Services Sector Works

Generally, the financial services sector facilitates the purchase and sale of securities on the primary (new issues and IPOs) and secondary markets through the process of financial intermediation. Owners of surplus funds offer their savings to businesses with the expectation of an adequate return. Financial institutions play an intermediary role, allocating funds based on the relative rank of projects and companies, according to their expected returns and risk profile of the project and/or company. Figure 1 depicts the flow of funds within a typical developing economy, such as Jamaica.

Table 1 summarizes the typical types of investors and institutions found in Jamaica, a typical economy with a developing financial structure.

In 2002, Jamaica’s literacy rates (and hence, potential for human resource development) compare favorably with the rest of Latin America/ the Caribbean and other lower middle-income

Figure 1. Flow of funds within a typical developing economy (Compiled from information contained in Santomero & Babbel, 2001)

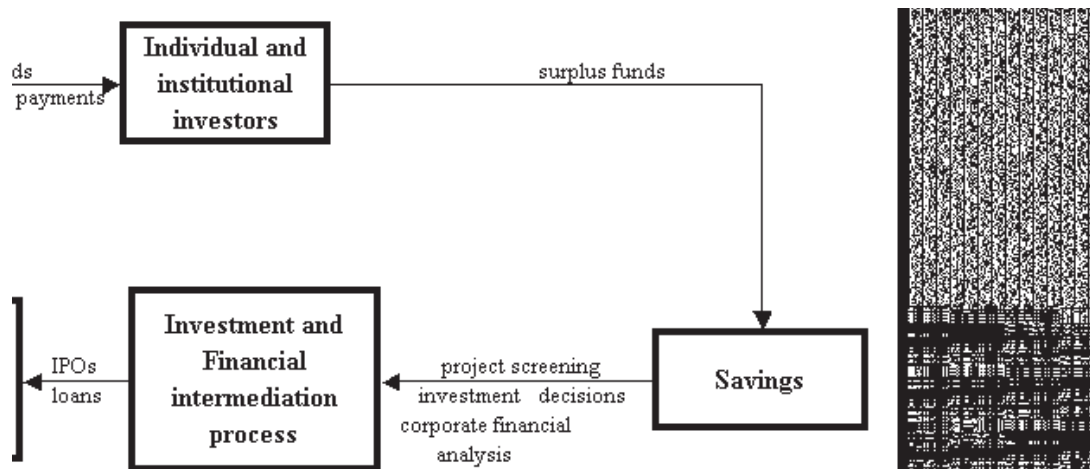

Table 1. Structure of the financial services industry in Jamaica (Source: ICT at a Glance-Jamaica, The World Bank October 3, 2003)

Investment Services Providers	Investors
Life Insurance Companies	Pension funds
Stock/Money market brokers	Life and General Insurance companies
Merchant/Investment Banks	Commercial banks (Usually investments are made only on a short-term basis, due to legal restrictions.)
Trust companies and portfolio managers	Other institutional investors, and individuals

Table 2. Economic and social metrics—Jamaica and Latin America (Source: ICT at a Glance Jamaica, The World Bank October 3, 2003) (Source: Compiled by the author, November 2003)

	Jamaica	LATAM & Carib.	Avg. lower middle
	2002	2002	income nations 2002
Adult literacy rate (% ages 15+)	87.6	89.5	86.6
Urban population (% of total population)	57.1	76.2	49.4

countries. With a larger rural-based population than most Latin American/Caribbean countries, it becomes important to improve the technology infrastructure of Jamaican rural communities.

Training and Infrastructure Considerations

Without adequate training and infrastructure, the securities market will not be able to conduct its activities to international standards. Tables 3, 4 and 5 highlight comparative indicators of the level of development of the ICT sector in Jamaica as compared with other Latin American and Carib-

bean countries and other lower middle-income nations in 2001 and 2002.

In 2002, Jamaica compared favorably with the rest of Latin American/Caribbean and other lower middle income nations with respect to ICT infrastructure and access, computers and Internet usage and the ICT business and regulatory environment. The sole exception was the number of secure servers located in the island, a key requirement for the transmission of confidential information across the Internet. Telecommunications costs remain prohibitively high—the result of the small scale of operations over which the companies recover their overhead costs. At the time of final edit, the

Table 3. ICT metrics for Jamaica compared with LATAM and lower middle-income countries: ICT infrastructure and access (n.a. Not Available: Sources: ICT at a Glance-Jamaica, The World Bank September 9, 2002 and October 3, 2003)

	Jamaica 2001	LATAM & Carib. 2001	Avg. lower middle income nations 2001

Monthly off-peak access charges: service provider charge (US\$)	49.3	n.a.	16.7

ICT and the Efficient Markets Hypothesis

Table 5. ICT metrics for Jamaica compared with LATAM and lower middle-income countries-ICT business and government environment (n.a. Not Available or Not Applicable [ratings from 1 to 7. 7 is highest/best]: Sources: ICT at a Glance-Jamaica, The World Bank September 9, 2002 and October 3, 2003)

	Jamaica 2002	LATAM & Carib. 2002	Avg. lower middle income nations 2002
Broadband internet access availability	2.5	4.0	3.6
Local specialized IT services availability	4.2	4.5	4.3
Competition in ISPs	4.7	4.0	4.2
Government online services availability	3.3	3.3	3.1
Laws relating to ICT use	3.3	3.3	3.3
Secure servers	5	2,103	2,769

author was unable to locate updated information on the metrics for the ICT industry for the year 2003. However, it is unlikely that the island's standing has been lowered as the government and private sector have made significant improvements to the telephony/ICT infrastructure since the start of the 21st century so as to attract international investments and facilitate increased productivity among local businesses.

HOW ICT HELPS IMPROVE MARKET EFFECTIVENESS AND EFFICIENCY

Investment Information

The two critical issues in customer relationship management (CRM) are as follows:

- The availability of accurate information to all existing and prospective investors.

- The timely delivery of information (in or near to real time) to all parties to facilitate prompt decisions.

In 2003, the consulting firm CaribbeanPortfolio.com (2003) conducted a survey among Jamaican institutional investors. The participants comprised 20 of the largest institutional investors in Jamaica. The findings revealed that investors ranked the timely delivery of transaction information and a prompt response to client inquiries as critical to the success of the investment decision-making process. The Jamaican financial services sector has largely addressed these concerns through the delivery of trading information at the end of the trading day to the major investors. One firm, JMMB Securities Limited provides text messaging and daily email notification of transactions to its individual investors. Unfortunately, this information is not available in real time.

Operations Management

Operations management is concerned with:

- Trading systems (inter-broker and broker-client systems);
- Settlements (broker-client/broker-broker) Security registration, transfer and custody; and
- Dividend accounting and payments.

The above sub-systems are established using intranet or extranet-based modules. As part of the final phase of its modernization program, the Jamaican financial markets have implemented a Central Security Depository. The Jamaica Central Security Depository (JCSD), "... a wholly-owned subsidiary of the Jamaica Stock Exchange, is a facility for holding securities which enables share transactions to be processed by book entry. A book entry system is an accounting system that facilitates the change of ownership of securities electronically between parties, without the need for the movement of physical documents. In short, the JCSD is a means of recording the ownership of shares" (JCSD Web site).

Legal Considerations

Grant (2001) argues that any ICT or e-commerce model adopted by the business community will require updated legislature and supporting infrastructure (especially security arrangements) for its successful implementation. Two fundamental changes to the law are proposed:

1. E-Signature or E-Transaction legislation;
2. Laws Protecting Parties, Transactions, Systems and Data.

Such legislation would render signatures as legally binding as those done in print or handwritten form. The supporting infrastructure would

protect the privacy of the participants, transaction data, and confidentiality of sensitive information, which are critical requirements for the transmission of financial data in cyberspace.

To date, the major regional stock exchanges have been able to conduct cross-border trading operations with a high degree of success, primarily because transactions have been limited to a small number of players and a single network connecting the three major Caribbean financial markets. Grant (2001) notes the difficulty in implementing secure databases. The author also found it an extremely laborious and time-consuming process to become a trusted member of an international network to be able to sign documents electronically and transmit email with a verifiable identity, as there was no trusted member of that network residing in the island of Jamaica. Updates to existing intellectual property laws and revisions to existing consumer protection laws are also necessary to support the new business environment.

Audit Considerations

This concerns the nature of transaction documentation and audit confirmation available to the accounting and audit community. The Caribbean-Portfolio.com (2003) report noted that, "... 65% of interviewees preferred that their transactions be confirmed by letter or contract note. For 30% of respondents, email or online verification of transaction was preferred, primarily because the information was accessible at the client's convenience and be available for immediate delivery to its auditors. Almost 68% of respondents preferred settlement by same day cheque, while just over 30% preferred to settle a transaction by direct transfer of funds transferred to/from a bank account..." (CaribbeanPortfolio.com, 2003). There was some concern that the securities regulatory bodies and the local accounting fraternity had not yet updated their practices to recognize the validity of online or electronic transactions and

documentation. It is hoped that the enactment of relevant legislation will force these entities to update their rules.

FUTURE TRENDS AND OPPORTUNITIES FOR ICT IN THE FINANCIAL SERVICES SECTOR

Hardware

Opportunities exist for hardware manufacturers and distributors in the provision of affordable mobile and wireless/satellite technology solutions, as more than half of the population of Jamaica is based in rural communities. The rural parts of Jamaica consist of rugged mountainous terrain with isolated districts scattered throughout the hilly interior. Satellite and wireless technology are considered more appropriate due to the high cost of installing wired telephone service in a hilly terrain.

There will be a demand for hardware used to provide faster wired Internet access services, as existing users upgrade their Internet access from dial-up services to services offering dedicated access and faster connectivity such as T-1 and ADSL, to access information as soon as it becomes public. Broadband connectivity must improve to speeds available in the major financial centres. High speed Internet access should be made more affordable and its implementation in a home/small business network rendered user-friendlier.

Software

Much of the software requirements of the financial services industry are available from the major financial centres, and may be customized for use under local legal, tax and accounting practices. Others are proprietary systems developed by local programmers.

Training and Human Resources

There will be an increased demand for affordable training services in basic computer use, as computers will become an important part of daily life. The demand for training in the use of wireless/mobile technology will increase as providers develop solutions to meet the needs of the rural population inhabiting the interior hilly regions of the island. Online training is an excellent means of reaching the rural populace. Institutions and service providers will demand for trained and certified system administrators and technicians to implement and support wireless and mobile systems, and to support a growing user base.

There will be a demand at least initially for trained and certified software engineers and project managers to customize and implement trading and security accounting software, as some security registrars still maintain their databases in manual form.

CONCLUSION

ICT have transformed the manner in which the Jamaican financial markets operate. However there is scope for improvement especially in the delivery of Internet access to a larger number of the rural populace. It may be argued that persons living in isolated rural communities, who have sufficient excess cash, already have access to technology. Those who lack this knowledge and technology are likely to improve their lot if afforded the opportunity to gain access to education to improve their earning power.

Once the requirements in the previous sections are satisfied, in the form of a fully-integrated system, that is available to a majority, if not all of the population, then a necessary condition for the existence of an efficient market would have been satisfied, as information would be available to all

parties at the same time, on a timely basis, and subsequent payments would have been accounted for accurately and promptly, with minimum loss of interest on outstanding balances.

KEY TERMS

Arbitrage: The simultaneous purchase of an undervalued security and sale of an overvalued but equivalent security to obtain a risk less profit on the price differential. Taking advantage of a market efficiency in a risk less manner.

Back Office: Settlement and related processes, including the process of paying for transactions conducted on the financial markets.

Customer Relationship Management: The set of automated processes designed to improve customer service.

ICT and the Efficient Markets Hypothesis

Efficient Market: A market in which any relevant information is immediately impounded in asset or security prices.

Financial Intermediary: A bank, securities firm, or other financial institution that collects deposits and makes loans, manages the risk associated with the loan process, and/or facilitates the flow of capital between operating units and the economy.

Financial Structure: The set of institutions and processes that comprise the financial system.

Primary Market: The market for new securities issues. In the primary market, the security is purchased directly from the issuer. Includes IPOs (Initial Public Offerings of shares to the public).

Secondary Market: A market in which an investor purchases a security from another investor rather than the issuer, subsequent to the original issuance in the primary market, also called the aftermarket.

Teledensity: The number of telephones per 100 people in a region.

Chapter 8.3

Creating Competitive Advantage:

The Emergence of a New Business through Collaborative Networks—An Empirical Case Study in the ICT Sector

Arla Juntunen

Helsinki School of Economics, Finland

ABSTRACT

This chapter addresses collaborative business networks at the level of industry/cluster networks, which is important and relevant from the strategic management perspective in several industries. This chapter examines two current “hot topics”: the emergence of a new Internet driven business group, and its construction through a series of intentionally developed collaborative networks. Networks are seen to offer firms collective benefits beyond those of a single firm or market transaction. The author of this chapter aims to contribute to the development of the emerging theory of network management by integrating notions from the industrial network approach and the resource-based view of the firm, in particular its extensions into dynamic capabilities and learning. The starting premise is that the characteristics

of the task that organizations try to accomplish through forming a specific collaborative network influence, the management of that network, and thus, the capabilities developed and required. This chapter is based on a longitudinal case study in the ICT-sector.

INTRODUCTION

This study examines two current “hot topics”: the emergence of a new Internet driven business group, and its construction through a series of intentionally developed *collaborative networks*. This is a highly relevant topic from a number of perspectives. First, relatively little academic research into so-called *e-business* has been published, in spite of its huge impact on economy (Amit & Schott, 2001). Many Scholars argue

that network organizations are expected to take the leading role in economic and social innovations in the world of increasing globalization, connectivity, and knowledge intensity (Castells, 1996; Grabher, 1993; Jarillo, 1993; Parolini, 1999; Thompson et al., 1994). Second, in spite of the few seminal studies (Alajoutsijärvi et al., 1999; Lundgren, 1991; Håkansson & Lundgren, 1995; Håkansson & Waluszewski, 2002) we have no more than a rather scant understanding of the dynamics of the emergence of business networks, and especially about the role of individual actors in this process.

Furthermore, the companies operating in a network context need to learn to master both the social and business networks in order to succeed in their business networks (e.g., Lechner & Dowling 2003; Uzzi, 1997) and use the knowledge and information shared in these networks to create competitive advantage. The partners and relationships in networks have also been studied in social networks studies (e.g., Griffith & Harvey, 2004). Relationships in collaborative networks can be divided as follows: Firstly, the relationships involved in research and development activities in software and hardware (platform) technology development and their production, including R&D organizations, universities, and research laboratories (Lee et al., 2001; Anderson & Jack, 2002), or as Lechner and Dowling (2003) stated, knowledge, innovation, and technology (KIT) relationships and networks. Secondly, relationships involved in marketing and distribution, including in after-sales services and maintenance, distribution and marketing networks, such as advertising agencies, marketing consultancies, and various distribution channel partners that enable access to new or current markets, and provide new market information and expertise in commercializing a product-service offering (Larson, 1991; Lechner & Dowling, 2003; Rocks et al., 2005). Thirdly, network actors facilitating or supporting business processes include business

associations (Vanhaverbeke, 2001) and financial partners (Birley, 1985).

This chapter aims to show how an intentional networking among different actors can benefit a focal actor in developing a new business group based on emerging technologies, and thus, create competitive advantage. This study is based on a longitudinal case study in the ICT sector (Juntunen, 2005), and it takes the viewpoint of a focal actor. The author looks at how new breakthrough technologies (i.e., xDSL, multimedia, mobile technology, Internet) and the combination of formerly separate technologies and businesses are transformed into a viable business—the so-called *home commerce* business group—during the time period of 1990-2003. *Home commerce* refers to a set of Internet-based services targeted for consumers and accessible at home via different terminals. This study also examines how the focal actor tries intentionally to construct this new business group by developing of a series of interlinked strategic alliances and networks of organizations. Using the insights gained during this process the author tries to identify the capabilities that the focal actor develops, giving particular attention to network capabilities. The study of network *capabilities* is a rapidly growing area of research, which combines aspects of industrial network theory and the dynamic capability view of the firm. The basic idea is that companies must develop specific organizational capabilities, which the author calls network capabilities, in order to operate and survive in a network context (Möller et al., 2003; Möller & Svahn, 2003, 2006) and to create competitive advantage (Ulaga & Eggert, 2005). This view is supported by the work of Gemunden and Ritter, who speak of network competence (Gemunden & Ritter, 1997; Ritter, 1999).

Academic interest in different forms of inter-organizational collaboration has increased considerably during the last decade. The author has adopted the following theoretical approaches

in the empirical study: industrial network theory, and the resource-based view of the firm, in particular its extensions into dynamic capabilities and learning. As the emphasis in this study is on the empirical analysis, only a brief discussion of these approaches is provided.

The chapter is organized as follows. The author starts by discussing the conceptual background for the study. The methodological solutions are then described and arguments for them are presented. The fourth section of the paper is the case analysis, where periodic description of the emergence of the home commerce business group (HCB) is covered. The types of collaborative networks that are considered to be critical in this emergence are also discussed, with special attention being paid to identifying the network capabilities, through which the focal actor was created. The role played by these network capabilities is analyzed. A discussion of the theoretical and managerial conclusions and suggestions for future research conclude the chapter.

BACKGROUND

Academic interest in different forms of inter-organizational collaboration has increased considerably during the last decade. The author has adopted two theoretical approaches in the empirical study: industrial network theory and the resource-based view of the firm (RVB), in terms of dynamic capabilities and learning. The study emphasizes on the empirical analysis, and a brief discussion of these approaches has been provided.

Industrial Network Theory

The industrial network or “markets-as-networks”-approach (INT) pursued by the industrial marketing and purchasing group (IMP) view industrial markets as networks of inter-firm relationships.

Industrial network theory (INT) provides the basic conceptual tools, the actors who carry out value-activities through the resources, and capabilities they command (Håkansson & Snehota, 1995). It stresses the importance of business relationships as a coordination mechanism on a balance with markets and hierarchies, and their role in supporting learning and innovation in industrial systems (e.g., Håkansson, 1982, 1987, 1989; Lundgren, 1991). Networks represent a complex system in which different interdependencies between actors are characterized by both competition and cooperation, continuously constituting and reconstituting business fields (Alajoutsijärvi et al., 1999; Halinen et al., 1999; Halinen & Törnroos, 1998; Håkansson & Waluszewski, 2002; Mattsson, 1985). A development of new technical innovations and solutions (e.g., Håkansson, 1989; Waluszewski 1990; Lundgren, 1991) require continuity in relationships (i.e., long-term relationships). Also, they claimed that interdependence between actors and technologies is apparent (e.g., Håkansson, 1989; Lundgren, 1991; Waluszewski, 1990). Moreover, any single firm has only limited control over its relationship portfolio and network position (Håkansson & Ford, 2002). The position describes how the firm is connected to the other actor that is to what external resources it has access, with which actors it competes and includes the actor’s internal resources (Mattsson, 2003). In an intentionally created business network, a focal actor is presumed to have some kind of power to control and mobilize other participants in the business network (Juntunen, 2005).

The firm negotiates through a network of relationships within networks of organizations. First, it is important to make a distinction between a network of organizations and a network organization. Network of organizations refers to any group of organizations or actors that are interconnected by relationships (Möller & Svahn, 2003, 2004). According to Axelsson and Easton (1992) and Håkansson and Snehota (1995) any market can

Creating Competitive Advantage

Vignette 1. The industrial network approach offers some useful concepts that are important in this study.

A business network refers to the overall configuration of interconnected actors around a focal actor. A network environment, a macro network, refers to the overall configuration of interconnected organizations around a focal actor. The surrounding macro network includes such entities as a market area, economy and society that the focal actor cannot openly influence. The network environment in this study incorporates many other companies which are not visible to the focal actor and to a particular net, and which cannot be directly influenced by the focal actor.

be described as a kind of a macro network. This markets as networks view also compares to that held by scholars of economic sociology (Granovetter, 1973, 1985; Knoke, 2001; Uzzi, 1996), and prevailing in the network externalities discussion in economics (Katz & Shapiro, 1985) as well as in the recent marketing studies of “network markets” (Frels et al., 2003; Srivastava et al., 1998).

Another relevant aspect is provided by the concept of embeddedness, which refers to an organization’s relations with and dependence on the different types of networks (institutional and political networks, technological systems, and institutions), which form an organization’s “environment.” All these simultaneously improve the organization’s actions, its potential relationships, and the outcomes it may achieve (Halinen & Törnroos, 1998; Lundgren, 1991). In other words, actors in a network should be viewed as important change agents and not only as passive adaptors to a faceless, changing environment.

When industrial network theory primarily focuses on the general characteristics of organically-evolved networks, for example, on their

structure and development processes (Möller & Halinen, 1999), the emerging strategic network approach is primarily interested in the creation and management of intentionally-formed network organizations featuring a specific set of actors (Jarillo, 1993; Normann & Ramirez, 1993; Parolini, 1999).

Resource-Based View, Dynamic Capabilities and Organizational Learning

Many practitioners have opined that strategy depends on learning, and that learning depends on capabilities (e.g., Prahalad & Hamel, 1990; Mintzberg et al., 1998, p. 213). Unique company resources and capabilities are, therefore, seen as a primary basis of profitability and the basis for formulating its longer-term competitive advantage. This organizational emphasis on restructuring, reengineering, outsourcing, and forming alliances to build unique capabilities became known as the resource-based view (RBV) (Barney, 1991; Penrose, 1959; Rumelt, 1974; Zollo & Winter, 2002).

RBV perspective suggests that a firm is a collection of heterogeneous resources (Wernerfelt, 1984) and also, that a company's performance is related to differences in its resources. Resources are not easy to imitate and they form the basis for competitive advantages (Amit & Schoemaker, 1993; Barney, 1991).

The RBV-approach and its knowledge-based extension of inter-organizational collaborations conceptualize the firm as a collection of resources, of which knowledge and core capabilities are critical elements in achieving, maintaining, and renewing competitive advantage. Companies differ in how they can control resources that are necessary for implementing strategies. The core behavioral assumption is that companies are able to learn by acquiring, assimilating, sharing, and dissimilating knowledge within the organization and between organizations. RBV sees the knowledge, capabilities, organizational culture, and management as sources of competitiveness. The resource-based argument of alliance formation suggests that firms use alliances to establish the optimal resource configuration that maximizes the value of their resources. Companies use alliances and other types of cooperative forms to develop a value creating resource base that a single company could not have formed (e.g., Das & Teng, 1998; Möller & Rajala, 1999; Blomqvist, 2002).

The concept of dynamic capabilities became an addition to the RBV approach in the middle to late 1990's. The main thrust in the discussion of dynamic capabilities has been how firms integrate, reconfigure, renew, and transfer their own resources and the resources they control. Although in relevance of exploiting external resources (Teece et al., 1997), the importance of "alliance and acquisition routines that bring new resources into the firm from external sources" (Eisenhardt & Martin, 2000, p. 1108) and the "ability to integrate efforts of different actors" (Grant, 1996) have been mentioned, the challenges involved in operating in a complex network remain fairly unarticulated (Kenis & Knoke, 2002; Park, 1996)

The RBV and IMP approaches both view a company as an actor in a web of relationships which influence the firm's conduct, survival and success. While the RBV approach focuses on the constraints that a dependence on exchange partners poses and emphasizes the firms' pursuit for independency by increasing the firm's resource base, and thus, productivity (e.g., Rumelt, 1984; Wernerfelt, 1984), IMP theory focuses on accumulating benefits and effectiveness via a web of relationships (e.g., Ford et al., 2003; Håkansson 1987,1989). The dynamic capability -view adds the dimension of seizing business opportunity via the creation of new capabilities dynamically suitable for the changing situation within both a network and a business context.

In the construction of a new business group—which is often based on the ability to combine several technologies and coordinate the resources and capabilities of various actors coming from different fields—both knowledge and learning can be expected to play core roles. The author draws on studies of "knowledge management" (Larsson, Bengtsson, Henriksson, & Sparks, 1998; Nonaka, Toyama, & Konno, 2001) which suggest that inter-organizational relationships allow possibilities for collaboration, knowledge transfer, knowledge combination, and knowledge exploitation. For a more in depth discussion of inter-organizational learning, see Holmqvist (2003); and for a discussion of the role of knowledge and learning in different types of strategic networks, see Möller and Svahn (2003).

As a summary, a potential criticism of this study may concern the way these multiple research traditions were utilized for providing concept for analyzing the empirical material. The purpose of this was to have a selection of different, but interrelated, conceptual perspectives, to match the complexity and multi-layered characteristics of the phenomena under study. While it can be argued that using a single research tradition may have provided a more focused analysis, such a study would have been able to only partially cover the

multidimensional and comprehensive findings achieved with the multi-theory approach. Another important aspect is the layered character of the new business emergence. In order to achieve a holistic view of the complex causal relationships between technological evolutions, strategic intentions of major actors, and strategic networks, study designs with multiple level of analysis is recommended.

RESEARCH SETTING AND METHODOLOGY

This study also argues that a better theoretical and empirical understanding of the mechanisms by which a focal actor constructs its business and networks is needed. Currently, it is not clear which specific factors in the various collaborative forms determine the positive outcomes and competitive advantage for a focal actor.

This study argues that an inter-organizational collaboration is needed to construct a new business. The goals of this study, for example, to identify, describe, and analyze how a new business group is constructed in an environment of dynamic change, exert a strong influence on the choices of methodology. In order to capture the construction dynamics, a longitudinal study is required in a field that is characterized by technological and commercial change and uncertainty (Huber & Van de Ven, 1995). The explicit focus of this study is the potential implication for the formulation of theoretical propositions regarding the emergence of a new business, and what capabilities and managerial processes are required in the development of business networks.

Furthermore, as the author wishes to examine the interaction between a focal actor and the networks in which it is embedded, an approach was needed to capture how events unfold in a specific context: this requirement is matched by the strong aspects of a longitudinal case study (Pettigrew, 1997; Van de Ven & Poole, 1990).

As examining change in a longitudinal study is very intensive, It was decided that the focal actor in this study should be a single organization, *Elisa* (the 2nd largest tele-operator in Finland, see www.elisa.com), and more specifically one of its business groups *the home commerce business group* (HCB).

Development of the home commerce business (HCB) in Elisa in Finland based on several emerging technologies and its commercial development has been influenced both by the “e-hype” period of the late 1990’s and the bursting of this “bubble” in the early 2000. The study was temporally limited to the time period from 1990 to 2003. The time period was long enough to capture the developmental process of a new business, home commerce business (HCB). The selection of a single corporation from which the multiple cases were chosen naturally brings limitations concerning the generalization of the results of the study. On the other hand, a multiple-case study within a single corporation with excellent data access made it possible to understand the phenomenon under study more profoundly. This decision was also guided by Elisa’s cooperative attitude shown towards the study.

Elisa Corporation is a nationwide telecommunications group whose core business areas are ElisaCom, Elisa Mobile, Elisa Networks in Finland, and Elisa Kommunikation in Germany. HCB was part of ElisaCom. The business services HCB provided, as well as the technologies used, differed from those used earlier in the Elisa, and the processes, functions, activities, business requirements, and marketing and business strategies were seen to be different to those of traditional telecommunication business (i.e., fixed line telephone business). HCB integrated several technologies, capabilities, and resources from a number of actors in different industries to create services for consumers and communities, (e.g., KotiporttiTM which consists of various subscriber connections and community services; e.g., Kaasinen, 2001, p. 51); household monitoring

and security systems; Efodi -learning space: IS-services for publishers, schools, groups, students and teachers. The development process during the years 1990-2003 was explored and evaluated, and an attempt was made to understand the factors and events affecting the development of business networks and the capabilities required.

The present study concentrates on the focal actor and presents the business and network development from the focal actor's point of view. In view of the richness of the material from the case corporation, it was decided to limit the perspective to the focal actor. The focal actor was one of Elisa's business groups; the home commerce business group (HCB) integrated several technologies and resources from a number of actors to create services for consumers and communities. Home commerce, in this instance, refers to a set of Internet-based services targeted toward consumers and accessible from home using various terminals. Internationally, the concepts of "*future home*," "*smart home*," "*intelligent home*," "*digital home*," "*networking home*," "*smart environments*," "*internet home*," "*automated home*," and "*smart housing*" are used for platforms and services in this business (Masala, December 16, 2003). The focal actor, HCB, uses the terms "Future Home" and "Smart Home" in the same context (Masala, December 16, 2003).

Research documentation in this case study consists of both information about the telecommunication industry and the case corporation, Elisa, and HCB's development during the period under study. About 20 persons representing various business units and subsidiaries of Elisa and cooperating partners were interviewed during the period of 1999-2003 (see reference list). Data gathered consists of articles, project documents, e-mails between members of the projects, memorandums concerning strategy and business plans, and annual reports from the years 1990-2001. As the development of the home commerce business (HCB) primarily took place through inter-organi-

zational projects the documents used in the case were arranged in chronological order by project. Even if majority of the material came from HCB-based sources, this does not diminish the value of the conceptualized findings, however. It can be claimed that the conceptualized findings have more general relevance, particularly for firms operating in dynamic, rapidly changing fields characterized by several interlinked technologies. It is also claimed that this relevance reaches beyond the limited historical period.

The research design is a logical sequence that connects the empirical data to the initial research questions (Miles & Huberman, 1994; Yin, 1994). Since there are only a few seminal studies in e-business and on the emergence of business networks and the focal actor's role in the development process this study could be labeled as explorative but it also has some explanatory characteristics (Yin, 1994). The qualitative methods make it possible to develop a thorough understanding of a complex and a multi-dimensional phenomenon in a specific context. The case design here is a multiple-case study but conducted within one corporation.

The reason for choosing a case study approach lies in the in-depth knowledge needed regarding the evolution of different collaborative forms and their managerial processes. Information about these phenomena requires good access to an organization in order to be able to identify them (Heide & John, 1995; Yin, 1994). While a case study is claimed to increase understanding of the complexity of process and change (Cassel et al., 1994; Pettigrew, 1990; Van de Ven & Poole, 1990). Hartley (1994) emphasized the tailor-made nature of a case study because it allows observation within the context of a real-life situation. Furthermore, the longitudinal case study approach was selected so this case study can be described as cases of on-gong processes to increase the general understanding of the phenomena studied (see Carson et al., 2001, pp. 94-95).

Emerging Home Commerce Business Networks: Development Process During 1990-2003

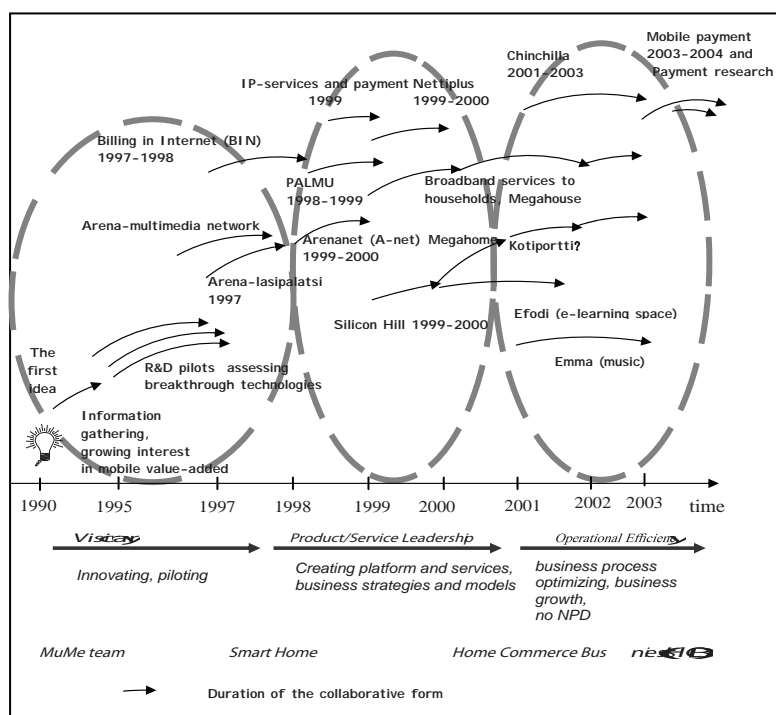

First, this chapter provides an overall view of the development process of Elisa's *home commerce* business group (HCB) through the period 1990-2003. The types of networks through which HCB mobilized this development are then examined together with a discussion of the capabilities required and created during this emergence process. The networks start as technology project networks and develop towards strategic networks with strategic intentions and collective network strategies.

The Period of Innovating 1990–1998

European telecommunication networks of the 1980s and early 1990s were constructed under

monopoly conditions (Beardsley, Bray, & van Rooijen, 1995, p. 157). During the first years of this study period, the main drivers of change were technology (e.g., broadband, multimedia), the deregulation in 1995 in Europe, and globalization of the telecommunication markets. Once the economic recession of the early 1990s in Finland was over, Elisa began investing in new R&D projects which led eventually to organization of the MuMe-team (this was the Multimedia team which later became HCB). This team participated in R&D, technology assessments and multimedia, Internet, mobile, and xDSL-based pilot projects. Figure 1 is a broad view of the whole process and the main projects. During this phase, development was strongly guided by the early vision of a single core individual in HCB (located in HTC, Helsinki Telephone Company, later Elisa). The capabilities acquired during this phase were technology-and

Figure 1. An overview of HCB's different collaborative forms from 1990 to 2003

project-related (For more thorough description of projects see Juntunen, 2005).

The central MuMe-team worked closely with Comptel, a company owned by the case corporation, which was its former IT-department. Cooperation with Comptel was essential when learning to integrate new services and products into existing architecture and platforms and also in product maintenance (i.e., on-going rationalizations of products, services, and IS/IT solutions). Benefits of this strategic dyad relationship were that both parties learnt and acquired new information and knowledge about the daily changes taking place and innovations being made inside the case company. Comptel was also able to use the knowledge gathered from this relationship in its other projects, including international ones, and this benefited the whole organization. When other resources or capabilities were required to develop new services and products, external partners were engaged solely on temporary, project-based contracts. Towards the end of this period, in addition to its close cooperation with Comptel and related partners, HCB also became an active member of national and global cooperative forums in which the competing and collaborating companies from ICT-sector participated, developing new standards and assessing the possibilities offered by new technologies.

In the “e-hype” years of 1997-1998, the general assumption was that a large part of the fixed-line network would be replaced by broadband access technology in the following 5 years. The Internet had also shown its potential as a platform for telecommunication, telephone, and other Web-based services. One important development step was PALMU (see Figure 2, Picture 1), a technology project funded by TEKES (The Finnish Technology Agency) which focused on creating secure billing via the Internet (Hölttä, 1998a, 1998b, Palmu-projektisuunnitelma, Palmu-kokousmuistio). A user-friendly and secure method of e-payment was a prerequisite for new ways of selling goods in Web-based markets. It was expected that

flexible payment methods and well-functioning customer interfaces would encourage rapid adoption of e-services by customers. The possibility of differentiating and integrating services in new ways would open opportunities to introduce self-service and the provision of services on demand (HPY Research, 1998). In this network, the case company was an equal partner with the other participants. The primary goal was to find a way of creating efficient web-based services and payment methods in the new network environment (Isomäki & Jäntere, 1998; Palmu, 1999). Both technological and business visions drove this kind of R&D technology-cooperation and technology piloting.

The results of this wider research into enabling technologies were transferred into the more business-oriented strategic dyad with Comptel and its surrounding network, for further development. HCB’s relationship with Comptel was very useful as each actor was a specialist and had its own support network, while there was sufficient common ground and mutual experience to co-create new solutions. As an IS/IT provider, Comptel maintained a portfolio of relationships from its business point of view while HCB initiated relationships from its perspective of starting to develop the first ADSL-based services while maintaining the vision of new home commerce business. Both actors could, at the same time, have the roles of a product developer and an IS/IT provider. During this period, Comptel, having gained significant knowledge in providing mediator-software services, embarked on rapid global growth.

The Period of Product/Service Development 1998-2000

Developments in 1990-1998 resulted in the creation of a technological platform of enabling Internet and broadband technologies, which could be used in a more business-oriented development of the home-commerce area. In Finland, this coincided with the deregulation of the telecommunication

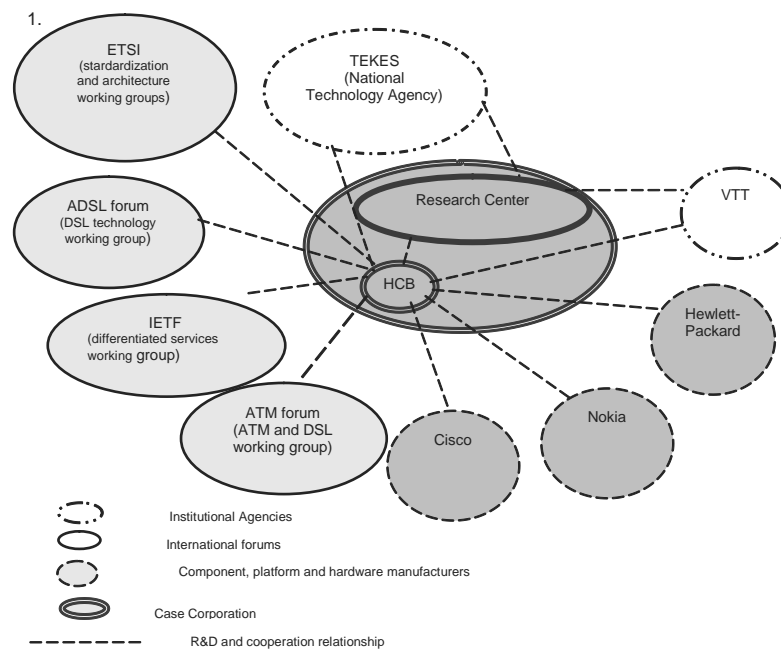

Creating Competitive Advantage

sector in 1998. During the period 1998-2000, the IT boom and rapid changes in competitive environment caused organizational changes, while new business and related projects received a higher proportion of resources and investments than they had before. R&D projects completed in 1990-2000 provided insight and direction suggesting the types of new knowledge, resources, and capabilities required when constructing architecture based on the new enabling solutions.

In Elisa, it was clearly understood that gaining competitive advantage in the new Internet and multimedia-driven business required additional technology, business, and managerial capabilities. This capability gap was perceived to be growing wider until Elisa's top management decided in 1998 to start building capabilities by establishing a product/service-oriented business unit called Smart Home (which later became HCB) and provided funding for further network projects.

The first 'real' business network aimed at new multimedia-technology-based business was Arenanet (A-net) (see Figure 2, Picture 2). The driving vision behind Arenanet, a coalition of culture and technology triggered by the City of Helsinki, European Cultural City of 2000 project, was to offer broadband-based services to every single home in Finland (Lehmus, 1999). The ambitious objectives of "Helsinki Arena 2000" were: to create a virtual Helsinki, a next generation multimedia network environment for Finland's capital city, to provide a forum for citizens, and a place where culture and business could meet (Salmi, 1999; Tenhovuori, 1996). By joining this network, smart home group (HCB) was aiming to create competitive advantage in this area of e-business, to strengthen both its role and its image, and to expand its customer base. It was a deliberate strategic move to combine Smart

Figure 2a. Picture 1: Equal partners in a network, (PALMU): Technology project-network with cooperation with competitors and institutions and international forums

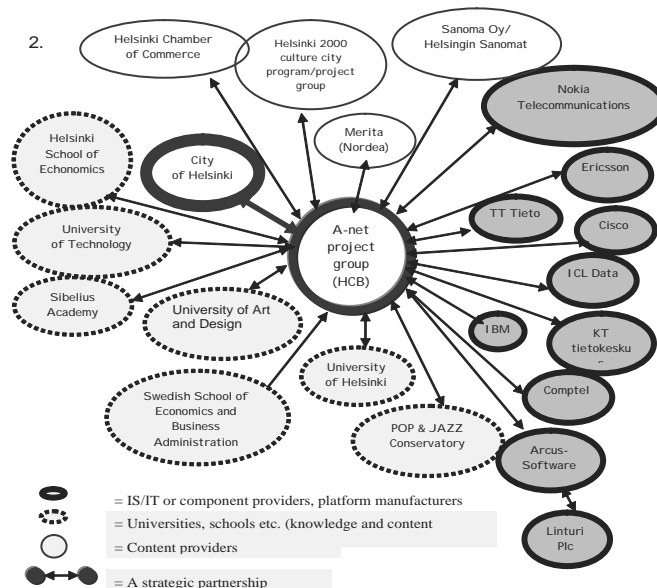

Home's (HCB's) technological knowledge with new business development.

Actors in Arenanet (A-net) were chosen primarily for the purposes of creating a broad-ranging service and information base for an "information age city." The actors in this network were both global players like Nokia, Cisco, and Hewlett Packard as well as national players like Elisa, Linturi, and the city of Helsinki. Relationships in this network were controlled and coordinated by the A-net project group in the case company and this group later became part of HCB. A-net also initiated a change from the strong emphasis on the relationship with Comptel towards increased networking with other businesses. A-net was a complex, temporary business network attempting to combine the knowledge and capabilities of several actors, but there was no clear view on how to manage network relationships or how to maintain the actors' interest in the cooperation. Smart home (HCB) and A-net project group it-

self lacked a clear vision of where this business development might lead, and especially whether and how it could be made profitable.

The exploration shows that rather than being a real business network, A-net was still more akin to R&D, a project for gaining experience of how to be in the multimedia and Internet-based business. On the other hand, A-net proved invaluable as a means of learning and establishing relationships. The hub company gained important knowledge of this type of networking and cooperation, which involves issues such as the types of resource and capability required, how to continue in the multimedia and Internet-based business, and determining the types of service that would interest consumers. The A-net experience helped the key members of the smart home (HCB) realize that a network is an entity to be taken care of and that in business networks, there are different actors and different roles.

Picture 2b. Arenanet (A-net): A coalition of technology and culture

Creating Competitive Advantage

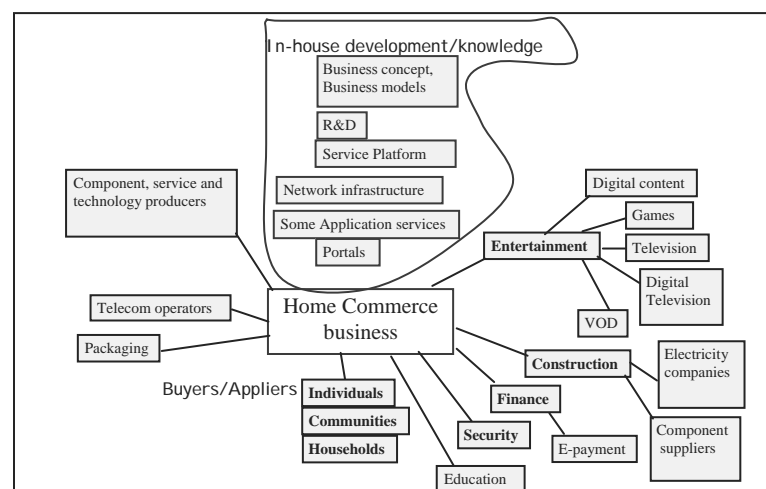

One important realization was that the primary reason for some actors' participation in the network was to gain knowledge and experience, which they could use in their own projects and in creating competitive services. Although a management board to control and coordinate the development of A-net existed, it did not effectively manage the roles of actors involved and the network's future development. A-net was also the first project in which actors from several different industries were involved and doing business together with HCB. The network was closed down in the end of 2000.

Even if the A-net was not a success from the business point of view, there was a consensus that networking is essential when dealing with multiple technologies and platforms within several industries. The experience confirmed that, in a context where knowledge is sophisticated, expanding and widely dispersed, the innovation and commercialization must be carried out through collaborative networks. Based on experience resulting from A-net, the case company initiated the *megahouse* and *megahome* project networks targeted at further development of the technology architecture and

basic services, as well as new home commerce services. They became so called mega concept. What differentiated the mega-concept from previous collaborative networks were the advantages resulting from being the first actor in this area and its foundation on risky and bold resource commitments. However, the successful integration of technologies, marketing, and innovative business models did not automatically translate into a sustainable strategy and advantage, the construction of organizational-specific dynamic capabilities was required.

In the mega-concept's value net, HCB's roles were as the hub, for example, the intermediary and the value chain integrator. HCB integrated the value chains of several industries. It also developed and provided the collaborative platform. HCB designed the net's architectural structure. It created a virtual community solution for households (Kotiportti™) and for teachers and students (Efodi—the e-learning space). In accordance with this, HCB provided the security solutions and services because Datatie, a subsidiary of Elisa, had provided those services previously. Those services were now integrated to the same interface

Figure 3. Overview of the home commerce business (HCB) and industries involved in mega-concept

and platform by HCB. The roles of the other actors were as software, component, device, application, content and service, access and network providers (i.e., Internet, broadband, fixed, or wireless network), as well as infrastructure and platform manufacturers. When comparing mega-concept to A-net, the main difference was that in A-net, HCB was not capable of preventing opportunistic behavior. Figure 3 shows the different industries involved in mega-concept.

The number of competitors in the future home market was few during the early phase but there was a proliferation of competitors by the beginning of the 21st century. The basis of competition became more defined. Initially, it was a question of attracting customers and building customer base. The vision for the future home and home commerce business was to maintain its position as the pre-eminent provider of home commerce services and information. To achieve that goal, HCB had to continue to enhance both content and site services and further diversify revenues, achieving cost savings through process redesign in order to remain dynamically efficient in the future.

Learning new technologies, integrating and implementing them into a business context underlay the main learning race within the ICT-sector during the 1990s. The capabilities developed around these new technologies and the businesses based on them were the source for HCB's competitive advantage. Moreover, the results show that an innovative actor has to be able to develop capabilities in network management. Without these managerial capabilities the actor is not capable of influencing, orchestrating, and mobilizing the other net members.

In addition to the strong competence learning, as well as service technology and concept development, the 1998-2000 period can also be characterized as the top management team of the HCB 'giving promises' to the corporate management and other constituencies. This relates to the question of communicating the potential growth

and profitability of multimedia and Internet-based business. This intra-organizational agenda "selling" resulted in HCB being given the resources it required to participate and mobilize all the development networks, and resulted in HCB achieving leadership in ADSL connections and the leading position in smart-home/future-home solutions (e.g., KotiporttiTM, household monitoring and home security systems, digital television services) in Finland.

The Stabilization Phase 2001-2003

The years 1998-2000 were time of the 'IT-boom' and "e-hype" in Finland as well as in Europe. During that time, Elisa's R&D was allowed to test and fine-tune their products to be perfect in every way possible.

However, the years 2000-2003 showed unpredictable economic situation in the ICT-sector, and R&D investments were expected to have a short pay-back time and there was no extra time to spend in perfectionism in product designs. The years 2001-2003 showed the impact of exogenous factors, such as the burst of the "IT-bubble" and associated declining profits in the ICT-sector, in Elisa in many ways. The impacts seen included:

- **At a business level:** termination of unpredictable business, concentration on core and profitable products and services, the pruning of non-core business, the analysis of future business possibilities, and the investment in promising technological and business areas
- **At the organizational level:** the retrenchment of employees, the restructuring of the organization
- Customer service was considered to be more important than in the years of rapid growth and expansion seen during 1998 to 2000.

The reduction of investment in R&D affected HCB to the extent that the new product develop-

Creating Competitive Advantage

ment was terminated and HCB instructed to concentrate on their core business and key products like ADSL and Kotiportti™. Processes and interfaces of services underwent tuning to increase efficiency. Senior management's key motivation in investing in the new home commerce related business projects was because they saw these as a way to enhance current businesses and create new business opportunities. Organizational restructuring affected so that a couple of new emerging businesses were merged to HCB.

The formation of internal networks to focus on certain R&D areas of the business had changed within the case corporation. Whereas, in the 1990s, R&D was focusing on single technology pilots, in 2001-2003, the focus was on business issues and technologies related to that business.

In addition to networking within the case corporation, external partners were more precisely assessed, chosen, and classified not only for today's business needs but also with regard to future business needs. HCB's management needed to focus its attention to dynamic resource flows between actors in a business network. The managerial capabilities were needed to steer external resources toward supporting network's objectives. HCB retained only those activities to itself in which they excel over any other players in the markets. The management in Elisa was also required to have collaborative process design and management tools such as Elisa tried to develop in its knowledge management (KM) platform in late 1990s. The competition was not only between companies but also a competition of resources capable of adding the most value to the network.

Technological knowledge, the fast pace of technological developments and the business possibilities offered by the integration of technologies and businesses required more resources than HCB had originally envisaged. The concentration of business activity in an area, in which they performed optimally, including broadband,

home automation and future home solutions, was sufficient for HCB.

HCB had realized that the formulation of a business plan and the collective strategy of a network involved understanding the structure of each industry engaged in the network, finding the competitive advantage and determining how a business house will compete in the markets. HCB had learnt that growing a new business involved the establishment of partnerships with prominent companies, seeding the market and encouraging partners to participate in the creation process of a new business.

In HCB's internal service development, its role initially changed from product and service developer to platform developer and provider, eventually moving towards a role as service environment-provider in which the service environment included homes, buildings in general, and communities.

Role of Networks in Creating a Business and Management Capabilities

The descriptive analysis of the construction of a radically new business group highlights the relevance of networks in this process. It also provides insights into the building of dynamic network capabilities through collaborative networks. The nature and goals of networks and networks changed in a systematic manner as HCB developed during 1999-2003.

In an entirely logical manner, the early years (1990-1997) were characterized by participating in and mobilizing networks for the development of technological knowledge. The strategic alliance with Comptel, the multimedia projects and R&D networks, and participation in the Finnish Technology Agency (TEKES) financed e-payment project network, and all were crucially important in helping HCB to create the technological platform it needed to start offering Internet and broadband-

based services to businesses and consumers. Through this collaborative networking, HCB's core team learned that, in addition to the specific technological capabilities, it is essential to have networking capabilities, such as partner evaluation and selection, multiparty-project participation, and management. Because of the number and continuity of these primarily project-based networks (see Figure 1), HCB was able to build routines and a managerial infrastructure that turned primarily into people-embodied competencies with dynamic organizational capabilities. In conceptual terms, this process is termed as the experience accumulation and knowledge articulation learning mechanisms as suggested by Zollo and Winter (2002)

Furthermore, participation and the coordination of the A-net (the network coalition aimed at turning Helsinki into an e-city) was a turning point where the emphasis in HCB's network mobilization shifts from technology cooperation to business development. The A-net experience sensitized the HCB management team to the necessity of developing a network management capability; the careful selection of network members, and the provision of comprehensible roles with specific responsibilities, direction, and coordination. Development of these capabilities was carried out in the large, multi-firm and multi-industry networks (*megahouse* and *megahome*), which further emphasized aspects of network mobilization and management capability such as negotiating skills and the creation of new forms of contracts.

Another major learning experience that was already perceived during late R&D project networks, but really accentuated by the disappointment of not achieving any direct business objectives with the A-net, was the realization of the crucial role played by new business models in home-centered, Internet and broadband-enabled e-business. Without a clear and jointly agreed view about the earning modes and shares of each

network member (e.g., operator, software provider, content providers, portal owner) the network management functions faced continuous conflicts and inefficiency. In brief, a good network mobilization and management capability was highly dependent on the focal actor's competence in designing effective and attractive business models.

What enables a management team to design a good business model in a fast developing business sector? Accumulated experience gained from several networks and from participation in industry-wide forums provided the HCB team with a visioning capability for the unfolding business sector. This allowed them to assess the business opportunities from the perspectives of potential network members and led to viable and mutually attractive business models. This "framing capability", which makes it possible to create an overarching view of the architecture of a business group in which the value-systems of different business sectors merge, is very hard to achieve. On the basis of the case evidence, it appears that the HCB team was able to accomplish this.

As a team, HCB was considered more of a profit and innovation center than a cost center and they were encouraged to develop through internal training programs and through different technology networks. Also, they did their own market research.

This case of HCB could also be seen as a case of intrapreneurship—fostering entrepreneurship within an established organization. HCB's management team put together team of enthusiastic volunteers, sponsored by Elisa's senior management. It was a way for an established organization to find new markets and new top products. HCB's team could be considered as inventors as they stepped out of their traditional roles within the established business, they were creative and took risks. Moreover, they worked towards minimizing the risks using the collaborative networks to more efficient and effective product production and sales. The success of HCB also showed a

way to increase the speed and cost-effectiveness of technology transfer from research and development to the marketplace. It also seemed that success was based on the organizations ability to take on concurrently multiple and contradictory business elements through an organizational managerial structure that combined a mix of self and centralized government.

CONCLUSION

This study makes several contributions to the evolving theory of network management. It provides empirical evidence for the crucial roles played by different types of networks and networks in both the emergence of a radically new business group and in learning the managerial capabilities required to not only survive in this context but also to create it.

Different alliances, project networks, R&D forums, and large-scale project networks provided different types of learning experiences. In brief, they provided the case company with different resources and knowledge; in other words, they fulfilled the different functional needs that evolved during the evolutionary process. The author contends that a core management capability in this type of environment is the ability to utilize the available networks and mobilize one's own networks to meet the resource and learning needs that exist. This is not, however, an organizational capability which is inherent. It presumes two aspects—visioning and networking resources and capabilities. Firstly, a comprehensive or “architectural” view of the field, which enables a company to envision its development, at least a few steps ahead. Through visioning, an actor can anticipate the technologies and other capabilities it must develop. Visioning alone is not enough; the resources to carry out networking must also exist. In the phase where an actor wishes to mobilize its own strategic network, it must also be able to offer an attractive development agenda or business

model if it is to engage partners with cutting-edge knowledge in their own areas of operation.

This “functionality” perspective on the role of networks suggests that firms with an “architectural” vision and adequate resources can, through network relationships, purposefully attempt to create an extended pool of resources and capabilities that matches their current and foreseeable needs. If this attempt is successful, a success circle may result.

In addition to this functionality aspect of network collaboration and network management, the case analysis highlights the relevance of understanding the process-like nature of capability development. Only after exposure to a variety of continuing networking experiences, the management team of the case firm was able to identify and systematically start developing network-management capabilities. This provides additional support to the experimental learning view of dynamic capabilities (Zollo & Winter, 2002). As seen in this case, the intelligence in a network structure is its ability to share, modify, create, and distribute information, knowledge, and resources among the different parties, and thus develops and creates network capabilities that can change and dynamically develop over time (see also Möller et al., 2003; Möller & Svahn, 2006). Creating competitive advantage with the capabilities developed and acquired, the case company succeeded in gaining the leading position in ADSL-services at the end of the 1990s which supports the earlier studies of creating competitive advantage (e.g., Penrose, 1959; Rumelt, 1974; Wernerfelt, 1984; Barney, 1991). On the other hand, since network participation also has the character of an investment, as emphasized by the industrial network theory (Håkansson & Snehota, 1995), creating a variety of resources and gaining the knowledge cannot be achieved without an associated cost. Taken together, these findings provide support for and expand the extent of discussion on network capabilities.

These findings have important theoretical and methodological implications. First, they support the industrial network approach (Håkansson et al., 2004) and the Resource Based View in emphasizing the key role of combining the heterogeneous resources controlled by various actors in order to be able to create new technological and business solutions.

Moreover, knowledge of processes, particularly in relation to tuning R&D processes, in late 1990s made it easier for HCB to create a competitive advantage. The corporate vision provided a continuity of direction, which allowed HCB to create unique skills and capabilities and to build a strong reputation of superior technical knowledge in certain new technology areas (cf. Porter, 2001, p. 71).

Cognitive aspects of social capital can be seen as human-related aspects and motivation for collaboration (e.g., Nahapiet & Ghoshal, 1998; Anderson & Jack, 2002). From the focal actor's perspective, this study shows that in the relationships involving actors and networks related to the supply-side; for example, research and development activities, as well as in/out-sourcing of components and platforms required in software and platform development and production, the cognitive aspects of social capital providing value to software vendors include capabilities in both current technology, as well as in emerging future technology. In addition, innovativeness, flexibility, and adaptability seem to be linked to cognitive capabilities of the network actors. These relationships involve actors and networks facilitating and supporting business; for example, those partners who do not directly contribute to the value-creation process, cognitive capabilities are related to business strategy, marketing, and management.

As a conclusion, the emergence of a new business is clearly a combination of the evolution of technological and market factors which are not controllable by any one actor, rather it is accu-

mulation of the intentional strategy of developing collaborative forms—alliances, partnerships, and strategic networks—by the focal actor. First, this study shows that a focal actor can clearly promote its business by developing its business and social networks as seen in this case study. Without this strong intention or strategy, the focal actor would not have been able to develop its position in the emerging new Internet and mobility related services. Second, the results show that an innovative actor has to be able to develop capabilities in network management. Without these it cannot influence and orchestrate the other actors whose resources and competences are required in creating the technological platforms underlying new business services nor the services themselves. Network management was seen to be composed of such strategic level competencies as being able to design differentiated strategies for different types of networks, perceiving the networks and partnerships as an interrelated portfolio of collaborative forms, and being able to develop different contractual forms for different type of collaborative forms.

Finally, the global ICT-policy making addresses primarily the removal of all obstacles that might stand in the way of the unconstrained operation of the various international ICT actors on markets. Scope and direction of national ICT-strategies are influenced by the emerging global systems of the ICT-sector's governance. A successful national ICT-strategy as a part of a global ICT development can assist in the development of flexible and decentralized industrial production and R&D business networks, and thus, improve the competitive position of local ICT-suppliers in national markets against the global competitors. Through business networks, new global communities are being established. Increasingly, organizations in various countries are integrated into these webs of horizontal and vertical information and knowledge exchange. However, the biggest challenge for both the

national and global ICT-strategies are to ensure the sustainable growth and the development of the ICT-sector and ICT-related capabilities and skills. This sustainable development will not be possible only through technology development but by development of national and international policies. Business networks can offer new sources of innovations and knowledge, and thus, assist in developing the skills and capabilities needed in national ICT-development and assuring the competitive advantage locally or internationally.

Future Research Directions

ICT has been recognized as a major catalyst for socioeconomic development, therefore, the experiences and information of the usage of ICT are of key importance. ICT can be used in service of broader strategic objectives in a number of development sectors, for example: health, military, education, e-commerce, and e-government. Many innovative partnerships between governments, businesses, and private companies have been formed to build collaborative networks and deploy advanced ICT applications both nationally and internationally. However, we still lack the analytical and political tools to better conceptualize the business-university-government networking, and the role of each partner in the strategic ICT-development. Due to this networking, we also need tools to evaluate the processes and working methods cross different industry and organizational boundaries. Interaction in ICT-developmental projects between organizations is undertaken with intention to achieve an economic goal, with strategic objectives being implemented to obtain final economic rewards. Further, economic goals involve some overlapping of self and collective network-level interest. And probably, there is some disparity between interacting organizations on their combinations of expected self and collective network-level interest in the collaborative networking.

In addition, we need new frameworks to monitor and evaluate ICT-enabled projects and their role in national, economic, and/or business development. Measuring the benefits and failures of ICT development is particularly interesting because available data is limited. Collaborative networking in ICT-projects is difficult to track and there is a lack of exact data to serve as the basis for wide-scale policy decisions.

ABSTRACT

This chapter looks at the origins and evolution of microfinance and explores some of the challenges faced by microfinance institutions (MFIs). It examines the costs and benefits of using ICTs as a means of increasing the effectiveness and efficiency of MFIs enabling expansion and outreach to remote populations. Specific technologies such as smart cards, PDAs, and MISs are explored in detail and case studies are provided. MFIs can also use ICTs to facilitate income-generating opportunities for borrowers, and the case of Village Phone will highlight this potential. It is hoped that this chapter will advance the case for the continued use and research into the synergistic combining of microfinance and ICTs.

INTRODUCTION

In the international development community, there have been numerous discussions on methods for reaching the millennium development goals (MDGs)¹ by 2015. Stakeholders from all walks of life have many suggestions for eradicating poverty from this world where 1.2 billion people still live on less than \$1 a day.

Poverty-intervention tools will be of vital importance if we are to achieve the MDGs, especially the goal of reducing the number of people living in poverty by half by the year 2015. It is acknowledged that:

access to financial services provides the poor with the means to make improvements in their lives—in other words, to achieve most of the MDGs—on

their own terms, in a sustainable way. Access to credit, savings, or other financial services is only one of a series of strategies needed to reduce poverty and achieve the MDGs.²

Microcredit and microfinance, which involve providing financial and other services to the poorest³ people in developing countries, has proven to be a practical way to assist them in working their way out of poverty. Microcredit refers to small collateral-free loans targeted to the poor, provided by a bank or other institution. Microfinance involves not only loans, but also other financial products such as savings, insurance, and transfer services to the poor.

Microcredit and microfinance are recognized as effective tools for the reduction of extreme poverty and the creation of sustainable economic development. It is in the best interests of those living in poverty that the most effective strategies for reducing and even eradicating poverty be identified and implemented. Whether poverty is created because of the death of the head of a family, changes in economic policies, wars, or natural disasters such as a tsunami, poverty alleviation requires that the best alternatives be found to help poor people build their lives. As poverty-reduction tools, the strengths of microcredit and microfinance are that they are sustainable over the long term and also encourage the independence and self-sufficiency of their recipients.

The concept of microcredit originated in 1976 in Bangladesh when Professor Muhammad Yunus lent money out of his own pocket to prove poor people were bankable and creditworthy. Over the last 30 years, microcredit has evolved to the point where the United Nations declared 2005 as the International Year of Microcredit. According to a United Nations Development Programme (UNDP) administrator Mark Malloch Brown:

microfinance is much more than simply an income generation tool. By directly empowering poor

people, particularly women, it has become one of the key driving mechanisms towards meeting the Millennium Development Goals, specifically the overreaching target of halving extreme poverty and hunger by 2015.⁴

Information and communication technologies are considered tools for poverty reduction. Hans d'Orville (2001, p. 1) states that "in the developing world, information and communication technologies (ICTs) are proving formidable and cost-effective development tools. Properly used they can reduce poverty; empower people; build capacities, skills and networks." ICTs⁵ have been identified as mechanisms to help microfinance institutions (MFIs) overcome their operational challenges when expanding in remote and rural areas. Brown (2001, p. 1) said "he is convinced that ICTs can help us reach the targets established by world leaders at September's Millennium Summit, including the goal of halving poverty by 2015."

The challenge for microcredit and microfinance institutions is to fulfill the large unmet demand for financial services. The expansion of financial services to reach large numbers of the poorest of the poor is an obstacle confronting many MFIs. MFIs are faced with high transaction costs and institutional inefficiencies that inhibit their ability to reach the underserved segment of the population in remote rural areas. ICTs working in synergy with MFIs can assist in the efficient delivery of credit to the poor, in creating income-generating opportunities for the poor, and in further enhancing the outreach of MFIs to the marginalized poor in remote rural areas. ICTs can reduce poverty by improving the ability of the poorest people to access financial services. In fact, Attali (2004, p. 1) states that "new information and communications technologies constitute essential factors in the growth and ability of a microfinance institution to build capacity and are consequently vital tools in the fight against poverty."

The need for MFIs to lower transaction costs and to expand the scale of the delivery of their financial services to the remote rural poor in regions such as Latin America, Asia, and Africa make experimentation with innovative technologies by microfinance organizations attractive. The current utilization of ICTs such as the standard management information system (MIS), smart cards, personal digital assistants (PDAs), cell phones, and other technologies allow MFIs to service their clients more efficiently through “the reduced amount of paper work, access to information and ability to compute complex analyses” (Siu, 2001, p. 1). The integration of ICTs into MFIs is a relatively recent development, and there are many unknowns associated with its execution. This chapter explores the implementation of some of these new technologies by MFIs and the associated benefits and pitfalls. One publication⁶ concluded that “ICTs will continue to impact microfinance operations worldwide. As prices of relevant technology like ATMs [automated teller machines], biometrics, voice recognition, smart-cards, and PDAs continue to fall, more MFIs will be able to take advantage of the benefits they offer” (p. 4). ICTs show great promise for microfinance institutions with respect to efficiency, scale, and outreach.

There are concerns that providing access to ICTs could exacerbate the existing digital divide. However, it is shown that ICTs integrated through poverty-focused programs has been instrumental in narrowing the digital divide. Broadly, the digital divide is the wide technological disparity between countries (North and South) and between groups (rich and poor, men and women, rural and urban) within developing countries. It is a major challenge for our information- and knowledge-based world to overcome this digital divide; however, there is no question that ICTs can be used to facilitate groundbreaking initiatives for poverty reduction in the developing world. Gilhooly (2001, p. 1) says that “the sooner the world accepts it, the sooner

ICTs will play a possible crucial role in the global effort to reduce poverty and create a better life for all.” The divide will persist if left alone. Commitment from various stakeholders and sectors can aid in diminishing the divide. As with other stakeholders such as the United Nations, Canada recognizes the growing divide and has a “commitment to closing the digital divide through domestic innovations, an ICT agenda, involvement in the G8 Digital Opportunity Task Force (DOT Force) and investments in developing countries” (*CIDA’s Strategy on Knowledge*, n.d., p. 4).⁷

In short, it is widely acknowledged that the business of fighting poverty is not an easy task, and it is equally accepted that neither microcredit and microfinance nor ICTs are answers in themselves for solving all development problems, but they can be used in combination as tools for poverty reduction. Brown (2001, p. 1) says, “as with all tools, the usefulness of ICTs depends on how they are employed.” The convergence of the ICT and microfinance sectors strengthens the possibility of reducing the inequities of poverty. Attali (2004, p. 1) further states, “*ICT can play a major role in the fight against poverty and at the same time, it is precisely in the context of the fight against poverty that these new technologies can help to reduce the digital gap most effectively.*” The synergy and partnership of stakeholders in and across both the ICT and microfinance sectors provide huge promise in the attainment of the MDGs, especially the goal of halving poverty by 2015.

THE EVOLUTION OF MICROCREDIT

The Origin of Microcredit

Professor Muhammad Yunus, an economist and former professor with the University of Vanderbilt in the USA, is credited with originating the concept of microcredit in 1976. At that time,

Yunus had returned to Bangladesh where he was teaching at the University of Chittagong. He realized the economic theories he was teaching were not solving the problems of the poverty-stricken people outside his own classroom. As part of a research project, and out of his own pocket, he loaned \$27 to about 42 villagers to finance their tiny businesses or income-generating activities. They all repaid their loans and made a profit. He then used his own savings as collateral with conventional banks, cosigning for more loans to lend to the poor. Despite numerous successful projects in several villages and regions of Bangladesh that demonstrated the poor do repay their loans, Dr. Yunus was unable to convince traditional banks that poor people are creditworthy. To address this situation, he founded the Grameen Bank in 1983, thus starting the revolutionary innovation that came to be known as microcredit. Until this time, poor people were at the mercy of money lenders who charged exorbitant interest rates that often forced the borrower into deeper poverty.

The Grameen Bank is owned by the poor. They are stockholders and hold positions as board members. Grameen Bank has now reached over 6.1 million borrowers in Bangladesh, 96% of whom are women, and has proven itself as an innovative leader in bringing credit without the requirement of collateral to the doorsteps of the poorest of the poor. It has loaned over US\$5 billion with loan amounts averaging less than \$200, and can claim an exemplary repayment rate of 99%. Fifty-five percent of Grameen borrowers and their families have raised themselves above the poverty line, and the remaining borrowers are moving in the same direction.⁸

The word microcredit means the provision of small collateral-free loans to the poor, most of whom are women, for the purposes of self-employment. Grameen-style credit is based on the philosophy that credit is a fundamental human right, that poor people are creditworthy, and that they have inherent skills and abilities that are unde-

rutilized or not utilized at all. Loans are provided for income-generating activities and housing for the poor, but not for the purposes of buying food (consumption). Grameen delivers credit to the poor; the poor do not have to travel to the bank. Other Grameen loan products include savings deposits and insurance. The bank also encourages social empowerment through the formation of groups and centers where women are given the opportunity to take on elected leadership roles, and this leads to borrowers participating in the local government electoral process. The 16 decisions followed by all Grameen borrowers include the promotion of health, the growing of vegetables for consumption, the selling of any surplus vegetables, and the education of their children.

In 1989, Grameen Trust of Bangladesh was created to support Grameen replication programs worldwide. It provides training, financial, technical, and other support to microcredit practitioners and replicators of Grameen-type credit and savings programs. One hundred and thirty-eight Grameen programs have now been replicated in 37 countries. Some include adaptations suited to a country's unique environment, but each maintains the Grameen Bank's philosophy. In 2004, the Grameen Trust introduced a new program called the Grameen Build, Operate, and Transfer (Grameen BOT) program. Where Grameen Trust normally relies on partnership organizations to implement a microcredit program, it has moved to into directly implementing programs especially in countries in difficult situations. It identifies a country and recruit staff to implement a program with the focus of targeting and reaching the poor and to achieve institutional and financial sustainability. This project has so far reached 7 countries including Costa Rica, Kosovo, Turkey, Zambia, and most recently Indonesia, serving the Tsunami affected individuals of the province of Aceh (Grameen BOT program, n.d.).

Microcredit Evolved into the Future

Microcredit, a concept involving lending or the provision of credit, has become a global initiative and has been adapted by numerous institutions in various regions of the world to include additional financial services or products such as transfers, deposits, insurance, and so forth. Credit with these additional services is often referred to as microfinance. Littlefield (2005, p. 1) further describes microfinance as:

driven by the simple idea that people in developing economies need access to affordable financial services that allow them to make deposits, transfer funds between urban and rural areas, and protect themselves through crop and life insurance. These services help individuals better manage risk and plan for the future, and provide an important buffer for sudden emergencies, business risks, and seasonal slumps.

Microcredit and microfinance institutions involved in the delivery of credit and other services include nongovernmental organizations (NGOs), cooperatives, credit unions, nonbank financial institutions, and some formal banks.

In the 30 years since the origin of microcredit, it has evolved from providing small loans to the poorest women to fund their income-generating activities into an international movement in which microfinance institutions are encouraged to become sustainable financial entities that serve regions where financial services did not previously exist.

In February 1997, over 2,900 participants gathered in Washington, DC, to launch the Microcredit Summit goal of “working to ensure that 100 million of the world’s poorest families, especially the women of those families, are receiving credit for self-employment and other financial and business services by the year 2005.”⁹ The Microcredit Summit campaign was instrumental

in the recognition of microcredit and microfinance as contributing factors for achieving the MDGs and in having 2005 declared as the International Year of Microcredit by the United Nations. In November 2006, the Global Microcredit Summit will be held in Halifax, Nova Scotia, Canada. At this meeting, a report on the progress of the 2005 goal will be presented, and the expansion stage of the campaign in support of the MDGs will be launched.

Many other independent initiatives are under way that emphasize the significance of microfinance as a tool to fight poverty. The World Bank and the Consultative Group to Assist the Poor (CGAP) are collaborating with national committees worldwide. Their goal is “to raise awareness of microfinance as a tool to empower and improve lives, in addition to developing strategies to face the challenge of scaling up resources to reach the estimated three billion people who still lack access to formal financial services” (Littlefield, 2005, p. 1).

Microcredit and Microfinance as Poverty-Reduction Tools

Who are the poorest people? The face of extreme poverty can be seen in Nibha Rani Sharkar, a borrower of the Grameen Bank. In a 1995 interview, she described how the Grameen loan program transformed her life and the lives of her children. Her husband died and she was left to raise their three boys, ages 3, 8, and 12. Before receiving a loan from Grameen, she could not afford to feed her children. She and her oldest son worked at another villager’s home as domestic servants, and in return they received a daily kilogram of rice. The children were fed mostly on rice mar, the drained liquid from the boiled rice. With her first loan of \$50 from the Grameen Bank, she bought a cow and sold the milk to earn an income. Two years later, she sold that cow, made a profit, and bought two others. Within 5 years, Nibha owned

several cows, chickens, and three fourths of an acre of land. Her children are now all in school and eat three healthy meals each day. All microcredit and microfinance programs worldwide—in Asia, Africa, the Middle East, Latin America, and the Caribbean—have similar stories to tell of their programs' impact on the lives of their clients as they lift themselves out of poverty. Microcredit and microfinance work to empower these individuals to lift themselves out of poverty and become self-sufficient.

Microfinance is by no means a panacea, but it is a powerful poverty-reduction tool, and its impact on the MDGs is far reaching. Morduch, Hashemi, and Littlefield (2003) conclude that access to financial services reduces poverty, and its effects are demonstrated in multiple ways. Access to microfinance services therefore become the basis for which other essential interventions depend. This is further explained when they state that:

evidence from the millions of microfinance clients around the world demonstrates that access to financial services enables poor people to increase their household incomes, build assets, and reduce their vulnerability to the crises that are so much a part of their daily lives (and this) also translates into better nutrition and improved health outcomes, such as higher immunization rates. It allows poor people to plan for their future and send more of their children to school for longer. It has made women clients more confident and assertive and thus better able to confront gender inequities. (p. 1)

In terms of sustainability and the impact on the lives of the poorest people on a large scale, they further say, "Microfinance thus offers the potential for a self-propelling cycle of sustainability and massive growth, while providing a powerful impact on the lives of the poor, even the extremely poor" (p. 1).

The Challenges of Microcredit and Microfinance Institutions

Many of the poorest people worldwide still lack access to formal financial services and still have to rely on informal financing methods such as family members, savings groups, and money lenders. The central challenge is how to address the large unmet demand for microcredit and microfinance services for the poorest people. Magnette and Lock (2005) estimate that in 2004, the demand for microfinance services globally was 500 million clients, of whom only 80 million were served by the estimated 7,000 to 10,000 microfinance institutions that exist. Financial services to these 80 million clients reach mostly the urban and peri-urban areas. MFIs have difficulty reaching the rural, remote, and low population-density areas. They are faced with the challenge of finding ways to overcome these obstacles and increase the scale and depth of their outreach while still operating efficiently.

While the focus is on MFIs to achieve scale and efficiency to enable them to reach large numbers, they equally have to ensure that they are in fact not excluding the target population of the 1.2 billion people that live on less than \$1 a day. Reaching and having an impact on the poorest people is not an automatic process. Simanowitz and Walter (2002, p. 60) indicated that "conventional microfinance acts through both deliberate and unintentional mechanisms which exclude the poorest. Programs therefore need to be designed to include the poorest, and to facilitate mechanisms that will lead to poverty impacts." Furthermore, "achieving good poverty outreach is about providing the right products as far down the poverty scale as is possible" (p. 64). Two important measurements of poverty outreach are "working in the poorest areas of the country and working with the poorest relative to the population in an MFI's operational area" (p. 64).

For MFI practitioners who are committed to ensuring both targeting and outreach to the

poorest segment of the underserved, there are poverty-measurement tools¹⁰ that exist to help MFIs monitor the depth of poverty reached.

THE IMPACT OF INFORMATION AND COMMUNICATION TECHNOLOGIES ON MICROFINANCE INSTITUTIONS

What are ICTs?

ICTs are defined as the transfer of information and data and include both old and new converging technologies. *CIDA's Strategy on Knowledge* (n.d., p. 7) states that "ICTs such as radio, television, telephones, computers, and the Internet can provide access to knowledge in sectors such as agriculture, microenterprise, education, and human rights, offering a new realm of choices that enable the poor to improve their quality of life." This section will focus on the new and advanced ICTs as enabling tools for transferring data and information to aid the effectiveness and efficiencies of MFIs in order to extend services to the poorest people in rural and remote areas.

Below are descriptions for a number of enabling technologies that are of potential use to MFIs. An MIS is a core information system that includes such functions as portfolio tracking, internal control, accounting, data analysis, and internal and external reporting functions to help MFIs make appropriate policy decisions and manage information more effectively and efficiently. Credit scoring allows an MFI to analyze a client's historical data, while providing links between a client's characteristics and behavior with the assumption that those links will predict how clients might act in the future. Scoring technology can assist MFIs to analyze past behaviors of clients to better assess loan applications, develop more effective loan-collection methods, create more effective target marketing strategies, and increase client retention.

PDA's are small handheld devices that field officers can use to do financial calculations and manage both client and MFI information. With data electronically stored, loan officers can readily gain access to client information, which assists them in activities such as loan processing, reviewing clients' historical data, and monitoring loan portfolios.

Smart cards are small plastic cards that can easily fit into a wallet. They have an embedded microchip that processes information or stores data and works like an electronic passbook to facilitate savings, deposits, and money transfers.

Point of sale (POS) is a device or system that is located at a physical location often remote from a main branch such as in a retail outlet. It is able to perform some of the financial transactions normally associated with branch banking such as the transfer of funds from one account to another or from a customer to a retailer.

Mobile phones allow clients to use a cell phone to call into an automated system to conduct business transactions and to access and request information. They also allow clients to charge others for use of their mobiles, especially in regions without a regular telecommunications infrastructure.

An ATM is a machine that facilitates banking transactions that would otherwise be serviced by staff. It provides account information, accepts deposits, and aids cash disbursement and balance transfers.

Biometrics technology measures an individual's unique physical or behavioral characteristics such as fingerprints and voice patterns to recognize and confirm identity. This technology is used in association with ATMs and POS.

Interactive voice response (IVR) technology allows clients to access an automated system through standard or mobile telephones to do banking transactions and get other information such as office hours and branch locations.

Internet banking allows clients to perform transactions similar to telephone banking, which

include verifying account information, making bill payments and money transfers, and accessing new product information.

Appropriate and Enabling ICTs for Microcredit and Microfinance Institutions

In light of the challenges MFIs are facing in terms of high transaction costs and the lack of outreach to isolated and sparsely populated rural areas in regions such as Africa and Latin America, several microfinance institutions worldwide are experimenting with various new technologies to lower operational and transaction costs, improve efficiency, aid in accurately tracking operations, and expand scale and outreach. Frankiewicz (2003) indicated that in terms of institutional technology usage, CGAP's survey of 150 MFIs worldwide:

found that only about one-third of the MFIs in Southeast Asia and Africa are computerized, compared to more than three-quarters of the MFIs in Latin America, Eastern Europe and Central Asia. Worldwide, 46% of MFIs still have very low-tech systems, either manual or spreadsheet-based MIS. The remaining 56% have more advanced systems, either custom outsourced systems (24% of the institutions surveyed), systems built in-house (20%), or applications purchased off the shelf (10%). (p.p 14-15)

There are MFIs of varying sizes and ranges of experience. Smaller MFIs still utilize manual ledgers and spreadsheets for record keeping. However, the majority of MFIs require information system (IS) technology to help them track, report, and analyze information for internal and external use. ICTs or delivery technologies appropriate for MFIs usually start with the core MIS. Other IS technology includes a handheld device such as a PDA that records client information, smart cards, a client-held device that stores customer information, scoring technology, a means

of analyzing and forecasting client behavior, and connectivity technologies (broadband or VSAT, a wireless data connection through satellite) that transfer data to staff and branches.

The more advanced delivery technologies that larger MFIs and some banks use include low-cost and standard ATMs and cell- or mobile-phone banking. POS systems are often placed in public retail outlets for use with credit and debit cards, and allow clients to do electronic payments and other transactions. All of these technologies facilitate customer financial transactions such as deposits and payments, and cash withdrawals and transfers. Biometrics, the fingerprint technology associated with smart cards that assists with verification and security of a client's identification, is also used by MFIs.

Frankiewicz's (2003) seminar report made reference to Elizabeth Littlefield's statement:

Technology certainly has the potential to help us do the one thing that microfinance has not been able to do except in very few places thus far and that is scale up exponentially. It can do this by enabling a rapid expansion in access points through improving operations, profits, customer service and, importantly, outreach to underserved populations, especially in rural areas. (p.73)

The report further recounts the seminar discussions on enabling technologies appropriate for MFIs and access points or contact points where clients can gain access to financial products and services that provide them with greater flexibility and convenience. These enabling ICTs and access points are thus seen as an added bonus for MFIs in terms of customer service. The tables below describe the various technologies, state the requirements for implementation, list any associated advantages or disadvantages associated with use, and therefore suggest the applicability of these technologies for MFIs globally.

In addition, case studies are provided below to further illustrate the scope of available tech-

Table 1. Summary of access points and their enabling technologies¹¹ (Source: AfriCap Seminar: Information Technology as Strategic Tool for Microfinance in Africa; used with permission from AfriCap Fund)

Technology	Description	Requirements	Pros	Cons
Automated Teller Machine (ATM)	A machine that can furnish account information, accept deposits, effect balance transfers, and disburse cash	<ul style="list-style-type: none"> Reliable and affordable communications and power infrastructure Central database Ability to securely transfer currency to machines 	<p>For clients:</p> <ul style="list-style-type: none"> Convenient service Flexible account access Increased hours of operation <p>For MFIs:</p> <ul style="list-style-type: none"> Reduced transaction volumes and costs No staff needed to complete transaction Can attract savings deposits 	<ul style="list-style-type: none"> Expensive to own and operate Need for integrated systems Maintenance and cash refilling is costly Security issues (including transport of cash)
Mobile Branches	An ATM on a truck or a branch in a bus that goes from one village to another in rural areas that can be served infrequently (e.g., once a week). Combines ATM functionality with operational staff	<ul style="list-style-type: none"> Should be combined with smart cards and POS devices MFI staff capable of providing a range of services 	<ul style="list-style-type: none"> Full range of financial services Expands branch network to low-density rural areas Much lower cost than setting up a branch More secure than a permanent ATM Not dependent on telecommunication infrastructure 	<ul style="list-style-type: none"> Clients can only transact when the mobile branch is in the village Higher per-unit cost than ATMs Need a staff of two to three to drive and service the mobile branch Higher operating costs (travel distances, maintenance)
Point of Sale (POS) Device	Small machine located at a point of sale that can be used to authenticate the transfer of funds from customer to the retailer	<ul style="list-style-type: none"> Retailer buy in and support Solid communications infrastructure Centralized database Coordination between institutions 	<ul style="list-style-type: none"> Significant reduction of paperwork No need for data-entry personnel Immediate reconciliation of transactions 	<ul style="list-style-type: none"> Expensive to implement and operate Need for interinstitutional coordination and shared infrastructure

Enabling the Expansion of Microfinance Using Information and Communication Technologies

Table 1. continued

Technology	Description	Requirements	Pros	Cons
Smart Cards	Wallet-sized plastic cards with embedded computer chips that can process information or simply store data	<ul style="list-style-type: none"> Reliable electrical and communications networks Dial-up facility for updates Software integration between cards, readers, and central MIS Presence of associated technologies 	<ul style="list-style-type: none"> Store information No need for real-time connection Automated transactions More secure Quicker administrative functions Increased transaction accuracy 	<ul style="list-style-type: none"> Need to purchase associated technologies High up-front development costs Security issues with stored information
Mobile Phones	Permit client to request information from, or conduct business with, an automated system through a mobile phone	<ul style="list-style-type: none"> Solid MIS Centrally stored, real-time data Network availability at affordable rates 	<ul style="list-style-type: none"> Not reliant on poor landline phone infrastructure Permits access to rural clients Frees staff time 24/7 accessibility 	<ul style="list-style-type: none"> Lack of mobile network in rural areas High cost of operation Expensive to install and maintain Need for centralized database
Interactive Voice Response (IVR) Technology	Allows callers to request information from, or conduct business with, an automated system by speaking into a telephone or inputting information through its keypad	<ul style="list-style-type: none"> Easy and affordable telephone access for clients Centrally stored, up-to-date data Secure databases 	<ul style="list-style-type: none"> Can serve many clients at once 24/7 service Frees staff time for more personalized tasks (business counseling, collection calls) 	<ul style="list-style-type: none"> Need access to telephone services Initial costs between \$10,000 and \$50,000 for in-house system Need for central system to control personal identification numbers (PINs)

Table 1. continued

Technology	Description	Requirements	Pros	Cons
Personal Digital Assistants (PDAs)	Small, handheld digital computers that can run specialized programs to manage MFI and client data and perform financial calculations	<ul style="list-style-type: none"> Well-functioning MIS High-speed access to MIS data from branch offices Capable technical support Solid institution and good products 	<ul style="list-style-type: none"> Increased productivity of field staff Applicable to wide range of tasks Can run various software programs Can standardize procedures Reduced volume of paper records Reduced labor costs 	<ul style="list-style-type: none"> High initial and maintenance costs Long development process (9 months to 2 years) Need for custom-designed database applications
Internet Banking	Internet technology enables users to perform a variety of banking activities, including fund transfers, bill payments, and securities trading	<ul style="list-style-type: none"> Solid MIS infrastructure Centralized database Reliable and affordable communications and power infrastructure 	<ul style="list-style-type: none"> Flexible account access No staff needed to complete transaction Increased hours of operation Eliminates need for data-entry personnel 	<ul style="list-style-type: none"> Need Internet access and connectivity Need for integrated systems High initial costs Typically requires higher income and higher literacy rate
Biometrics Technology	Measures an individual's unique physical or behavioral characteristics to recognize and confirm identity	<ul style="list-style-type: none"> Reliable electrical power for card or biometric readers Solid processes and adequate staff Software integration between cards, readers, and central MIS 	<ul style="list-style-type: none"> Greater security Convenience for clients Local verification Speedy verification that does not require staff User identity is stored safely and is tamper free 	<ul style="list-style-type: none"> Time, money, and energy required for setup and maintenance Need to train users Slow user acceptance or user refusal System integration may require changes in other pieces of hardware

nologies for the delivery of financial services, including the basic MIS system, PDAs, smart cards, POS, low-cost ATMs, biometrics, and mobile phones.

Management Information System

Gibbons and Meehan (2000) claim that the use of MIS will improve efficiency and increase the outreach of microfinance institutions, which suggests it to be a necessary technology for MFIs. Therefore, as MFIs scale up activities to reach more clientele, a well-defined and well-functioning computerized MIS is required. A full and complete MIS would include all the systems an MFI would need to help generate, track, and analyze information efficiently on staff and clients, as well as provide management systems for effective decision making. Most MFIs have an MIS consisting of an accounting system and a portfolio-tracking system (financial products such as loans and savings), and other systems on client impact and human-resource management. The MIS provides management with an overview of the organizational performance to guide them toward their goals of poverty reduction and building a sustainable and efficient organization. It helps them review performance on products, staff, and clients. The MIS also aids in external communication.

Although it is not a replacement for good and effective management, MISs provide information that is useful in addressing management inefficiencies relating to staff morale, operational, and procedural problems. A well-functioning MIS can be the basis on which other advanced technologies are built to enhance MFI client outreach. In the case of the Grameen Bank, almost all of their branches (1,315, out of 1,609)¹² have access to a computerized MIS. At weekly meetings, branch field officers have readily available computer-printed information on borrowers' repayment schedules. If clients repay their loans

according to the schedule, nothing is written but their signatures; therefore, the field staff spends less time on paperwork and are able to give more time to the clients.

Personal Digital Assistants

PDAs are small handheld computers that run specific programs to manage the MFI, client information, and aid in financial calculations. PDAs are custom-designed to be compatible with the institution's MIS. For PDAs to provide maximum benefit, they need to have high-speed access to data from the MIS at the branch offices. PDAs are not a substitute for an MIS, but a supplementary tool. They allow loan officers to access information from their MFI while in the field. From the field, they can access an electronic list of clients with loans in arrears and arrange for loan collection, see clients who are ready to apply for their next loan, and easily obtain background information including client data and records. From certain locations they can update their client records to the head-office MIS immediately or daily, thus reducing the need for data-entry clerks.

MFIs are exploring the use of PDAs to improve performance on a number of levels such as standardizing the institutional methodology and operating policies, aiding in the effectiveness and efficiency of loan officers, improving accuracy in data collection and reporting, and obtaining access to information while in the field.

As a result of the growing competition in the microfinance sector, particularly in Latin America, many MFIs are forced to lower operational costs and improve services and are therefore looking to PDAs to reduce the relatively high cost of labor. PDAs have been used as a microfinance tool since 1999 when they were first introduced by two Mexican MFIs, Compartamos and FinComun.

ACGAP IT Innovation Series paper evaluated the use of PDAs in 10 Latin American institu-

The findings reported by Waterfield (2004) for the Latin American case studies

MFI	Results
Adopem - Dominican Republic	<ul style="list-style-type: none"> • Improved client retention • Time frame for loan delivery reduced from 5 to 2 days • 60% reduction in paperwork • 50% reduction in data-entry cost • 35% increase in productivity of loan officers
BanGente - Venezuela Banco Solidario -Ecuador	<ul style="list-style-type: none"> • Improved efficiency of work flow • Decreased operational cost (both of these results were not quantified)
Microfin - Mexico	<ul style="list-style-type: none"> • Time saving noted by field staff • Improved consistency of work
Compartamos - Mexico	<ul style="list-style-type: none"> • Suspended use due to different priorities • Management believed PDAs were implemented too early • Difficulties and interface problems between MIS and PDAs

tions, as well as one MFI in the Philippines and one in India. The findings reported by Waterfield (2004) for the Latin American case studies are as follows.

The Waterfield (2004) survey indicated the following benefits of PDAs:

- Assisted in the standardization of the work process
- Increased the accuracy, productivity, and efficiency of field workers
- Improved loan delinquencies
- Improved management of time by field staff
- Increased accuracy and faster credit-approval process
- Decreased paper records

Smart Cards

Smart cards are similar to debit or credit cards in that they are made of plastic and are sized to fit into a wallet. Microchips (microprocessor and memory chip) are imbedded into the smart cards, and these allow for the storage and processing of data.

Smart cards can be used by MFIs to automate client transactions. They store all client savings, loan, and other product information. They operate like a debit card, an electronic passbook, or a credit card in that transactions are recorded once electronically, and this speeds up the transaction process and increases accuracy. For security purposes, smart cards also store clients' fingerprint images, and these are compared to images taken by biometric scanners during transactions.

Smart cards assist MFIs to reduce the volume of paperwork, decrease transaction times, and reach more clients.

The following are the experiences of three MFIs that used smart cards and combined them with other technologies.

SKS (India)

In 2001 and 2002, Swayam Krishi Sangam (SKS) of southern India implemented a 1-year pilot project with smart cards combined with PDAs. The objective was to increase the productivity of loan officers by saving time during client-centered meetings, decrease the number of errors produced by a manual recording system, and provide quick access to data for reporting and monitoring by management. SKS also intended to create a technology infrastructure through which other services could be facilitated—including emergency loans, credit scoring, automated cash access, and real-time application processing. The smart cards cost SKS \$3.40 each.

After 1 year's use of the combined technology (PDA and smart cards), SKS reported an increased accuracy in the recording of transactions and increased efficiency in the delivery of information to the central MIS. However, a significant increase to the productivity of loan officers was not realized as field officers increased their efficiency in manually recording transactions.

SKS suspended its use of smart cards because of the high up-front costs (over \$125,000) to develop the technologies. Even though SKS did not continue using this technology because of scarce resources and the high implementation costs, the pilot project proved that poor and illiterate people are able to use and understand technological devices, thus “making technology a viable infrastructure for providing additional services in the future” (Whelan, 2004, p. 3).

Prodem FFP (Bolivia)

In 2000, Prodem FFP, an MFI in Bolivia, partnered with Innova (a local software firm) to introduce smart cards. The goals were to reduce operating costs for services to rural areas and to eventually create a low-cost ATM referred to as Smart ATM (SATM). Innova developed the software to have the smart card furnished with client identification data that included fingerprint templates, and also with client financial data from the Prodem Financial processing system. The smart card facilitated withdrawals, currency exchanges, deposits, money orders, and other services.

A number of benefits were derived from the implementation of smart cards. The smart cards significantly reduced the wait time for clients; for instance, clients no longer had to line up to check their balances. Also, transactions were automated, which increased accuracy and security and helped protect user identity. The smart card served as an electronic passbook, and this eliminated paper transactions and allowed clients to perform a wide range of financial activities such as buying money orders, making currency exchanges, and making deposits and withdrawals. The integrated technologies of smart cards, ATMs, and fingerprint identification (biometrics) provided a competitive edge for Prodem PPF, and it attracted more depositors because of its quick and convenient service. Smart cards hold the flexibility to add other products that may be implemented in the future by Prodem FFP.

Microfinance Networks (Uganda): The Remote Transaction System

In 2002, Hewlett Packard joined with seven organizations (Foundation for International Community Assistance [FINCA] International, ACCION International, Freedom from Hunger, BizCredit, Echange, PRIDE Africa, and Gra-

meen Foundation, USA [GFUSA]) and formed the Microdevelopment Finance Team (MFT) to examine how technology can assist in increasing the scale of microfinance given the challenges that the industry is experiencing, “including the lack of industry-wide standardization, high transaction costs, and the inability to reach out to rural areas” (Magnetite & Lock, 2005, p. 1). The MFT created the remote transaction system (RTS), “a combined technology and business process which supports both group and individual lending, on-line and batch offline processing, and back office synchronization” (Magnetite & Lock, p. 1). The goal was to create an industry standard, assist the MFIs in cost-effective outreach to remote clients, and advance microfinance to a new stage of development.

The project was piloted for a 1-year period; however, this did not prove to be a sufficient length of time, even with an advance 3-month preparation period. A local team was hired to manage and implement the project. The RTS was piloted in Uganda with the partnership of three MFIs operating in Uganda: the Uganda Microfinance Union (UMU), a partner of ACCION; FINCA; and the Foundation for Credit Community Assistance (FOCCAS), a partner of Freedom from Hunger.

The RTS involved the use of sturdy handheld devices that communicate through GSM¹³ cellular networks, and these were combined with the use of smart cards. The smart cards hold account information and are given to clients and field officers to use with the POS device. Clients insert their cards to do their banking transactions, including making a loan payments, and the POS device provides a receipt. The POS system works off line in the field, but when the device is connected online, financial data is transferred via a server to the MFI’s MIS. The server could be something as simple as a basic computer with a straightforward software program that could be easily maintained by branch staff members.

The Remote Transaction System eliminated time spent on manual reporting, thereby reducing rural operating costs. The electronic data collection increased client confidence in the MFIs, as well as aiding in fraud reduction. Additionally, “the system, if used by the industry as a whole, might allow MFIs to take full advantage of latent synergies that exist among geographically and financially diverse institutions” (Magnetite & Lock, 2005, p. 1).

The value of RTS was assessed against the practices currently in use in the microfinance industry with group, branch, and individual clients. The results demonstrated that the most commercially-oriented of the three MFIs derived the most benefit from the technology largely because they were ready to adjust their business model to take full advantage of the RTS: “The advantages of the system as implemented included automation of transactions, reduced client time and travel, more frequent payments, reduced cash management risk, and avoidance of costs for ‘brick and mortar’ branches” (Magnetite & Lock, 2005, p. 1).

The RTS Uganda pilot-project implementation was short and only involved hundreds of clients, so the impact in terms of the scale of the technology was not clear. There were benefits to clients in rural areas who would otherwise have been excluded. The Microdevelopment Finance Team confirmed that there were advantages to the formation of nontraditional partnerships among nonprofit organizations, for-profit groups, and development agencies. Furthermore, “If the potential for enabling remote transactions, expanding services into rural areas, and altering business practices can be achieved, then the RTS could potentially have very significant developmental impact” (Magnetite & Lock, 2005, p. 1).

Summary of Benefits of ICTs to Microfinance Institutions

The above case studies suggest a number of benefits that technology can bring to MFIs. Ivatury

and Pasricha (2005) also mentioned several benefits from a wide range of technologies employed by various MFIs. These include more informed decision making and better reporting through the use of well-developed and well-managed MIS systems. Lower operating costs are another benefit through the use of a scorecard to predict customer payment patterns. Increased deposits and customer convenience are other benefits that were also demonstrated in Prodem's program. Other benefits include increased flexibility for clients, improved customer convenience, and increased number of rural customers.

The Challenges of Integrating Information and Communication Technologies by MFIs

While ICTs hold the promise to increase the efficiency of microfinance institutions and expand outreach to the rural poor by lowering transaction costs, there are obstacles for MFIs to overcome in the integration of ICTs. Hishigsuren (2006) indicated that many of the current ICT applications in the field are employed by the mainstream financial institutions who may not be serving the poor. For MFIs, whose primary mission is to reach the poor and reduce poverty, many of their ICT applications are still in the pilot stage. Also, those MFIs that have gone beyond the pilot stage of integrating ICTs are limited. It is further suggested that it will be sometime before MFIs will be able to fully utilize all the potential of ICTs, and that they should consider taking small steps and seriously consider the cost-benefit analysis when integrating ICTs in some functions of their operations.

The major challenges for MFIs in incorporating ICTs within their operations is not the availability of ICTs, but rather the costs associated with the implementation of ICTs, and the issues involved in choosing the appropriate technology that would give the maximum return on investment. The benefits associated with ICTs come at a price.

Software creation and implementation, including application software and the interface between the handheld or branch systems and the MIS, and hardware costs, as well as the time involved for software and hardware development all must be evaluated by the MFIs. Additionally, MFIs would normally need to hire an external firm to manage the development of the software and user interface: "Delivery technologies have the potential to reduce the costs of serving the poor. But in many countries these technologies have yet to prove themselves more cost-effective than manual operations."¹⁴ Technology systems for long-term support of MFIs are costly, especially when taking into account the need for MFIs to adjust to changes in customer needs and the economic and regulatory situations in which they operate. The price of software and hardware is about 15% of the total implementation cost, but the bulk of the expense involves staff time for training and adjusting to the new system.

Further, Ketley and Duminy (2003) stressed that technology is changing the banking arena and that the poor are increasingly becoming an attractive market for conventional banks. Therefore MFIs must be aware of this "challenge or risk becoming irrelevant." However, even with the cost factors, "MFIs cannot afford not to develop an appropriate technology integration strategy" (p. 2).

BRIDGING THE DIGITAL DIVIDE: GRAMEEN VILLAGE PHONE MODEL AS A CASE STUDY

This chapter has focused on ways in which MFIs are using ICTs to expand and strengthen their services. However, MFIs have developed a second method of using ICTs. ICTs are also being used as income generators for borrowers. Grameen Village Phone provides a good example of this type of use whereby borrowers or microentrepreneurs use the loans of the MFI to purchase ICTs, in this

case cell phones, which they then use to generate an income by providing services to villagers. In addition, there is future potential for the MFI to be greatly impacted; Frankiewicz (2003) suggests that “such microentrepreneurs can become agent access points for an MFI, facilitating access to certain services at a much lower cost than a traditional delivery channel (i.e., physical branch or permanent field staff) ever could” (p. 53).

The digital divide has become a concern for many in various sectors of international development. The CIDA strategy report states that as “of 2000, 70 percent of the world’s poor live in rural and remote areas, where access to information and communication technologies, even to a telephone, is often scarce—over one-third of the world population has never made a telephone call” (p. 8).

The Grameen Bank has developed trust and credibility, and established strong ties with thousands of rural villages and millions of the rural poor served by its microcredit programs. With this established network of clients, Grameen Bank was able to leapfrog into a position of using telecommunication technology to create the Village Phone concept. The Village Phone offers a solution for many remote and rural villages where telecommunications service is nonexistent because of the high cost involved in building and administering services where no fixed telephone lines exist.

The Village Phone methodology was pioneered in Bangladesh in 1997 by the Grameen Telecom of Bangladesh (GTC), a nonprofit organization under the Grameen family of companies. GTC partnered with the Grameen Bank program that provides small collateral-free loans to the poorest people in Bangladesh, and with GrameenPhone Ltd (GP), a for-profit company that is licensed to manage a mobile cellular network in all of Bangladesh. GTC buys bulk airtime from GrameenPhone Ltd. Buying airtime in bulk allows GTC to negotiate better rates, and it is then able to pass on savings to the Village Phone operators who get their loans

from Grameen Bank to purchase the phones and use them to generate income by providing a service to customers in the village.

The objectives of the Grameen Telecom Village Phone program¹⁵ are as follows:

1. To provide all of rural Bangladesh with easy access to telephone services
2. To offer a new income-generating activity for the villagers
3. To utilize the maximum potential of information technology, and bring it to the doorsteps of villagers
4. To use telephones to connect the rural population and bring new opportunities to them, as a new tool or weapon in the fight against poverty

Several social and economic benefits are derived from the Grameen Village Phone program. Richardson, Ramirez, and Haq (2000), in a study commissioned by CIDA, concluded that the Grameen Village program yields “significant positive social and economic impacts, including relatively large consumer surplus and immeasurable quality of life benefits.” (pg. 48) The study further indicated that the:

consumer surplus for a single phone call ranges from 2.64% to 9.8% of mean monthly household income. The cost of a trip to the city ranges from 1.93 to 8.44 times the cost of a phone call, meaning that the real savings for poor rural people is between 132 to 480 taka (\$2.70 and \$10.00) for calls that substitute for travel between the village and Dhaka. (p. 49)

The social and economic benefits can be summarized as follows:

1. Bangladesh is a labor-exporting country, and 42% of Village Phone users’ calls are made regarding remittances from family members working overseas. Through the

use of the phones, villagers have knowledge of the market rates and are able to negotiate better exchange rates on money sent from abroad.

2. Without the use of a phone, villagers have to travel long distances to provide or receive information. By spending the money to make a phone call, the family saves by not having to send a productive member on a journey that might involve hours of traveling time merely to deliver or receive information. The study shows that the cost to travel for information is up to 8 times more expensive than making a phone call.
3. Farmers are able to get better prices for their products by directly calling the markets themselves rather than using a middle-man.
4. Village Phone offers microentrepreneurs the ability to link with clients from various regions, providing opportunities to expand their microbusinesses.
5. Village Phone users generate their own business by reselling the information they gather to other villagers.
6. Phones have proven to be valuable in emergencies, such as arranging for medical help during natural disasters.
7. There is clear evidence that Village Phone operators have increased their social status in the village. Cell phones are a status symbol of the rich, and the Village Phone in a poor woman's hand elevates her status significantly. This increased social status is noted when a wealthier villager comes to the poorer woman's house to use the phone. The poorer woman's house becomes the center of activity, with villagers waiting to make or receive calls. The operator also has knowledge of the business of other village members. The additional income made further increases her economic status.

Since the Grameen Telecom Village Phone program's inception in 1997, 150,000 Village Phones have been distributed, and the program has spread to more than 35,000 villages in 61 out of 64 districts of the country. GrameenPhone reaches 3 million subscribers.

Yunus (2000) stated that:

Bangladesh is the only country in the world which could take mobile telephones to the poor women in the villages in a very successful commercial way because of micro-credit. That has laid the foundation for future inroads of IT services like e-commerce, e-healthcare, e-literacy, e-education, e-jobs etc. to the villages in general, and to the poor women in particular. With IT we can put the whole world in the hands of the poor. (p. 1)

Replicating the Grameen Village Phone Model

The Grameen Telecom Village Phone program in Bangladesh has proven to be a successful initiative demonstrating that technology can positively affect the lives of many rural villages. The Grameen Technology Center, a project under the Grameen Foundation USA (GFUSA),¹⁶ has started replicating the Village Phone model to prove this model could work outside of Bangladesh. It piloted a Village Phone project in Uganda with four objectives:

1. To provide the rural communities of Uganda with valuable communications services to enable them to break the cycle of poverty
2. To validate, measure, and document the Village Phone model in a single country outside of Bangladesh
3. To establish a generalized replication model for the Village Phone program
4. To disseminate this learning to the commercial telecommunications sector and the worldwide development communities so as

to catalyze and establish a global Village Phone movement (Keogh & Wood, 2005)

About Village Phone Uganda

GFUSA collaborated with the local telecommunications provider MTN Uganda. In addition to MTN Uganda, Grameen Technology Center established partnerships with eight microfinance institutions. These MFIs were FINCA, FOCCAS, UMU, Uganda Finance Trust (UFT), Feed the Children, MedNet, Hofokam, and Post Bank. GFUSA's extensive partnerships with the various MFIs permitted MTN Village Phone to reach a scale that would allow for "financial and social sustainability" (Grameen Foundation, n.d.).

The Village Phone operators first began their business in Uganda in March 2003 with the official launch of MTN Village Phone as an independent company in November of that same year. Keogh and Wood (2005) said, "Twelve months into formal operations, Village Phone operators in Uganda were selling an average of six times more airtime than is consumed by a typical MTN Uganda subscriber" (p. 13). FINCA Uganda, one of the partners, claims that "village bankers now have access to a powerful tool that can greatly improve their existing businesses' productivity—or be a new business itself." Below is a success story from one of FINCA's clients.

Sarah Sempa, a married mother of four, operates a small retail shop in the village of Namulesa in the Jinja district. She took her first FINCA loan in 2003 for 100,000 Ugandan shillings (\$57) and invested it into her business. When she learned of the Village Phone program, she reasoned that her busy trading center was the ideal venue and decided to diversify. Now she earns an additional \$25 to \$30 weekly, and estimates that people travel from as far as 2 miles on foot to buy minutes of airtime on her Village Phone.¹⁷

The replication of the Grameen Village Phone program in Uganda proved successful. The Vil-

lage Phone model has now been documented, and a manual¹⁸ for replication is available. Another Village Phone replication project is now being piloted in Rwanda.

Microfinance institutions worldwide with knowledge of and existing ties to the rural poor through the provision of financial services can position themselves to become the vehicle through which the Village Phone can be introduced as a new service. The replicable business model for this program starts when a client from an MFI is given a loan to purchase a Village Phone starter kit. The cost of the starter kit ranges from \$200 to \$250 and includes "a mobile phone, prepaid airtime card, external Yagi antenna, signage, as well as marketing and other materials necessary to get started" (Keogh & Wood, 2005, p. 3). This starter kit is provided by the Village Phone company that has developed a relationship with the MFI to offer products to their clients. The Village Phone company negotiates wholesale rates for airtime with the telecommunication provider, who in turn provides Village Phone operators with access to existing telecommunications infrastructures. The Village Phone operators can offer telephone calls at affordable rates to the individuals in the community. In the business model, there are no subsidies and a win-win situation for all parties involved in the partnership is created. With proceeds from the business, the Village Phone operator repays the MFI loan and also purchases additional prepaid airtime cards. The MFI earns money from the loan and also a percentage of the revenue from airtime sales. The telecommunications provider earns money through volume sales of airtime, and the Village Phone company earns enough money to continue to promote and expand the program.

Keys for Success

Keogh and Wood (2005, pp. 12-14) explain the keys for success:

There are four vital elements to ensure the long-term success of a Village Phone program:

1. The program should be structured so that all parties benefit.
2. The microfinance sector should be used as a “channel to market.” The social structures encouraged by microfinance institutions through groups, centers, and solidarity guarantees create a ready-made market for end-user consumers.
3. The telecommunications provider should provide wholesale airtime rates to Village Phone Operators to allow them to provide affordable services while simultaneously earning enough margin to repay their loan.
4. In-country staff should manage the business.

The Village Phone model has provided a way to bridge the digital divide. Through the use of the microfinance sector, the telecommunications sector is able to gain access to the large untapped rural markets they could not reach before because of the high cost of infrastructure development and maintenance. The Village Phone program potentially targets and reaches the poorest of the poor, women, and the illiterate within developing countries while holding the promise of helping to narrow digital disparities.

CONCLUSION

Like microcredit and microfinance, ICTs are not a panacea, but a powerful tool to aid microfinance institutions to become sustainable by reducing transaction costs, increasing scale, and expanding outreach to the remote areas, thus closing the gap in the demand for microcredit. The implementation of ICTs by microfinance institutions is still in its infancy, and it is not an easy or inexpensive process. Stakeholder collaboration within and

across both the ICT and microfinance sectors and proper business planning by MFIs is necessary for cost effectiveness and to derive maximum benefits in implementation. As the cost for appropriate MFI technologies continues to decline, and the innovation and development of new technologies leads to further reductions in cost, MFIs will be able to reach larger numbers of the poor and more isolated and underserved rural poor. While the synergy of the microfinance and ICT sectors shows great promise for the achievement of the MDG of halving poverty by the year 2015, reaching the 1.2 billion people living on less than \$1 a day will also depend on individual MFIs’ commitment, mission, and program design to target the poorest.

Chapter 8.5

Management of New Genetic Knowledge for Economic and Regional Development of Ethnic Minorities in China

Jan-Eerik Leppanen

International Institute for Asian Studies (IIAS), The Netherlands

ABSTRACT

The banking of genetic appliances and DNA represents an attempt to understand sustainable use and preservation for the benefit of current and future generations. The goal of this chapter is to highlight BioBanking as a tool for accelerating knowledge, understanding, conservation, and sustainable use of biodiversity. Genetic biobanks, collected from indigenous peoples, may pose some ethical risks for the ethnic populations. The new information in the hands of insurance companies, employees or governmental agencies could mean insecurity for ethnic minorities if the use of information violates the fundamental human rights of ethnic people. The new genetic knowledge may alter the relations between the individual (the self) and the community; the individual and the state; and the community and the state. This chapter will explore the technical issues, difficulties and benefits this

tool provides when dealing with marginalized ethnic populations in Southwest China.

INTRODUCTION

In this chapter, the author has tried to give an overview on genetic sampling¹ of ethnic minorities (*minzu*)² in China and to the different claims companies and research ventures have on this industry. It will look at the following question: how the new genetic knowledge—acquired by biobanking activities—could be turned into ethically sustainable, economic, and regional development of ethnic minorities in China.

The banking of genetic appliances and DNA represents an attempt to understand sustainable use and preservation for the benefit of current and future generations. The goal of this chapter is to highlight BioBanking as a tool for acceler-

ating knowledge, understanding, conservation and sustainable use of biodiversity. This chapter will explore the technical issues, difficulties, and benefits this tool provides when dealing with marginalized ethnic populations in Southwest China. This theoretical framework can be applied to the lives and conditions of ethnic people in other parts of East Asia (southwest), Southeast Asia (north, mainland) and in South Asia (far west).

Indigenous people groups in Southwest China and in other parts of northern Southeast Asia (mainland)³ go through development challenges that are, most of the time, transboundary. Some of the issues concern migration, effects of reforms (P.R.C), and technological knowledge. Genetic biobanks, collected from indigenous peoples, may pose some ethical risks for the ethnic populations. The new information in the hands of insurance companies, employees or governmental agencies could mean insecurity for ethnic minorities if the use of information violates the fundamental human rights of ethnic people. The new genetic knowledge may alter the relations between the individual (the self) and the community; the individual and the state; and the community and the state. This chapter focuses on genetic sampling holistically. This implies that the processes of change alter the social constructions in which minority people live.

However, the banks are also a new potential source of material wealth and health knowledge resources if the new information is applied according to local needs. The issue of information management with genetic knowledge is an ethical one, since businesses are primarily looking for profits, not for the rights of vulnerable people. It is probably impossible to find a perfect solution for biobanking enterprises. However, to avoid the mentioned problems, a model named “Charitable Trust” could be a resourceful framework to apply for the ethnic communities in the Southeast Asian region. This bank, originally proposed by D. and R. Winickoff, is a model for genomic biobanks, which is seen as superior to commercial

biobanking. A biobank organized as a charitable trust is created by a trust agreement between the research subject and the owner of the bank. Since the relationship with the “bank” manager and the research subject is mutual, it will be less easy to mishandle the rights of the sampled population. It would be even more advantageous if the “trust” being community based and owned biobank and resource rights regimes that seek to recognise the essentially community-based nature of much of the knowledge related to biodiversity.

The transformations brought about by the “knowledge economy” or “Information Society” are conventionally thought of in global or national terms. But as globalisation and the outcomes of new information and communications technology (ICT) have influenced people around the globe, they are also reformulating and restructuring the regions, though in multiple routes and often with highly differentiated results. The resources accessed from this article focus on the use by Asian regions and localities of ICT to support and promote the wealth and welfare of their citizens, businesses, and environments.

BACKGROUND

Economic and regional development in the context of Chinese minorities is interlinked. Minority dwellers in mountainous regions are, in general terms, worse-off compared to their fellow countrymen. This is because steppe regions means of livelihood are more limited and means of communication and transportation are restricted due to the great financial costs resulting from the demanding geography. In China, the minorities’ migration from the plains to the mountains have taken several routes and included a multiple number of historical events. A dominant theory claims,⁴ that minorities were pushed, step-by-step, ever higher to the mountains by the majority (Han) people, when the competition of the cultivable land area became more intense. Although this

is not the *de facto* situation in the case of many minorities, moving up to the mountains is not all natural phenomenon and the regional development efforts involves both parties, majority people and minorities alike.

Economic-regional development of ethnic minorities suggests that in order to advance the business and profit-making changes of indigenous peoples, the regional and geographic conditions need to be taken into account. The goal of any development plan must be to ensure that communities are strengthened, and rural people are not pressured to abandon their native lands and move to bigger cities and suburbs in the hope of better financial prospects and economic stability.

ECONOMIC DEVELOPMENT OF ETHNIC MINORITIES IN CHINA AND ASIA

Most of China's rural poor live in its hilly and mountainous regions, and in recent years the government has concentrated its "war on poverty" in these areas. Among the poorest of the poor are China's minority peoples, not least because they are outside the dominant culture and language. Unemployment is a huge problem in China, and the Yunnan province is among the country's poorest. Half of the population earns less than \$80 a year. Bureaucrats and population planners often see few options for the employment of ethnic minorities. The options are limited to tourism industry, service industry, or to tertiary industry (Yardley, 2004).

The economic importance of migration, and its effect on social change, is also a key factor among the minority peoples in the Southeast Asia region. Ethnic men seek casual unskilled work, often over the border, in Myanmar or Laos. But these laborers seem to be even more vulnerable to exploitation by employers, as their own languages are not spoken on the plains and in the cities. Indeed, each minority group has its own

distinct customs, practices and language, which remain a source of pride and definition. Low levels of literacy and limited access to news and information, plus some residual prejudice against minority peoples, make life even harder.

The ethnic informants talk of enlarged opportunities to earn money since China's economic reforms took hold, and express a preference for the new system of working for oneself rather than communally. Family networks remain a crucial source of support, financial and practical. Health facilities are both limited and too costly for some, especially for reproductive health, and this, combined with women's heavy workload meant many narrators suffered constant ill-health.

There is a strong belief among most narrators that they could raise their living standards significantly if they could get a little more training and investment. Being minority people with different languages, some feel they have not benefited from the same educational opportunities as the majority Han. But poor roads still limit people's ability to market their produce, and several ethnic subjects say lack of electricity is another hindrance: "Our lives will be better after the road is built and the electricity connected. You see, everything has to be done manually. I want to learn more skills. My thoughts cannot catch up with the Han—my literacy level is low, and I have poor technological knowledge."⁵ Another informant stated that: "We Miao people live in remote and backward mountain areas. Although we have had some development in these years, there is still a big gap between us and other peoples."⁶

China's economic reforms have shifted an almost uniformly poor nation into an increasingly prosperous one in the space of a mere generation. But the downfall of socialized medicine and astounding cost increases have opened a vast gap between health care in the cities and the rural areas, where the previous system of free clinics has disintegrated. The government, which under President Hu Jintao has made prioritised rural living standards in its reform agenda, has

recently announced an expansion of this experiment, with increased fees and increased coverage, but the impacts on the health crisis is still to be seen. As a result, in less than a generation a rural population that once enjoyed universal, if basic coverage, is now 79% uninsured. One of the great policy changes of modern times, China has disorganized its rural communes, privatised enormous segments of the economy, and moved public health resources away from rural areas and toward the cities. Public hospitals were pushed for charging commercial rates for newly designed drugs and most procedures, and today the wages of health care workers are normally linked to the amount of money they generate for their hospitals (French, 2006).

COMMERCIALIZATION OF HIGH-TECH SECTOR

Clearly, one of the biggest changes and challenges in the professional life of Chinese scientists is the commercialization of research (Baark, 2001). The big picture of commercialization becomes more evident if one looks at the growth of contract research in universities and research institutes. This is happening even when they are not starting their own companies. As soon as Chinese firms have begun to face the challenges of market competition, they have found that productive relationships with centres of research are lucrative. This applies to all types of Chinese companies, including state-owned enterprises, TVE's, and the startup of "new technology enterprises," all of which have sought to contract universities and research institutes for research and technical services (Baark, p. 142).

The commercial considerations in Chinese science are also seen in the actions and strategies of foreign multinational companies (MNCs) in China. The two principal modes of MNC penetration of the system are the establishment of

research centers in China and the uses of Chinese universities and research institutes as contractors for outsourcing research, development, and technical service activities. Working with MNC's is both attractive and professionally rewarding for many Chinese engineers and scientists. For these reasons, foreign firms have been able to employ some of the best and most talented from the research community. These newly discovered activities of MNCs in China have caused concerns over a new type of "internal brain drain."

In addition, the state remains the important source of funding for the nation's research activities that ensures that the influence of the bureaucratic policy culture remains strong. Chinese policymakers still have a long way in redefining the role of the state in the support of science (Baark, 2001). In terms of academics, the present age where China is and where it is further entering is an age of experts in which the relative importance of critical intellectuals to the public is declining while knowledge-based and profit-oriented professionals are becoming increasingly important (Gu & Holman, 2004). Marketization has generated fraudulent, get-rich-quick schemes among scientists. An interesting example of commercially inspired product fraud, and constructive responses to it from within the technical community, is seen in a dispute over the nutritional value of nucleic acid.⁷

Commercial involvement in genetics induces a moral environment in which blood is cherished *both* as the object of dignity *and* as the object of commercial interest. In this landscape blood has to be exchanged in nonmarket terms, with the ambition of fulfilling *both* moral hopes of better health *and* financial expectations (Hoyer, 2005). But the problem is that those material expectations may not be filled and the companies doing the research are collecting the rewards nevertheless. Specialized, for-profit firms may collect huge earnings through their access to human commodities. Access to sophisticated technologies also proves

highly effective in the expansion of procurement activities, with the result that various agencies may essentially buy their way into understaffed and poorly funded labs. In short, access to advanced technologies can improve authoritative power and, eventually, generate the necessary capital to facilitate boundary expansion (Sharp, 2002). It must be stated, however, that technologies are only one of several tools that may serve capitalist interests. There is a tendency to the bureaucratization of medico-scientific knowledge and its progress to a sophisticated form of mystification. Different knowledge (be it the values assigned to fetuses or cancer medications) is thus encoded with new layers of meaning, which, ultimately, obscure their origins and transform their usefulness within medico-corporate structures (Sharp, 2002).

CHINA AND INFORMATION SYSTEMS: A CASE STUDY OF GENETIC DATABASES

In the Chinese context, personal information systems of ethnic minorities and other genetic databases is most often nationally coordinated and governmentally monitored. Regional research divisions function as a coordinative body in a larger information system. A case example of the Chinese interlinked (bio)information system is the Chinese Biodiversity Information System (CBIS), which is constructed to a National Biodiversity Information Center (NBIC). It consists of one central information system and five disciplinary division information systems, and more than 30 data source information systems. Some of the regional divisions are handling genetic information of ethnic people. The data sources include specimen collections, botanical gardens, natural reserves, field ecosystem research stations, seed banks, geneplasm banks, and research groups. The CBIS aims to.⁸

Genetic Databases and Current Issues

The concept of genetic databases is not new. For the last 30 years it has been common practice to establish registers of patients with hereditary illnesses, aimed at providing genetic services to families with these conditions. But the new generation of genetic databases are quite disparate, both in size and format. In many cases, they involve exceptionally large populations. For example, the Icelandic Health Sector Database aims to link health records with genealogical information and information about genotype. DNA samples will be collected with informed consent, whereas entry into the health records database is by presumed consent. Genomic databases are often described as population biobanks. In these biobank databases, a range of further information relating to the individuals whose genetic data are stored complements that genomic data.

There is still substantial controversy about the desirability of establishing databases and the many ambiguities regarding access and control. Concerns are engaged with individual risks which revolve around those arising from access to genetic information, both by individuals themselves and by third parties. In the latter case, these might include health insurance companies, government bodies, or the legal profession and police. The questions of confidentiality and access to these databases play an important role here. Although much effort is being put into protecting individuals, there are still possibilities for the misuse of the databases.

What has also been suggested is that genetic research based on stored (human) biosamples may have the effect of stigmatizing entire countries or particular groups of individuals, and there are concerns about commercial exploitation without adequate compensation. Also, because scientific research depends on freedom of access to samples

and information, the commercial ownership of these databases may have a damaging effect on genetic research. As well as these concerns, there are a variety of socioeconomic and ethical issues advanced by this new trend in genetic science.

It is not definite whether individuals who donate DNA samples for these databases are entirely aware of the potential risks involved, and it is even less clear whether some of the arrangements that have been made with the private sector, which is becoming increasingly involved in these enterprises, are appropriately controlled. It is also not apparent how information, particularly unexpected findings, will be handled in these large population studies and how these DNA samples will be used above and beyond the stated aims of those who are establishing the databases.

One of the reasons genetic databases are being built is when health information is needed to be stored in one central location. Some developing countries, or geographical areas within developing countries, represent attractive opportunities for the development of such databases when the population is comparably genetically homogenous due to limited migration in or out of the area. These databases vary and individual data are typically made nonidentifiable to users of the database. The databases are in some cases developed by public health authorities in the country, sometimes in cooperation with private corporations as in the deCODE database in Iceland, and in other cases chiefly by private corporations. These databases raise a number of ethical issues, which includes profit sharing with the community from which the data are gathered.

A second crucial informed consent issue, both for databases and for other genetic research is whether health information or genetic material can be used for other purposes beyond those for which consent was originally given without obtaining additional consent for the new uses. It has been suggested that material or information should not extend beyond those for which consent

had been given. Genetic information about a specific health risk of a particular individual may imply a similar risk for other family members. In cases of comparatively isolated groups, which are unusually genetically homogenous, information about individuals may have implications not only to immediate family members, but also to the wider group.

Many of the risks in biobanking can be expected to increase in developing (and many developed) countries in the future. Responsibilities to provide proper biobanks/genetic information systems are being shifted from the public sector to the private sector in many countries, where private insurers make use of risk rating for health insurance. As a wider range of genetic tests become available and their cost continues to decline, the incentives and abilities of insurers to use this information to discriminate against individuals with risks of developing serious disease is about to increase.

Being labelled as having “bad” genes can have variety of serious social and psychological consequences for individuals, and this stigmatization may be stronger and more common where the levels of education and understanding is low. This is the case in many parts of Eastern and Southern parts of Asia.

Ethical, Legal and Social Issues (ELSI) in Genetic Research

Due to expensive medical and genetic services individuals’ needs sometimes become highly variable and unpredictable, and typically if they are provided through some form of insurance. This may happen within a national health system, but increasingly in many Asian countries, at least in part, and especially in China, through private health insurance. If increasing amounts of information become available to insurers about genetic risks, many people will face large differences in their health insurance costs from genetic risks. In this way, they will be denied of health

insurance, or be unable to afford it at all. Similar ethical concerns apply to the use of genetic testing by employers or potential employers.

The populations of very poor developing countries are especially vulnerable to economic exploitation by much richer developed countries or multinational corporations in genetic research or the development and use of genetic databases. Also, low education levels in some developing countries and limited familiarity with genetic medicine or research present special obstacles to obtaining truly informed consent from the population. A general feature of many developing countries is a lack of any well-developed regulatory apparatus to deal with either the scientific issues in genetic research and technology, or with the ethical, legal and social issues. As genomics becomes more prominent in many developing countries, it becomes an important priority to develop necessary regulatory structures for addressing both the scientific and ethical issues. These regulatory bodies may formulate policies and action plans incorporating better utilization of electronic databases.

Electronic Data and Population Profiles

Electronic records can be accessed in combination with other databases in diverse geographic locations. This linking capacity makes it possible to compare the data to get a profile of an identifiable person or population with neither personal identifiers nor other confidential information. What are seen problematic with people related to electronic data are the privacy problems. These side effects are always difficult to deal with. Firstly, are the ownership issues. Technological advances allowing easy access to such data make it difficult to determine who is the “owner” of the computer record. Many people take it for granted that the patient owns his or her genetic record and should

continue to be named as owner. But then again, one argument speaks for privacy protection when data is compiled anonymously. One important point to remember for the potential misuse of information is that the risks of fraud and abuse of individual medical information may not come from outside hackers, but mainly from those described as “authorized” users (Floya, 2001).

One practical example of a type of health record where potential misuse may take place is a record which combines lot of different kind of information and where medical and genetic information is linked through technological networks to other databases, like employment data, tax and credit records, insurance, welfare, and custody files. This could also be called as “centralization of sensitive information.” The problem with the centralization is that it places too much power in a single public agency. But the decisive question is not the access to information but it is the control over the information. It would then be necessary to think of certain guidelines of restricting access to medical and research data only to those with proper authorization for providing adequate safeguards. Furthermore, even with the addition of guidelines for protecting privacy, other questions remain unanswered. It is important to know: (1) which groups should oversee enforcement of the guidelines and, (2) how effective such enforcement could be (Floya, 2001).

However, there is a growing interdependence between information communication technology (ICT) and genetic and genomic research. Some ethical issues that have traditionally been associated with ICT are now also at the center of recent ethical concerns involving genetic and genomic research. The dependence on ICT may give some insight into why many issues in the fields of ICT ethics and genetic/genomic ethics now intersect at some points and converge at others (DeCew, 2004).

SOLUTIONS TO GENETIC INFORMATION MANAGEMENT

It has been suggested that the potential harm of the genetic revolution may rather lie in the ability of technology to distribute the available resources even more unequally than is currently the case, and in that way enforce and strengthen the existing disparities and inequity. On the other hand it is suggested that genetics might have enormous potential in leveling the existing inequalities and providing a more just and equitable existence. There are also views that dispute the application of a benefit-sharing framework within genetics. These are mostly related to a perception that benefit-sharing actually legitimizes the attempts to commercialize and profit from (human) genome (Simm, 2005). Habitually, these lead to biopiracies.

Biopatents and Biopiracy

The appropriation of indigenous knowledge on medicinal plants or human genetic information by multinational companies or other international, national, or local agencies is known as “biopiracy,” and it happens often without prior consent or compensation. Indigenous ethnic peoples rarely benefit from the financial gains of this new genetic knowledge. Pharmaceutical companies are quick to impose patents and exploit traditional knowledge, which has existed in indigenous communities for generations. The so called “TRIPS-plus” (Trade Related Intellectual Property Rights) treaties allow western countries to bypass current WTO limits on patents related to indigenous biodiversity.

The Coordinator at GRAIN, H. Hobbelink (YEAR), said in an interview: “in country after country TRIPS-plus agreements undermine national decision making processes and hijack policy options for the South, having serious consequences for farmers, research and the public interest” (p. 3). They are “manipulative” and “undemocratic”

and make the debate on patenting irrelevant and outdated (BMA, 2001). In the meantime, the government of the United Kingdom has established a new commission to study how gene patenting rules can be enhanced to take account of the world’s poor. The Commission on Intellectual Property Rights [CIPR] investigates the exploitation of traditional knowledge, the effects of TRIPS, human gene patenting, benefit sharing, and issues of consent (Grain, 2001).

Some of the most well known examples of the collision between traditional knowledge and genetic research are the “RiceTec” and “bintangor tree HIV/AIDS drug.” The U.S. Patent and Trademark Office (USPTO) has endorsed three patents for hybrid strains of basmati rice and awarded them to a U.S. company, RiceTec, regardless of attempts by the Indian government to have all the patents that were originally granted in 1997. USPTO commanded to disclaim RiceTec from calling the rice “basmati,” but allows them to label it “a superior basmati rice.” This has caused some major discontent in India. The Indian Government postponed in recognizing India’s claim to have basmati protected under geographical indication provisions at the WTO. India had been victorious, since RiceTec has been forbidden the use of the word “basmati” as a trade name (Devraj, 2001).

U.S. based pharmaceutical companies plans to develop a new anti-HIV/AIDS drug from Sarawak’s native bintangor tree, which has evoked NGO’s to criticize these schemes. M. Bujang of the Borneo Resources Institute says the East Malaysian state’s natives are in danger of having their traditional knowledge of medicinal plants stolen by biopirates. He indicates that the concept of property rights is unfamiliar to them. The locals openly share benefits from traditional knowledge that have been passed down through generations. Borneo Resources Institute tries to make sure a share of any profit arising from native wisdom goes to the people of Sarawak. In the meantime, the state-led Sarawak Biodiversity Center (SBC) has started a project to record, in writing, the

orally transmitted knowledge of the locals. The reason for the project is found from the research finding that recognition skills are fast disappearing. Today's young people can often name only 10-20 medicinal plants and animals whereas the previous generation knew hundreds of different species. Local populations would be able to keep any written records to themselves and, therefore, guaranteeing a share in any financial benefits arising from that knowledge. The records will also help Malaysia's attempts to implement the International Convention of Biological Diversity, requiring countries to ensure benefits derived from research of native genetic resources that are shared with indigenous peoples (Chalmers, 2001). The author prefers formation of charitable trusts that may take care of these issues and evolve as a catalytic agent for economic empowerment of the indigenous communities.

The Charitable Trust

In a 2003 article, D. and R. Winickoff (2003) proposed the charitable trust as a model for genomic biobanks which is superior to commercial biobanking. A biobank organized as a charitable trust would be created by a trust agreement under which the participant in the research (or settler), "formally expresses a wish to transfer his or her property interest in the tissue to the trust" (p. 1182). By donating the tissue samples to the biobank, the donor contextually appoints the recipient as trustee of the property, who has legal fiduciary duties to keep or use the property for the benefit of the beneficiary.

Winickoff & Winickoff (2003) argue that the charitable trust presents three clear advantages, namely (1) the protection of the participants' rights, (2) the propensity to build participants' trust, and (3) the protection and maximization of the scientific value of the biological collection. Furthermore, the charitable trust model presents at least three more advantages if compared to a model based purely on contractual relationships. First,

the charitable trust model favors the *separation between control and use of the collected samples*. Large collections of human tissue are often being developed as resources that enable future research projects rather than as tools to enhance pre-existing genetic investigations. Therefore, a person who stores samples and data is often not the user of the same data because that person is not carrying out genetic research directly. However, in the real world, *storage of material and of the owner are often separate*, and having an *institutional framework*—such as the charitable trust model—that builds upon this distinction shows a clear advantage (Boggio, 2005).

In practice, transparency and opportunity for ethics review are enhanced if storage and use are separate. In this scenario, third-party researchers interested in accessing the samples would always be required to file a request to access the samples—or the genetic data that are derived from the samples. By filing such requests, external researchers would make explicit the circumstances and the intended purpose of their access. This practice would certainly favor a transparent access to databases and accountability of both the third parties towards the trustees and of the trustees towards the "general public."

Second, the charitable trust model provides a governance framework that facilitates the participation of donor groups in the management of the database. Third, the charitable trust model facilitates balancing the different interests that are affected in large-scale DNA collections. The trusted biological samples can only be used to serve the interests of the beneficiary. Thus, each request for access shall be balanced against the interest of the "general public" (Boggio, pp. 44-45). Now, the author would like to focus on the Chinese genetic information management system.

In China, the state still has a lot of control over the private life of individuals in the field of health and sickness. People are inclined to follow the advice of physicians because people's lives depend on them. To give blood samples for the

common good is not perceived as an additional burden if the results of ignoring the genetic tests would carry some disagreeable consequences on their lives. But the decision to join genetic sampling is being done under the pressure, not free willingly by the research subjects. If there is no necessary institutional framework (as is suggested in Winickoff's model) to support subjects' rights, it becomes difficult for them to claim their share of the new genetic knowledge. Another determinant of sound research ethics in genetic sampling is the level of awareness/knowledge that research subjects have about their rights. When the population being sampled consists of ethnic minorities, communication is then, naturally, cross-cultural. Language and cultural differences should be taken into consideration when research is planned and conducted so that research participants have a full understanding of the research project.

Sometimes in Chinese academia, what is researched, to what purpose the information is used, where it is used, and who is drawing the conclusions from the research data is not agreed upon mutually. These setbacks could be avoided if the storage of material and of the owner would be separate and there would exist a separation between control and use of the collected samples as suggested in Winickoff's model. This would lead to a conclusion that the Chinese *minorities* as a research populace would be in an especially vulnerable position since they are less significant in size and power than the majority, *Han*, people. However, in the Chinese context, ethnic minorities are in many ways "strong" and dynamic agents. It is a simplified truth to claim that minorities face a vulnerable position because of restrictive obligations enforced by the government. Yet, minority privileges surpass those of the Han Chinese in the number of children permitted to a couple (generally more than one) and the special position in minority language schooling, although this has regional variation.

Minorities are not automatically voiceless, but further effort is surely needed to make their

claims heard on minority matters, since minority administration is de facto in the hands of the *Han* people who make up approximately 92% of the whole population. This is true in the area of human genomics projects, for example, solely about research conducted on ethnic subjects. The existence of a "colorful" cultural variety of 54 Chinese minority people groups is one of the founding reasons for Chinese human genetic programs. But, it has to be said, the whole idea of Chinese ethnic (*minzu*) groups with clearly defined borders is a fleeting, contingent, and rather modern invention. With a history of only 50 years, the Chinese *minzu* map and theory live new renaissance. Chinese officials have adopted new DNA analysis based techniques in archeology and forensic research to prove their theory correct: that in China there exist only 55 nationalities altogether, and that regional linguistic and cultural variation is non-existent within these groups.

FUTURE ISSUES

A medium and long-term scientific and technological development program, which was first put forward in the proposed 11th Five-Year Plan (2006-2010), will set the pace for all Chinese technological policies from 2006 to 2020. The program, on which over 2,000 experts and scholars spent more than two years, rolled out the blueprint for an innovation-oriented China. China is seen as a country in which science and technology play an enhanced role in promoting economic and social development and safeguarding national security, in which research in basic science and cutting-edge technology are strongly emphasized (Zhang, 2006, p. 24). The newly adopted scientific development program has made it clear that by 2020, scientific and technological progress should contribute about 60% to the country's economic growth with 2.5% of its GDP devoted to scientific research and development, including genetics and information systems (Zhang, 2006, pp. 24-25).

In the private industry sector, Big Pharma and Western biotech companies appear to have gotten over their concerns about intellectual property protection in China, traditionally a barrier to outsourcing this type of work. They have found that the “grass is greener” for biotech development in China, where costs are much lower (Young, 2006, p. 36).

The most recent Chinese Government’s White Paper⁹ concerns regional autonomy of ethnic people. It says that the country’s regional autonomy system for ethnic minorities adopted half a century ago has been in conformity with the country’s development goals and proven to be in the common interests of all ethnic groups. After New China was established in 1949, the white paper says that the Chinese government began to introduce the system of regional autonomy for ethnic minorities to all regions where ethnic minorities lived in compact communities. By the end of 2003, China had established 155 ethnic autonomous areas. Of these, five are autonomous regions, 30 autonomous prefectures, and 120 autonomous counties (banners). According to a national census in 2000, of the 55 ethnic minorities, 44 have their own ethnic autonomous areas. The area where such regional autonomy is practiced accounts for 64% of the entire territory of China. However, not all the policies during the socialist governance have been beneficial for the minorities, and even the Chinese government acknowledges this reality. The white paper states that the economic and social development level of western China’s minorities is still low compared with the more developed eastern areas. It further urges development work in remote and backward areas in Southwest China (PDO, 2005). The challenging task of implementing the technology investment and development plans for the following years is in the hands of government cadres and party leaders. It is decidedly important that the needs of the ethnic people are prioritised and their economic-regional prospects are given necessary importance.

CONCLUSION

In this chapter the author has tried to argue that there are a number of development needs among the ethnic people groups in East Asia, Southeast Asia, and in South Asia. However, the nature of most of the regional and economic development conditions of these ethnic minorities is trans-boundary. The indigenous people groups that are situated in the mountainous border provinces in the states of East Asia, Southeast Asia, and South Asia, face similar difficulties due to their linguistic and cultural dissimilarity from the dominant majority populations.

It has been observed that economic reforms in China work towards finding increased access to money. However, there are a great number of hindrances that are making it more difficult for ethnic people to meet their necessities: employment (they are outside the dominant culture and language), schooling (illiteracy and limited access to information), and technological skills. In this context, genetic biobanks may pose some ethical risks for the ethnic populations, but at the same time can also be treated as a new potential source of material and health knowledge resources. They can be:

- Disease gene mapping in which profits arising from the biobanking go to the people and this may boost the local economy.
- Other plant and nature related to new genetic products based on traditional knowledge of ethnic people; any profit arising from native wisdom goes to the ethnic people.
- IPR should be part of technological training of ethnic people; this would improve the know how of genetic information system management.
- A community owned biobank (charitable trust) which could provide a financially sound solution that stands by the side of marginalized ethnic people.

There is much to be discussed on the choices that scientists and medical doctors are making while handling the data of ethnic minorities. The new information extracted from minority people is handled by bio-technicians, bio-genetic engineers and genetic laboratory personnel. But, there is no self-evident way to interpret the data of ethnic people in China. Since the beginning of the *minzu* classification system, there has been ongoing negotiation over the truth-value and existence of these groups, and questions such as what the forms of ethnic minority representation are today and what it was in the 1950s, 60s, 70s, 80s and in the 90s. Any argument over or notion of the “nationalities” characteristics’ is, and must be, politically charged, since the whole existence of the *minzu* system is a calculated and systematically constructed socio-political invention.

In general, to pass on someone’s genetic information to the wrong hands does not necessarily carry potential hazardous immediate consequences. But, the information becomes fundamentally sensitive if it affects the ability of minority peoples to choose where to work, what kind of position they maintain in their local community, what types of insurances are available, and so forth. Genetic databanks can open up some doors but they can also restrict available lifestyle choices. The point that the author is trying to make here is that, by considering the small numerical representation of minorities in governing bioethical bodies and their disrespected position in the nationality hierarchy, it is more difficult for them to make claims for injustices done to them. This also relates to the question that goes into the very essence of the minority debate: what, actually, is a minority to the majority; does the relationship signify weakness or strength? If and when this relation is grounded on differences, asymmetry and subject-object relations, the outcomes of human genome studies on minorities can never be purely value-free. The Han majority is the arbiter of the campaign; they thus control the conclusion drawn from the result as well.

ENDNOTES

¹ Genetic sampling of ethnic minorities primarily conducted in the Southwestern province of Yunnan, bordering Vietnam, Laos, and Myanmar. Yunnan comprehends 25 out of 55 Chinese official minorities in total. The main sampling projects are Chinese Human Genome Diversity Project (CHGDP) and International HapMap project.

² The original idea in the nationalities' mapping endeavor was to understand the diversity of the newly founded Peoples' Republic of China. Through the decades, it has turned into a "[slapping] endeavour" where the minority label should tell it all, but in truth it does not say always as much. During the past 50 plus years, people have been using not just the official label for the nominal group, but also other ethnic signifiers—some that are altogether more important than the *minzu* name. People in rural China have found it important to define themselves according to their place of origin, to their kin, tribe, or according to blood relations. Ethnicity consists of different, varying, and multilayered factors. Put together, they make up an interlinked web of something evolving and changing and sometimes unutterable. Unutterable because the words used to describe ethnicity are in the process of change; a common vocabulary is sometimes unattainable because the linguistic differences are too great. Group names are one example of the described problem: it has usually both *emic* and *etic* versions of the same subject, consisting of the insiders' view of its world and then the

versions that outsiders tend to use when referring to the group. This is still a very rough divide because ethnic groups have dozens of specific group names for those speaking different languages and following varied cultural traditions.

⁷ Early in 2000, in advertisements and on the Internet, several Chinese companies claimed that nucleic acid is a nutrient that could resist ageing and prolong life. Ordinary Chinese citizens, lacking the technical knowledge to judge such claims, were attracted to the products in a kind of nucleic acid minicraze. Biochemist Fang Shimin, who has been living in the U.S. since getting his Ph.D. there, was appalled by the widespread "nucleic acid nutrient hype" and wanted to expose the "fraud in Chinese science." The matter eventually received international attention when articles on the issue and Fang's efforts appeared in both *Nature* (2001) and *Science* (2001) (Williams, 2005, p. 151).

Chapter 8.6

Visualizing ICT Change in the Academy

Gale Parchoma

University of Saskatchewan, Canada

ABSTRACT

This chapter introduces complexity theory as a theoretical framework for analyzing the influences of information and computer technologies (ICTs) on the structures, cultures, economies (reward systems), and pedagogical praxes within the Academy. An argument is made that the strategic adaptation of the academy's structures, cultures, economies, and pedagogical praxes to the knowledge economy can help build a future where Academy-based distributed learning networks will transmit ICT-mediated learning opportunities around the world, thus providing flexible access for a wide range of learners to fully participate in the global learning society. The author posits attunements to policies and practices to support institution-wide involvement in ICT initiatives.

OVERVIEW

This chapter addresses the technology management and change theme through the application

of complexity theory to information and communications technologies (ICT) change initiatives directed toward enhancing learners' access to higher education, opportunities to succeed, and experiences with human computer interaction (HCI). Academic organizational structures, cultures, economies, and pedagogies are analyzed for their alignment with successful integration of human computer interaction into learning experiences as a core activity within higher education. A variety of challenges to achieving institution-wide involvement in HCI are addressed. A series of adjustments to policy and practice is posited.

INTRODUCTION

The contemporary global learning society's demands upon individuals for life-long learning are now transforming and will continue to transform the traditional Academy. The adoption of information and computer technologies (ICT) to provide flexible access to distributed learning opportunities for working adults underpins this

transformation. The external economic forces of the new economy and its information technology paradigm may be the most powerful influence for this change. Simultaneously, the social forces of postmodernism, the interpretive turn, identity politics, and globalization are affecting change in the organizational culture of higher education and increasing demands for collaborative and distributed learning opportunities. At this juncture, traditional research universities may need to re-examine their policies and practices to effectively adapt to a complex, ambiguous, and dynamic, and technologically driven external environment. University leadership may need to strategically respond to these external pressing demands for change.

Internal organizational structures, cultures, economies (reward systems), and pedagogical praxes may need to be attuned to changing academic times. At the heart of this need for adjustment of university policies, procedures, and customs is the groundswell of demands for lifelong, personalized, customized, and distributed learning opportunities (Daniel & Mohan, 2004; McCalla, 2004; Tjeldvoll, 1998). Strategic responses to these demands are required to ensure that ICT-mediated solutions provide flexible access to high quality higher education and forestall the potential of models rapidly being developed by new for-profit higher education competitors (DiPaolo, 2003) from becoming disruptive technologies and eclipsing the role of traditional universities in the higher education sector (Archer, Garrison, & Anderson, 1999; Christensen, 1997). The Academy needs to embrace ICT solutions and their associated service orientation to ensure its ongoing position as the best option for higher education.

In order to achieve this transformation, leaders in traditional research universities may need to increase their capacity to effectively manage complexity. Control and direction need to be abandoned in favor of influence. Contextualized solutions to complex problems need to be deter-

mined via inclusionary, polycultural approaches to change (Sackney & Mitchell, 2002; Suter, 2001). Faculty members need to be engaged and willing to take innovative risks (Bates, 2000; Brown & Jackson, 2001; Olcott & Schmidt, 2000). Cost-effective, scalable innovations need to be researched and developed (Daniel & Mohan, 2004). To make this transformation possible, individual institutions need to more thoroughly understand their current situations and collegially create effective visions for the future—a future where Academy-based distributed learning networks will transmit ICT-mediated learning opportunities around the world, thus providing flexible access for a wide range of learners to fully participate in the global learning society.

THEORETICAL FRAMEWORK

Structural, cultural, economic, and pedagogical value positions within the Academy may not be closely allied to the potential for successfully increasing access to higher education via ICT-mediated learning opportunities (Brown & Jackson, 2001; Graves, 2001; Hanna, 2000a). Dealing with the complexity of issues in this range of value positions “does not mean controlling or eliminating them. It means tapping the power of complexity by accepting it, understanding its principles, and working with it as academic institutions work with faculty to transform teaching and learning” (Suter, 2001, p. 25).

Suter (2001) applies complexity theory in her development of five principles for transforming the Academy into a postmodern, technologically advanced organization. She argues, “When the speed of change (in demographics, demand, workforce, technology, economics) leads us to the edge of chaos, the command-and-control model” of organizational structures and functions “is not only counterproductive, it is simply not possible” (p. 25). Suter’s first principle advises academic leaders to “give up control and aim for

influence” through systematic sharing of “information,” “authority, responsibility, and the power to oppose” (p. 26). She argues that accelerating change requires institution-wide involvement and distributed leadership.

Secondly, adopting a stance of studying the Academy as if it were an artwork, is posited as an avenue to the creation of an “institutional vision” for a future where shared “goals worth working toward” can be achieved through “tracking important patterns” (pp. 28-29). Using an analogy to nature, Suter prescribes a reduce and reuse approach to creating streamlined, useful structures that fulfill multiple purposes, as well an over-arching common structure for institutional coherence. Paradoxically, she suggests investing in “polyculture and prototyping,” experimenting with diverse approaches, and accepting that “failure is necessary to create the conditions for successful change” (p. 31).

Finally, Suter promotes tapping “the power of limits,” through setting and communicating clear “boundary conditions” (p. 32). Boundary conditions are defined as limits within which the organization must manage its resources. An example of “the power of limits” is the extended use of research funding through application of findings to teaching and learning settings. Using Suter’s (2001) managing complexity framework, an examination of five aspects of each of structural, cultural, economic, and pedagogical value positions follows.

Organizational Structure

Five aspects of organizational structure, which have an impact on the successful adoption of ICT-mediated learning, include: tensions between hierarchical and decentralized organizational forms; bureaucratic and autonomous functions; individual and distributed leadership models; the relative comfort of gradual change and need for more rapid change; pressures for sustaining independent faculty roles; and pressures to

include emergent professions in collaborative, interdependent activities. Strategically mediating these tensions contributes to the “health” of the Academy:

‘Healthy’ institutions are ‘fit for purpose’; in other words, they are organized to ensure their goals and purposes are achieved in the most effective and efficient manner. The current structure and organization of most universities and colleges is largely historical and ... unsuited to new forms of technological delivery. (Bates, 2000, p. 36)

Despite this criticism, Bates (2000) acknowledges an important way in which traditional universities are well prepared to become highly functional, postmodern organizations. He notes a form and function paradox, which serves two basic needs of a postmodern organization: the need for a clear vision of organizational goals and purposes, and the need for flexibility and adaptability to effectively and efficiently meet those goals and purposes. “Despite its hierarchical organizational structure, a [traditional research] university is in practice an extremely decentralized organization” (p. 41). The existing hierarchical form provides opportunities for “strong leadership, characterized by clear but broad vision and objectives,” and an “integrating, coordinating and facilitating role” for senior management (p. 40). The functionally distributed decision-making ability allows a “large and creative ‘core’ of staff—faculty—who are able and willing to operate relatively autonomously, are concerned with the creation and transmission of knowledge, and have the power to develop and implement new ways of doing things” (p. 41), thus allowing the organization to be flexible and adaptable. This paradox of form and function has the potential to balance tension between centralized and decentralized control. It allows leaders to, at once, “give up control while ensuring that there are commonly shared principles for decision making aligned with the institution’s goals” (Suter, 2001, p. 27). In theory, strategic planning and faculty

autonomy can co-exist within the distributed leadership environment of the Academy.

However, faculty autonomy is a factor that affects the pace of organizational change. Few organizations allow the scope of latitude afforded to university and college faculty (Cahn, 1986). “The tradition-bound nature of the Academy has accommodated this latitude, and the slow pace of change in almost every aspect of campus life has made it a tolerable part of the academic landscape” (Hagner & Schneebeck, 2001, p. 2). Conversely, rapid technological development and change, especially rapidly accelerating “dependence on information technology,” “networking” (Bates, 2000, p. 40), and “prototyping” (Suter, 2001, p. 31) are hallmarks of postmodern organizations. The mismatch of the respective paces of traditional academic culture and postmodern organizational culture is a potentially powerful source of resistance to change (Hagner & Schneebeck, 2001; Hanna, 2000a). If the Academy is going to become flexible, adaptable organization, capable of providing learners with the necessary experiences “to develop knowledge and skills appropriate for living and working in a rapidly changing, technology-based society” (Hanna, 2000a, p. 46), the challenge of accelerating the pace of change within the Academy must be met. Engaging faculty in the process of change through clear and open communication and decision-making channels may provide leaders with sufficient influence to do so (Suter, 2001).

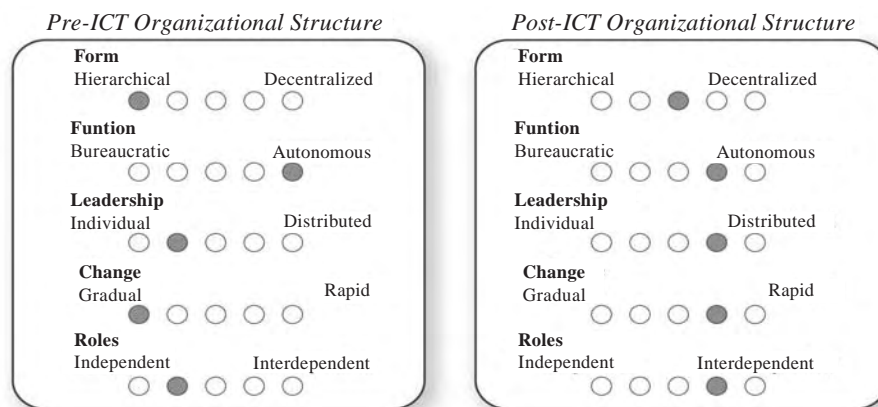

A further structural concern, one that impacts faculty autonomy, is a shift from independence to interdependence in scholarly work. In particular, emergent professions are beginning to be involved in the scholarly work of teaching. Traditionally, “university and college staffs have been highly skilled and ... well-trained for *research*” (Bates, 2000, p. 41). However, “*teaching* has not been not professionalized in the sense of being based on skills resulting from research into and analysis of teaching and learning processes” (p. 41). Rather, teaching has most often been an independent, role

model-based *art* or *craft*, which in comparison to research has “not [been] well rewarded” (Boyer, 1990, p. xii). However, in the development and implementation of ICT-mediated learning opportunities, the professionalization of teaching through study of such areas of knowledge as, “psychology of learning, organizational management research, communications theories, [and] human-machine interaction” (Bates, 2000, p. 41) is critical.

Yet, acquiring and maintaining current, in-depth understanding of these disparate fields, in addition to a specialty area of knowledge, is not always possible. Therefore, many, if not most, faculty members need to work collaboratively with teams of specialists occupying emergent roles (Bates, 2000; Hanley, 2001; Hanna, 2000a; Hutchins, 2000; Luker, 2000). Teaching with technology requires a shift from perceiving teaching as fulfilling a traditional, independent role to “one where teaching and learning are the products of an integrated group of individuals” (Hanley, 2001, p. 59). Emerging roles within the realm of academic teaching and scholarship include instructional designers, educational technologists, Web programmers, multimedia experts, computer scientists, and system engineers. In order to support a team-based approach to instructional development, academic leaders need to promote a culture of collaboration and change tenure and promotion standards that sufficiently reward faculty for time spent on collaborative instructional development activities.

Figure 1 illustrates five continua of organizational structure within the Academy: hierarchical to decentralized organizational forms, bureaucratic to autonomous functions, individual to distributed leadership models, gradual to rapid responses to change, independent to interdependent roles. In addition, in Figure 1 current and required conditions for successful adoption of ICT-mediated learning are hypothesized through the use of a stereo analogy. The premise of this analogy is that just as tone, balance, bass, and

Figure 1. Organizational cultures “in tune” with ICT initiatives

treble need to be adjusted to suit an audio recording, organizational structures need to be “in tune” with ICT initiatives.

Organizational Culture

Shafritz and Ott (2001) define organizational culture as a collage of ephemeral phenomena, including “values, beliefs, assumptions, perceptions, behavioral norms, artifacts, and patterns of behavior,” each of which contribute to “meaning, direction, and mobilization” (p. 361). Schein (1993) argues that a useful way to perceive organizational culture is “as the accumulated shared learning of a given group, covering behavioral, emotional, and cognitive elements or the group members’ total psychological functioning” (p. 372). An organizational culture requires a “common language” and “a common system of communication” as the basis for “group learning”—the ability to acquire and dispel “shared basic assumptions” (p. 373).

When elements of an organizational culture “have become maladapted” to the external environment, “it is ultimately the function of leadership to recognize and do something about the situation” (Schein, 1993, p. 370). Trice and

Beyer (1993) argue that *doing something about the situation*, changing an organizational culture, “is a relatively drawn out and slow process,” which “usually takes several years to accomplish” (p. 415). They recommend initiating change at “propitious moments, when some obvious problem, opportunity, or change in circumstances makes change desirable” (p. 417). The accumulative problems of decreasing public funding (Archer, Garrison, & Anderson, 1999; Bates, 2000; Hanna, 2000a; Mackay, 1996; Nesbit, 2004), opportunities to extend the Academy to better serve the needs of a global learning society (Alclay, 2003; Archer & Wright, 1999; Maduro, 1998; McLuhan, 1964; Norton, 2000; O’Driscoll, 2003), and changes in circumstances, such as the entrance of for-profit competition (Bates, 2000; Hanna, 2000a; Maduro, 1998), as well as the impacts of advanced information and learning technologies (Archer, Garrison, & Anderson, 1999; Bates, 2000; Hanna, 2000a; Nesbit, 2004) currently facing higher education, suggest that a *propitious moment* for cultural change is at hand:

The most important and immediate task for universities facing an uncertain future is to build a

culture that is friendly to and supportive of innovation and change at all levels of the organization. (Hanna, 2000a, p. 348)

Again employing Suter's (2001) managing complexity approach, an examination of five elements of academic organizational culture that affect successful adoption of ICT-mediated learning follows. Beliefs about institutional operations are examined along an independence/interdependence continuum. Values are traced from the tradition of emphasis on open discourse to inclusion of teaching marketable skills. Assumptions about the appropriate role of continuing education units within the Academy scan a range from public service to entrepreneurial venture. Perceptions of technology—from skepticism to enthusiasm—are explored. Artifacts, from lecture notes, assignments, and exams to ICT-mediated learning opportunities, are described in terms of the cultural changes associated with their use. Each of these elements is examined for alignment with the external forces driving and restraining change.

“The curtailment of public funding has become a year-to-year fact of planning life on the campuses” (MacKay, 1996, p. 10). As public funding is withdrawn “and as the ability of the universities, for reasons of equity and practicality, to replace these funds with other sources of revenue, such as tuition, becomes more restricted or disappears, the universities again face the fundamental question of how to rebalance themselves” (p. 10). Increasingly, public pressure is mounting “to ensure that, where possible, the universities act in a cooperative and complementary fashion as they conduct their institutional missions” (p. 10). As a result, “memoranda of understanding” between/among universities are being developed. At a basic level, these memoranda may outline credit transfer policies and joint course development and delivery initiatives among universities. More recent types of memoranda, made possible by ICT-mediated learning, include franchise arrangements, which

allow for use, revision, and reuse of electronic learning resources. This cooperative “reduce and reuse” (Suter, 2001, p. 28) approach to creating and managing resources is a well-suited response to an environment of fiscal restraint.

Fiscal pressure is also fostering a need “to forge many linkages and partnerships with external associations” (Hanna, 2000a, p. 339). Traditional research universities are under significant pressure to abandon the posture of “quiet enclaves for the pursuit of truth far removed from the busy world of commerce and industry” and to assume close linkages “with national economic and scientific objectives” (Nesbit, 2004, p. 104). A pervasive debate within the Academy involves increasing tensions between the academic value attached to “the traditional academic mandate of [fostering] a ‘lively exchange of ideas’” through open discourse and the economic value of “the teaching of [marketable] skills that can lead to required and satisfying careers” (Maduro, 1998, p. 42). Arguments against shifting the mandate further toward marketable skills include: such a change would amount to “prostitution of education”; and the Academy would end up “being in the pockets of industry” (p. 42). Given the “rapid growth in opportunities to profit from the production of knowledge,” the risk of “conflicts of interest” merits recognition (Nesbit, 2004, p. 106). However, counter-arguments, such as “the ‘job-readiness’ gap is growing,” and that “skill deficits” are contributing to Canadian “non-competitiveness,” (Maduro, 1998, p. 40) are equally worthy of note. While the clash between “commercial and academic values” (Nesbit, 2004, p. 106) requires significant deliberation, resolution may be found. Acknowledging the “polyculture” of the Academy (Suter, 2001)—in particular, the role that Continuing Education (CE) units can play in skills training (Hanna, 2000a; Maduro, 1998)—may provide an acceptable balance, attuned to both academic values and knowledge economy pressures.

The appropriate role of CE units is another source of debate. Many North American CE units' mandates originally referenced "the Wisconsin Idea": [that] the purpose of a university was not to educate a small, elite class, but rather to serve the educational needs of the community" (Archer & Wright, 1999, Three eras in university extension, para. 2). Subsequently, CE units have commonly been tasked with dual responsibilities of providing high quality educational services as a public service function and increasing accessibility to programming to non-traditional learners. Conversely, "especially in research universities, many faculty members question whether providing lifelong learning, especially for those in the workforce, is an appropriate mandate" (Bates, 2000, p. 15). As a result, "departments of continuing education (CE) usually have both fewer resources and a lower status than other university units" (Nesbit, 2004). Long-term erosion of institutional support for public service programming through declining financial support from university administrations (Bates, 2000; Maduro, 1998) has created significant fiscal challenges for CE units. Increasingly, CE units are expected to operate on a cost-recovery basis (Nesbit, 2004). However, undertaking entrepreneurial ventures tends to garner criticism from students and faculty, resulting in further erosion of academic status across the Academy (Maduro, 1998; Nesbit, 2004). This stalemate has contributed to North American universities losing an estimated "70 billion dollars a year" to "corporate universities" and "training centers," where in-house programs address CE gaps (Maduro, 1998, pp. 43-44).

Given the significance of the need for lifelong learning, driven by the knowledge and skill demands of the economy combined with the public perception that publicly funded universities have a major obligation to share new knowledge via new information technologies and support for lifelong learning, reconsideration of institutional support for CE units, and their use of ICT is warranted

(Hanna, 2000a). An institutional vision for a future where public learning needs are addressed through a reduction of the "rigidity of boundaries between [universities] and their external publics" through "interaction made possible by increasingly powerful technologies" (p. 343) has the potential to revitalize the relationship between the Academy and society.

If ICT-mediated knowledge sharing is to become a basic tenet of the future Academy, the challenge of developing technically competent faculties must be addressed by university leaders. Rogers' (1995) theory of *diffusion of innovations* "has quite deservedly been recognized as the baseline work" (Hagner & Schneebeck, 2001, p. 1) on perceptions of technological innovations. Findings based upon "intensive interviews with 240 faculty at the University of Hartford" strongly suggest that faculty tend to "demonstrate predominant characteristics" of Rodgers' four technological adoption groupings (p. 2).

The "first wave" or early adopters are "professors who represent the vanguard of innovation in teaching and learning" with technology (Hagner & Schneebeck, 2001, p. 3). However, "their work tends to be idiosyncratic" and is not scalable for broader use (p. 3). Engaging early adopters in scalable solutions requires clearly articulated processes and procedures, which are evidently more effective and efficient than individual efforts.

The "second wave" or "risk adversives" are committed to quality teaching and learning opportunities, and they are attracted to the potential of "new technologies" for improving "what they do"; however, they often lack "technological expertise," and require "significant levels of instructional support" (Hagner & Schneebeck, 2001, pp. 2-3). Risk adversives are often afraid that "their current success in teaching will not translate into the new teaching environments" (p. 2). Some "are hesitant to become engaged in the process of self-examination" (p. 2). Technological and peer support are critical for this group.

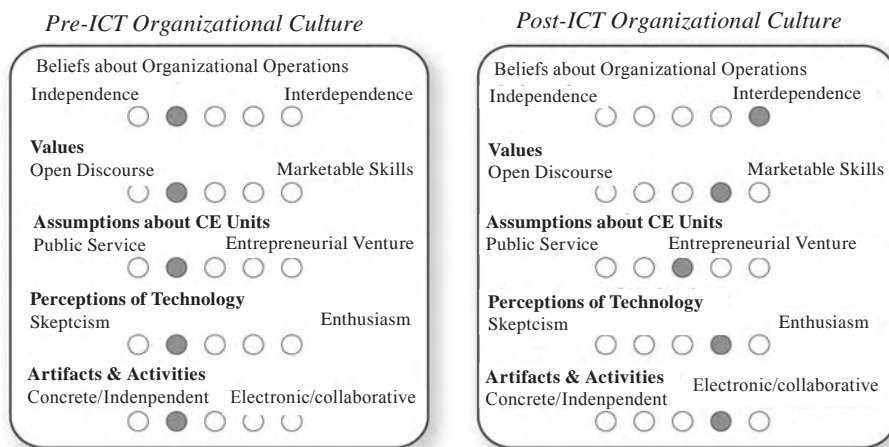

The “third wave” or “reward seekers” tend to focus on use of technology “to advance their professional careers”; therefore, their motivation “is closely tied to the university’s reward structure” (Hagner & Schneebeck, 2001, p. 4). “When they view adoption of new teaching and learning techniques as having a positive impact on tenure, promotion, and salary decisions, they will be more willing to transform” (p. 4).

The “fourth group” or “reluctants” are “those who are computer illiterate or firmly believe that traditional models of learning are superior” (Hagner & Schneebeck, 2001, p. 4). In some academic institutions, “there is a pervasive belief that faculty jobs are going to be replaced by the adoption of technology” (Olcott & Schmidt, 2000, p. 262). Fearful and “philosophically resistant faculty” increasingly risk being perceived as “anachronistic” and the professional consequences of that perception, including “an adverse impact on the evaluation of their teaching” (Hagner & Schneebeck, 2001, p. 5). One effective leadership method with this group is to communicate these risks through “faculty bodies, such as faculty senates” (Hagner & Schneebeck, 2001, p. 6).

Variant perceptions of technology—from the skepticism of reluctants to the enthusiasm of early adopters—warrant consideration in the design of engagement strategies. To circumvent cultural resistance to technological innovation, institutions need to determine their [particular] faculty mix and strategically plan appropriate support mechanisms and communication channels for each adoption group.

Organizational culture is often expressed through the use of artifacts for cultural activities. Whereas lecture notes, assignments, books, and exams are predominant artifacts in traditional educational settings, ICT-mediated learning artifacts include electronic learning resources and environments, and electronically mediated personal and professional experiences. The use of traditional educational artifacts emphasized concerted individual, isolated effort directed toward “abstract and relatively unconnected assessment processes such as . . . content examinations” (Hanna, 2000a, p. 345). ICT artifacts increasingly focus on “the ability to work in teams, to develop creative approaches to problem solving, and to learn continuously” (p. 344). Networked univer-

Figure 2. Organizational cultures “in tune” with ICT initiatives

sities are becoming “more and more concerned with ensuring that students know how to learn and to apply what they learn to real situations” (p. 344). This activity-centered approach to demonstrating learning represents a cultural shift from valuing abstract knowledge to valuing applied knowledge and skills—the same skills that are “necessary to live and work in a rapidly changing economy” (p. 64).

Figure 2 illustrates two hypotheses: one suggests a current state of academic culture, and one recommends cultural attunement for successful adoption of ICT-mediated learning opportunities.

Organizational Economies (Institutional Reward Systems)

Five aspects of organizational economies (institutional reward systems) that have an impact on the successful adoption of ICT-mediated learning opportunities include: tensions created by an emphasis on rewarding research activities more substantially than teaching activities; restricting the involvement of junior faculty in ICT development through out-date tenure and promotion criteria; emergent tensions between institutional rewards for commercialization of research discoveries and innovations and commercialization of ICT development activities; emergent issues about ICT intellectual property rights; and valuing work with graduate and traditional (full-time, on-campus) learners more than undergraduate and non-traditional (part-time, distance) learners.

Extending Suter’s (2001) approach to managing complexity, an analysis of these five elements of institutional reward systems that affect successful adoption of ICT-mediated learning follows:

Today... there is a recognition that the faculty reward system does not match the full range of academic functions and that professors are often caught between completing obligations... According to the dominant view, to be a scholar

is to be a researcher—and publication is the primary yardstick by which scholarly activity is measured... Given these tensions, what is the balance to be struck between research and teaching? (Boyer, 1990)

More than a decade after Boyer (1990) posed his question, the advent of ICT development as a teaching activity for faculty adds salience to it. ICT design, development, and delivery involve significant time investments from faculty (Bates, 2000; Hanley, 2001). Conversely, the same time investment could be made in research activities. If the Academy is serious about technological innovation in teaching praxis and does not adjust this mismatch of rewards, it will be difficult to engage faculty in ICT development initiatives (Archer, Garrison, & Anderson, 1999; Olcott & Schmidt, 2000).

Junior faculty members—the group that initially may seem most likely to adopt innovations—are, in fact, systematically discouraged by existing reward systems:

Interestingly, senior tenured faculty can venture out and be innovative, while junior non-tenured faculty must adhere to traditional norms. Translated, this means strict adherence to promotion and tenure criteria. In sum, for many junior faculty members there are not only few incentives but, in fact, underlying disincentives operating in this subculture. (Olcott & Schmidt, 2000, p. 264)

If technological innovation is to take hold in the Academy, the criteria for tenure and promotion must become more inclusive in determining legitimate scholarly activities, and this change needs to be perceived as an immediate, rather than a future, concern:

The currency of the Knowledge Age is information. More precisely, it is the creation, analysis, preservation, and distribution of information in efficient, easily accessible venues that give users

the immediate capacity to apply information and knowledge. (Olcott & Schmidt, 2000, p. 259)

In the New Economy, the academic tradition of autonomous pursuit of knowledge, for its own sake, is coming under increasingly powerful political-economic pressures. Fiscal challenges, combined with expanded opportunities to commercialize discoveries and innovations, are driving academic leaders to reward faculty for commercialization of research (Boyer, 1990; Nesbit, 2004). To date, few examples of commercialization of ICT-mediated learning can be found, but that may change. Increasingly, faculties who are skilled and experienced in ICT development are being “courted by private-sector companies, publishing firms, and government to develop technology-based content and instructional packages” (Olcott & Schmidt, p. 266). A logical next step would be to reward faculty for commercialization of teaching activities in comparable terms to those that currently exist for commercialization of research activities.

One element of commercialization of electronic learning resources that deserves particular attention is the question of who owns the intellectual property (IP) rights to ICT products that have been funded by academic institutions, and developed by faculty members in collaboration with instructional designers, multimedia, and information technology specialists. This question is complex, and to date, unanswered. Given that “cases have held ... that a professor who creates his or her own lectures (assuming they meet the test of originality and fixation, that is, recorded in a fixed format, such as print) owns the copyright in his or her own works” (Tallman, 2000, p. 194), it seems arguable that similar criteria would be applied to ICT-mediated learning artifacts. However, given the “vast resources the university invests in the creation” of ICT-mediated learning, “it is understandable that a university will claim ... ownership” (p. 194).

A further complicating factor is the status of the collaborators in the IP picture. Whereas multimedia and information technology specialists routinely belong to professional associations whose contractual relationship with the university includes relinquishing IP ownership of “work-made-for-hire” (Tallman, 2000, p. 194), instructional designers often hold faculty positions. The latter consideration brings to the fore questions concerning the respective values of content and design in ICT-mediated learning. As muddy as the IP waters appear to be, “there is a middle ground: copyright can be owned jointly” (p. 195). In sum, legal guidelines for sharing profits derived from the commercial exploitation of ICT-mediated learning artifacts may soon be a matter of significant contention between academic faculties and leaders. The manner in which this matter is managed could become a critical element in either driving or inhibiting faculty engagement in technological innovation.

A fifth consideration of existing reward systems are the variant returns on investment faculty receive for teaching and advising different types of students. The least profitable learners in the educational sector are individuals, who for geographic, economic, or academic reasons, cannot access a conventional university program. Typically, these non-traditional learners have registered in unclassified or non-degree programs offered via distance learning options. Distance education within traditional universities has typically been marginalized in Continuing Education and Extension Divisions, and is of little interest to the Academy at large (because neither status nor rewards were offered for this work); therefore, the tasks of teaching and advising non-traditional, part-time learners has often been contracted to sessional lecturers.

“In the environment of public universities in Canada, it is easy to identify [traditional, on-campus] undergraduates as being ... the university’s [second] ‘least profitable customers’” because

Visualizing ICT Change in the Academy

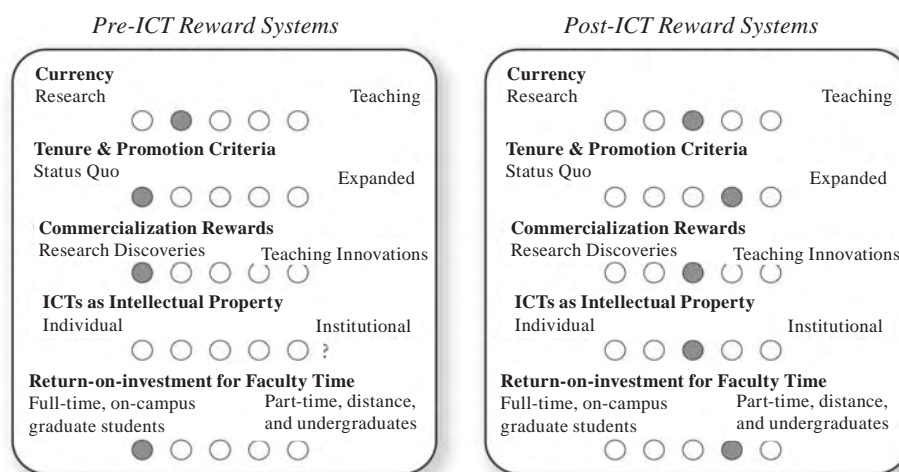

they do not contribute to the most “lucrative part of the ‘market’ addressed by research universities” (Archer, Garrison, & Anderson, 1999, p. 18). As research is the currency of traditional universities—the predominant source of tenure and promotion for faculty—and as undergraduate students rarely contribute to this currency, emphasis on undergraduate teaching may be less valued.

Recently, for-profit corporate universities have entered the post-secondary educational *market*, and have with variant levels of success, established themselves as players in the graduate “sector” (Bates, 2000; DiPaolo, 2003). In response to this emerging competition, traditional universities, to variant degrees, have implemented changes to graduate studies admission and residency requirements, and as a result, have created a third class of academic clients: professional or executive graduate students. The Universities of Toronto, Saint Mary’s, Western Ontario, McGill, Brock, and Concordia, for example, have launched Executive Masters of Business Administration programs, all of which involve flexible access,

such as weekend and evening classes, and many of which include part-time and e-learning options. While learners in programs such as these are involved in research, as part-time and/or remote program participants they are unlikely to contribute significantly to campus-based research programs. However, with annual tuition fees as high as \$20,000 (McGill, 2006) and \$16,500 (Brock, 2006) per year for e-learning options, tuition revenues can significantly contribute to funding on-campus research.

The fourth, and arguably still most-valued class of learners in traditional research universities, remains full-time, on-campus graduate students. These learners make significant contributions to the Academy through research and teaching assistant positions, thus freeing faculty to focus their time and energy on research and publication (Archer, Garrison, and Anderson, 1999; Olcott & Schmidt, 2000). As a result, the activities of full-time, on-campus graduate students currently are most closely aligned to existing faculty reward systems, thus providing the most return on investment for faculty time.

Figure 3. Organizational economy/reward systems “in tune” with ICT initiatives

However, the influence of the New Economy, combined with rapidly increasing educational costs (Bates, 2000), and the available option of e-learning may make full-time, on-campus graduate study less attractive. Further, “the public, the legislature, and consumers care about quality,” but they also increasingly focus attention on “cost-effectiveness” (Olcott & Schmidt, 2000, p. 269). Scalable e-learning systems are gradually becoming more cost-effective than campus-based programs (Bates, 2000), and if one takes a broader view, productivity and wage losses due to long-term study-related career interruptions are arguably also measures of cost-effectiveness. The “new generation of students who are more demanding, selective, and vocal about their educational” and financial needs may less often choose the full-time, on-campus route through graduate studies (Olcott & Schmidt, 2000, p. 268). Therefore, traditional research universities may be well advised to consider re-evaluating existing reward systems to provide incentives for increased faculty involvement with a broader variety of learners.

Figure 3 illustrates two hypotheses: one suggests a current “economic” state of the Academy, and one recommends reward-system attunement for successful adoption of ICT-mediated learning opportunities.

Pedagogical Praxis

With the advent of ICT-mediated learning opportunities, “faculty must begin to *design* instruction and not just *deliver* instruction (Olcott & Schmidt, 2000, p. 274). The professionalization of teaching, as a critical component of successful adoption of ICT-mediated learning, requires that faculty re-evaluate their pedagogical practices. “Habit, tradition, and culture have so far kept [many] faculty from addressing pedagogical practice and technological innovation” (Olcott & Schmidt, 2000, p. 274). An increasingly common institutional approach to address pedagogical practices

in the development of ICT-mediated learning is to involve instructional designers.

Instructional design—a combined art and science of teaching—is based upon principles of learning psychology, “cognitive science research and instructional models” (Olcott & Schmidt, 2000, p. 274). Research conducted through EDUCAUSE, a non-profit organization, whose membership includes “more than 1,800 campuses, organizations, and corporations” (Barone & Hagner, 2001, p. viii), strongly suggests the involvement of instructional designers, or at a minimum, provision of instructional design resources for ICT development initiatives “serves to increase quality and reduce risk” (Hartman & Truman-Davis, 2001, p. 51). Increasing quality and reducing risk are two of the most important concerns in ICT initiatives. Thus, a series of pedagogical considerations is warranted.

Five pedagogical considerations that have an impact on the successful adoption of ICT-mediated learning include: the changing nature of student enrollment patterns; customization and personalization of learning environments and experiences; transitioning from content-focused to learner-centered and service-oriented instruction; transforming classroom-based and distance education models into distributed learning opportunities; and designing ICT-mediated learning for reuse. Thoughtful, strategic responses of these five pedagogical issues can contribute to successfully managing the complexities of ICT initiatives.

One of the major challenges that traditional research universities face in the digital era—perhaps the most salient one—is determining who their prospective learners are and who future learners will be. Whereas geographical area, institutional reputation and mandate, as well as fee structures, may have been the criteria via which defined institutional “clientele” in the past, increasing job market demands, e-learning options, and lifelong learning needs are influencing the “student mix and competitive position” of universities (Hanna, 2000a, p. 337). Diversity in the range of job-re-

lated skills in demand and diversity in the range of learners *shopping* for courses and programs are contributing to demand for customized or personalized learning experiences:

Personalizing learning will require the development of new administrative and pedagogical processes, and learning technologies will play an important role in being able to accomplish this personalization effectively. (Hanna, 2000a, p. 337)

Personalizing learning also requires knowing who the learners will be and the range of individual needs that must be met. Failure to address the personalization issue has already caused a significant number of institutions to experience significant difficulty in implementing e-learning initiatives.

Rapidly increasing enrollments in higher education e-learning programs may not result in the equally high successful completion rates. Carr (2000, para. 13) reports a range of 20% to 50% attrition rates in distance education programs in American colleges. While these rates vary significantly among institutions, administrators generally concur that “course-completion rates are often 10 to 20 percentage points higher in traditional courses than in distance offerings” (para. 13). A metastudy of a broad range of correspondence-based distance education results, undertaken by the World Bank, reported “dropout rates ranging from 19% to 90% and an overall rate of 40%” (Potashnik & Capper, 1998, p. 43). Potashnik and Capper suggest that “while similar studies have yet to be conducted for technology-based distance learning, both intuition and the limited research already done suggest that the interactivity and novelty provided by most technology-based approaches may contribute to higher completion rates” (p. 43).

However, recent studies of attrition rates in online learning programs provide little supportive evidence that ICT-based approaches can

ensure higher completion rates. Jameson (2002) argues, “It is common in Web-based instruction to have high attrition rates” (p. 2). Neil (2002) reports, “Enrollment and attrition rates are both statistically greater in the online format” (p. 66). Lorenzetti (2002) concurs that while it is relatively easy to attract learners to online distance education courses, dropout rates can “range as high as 50%” (p. 1). MacGregor (2001) argues that not all learners are willing to try online approaches to distance learning, and “those who do sign up drop out in higher numbers than in a traditional face-to-face course” (p. 143). “Retention has been indicated as one of the greatest weaknesses in online instruction” (O’Brien, 2002, para. 1). Given these preliminary findings, the success of electronically delivered distance education products and services may not be as secure as projected demand statistics predict. Whether or not e-learning will be successful is a question that the learners, not the technologists, will ultimately answer. In short, the predominant question about e-learning has been, “If we build it, will they come?” Currently, the question is, “How do we design it to ensure they stay?”

One strategy for increasing retention rates is to place stronger emphasis on the needs of learners during the development and delivery phases of e-learning projects. This strategy involves moving away from traditional domain-centered pedagogy and toward a learner-centered perspective. The shift from domain-centered to learner-centered design is being undertaken in order to increase the effectiveness and relevance of teaching practice.

To date, comparative research on the effectiveness of online learning has tended to focus on classroom-based learning. As a result of this context, many early versions of online instruction extended classroom-based pedagogical practice into online learning environments (Gifford & Enyedy, 1999). Traditional classroom-based pedagogical practice has been highly dependent upon “the transmission model of knowledge transfer... [in which] knowl-

edge is an identifiable object that is possessed by a person, detached from any social context, that can be conveyed from the mind of the instructor to the mind of the student” (Gifford & Enyedy, 1999, p. 2). Given the epistemological perspective that knowledge-to-be-learned is an object that may be possessed and transferred, Domain Centered Design (DCD) tends to focus on design and development activities that lead to well-organized and well-presented knowledge objects (Sims, 2001). Rather than taking into account the needs, wants, and desires of the learner, “the focus of pedagogy from this perspective is to make transmission more efficient” (Gifford & Enyedy, 1999, p. 2). As a result, learners who use online products and services created from a DCD perspective tend to struggle with difficulties similar to those that have long challenged traditional distance learners who have used print-based materials (Beffa-Negrini, Miller, & Cohen, 2002).

In contrast to DCD models of knowledge acquisition, learner-centered, activity-centered, situated, and participatory models of instructional design and development focus on demographic and cognitive profiles of learners, prior knowledge, perceptions, preferences, needs, goals, characteristics, and experiences of learners. While individual theorists draw distinctions among learner-centered, activity-centered, situated, and participatory models (Gifford & Enyedy, 1999; Reeves, 1999; Vinicini, 2001; Wilson, 1995), for the purposes of this chapter, the commonalities among these models will be considered and will be referred to as learner-centered design (LCD).

The underpinning tenet of each of these models is a shift of *focus* from what is known about and what is valued within a content domain (DCD) to what is known about and what is valued by learners (LCD). This shift is away from primary concern for what will be taught to a careful examination of learner characteristics and to ensuring that learners will perceive content as worth knowing (Sims, 2001). Subsequent development activities are focused on ensuring that essential

content is contextualized in learner experiences and/or goals, so that learners will be motivated to value it.

A Boise State University (BSU) case study exemplifies the difference that may be made by a shift from DCD to LCD. In 1989 Boise State launched a distance learning online/off-Web, Masters’ degree program in Instructional Performance and Technology (IPT). A variety of undergraduate degrees were accepted for entrance into the program; however, much of the curriculum assumed prior knowledge in the fields of psychology, educational psychology, and instructional design. Most students were full-time working professionals in fields other than education or instructional design. A common motivation for entering the program was to make a career change or to specialize in training within an existing profession. All students were required to make substantial commitments of weekly time and long-term planning. The program was, for its time, rather expensive, and its service level to students did not match either its fee level or learner needs. Students were required to have access 15 hours per week to a computer system valued at approximately \$3,000 U.S. in order to interact with the *FirstReader* courseware system that delivered the program. Tuition fees per 3-credit course, by 1995, had reached \$999 U.S. Despite their considerable initial commitments, “between fall 1989 and fall 1996, 44% of the students had dropped out” (School’s Founder, 2002, p. 4). In a series of exit interviews conducted by Chyung (2001), the most often cited reason for attrition was “discrepancies between... professional or personal interests and the curriculum or the course structure” (Cause analysis, para. 1). Course developers at Boise State took this feedback seriously. A series of changes were made to the *IPT* curriculum and course structure. By the end of the 2000 term:

BSU’s department of Instructional Performance and Technology had decreased online attrition to

Visualizing ICT Change in the Academy

15% by focusing on its first-time Internet learners... The department also devised interventions to address students' unfamiliarity with the subject matter; varying interests, goals, and learning styles; and desires for personal contact and social interaction. (School's Founder, 2002, p. 4)

Aligning the *IPT* program more closely with learners' needs, wants, and goals, as well as providing additional student support mechanisms, resulted in significantly improved retention rates and student satisfaction ratings, which in turn, resulted in the continuance of the *IPT* program. A lesson learned in the *IPT* case is that for-profit e-learning ventures where discrepancies between fee and service levels persist, and where learner needs and aspirations are ignored, are unlikely to be sustainable over the long term.

Transforming classroom-based and distance education models into distributed learning opportunities has the potential to better serve traditional, on-campus learners and non-traditional, distance learners. Distributed learning adopts a learner-centered approach to pedagogy and "integrates a number of technologies to enable opportunities for activities and interaction in both asynchronous and real-time modes... This approach gives instructors the flexibility to meet the needs of diverse student populations, while providing both high quality and cost-effective learning" (Bates, 2000, p. 27). Distributed learning models provide faculty with more flexible working conditions, which in turn allow faculty the opportunity to more easily balance teaching and research responsibilities.

An element that distinguishes distributed learning from other modes of instruction is its use of ICT-mediated learning opportunities to facilitate peer-to-peer learning: "Students do not so much interact *with* the technology as *through* the technology with teachers and other learners" (Bates, 2000, p. 27). Interacting with peers via online communication promotes "collaborative learning," and builds teamwork capacities (p.

27). Interacting with teachers, and in some cases external experts in the field of study, extends learning for both traditional and non-traditional learners well beyond the campus of the university, potentially into previously inaccessible work- and research-related arenas. Thus, the benefits of distributed learning opportunities are well suited to the demands of the global learning society and strategically suited to university goals, such as the provision of high quality and cost-effective learning.

Finally, designing ICT-mediated learning opportunities for reuse is a topic of increasing interest. The escalating costs of designing and developing high quality ICT-mediated learning opportunities is driving this interest and creating a new area of educational research: reusable learning objects (RLOs). RLOs and RLO repositories are currently hot topics of debate across the educational sector (Wiley, 2002).

Even the definitions for these terms are controversial. The Institute of Electrical and Electronics Engineers' Learning Objects Metadata (LOM) Working Group (2002) defines learning objects as "any entity, digital or non-digital, that may be used for learning, education or training" (Institute of Electrical and Electronics Engineers, 2004, para. 1). This definition has been broadly applied in commercial venues, but has received significant criticism from the educational community because its breadth is perceived as meaningless. Wiley (2002) alternatively defines learning objects as "any digital resource that can be reused to support learning" (p. 6). Merrill (2001) offers a distinction between learning objects and knowledge objects: knowledge objects include "only the content to be learned but not an objective, presentation, or assessment; learning objects are distinct from knowledge objects in that they also include an objective, some instructional information, and assessment" (Wiley, 2002, p. 11).

Similar controversy surrounds the definition of learning objects repositories. Definitions range from an alternative term for a database to a special-

ized computer server that houses information in a structured environment, which is organized and accessed via metadata. “Metadata, literally ‘data about data’ is the descriptive information” about both knowledge and learning objects that allows them to be retrieved from an electronic repository via a search mechanism (Wiley, 2002, p. 8).

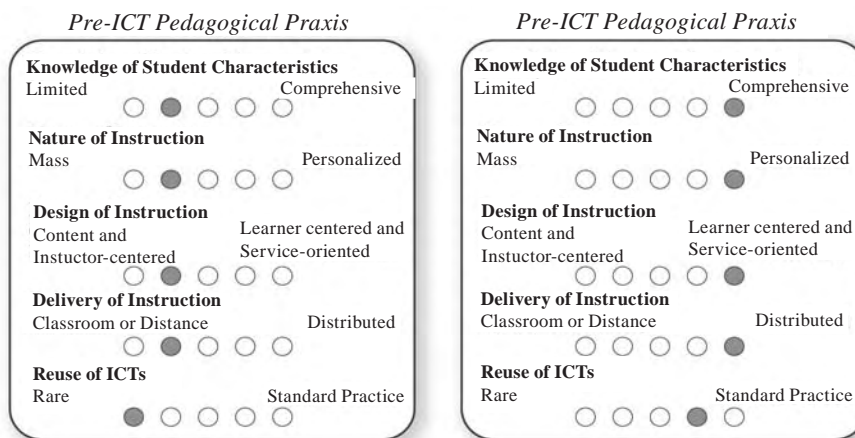

Definitional debates aside, reusable electronic learning objects and the repositories that house them promise sufficient cost-effectiveness to warrant attention (Barritt & Alderman, 2004; Daniel & Mohan, 2004). CANARIE, Canada’s advanced Internet development organization, has contributed \$10 million over the past five years to the research and development of reusable electronic learning objects and learning objects repositories (Wosk, 2003). This investment has been aimed at “attaining critical mass [of RLO users] to demonstrate value” and “addressing [the] major problem” of developing cost-effective approaches to managing ICT-mediated learning opportunities (p. 2).

In more advanced e-learning environments, learning agents can broker relationships among learners, experts, and objects by matching learner

profile information for the purposes of recommending specific resources and peer-to-peer, as well as expert-to-novice, support (McCalla, 2004; Mohan & Greer, 2003). In combination with learning objects and agents, user-tracing software can detect user-behavior, analyze behavior patterns, and assist the agents in making increasingly accurate recommendations (Zaiane, 2002). Thus, the system can *learn* to effectively link individuals to others who share their interests and who can provide peer or professional assistance. The system can also *learn* to recognize resources that match individuals’ learning styles and learner goals, thus enabling individualization of user experiences (McCalla, 2004). While data-mining and expertise-location tools are still in the research and development phase, in combination with learning objects technologies, their development holds significant promise for future community-building functionalities within e-learning systems.

Finding or creating cost-effective avenues to create, customize, use, and reuse ICT-mediated learning artifacts, and to create the conditions for communities of users to support each other in their

Figure 4. Pedagogical praxis “in tune” with ICT initiatives

learning goals, are emerging fields of research and development, which will be of significant interest to university leaders, who face concerns about “how and where to invest scarce resources” (Suter, 2001, p. 29) in technological innovations for teaching and learning. As accumulating existing ICT resources reach a management and maintenance crisis-point, these issues will come to the fore of the list leadership challenges in higher education.

Figure 4 illustrates two hypotheses: one suggests a current state of the pedagogical praxis within the Academy, and one recommends pedagogical attunement for successful adoption of ICT-mediated learning.

CONCLUSIONS AND RECOMMENDATIONS

The global learning society, and its demands upon members of society to learn their living, are now and will continue to transform the Academy. At this juncture, traditional research universities may need to examine their e-learning policies and practices to effectively adapt to a complex, ambiguous, and dynamic external environment. University leadership needs to strategically respond to the pressing demands of external forces for change. By attuning internal organizational structures, cultures, economies (reward systems), and pedagogical praxes to changing academic times, the Academy can embrace ICT solutions and their associated service orientation to ensure its ongoing position as *the best option* for higher education.

Chapter 8.7

Perspectives on 21st Century E–Learning in Higher Education

Lalita Rajasingham

Victoria University of Wellington, New Zealand

ABSTRACT

This chapter explores a new higher education paradigm given the changing environment that will come with the advance of globalization and the rapid development of the Internet. As economies evolve around a global network and the value of knowledge, societies rely on universities to help shape future education in an emerging knowledge society. As teachers and learners already find that they need to adapt to the presence of the Internet, university managers and administrators will need to adapt their structures, strategies, procedures and programs to deal with the processes of globalization. Based on international research, this chapter presents a vision, and a paradigm from which higher education might be constructed. The Sloan-C Five Pillars of Quality Online Education and new applications, HyperReality and Croquet, are examined as potential platforms to reframe future developments.

INTRODUCTION

In describing the concept of paradigms, Thomas Kuhn (1962), in his text, *The Structure of Scientific Revolutions*, meant “what members of a scientific community, and they alone, share” (Kuhn, 1977, p. 294) and went on further to suggest that “when paradigms change, the world itself changes with them” (1962, p.110).

Another equally important related concept as we examine changes in society is world-view—*zeitgeist*—which Michel Foucault calls an episteme, by which he means an all-encompassing body of unconscious knowledge peculiar to a particular time and place, and concludes that it is not possible for people in one episteme to comprehend the way people in another episteme think (Foucault, 1970).

Historically, higher education has seen many global paradigm shifts, with varying degrees of turmoil. The medieval university taught the word of God and began in monasteries in Europe and

in temples, madrassas and churches in other parts of the world. Essentially elitist and male, it served princes and priests.

The emergence of communications technologies, especially the printing press and the railways, gave birth to industrialization and nation states. Universities moved from explaining the world in terms of God's word to become part of the structure of the industrial age, explaining reality in terms of scientific rationalism, catering for a nation's managerial and professional elite, gradually including women. This is the paradigm of national higher education that we know today. However, with the developments of the Internet, the World Wide Web, broadband, digitalization, wireless, satellite, mobile phones and new applications of virtual reality, HyperReality and artificial intelligence to build collaborative, immersive simulated environments, our children and grandchildren will face very different educational environments. Higher education is once again undergoing a paradigm shift, as technologies add new global perspectives, and universities worldwide face new challenges at a time of unprecedented demand for higher education.

Current Scan

John Daniel (1996) suggests that given the demand for higher education and the inability of conventional universities as we know them to cope, even sustaining the current level of participation in higher education and particularly the growing demand in India and China, one new major institution would need to be created somewhere in the world each week for the next 30 years. Clearly, a solution is needed that moves universities from being based on building and transport technologies, which are becoming increasingly costly, to also operate with computers and telecommunications. Students, particularly adults, seek life-long learning opportunities anytime and anywhere more convenient for their dual roles of juggling personal and professional needs.

Donald Hanna (2002) argues the need to develop greater understanding of how teaching and learning, knowledge generation and preservation, organizational design and evaluation, and leadership can all function together within a changing and increasingly competitive external environment and create new ways to respond to diversity within higher education. He approaches the challenge of access and suggests that traditional campus-based universities are opening access points through technology enhanced e-learning, and the large 'mega-universities' described by Daniel (1996) are beginning to build more robust mechanisms, including interactions among students and faculty that are both face to face and supported by advanced information and communications technologies (ICT), such as the Internet. Providing access to higher education for increasing demand, both in the developed and developing societies, remains one of the main challenges facing governments. In his paper, Poley examines this issue from the perspective of gender, poverty and race (2000).

In the United States (U.S.), for-profit universities are being established to serve working adults, and new online, virtual universities and strategic consortia are also emerging; Hanna (2002) and Poley (2000) stress the importance of leadership with vision as universities become competitive and commercialized in the age of knowledge (Poley, 2000). According to Potashnik and Capper (1998), there are 11 mega-universities, each of which enrolls more than 100,000 students per year, with a combined enrollment of some 2.8 million.

E-learning and increasing fiscal constraints faced by modern universities are introducing some new pedagogical frameworks, learning environments and stakeholder demographics. University fees turn students into customers that demand life-long education. Rectors and vice chancellors are employed as chief executives rather than distinguished scholars. Research becomes that which is funded and formulaic instead of a search for knowledge and truth. These are the

Table 1. Mega-universities: Basic data (Potashnik & Capper, 1998)

	Name of institution	Established	Students in degree programs ¹	Graduates per year	Budget (million dollars)	Percentage of budget from		Unit cost ²
						Student fees	Government grants	
China	China TV University System	1979	530,000	101,000	1.2 ³	0	75	40
France	Centre national d'enseignement à distance	1939	184,614	28,000	56	60	30	50
India	Indira Gandhi National Open University	1985	242,000	9,250	10	42	58	35
Indonesia	Universitas Terbuka	1984	353,000	28,000	21	70	30	15
Iran	Payame Noor University	1987	117,000	7,563	13.3	87	13	25
Korea	Korea National Open University	1982	210,578	11,000	79	64	36	5
South Africa	University of South Africa	1873	130,000	10,000	128	39	60	50
Spain	Universidad Nacional de Educación a Distancia	1972	110,000	2,753	129	60	40	40
Thailand	Sukhothai Thammathirat Open University	1978	216,800	12,583	46	73.5	26.5	30
Turkey	Anadolu University	1982	577,804	26,321	30 ⁴	76	6	10
United Kingdom	Open University	1969	157,450	18,359	300	31	60	50

³ Central unit only

⁴ Open Education Faculty only

early symptoms of the coming paradigm shift. A play on Harold Lasswell's Communications dictum, the question is who will teach what to whom in what channel, with what effect in the knowledge society?

It is possible that the new paradigm of higher education will be located in cyberspace, as the changes we are likely to see over the next 20 to 30 years assumes that computing technology will continue to converge with telecommunications, that cellular and digital environments will become ubiquitous, that the trend to wear information technology will continue, that we will access distributed virtual realities as we do mobile phones now and that artificial intelligence will have a growing role (Tiffin, 2004). Such developments make it possible to rethink every aspect of higher education, from curricula assessment, instructional methodology, student entry, satisfactory academic status, fees, terms and timetables

within the framework of the Sloan-C Five Pillars of Quality Online Education.

Sloan-C Five Pillars of Quality Online Education

The Sloan Consortium Report to the Nation (2002), by George Lorenzo and Janet Moore, established the Five Pillars of Quality Online Education-- learning effectiveness, student satisfaction, faculty satisfaction, cost effectiveness and access-- as the values, principles and goals of asynchronous learning networks. Asynchronous learning networks (ALN) today commonly refer to 'online learning,' 'flexible learning,' 'e-learning,' 'virtual classes' and 'virtual universities,' reflecting the use of computer and Internet technologies to facilitate interactive communications between teachers and learners in an online learning environment. The Five Pillars are interrelated, and

conventional universities have a long and successful history of established procedures and structures for the interaction between the Pillars (Lorenzo & Moore, 2002). However, the rapid advances in speed and power of new clusters of digital technology enable fully immersive learning environments to replicate in different locations the communications functions of the multimediated, conventional face-to-face classroom. This will impact on the interrelation between Sloan-C Five Pillars, changing how teaching, learning, and knowledge creation and dissemination—the universals of universities—will be conducted in the future.

A Universal of Higher Education: The Teaching/Learning Function

There are some critical factors that constitute higher education, the universals of a university that will not change whatever the episteme, the place, the language, the culture or the medium used. From a neo-Vygotskyian (Vygotsky, 1978) perspective, higher education is interactive communication where teachers who have graduated help learners who have not yet graduated to apply knowledge to solve real-life problems. The main difference that distinguishes e-learning from on-campus learning is that instead of bringing students and teachers together physically by means of local transport systems and buildings for face-to-face interaction, it uses computers and telecommunications to bring them together as tele-presences on the global Internet.

The Internet is still evolving and will continue to do so. Curricula designed for use in a particular institution within a particular nation and context and posted on the Internet are now open to scrutiny from a global perspective, as the professional application of knowledge increasingly takes place in a global and a local context. The conventional university system is designed and localized for the nation in which it operates, teaching people how to be doctors, lawyers, teachers and pilots

in the paradigm of one particular country, and operate according to the rules, regulations, laws and language of that country.

However, with advances in the Internet, professionals need to know about international practice as they compete in the global economy. Pilots fly internationally as well as nationally. AIDS, SARS and Avian Flu know no frontiers, and doctors need to be able to collaborate internationally to deal with these pandemics. Students now compare and evaluate what is taught in other countries by using the World Wide Web, and linking in chat rooms with students from around the world. The inevitable march of higher education into a global tempo will only increase and will need curricula to match.

Globalizing Curricula

In his 1902 collection of essays on the Idea of a University, John Newman said:

A university, I should lay down, by its very name professes to teach universal knowledge. (Newman, 1996, p. 25)

Georgette Wang (personal communication with J. Tiffin & L. Rajasingham on “The Purpose of a University”, November 23, 1999) suggests that the purpose of a university is to address the great issues of its time. Today, in any media in any country we are informed about tsunamis (2004), hurricanes (2005), new viruses and pandemics, genetic engineering, free trade, terrorism and the impact of technology in all human communications. These issues echo the way world problems are listed and taxonomically mapped in the Encyclopedia Plus of World Problems and Human Potential (1996). These are the great issues of our time, and they are problems of global dimensions. Global problems need cadres of professionals equipped with skills to offer global solutions.

It follows that to be effective in e-learning, higher education needs to globalize its curricula.

The World Trade Organization's (WTO) General Agreement on Trade and Services (GATS) regards higher education as an information service that can be traded globally. A global trade in teaching has begun, as evidenced by the increasing number of online, virtual and e-learning courses on the Internet. However, as companies and institutions that market globally have discovered, there is more to globalizing a product than putting what works well in one country, in one paradigm and one episteme up for sale in another on the Internet.

The timely and useful book, *Partnering in the Learning Marketplace* (2001), foreshadows issues as education becomes global and competitive using innovative technologies. There is a growing smorgasbord of educational courses and degrees on the Internet, giving birth to a new marketplace where all our transactions—learning, business, shopping and working—are moving from place to cyberspace. "Marketplace" is a term coined by Rayport and Sviokla (1994) to distinguish the new virtual world of bits of information from the atomic physical world, and Kevin Kelly (1998) notes, "people will inhabit places, but increasingly, the economy inhabits space" (p. 94).

While the idea of a market where teachers and learners can trade is not new, the medium in which it takes place is new. As the Internet grows in power and robustness, a global trade in teaching is enabled as learners become customers and buyers, and teachers and universities become sellers of products and services in competition in the global marketplace (Tiffin & Rajasingham, 2001).

To respond to an increasingly sophisticated and market-driven learner satisfaction, academic departments in universities need to rethink, reformat and redesign their programs and structures as e-learning moves from being teacher-controlled to learner-centered, and becomes more connected with personal and professional experiences. Furthermore, learning and teaching will need to become increasingly interdisciplinary to mirror and respond to real-life problems and issues from

multicultural perspectives. According to Drucker (1999, 2000) the trend is amplified by learners' desire for a 'holistic' constructivist approach to knowledge, not just from their own specialized discipline.

The tendency today is to take an existing course designed for one country and adapt it to another, with serious consequences, especially for developing countries. Often, issues of cultural relevance, language, learning styles and protocols seem intractable because of copyright and institutional intellectual ownership issues, resulting in programs and courses being mothballed, wasting scarce financial resources. What is needed is curricula design for the global market to allow societies to act global and then localize in consonance with local thinking. This has the potential to upgrade relevance of what is taught. According to Tiffin and Rajasingham (2003), with instructional design principles for Internet-based learning, basic courses that are the currency of higher education-- whatever the country-- can be readdressed from the multiple perspectives of different countries, cultures and languages to develop new curricula to match global concerns.

The process of designing, accrediting, validating and assessing global curricula is critical in the higher education paradigm. The *Chronicle of Higher Education* and the *Times Higher Education* increasingly report academics worldwide deploring declining standards as universities become businesses for profit, reducing staffing, increasing on-seat student numbers and cutting staff and student support systems. The Oxford and Cambridge one-to-one tutorials as well as the five-to-eight student tutorials that existed in many universities in the Western world have now succumbed to planned obsolescence. As staff/student ratios rise, inevitably, standards fall.

Universities historically are places where students learn how to learn and develop critical thinking skills to apply what they learn to real-life problems. If universities continue their traditional ways of measuring learning via lecture mode

and in abstract, passive, relatively unconnected assessment processes such as class examinations, multiple-choice tests and other forms of memorization and recall, they will increasingly be at a competitive disadvantage (Hanna, 2002). In the knowledge society, collaboration and new construction of knowledge in culturally diverse learning environments will be the valued skills for competitive advantage.

Traditionally, it was the teacher who decided what goes into a conventional curriculum and how it will be assessed by setting and grading exams and summative measures if learning has taken place. This process has inherent flaws, because we still do not know what learning is and as yet there are no global standards by which to measure a degree, a diploma or a credit. There is no way of knowing if a degree from Peking is better or worse than one from Harvard, Heidelberg or Madras. Many countries have some kind of ranking for institutions of higher education that indicate a pecking order of prestige. Also, there are global listings that rank universities, but they do so on the basis of research, not teaching and effective learning outcomes. The report *Academic Ranking of World Universities – 2005* outlines the complex issues involved in ranking universities (Liu & Cheng, 2005). In a situation where there are no standards, how can universities compete in the new business world while maintaining their universals: the creation and dissemination of knowledge for the public good?

Adam Smith wrote, “When a man has learned his lesson very well, it surely can be of little importance where or from whom he learned it” (Peacock, 2001, p. 6). The proliferation of click for a ‘degree.com’ tends to devalue well-designed virtual courses, such as the digital content of the Massachusetts Institute of Technology (MIT) now available on the Web.

To be successful in the new technological environment, e-learning in higher education will need to adopt a rigor in course design, accreditation and assessment, and introduce new processes

and strategies beyond that which now operate in conventional institutions. This includes separating summative assessment from teaching and developing curricula in conjunction with national and international associations in the subject field, and so setting new global standards (Tiffin, 2004).

Access, Quality, and Costs: Non-Zero Sum Variables

In his thought-provoking paper, Daniel (2004) argues that sustainability as a route to development is a critical factor if open-distance education is to build on the respectability it has earned. Open and distance learning allows education to break out of the iron triangle that has constrained its impact throughout history, which Daniel describes as the vectors of access, quality and cost, where the assumption by educators and the public is that education is a zero-sum game between these variables. On this assumption, increasing access to education will lower quality and raise overall cost. Similarly, raising quality will increase costs and therefore reduce access. Daniel challenges universities to break this iron triangle and the link between quality and exclusivity in education.

While to change or not to change is no longer an option for institutions of higher learning, there are a variety of routes to making those changes, some producing greater success than others. Many of the strategies for change referenced in the current higher education literature that involve restructuring and quality management are framed around barriers to change and re-engineering processes that are not working, and begin from the perspective of cost deficit. Cost factors associated with going online are increasingly open to critical analysis, and there is a growing body of literature that addresses the issue of costing e-learning. Theoretically, cost is related to volume, and the more units produced, the lower the unit costs, thus introducing competitive trade in teaching.

Rumble (1997, 1999, 2001) suggests that any attempt to do comparative cost analysis between

online education and conventional face-to face or traditional print-based distance education is fraught with complexity because it is difficult to agree on the critical variables in each educational approach, and the different interpretations of what is meant by online education. Some take it to mean asynchronous Web-based learning, and others include synchronous interactivity, and what should be included in the costs (Rumble, 2001)? In costing e-learning, Rumble includes the costs of:

1. Developing e-materials
2. Teaching students online
3. Administering students online
4. Providing the infrastructure and support within which e-education can operate
5. Planning and managing e-education.

Rumble notes that cost studies in these areas are few; in the area of e-administration within education, he found none. Furthermore, he notes that none of the studies comprehensively identify overhead costs (Rumble, 1997).

Ling, Inglis and Webster (1999) discuss costing flexible learning, providing useful comparative costing analysis between on-campus and off-campus learning and teaching environments. Further studies on the subject of costing online learning and considering the cost benefits by Daniel (1996, 2003), Mason (1998), Bacsich (1999), Jewett, Finkelstein, Frances, and Scholz (2000), and Bates (1995) posit a major economic argument in favor of distance learning that produces graduates cheaper than from a conventional institution.

E-learning based on advances in innovative technologies has the inherent capability to cope with the future escalation of global higher education, and implies the adoption of a new educational paradigm where students are empowered with teachers as advisors. There is no longer one answer, but the construction of collaborative and culturally appropriate understanding of meanings and knowledge. Universities in transition

to a new paradigm need to think beyond their current norms, structures and processes, and cannot afford to withstand too many stories of institutional failures.

Changing Teacher Roles

It is the teaching profession that faces some of the greatest challenges in future higher education as teacher roles change. In 1982, Dede made a prognosis for education, suggesting a new model of teaching and learning with new teacher roles, new teacher skills, new pay scales that will be fundamentally different from the last 100 years, and it will almost be a completely new profession. He has proved to be significantly prophetic.

In a world where communications and information technologies impact on all our endeavors, universities intent on meeting the challenges of innovative technology will need to invest in staff who have the skills of designing student-centered learning in new technological environments. Many of these technologies are already emerging, providing alternate loci of learning, not to replace the conventional classroom, but as its complement.

Emerging Applications on the Wings

Virtual classes use mobile phones and laptops to link with students from anywhere at anytime and in different time zones, everyone viewing the same power points and audio and video clips during the synchronous interaction, making it possible for communication between teachers and students independent of place. Eliminating building maintenance, transportation systems and the support infrastructures that bring people to them can mean that costs go down.

3G mobiles are used as accessories in handbags, around the neck, waist or wrist watches, where students send each other pictures of where they are and what they are doing, often with far greater familiarity and sophistication than their

teachers in the new cellular, digital environment. In the real world, learners are going to have to use this technology as they apply the knowledge gained from teachers to the problems they will encounter in the real world.

Information technology continues to shrink and become part of the environment. The race is on to develop the first nanofactories to introduce nanodevices in diagnostic and clinical medicine in the next 10 years. MIT has a research institute for applying nanotechnology to military purposes. It is argued that nanotechnology in higher education could introduce a future where students and teachers wear the kind of nanodatasuits that Drexler (1990) describes, where billions of interlinked nanocomputers and nanotransceivers are embedded in the fabric of people's clothes. Dressed in such smart clothing, students could step into a virtual class as they would a conventional class, only it would be a fully immersive and sensually realistic experience that improves on the conventional classrooms that students have known for the last 4,000 years. Rather than the classroom being a staid four-walled room, it could be the subject of the class--a volcano, the eye of a hurricane, a diseased heart, a Parisian catwalk or a performance of Hamlet in the Globe Theatre.

HyperReality

Some technological applications are emerging that would allow wraparound, immersive, collaborative and distributed learning, replicating the communications functions of a conventional classroom where teachers help learners to apply knowledge to problems in culturally appropriate ways.

Smart suits would give entry to HyperReality. HyperReality is the brainchild of Nobuyoshi Terashima, at Waseda University Japan. Between 1986 and 1996, Terashima led a team that developed a form of distributed virtual reality for teleconferencing he called Telesensation (Terashima, 1993). The technology allowed people who were

physically present in different places to meet as telepresences to work together on a common task. Something similar was developed in the U.S. by Jaron Lanier, who calls it Tele-immersion (Lanier, 2001). Revising the concept in 1996, Terashima began working on the idea of a spatio-temporal field of communication that makes connection not only between the real and the virtual, but also between artificial intelligence and human intelligence. He called this HyperReality (HR) (Terashima, 2001).

HR is the technological capability to intermix virtual reality (VR) with physical reality (PR) and artificial intelligence (AI) with human intelligence (HI) in a way that appears seamless and allows interactive communication. Two-dimensional (2D) images from one place can be reproduced in three-dimensional (3D) VR at another place. The 3D images can then be part of a physically real setting in such a way that physically real things can interact synchronously with virtually real things. It allows people not present at an actual activity to observe and engage in the activity as though they were present. The technology will offer the experience of being in a place without having to physically go there. Real and unreal objects will be placed in the same 'space' to create an environment called a HyperWorld (HW). Here, imaginary, real and artificial life forms and imaginary, real and artificial objects and settings can come together from different locations via information superhighways, in a common plane of activity called a coaction field (CF), where real and virtual life forms can work and interact together ... What holds a CF together is the domain knowledge (DK) that is available to participants to carry out a common task in the field (Terashima, 2001).

The HyperClass

The domain of knowledge in a CF could be the curriculum of a course in higher education that could be conducted in a HyperClass. A Hyper-

Class is a space where a conventional class is intertwined with a virtual class in such a way that virtual components can interact with physically real components. The components are people, objects and settings and the mode of interaction face to face (Tiffin & Rajasingham, 2003). The first experiments took place between Victoria University of Wellington in New Zealand and Waseda University in Japan in 1998. To the Japanese, the New Zealanders (as avatars) were virtual and to the New Zealanders, the Japanese (as avatars) were virtual. In other words, whether the participants were virtual or real depended on where they were in relation to each other. It was a form of teleconferencing where the avatars, the setting and the objects of study were 3D and virtual objects could be handled by, modified collaboratively and passed between the virtual and real people, allowing learning to take place in consonance with the learners' own cultural milieu. Although HR has still some way to go, the rate of development, particularly the increasing computer processing power and speed, suggests that in the future there will be no technological limitations to the number of centers and countries that can be linked together in a HyperClass.

Terashima's concept of HR, unlike Lanier's concept of Tele-immersion, has a further dimension. It is also a place where AI can interact with HI and enables artificial life developed in VR to cross into the physical world. So far, AI has developed logical-numerical intelligence that can be applied in clearly defined domains. This is why it is so readily adaptable to the HR device of a CF and to the paradigmatic nature of university subjects. Wherever knowledge can be expressed as a closed system with clearly defined rules and procedures, AI can be applied.

Just-in-Time Artificially Intelligent Teachers (JITAITs)

Vygotsky (1978) postulates that when a learner finds he or she cannot solve a problem by them-

selves, a Zone of Proximal Development (ZPD) opens. It is the role of the teacher to close that ZPD as quickly and effectively as possible, and hence the critical need to have interactive communication between student and teacher. However, today human teachers can only respond immediately to a learner during working hours and if there is only one student seeking help. In large classes, student questions have to wait until a teacher is available. In higher education, much learning is done asynchronously and students get feedback on an assignment a week or more after doing it. This is hardly an efficient way to close a ZPD. Most students have forgotten the things they found difficult. It is time for the JITAIT. As the name implies, this is an AI teacher that can be available whenever and wherever a student needs help (Tiffin & Rajasingham, 2003).

JITAITs are expert systems, effective where the domain of knowledge they address is restricted, paradigmatic and orientated toward problem solving. A JITAIT can, therefore, be an expert teacher on a subject that formed the domain knowledge of a CF in HR. JITAITs would always be ready to help any learner in the CF and would improve from each encounter with a learner, provided it received feedback from a human teacher. JITAITs could take over low-level repetitive student-teacher interactions, such as spelling and grammar checks that today are a standard component of computers, and frequently asked questions (FAQs).

JITAITs could also act as personal teachers to individual students. They could search for information, keep track of a student's individual program of study and help organize learning activities. Interlinked intelligent agents that manage schedules, meetings, e-mail and workflow are already used in office systems. The Web-based organization of programs of study taking place in universities around the world provides a framework for such a development. JITAITs could have avatar form and a personality and act as a guide and mentor in the manner of the servant-tutor pedagogues of ancient Greece, or the paper clip

wizard that today pops up when not needed (or when it is needed, it is less than useful and more of an irritating distracter). But it does not mean that in the future, these agents will not become more intuitive and intelligent.

JITAITS in the Levels of Teaching

Teaching has three hierarchical levels. Lower-level activities consist of marking those parts of tests, exams and assignments that have set answers, collating marks, registering attendance and managing class schedules. Such automatic activities could be computerized to leave teachers to teach.

The middle level is that of tutoring. It is where teachers interact with students to guide their learning. It involves listening to students, comprehending the difficulties they have in mastering a subject and its application, eliciting performance, explaining and demonstrating, monitoring student practice, marking assignments, tests and exams where answers are open ended, providing detailed feedback and answering student questions. This takes up teaching time and keeps student-teacher ratios down, because it involves one-on-one or small group communications, as much of the work at this level needs human understanding, although much is very repetitive. Each intake of students asks the same questions and has the same problems, and wherever this is the case, a JITAITS can be used. So the second level could be shared between human and AI tutors. As time went by and JITAITS handled more and more FAQs, their role would increase and the student-teacher ratio could be progressively increased without lowering standards.

The upper level of the hierarchy is that of the subject specialist, the professors and professionals who have achieved academic stature through research, publications and experience and can arbitrate on content. Their primary purpose is to communicate a synthesis of the subject matter in a way that brings it up to date, places it

in context and encourages students to question. They do this by lecturing. In the U.S., it is common in large universities to have such a person supported by a team of teaching assistants who do the tutoring, leaving the professor to lecture to very large classes. With e-learning, the professors could stream their lectures to the whole world, and there need be no limits to the numbers who could attend. Instead of being salaried employees, professors who could attract such numbers would be valuable property. They could relate to their universities in the way authors relate to their publishers (Katz, 1999), receiving royalties for each student taking their program.

Croquet

This is another potentially useful application. The need for designing a more responsive, collaborative, online, global, virtual university environment led Julian Lombardi and his team in the division of information technology, University of Wisconsin – Madison to develop Croquet. A multi-user 3D environment, it is a multi-institutional initiative under development at the Universities of Wisconsin – Madison, Minnesota, Kyoto and the Hewlett Packard Research Labs. Croquet is an ‘overlapping windows’ computer interface and represents the next step beyond today’s desktop computer interface; and unlike HR, which today is dependent on proprietary software, Croquet capitalizes on open-source programming language and advanced networking capabilities available in university campuses.

According to Lombardi, the aim is a learning environment for spontaneous interaction between cross-disciplinary and cross-institutional communities of practice. Within the Croquet environment, faculty, staff and students of the participating institutions will be visible to one another (as digital avatars) and able to move quickly and seamlessly among multimedia learning resources, including 3D models, whiteboards, Web pages, video

footage, flash animation, simulations, streaming video, television broadcasts and PowerPoint presentations. As in a traditional face-to-face classroom, learners will see one another 'handling' learning objects and resources, and support each other with real-time feedback. Croquet is scheduled to be commercially available in 2007 (Lombardi, 2004).

The Research Function

Another universal of higher education—the creation, dissemination and application of knowledge—is its research function that defines the nature of higher education, whatever the medium used. This is an important function of universities, to grow the economy, lift the level of innovation and help understand social needs.

Learners enter higher education from a basic educational system in which the knowledge they learn to apply is approved and sanctioned by society. However, when learners leave higher education systems and apply the knowledge they have learned to real-life problems, they discover the difference between practice and theory. A universal of higher education is learning to question received knowledge and endlessly re-address it in search of a better way. According to Tiffin and Rajasingham (2003) without this process, knowledge becomes dogma and formulaic, and education becomes training.

The essence of teaching in higher education is to encourage questioning of the knowledge paradigm. It is why higher education should be linked to research and why a JITAiT could never replace a human teacher or professor. A JITAiT can respond to FAQs and assess assignments that already have answers, but it does so from within the logic of the paradigm. A JITAiT would not be able to deal with the contradictions that arise from problems that do not fit the knowledge paradigm. It requires a human with an open, critical mind to cope with the paradox in knowledge.

Will an institute of higher education in an e-learning environment that grows increasingly dependent on JITAiTs be able to cope with the questing nature of knowledge? If a JITAiT encounters a new question from a student that it cannot answer, it passes it on to a human teacher who, in effect, programs the JITAiT to answer such a question in the future. If, however, the human teacher cannot answer the question, then he or she passes it to the content specialist; and if the specialist cannot answer, there is a basis for research. Such a system would allow interesting questions of our times to emerge, and generates the need for further ongoing research.

CONCLUSION

Higher education takes place in a communication system where mature learners and teachers interact so learners can apply knowledge to problems and question what they are doing. The technology that makes this communications possible is changing, and will continue to change. What will not change is the interactive communication process of higher education, where we will continue to explain, demonstrate, question and set problems, and we will do this by talking and writing, as we have been doing since the days of Pythagoras, Socrates, Confucius and Buddha.

However, within the framework of the Sloan-C Five Pillars for Quality Online Education, it is argued that e-learning in higher education has the capability to make higher education more efficient, more cost effective and more accessible, and increase student and staff satisfaction, offering a paradigm shift beyond current norms and processes. But will it improve the way we learn and teach? Just as doctors seek to understand what causes disease, educators have yet to understand what causes learning. Until we have such knowledge, we need to continue the old way of doing things face to face that has worked since

classes were held in caves. E-learning in higher education will need to find an optimum mix of the old and new.

No matter how sophisticated and multimediated the virtual class, learners still strive for the soft touch of the tangibly real. Both HR and Croquet, and other technological applications yet to emerge, have the potential to signal a new paradigm of education that resonates with the Sloan-C Five Pillars for Quality Online Education for effective e-learning appropriate for the multicultural, networked global knowledge society of the 21st century.

This chapter is predicated on continued technological advances, particularly broadband infrastructures that, in many countries, are still some way into the future. But as Robert Austin and Stephen Bradley argue in their article in the Harvard Business Review, *The Broadband Explosion: Thinking about a Truly Interactive World* (2005), when true broadband arrives, everything will change – work, play and society. Education will not be an exception. The higher education paradigm has already begun to shift.

James Madison University, USA

ABSTRACT

Educators have an ongoing challenge as they strive to stay up-to-date with new technology. One emerging technology, RFID (radio frequency identification) tags, has the potential to impact information systems in businesses as well as in our lives. Educators responsible for planning curriculum need to consider how to incorporate topics pertaining to RFID technology into a wide variety of technology courses. Therefore, one purpose of this manuscript is to give curriculum planners and teachers a summary of RFID by: presenting an overview of RFID technology; exploring RFID limitations and possible solutions; and examining the future outlook of RFID. An additional purpose further assists educators in

considering how to incorporate this new course topic into the curriculum by providing some teaching resources, objectives and suggestions pertaining to RFID.

INTRODUCTION

Today's educators need to have a fundamental knowledge of a wide variety of evolving technology. It has been stated that teachers need to "cross-fertilize ideas across technology and research domains" (Kalles & Papagelis, 2006). To accomplish this, educators need to continually scan the horizon for developing technology.

One such emerging technology is RFID (radio frequency identification) tags. RFID tags are

small, wireless devices that help identify objects, animals, and people.

RFID is just one part of the fast evolving telecommunications industry. Some educators have indicated that it is important for information technology students to learn more about the field of telecommunications (Choi, Teer, & Teer, 2005). As new course material is considered, either for introductory IT (information technology) courses or more specific upper level IT courses, it is important for educators to learn about RFID and determine if some course coverage should be devoted to RFID.

One purpose of this manuscript is to give curriculum planners and teachers a summary of RFID by: presenting an overview of RFID technology; exploring RFID limitations and possible solutions; and examining the future outlook of RFID. An additional purpose is to provide teaching resources, objectives, and suggestions pertaining to RFID. Hopefully, this will further assist educators as they consider how to incorporate this new course topic into the curriculum.

OVERVIEW OF RFID TECHNOLOGY

RFID is a type of automatic identification similar to bar codes. The difference between the two is that in RFID systems, an electronic device uses radio frequencies to communicate, whereas bar codes require line-of-sight scanning. For example, these tags can be used to track objects in supply chains and can even be found in the pockets, belongings, and bodies of consumers.

There are two types of RFID tags currently being used, UHF (ultra high frequency) and HF (high frequency). Tags can further be classified as active, semi-passive, and passive. Active tags are the most expensive and contain an internal power source; passive tags are powered by external radio signals; semi-passive can function either way. RFID tags are given a unique EPC

(electronic product code) and are installed with a transponder and digital memory chip. In addition to the EPC, the data contained within each tag may provide identification, location information, or product specifications.

The RFID system includes an electronic reader which enables data transmitted from tags to be read, stored, and eventually processed. The reader communicates with a host computer that runs software called middleware, which connects the data to specific applications. Readers are essentially a type of interrogator that use an antenna packaged with a transceiver and decoder. The reader sends out a signal that activates or “wakes up” a corresponding RFID tag which transmits its unique EPC code. Data can then be read from or written to the tag.

RFID tags are available in a variety of shapes and sizes, most of which are extremely small. RFID has made considerable progress recently with advancements in the technology, lower costs, and smaller tags. RFID systems have emerged as a practical auto-ID platform in industries as varied as automobile manufacturing, microchip fabrication, and even cattle herding (Weis, 2003). In some medical facilities, RFID tags are being used to double and triple check that the patient in the operating room is having the correct operation (Martin, 2005). RFID tags have also been used in disaster victim identification after the tsunami catastrophe in December 2004 (Meyer, Chansue, & Monticelli, 2006). Additional applications include the use of RFID to detect human activity. For example, an iGlove can track the objects grasped by the wearer. The iBracelet also tracks human activity and was found to be more aesthetically and ergonomically preferred to the glove (Smith et al., 2005). Current news articles indicate that RFID is being implemented in the areas of manufacturing and supply chain management (Loebbecke & Palmer, 2006). However, there are still several issues that are preventing RFID tags from becoming more prominent in today’s businesses and eventually replacing bar codes.

RFID: LIMITATIONS & POSSIBLE SOLUTIONS

Present limitations of RFID are primarily issues pertaining to security, privacy, and technology. In this section, these limitations will be explored and some possible solutions will be examined.

Security Issues

Security is one area of concern that is preventing the widespread adoption of RFID tags. Without the proper controls in place, private information could be stolen from products or other items containing RFID tags. Since most tags are passively powered and rely on wireless networks, they are open to attacks, which in some cases could be easier than picking someone's pocket. Security breaches to RFID tags could include physical attacks, counterfeiting, spoofing, eavesdropping, tracking, or denial of service (DoS). Any of these attacks would have a serious negative impact on a company as well as individual customers.

Security issues with RFID systems will first be analyzed by examining three main factors: availability, integrity, and confidentiality. These three pillars of security are referred to as the security triad (Glover & Bhatt, 2006).

Availability pertains to the system's uptime at the appropriate performance level or the amount of time that the system is available. Most system administrators would obviously prefer 100 percent availability, but there are various threats that negatively impact uptime. Poorly designed architectures are usually the most common reason for reductions in uptime. However, DoS attacks are another concern. This type of assault could occur when a criminal with the right tools and technology decides to send out a jamming radio signal in an RFID system that renders tags and readers useless.

Integrity addresses the accuracy and authenticity of the data transmitted. Some of the data transmitted via RFID usually includes a

company's product and shipping information as well as customer data. Threats to data integrity include both accidental and malicious modification of the data in a system. An example of this type of attack is spoofing, which could occur when someone swaps the tag data for Product A with Product B data to gain some type of advantage.

Confidentiality relates to limiting the access of information to authorized personnel only. Private data about customers or company information involving inventory and supply chains could potentially be read or stolen by intruders. This also relates to the issue of privacy, which will be discussed later. All three of the factors in the security triad can impact each component of an RFID system from the actual tags to the enterprise information system.

RFID tag security is vulnerable because currently the data stored is plain text or unencrypted. Adding encryption requires more space on the tag that results in higher costs, increased processing time, and a larger chip, all of which increase the size of the tag (Glover & Bhatt, 2006). Also, tags can be removed or replaced unless there is some type of physical supervision for RFID tagged items. RFID tags essentially listen and respond to a signal no matter where it comes from or to where it is being sent. To demonstrate the ease of retrieving information from a RFID tag, a Netherlands security firm successfully decrypted a RFID enabled passport in about two hours (White, 2006). The security firm was able to access a digitized fingerprint, photograph, and all other encrypted and plain text data on the passport by cracking a very predictable algorithm for the tag's password. Authorities in the United States had plans to implement a similar type of RFID tag in all American passports during the fall of 2006, but have now had to rethink the situation.

In a research study involving humans, an RFID tag called VeriChip was placed under the skin of Annalee Newitz. Applied Digital's VeriChip was approved by the FDA (Food and Drug Administration) on October 13, 2004, for

medical purposes such as tracking patients and storing medical information (Reynolds, 2004). All of the data on the chip was read and copied in approximately two hours, giving access to all of Newitz's medical records and as well as other private data (Kuchinskas, 2006). This VeriChip would be subject to all the same issues as a product RFID tag and more.

RFID readers are also susceptible to attacks due to the fact that they are normally connected to an internal ethernet using either wireless or wired connections. Again, data that travels from tags to the reader is not encrypted and the tags that are being read are not authenticated by the reader. For these reasons RFID readers are vulnerable to spoofing, DoS, and protocol attacks. Basically, anyone who is connected to the same network, has access to a wireless sniffer device, and possesses a basic knowledge of RFID reader protocols could carry out such an attack. Other problems exist when readers experience a collision. This can happen when the coverage areas of two different readers overlap causing interference with one another (Lahiri, 2005). Similarly, the presence of another wireless network in close proximity can interfere with RFID readers.

Potential solutions to the threats facing RFID readers include: (1) encrypting the data; (2) requiring authentication and authorization before allowing access to a reader's services; (3) establishing a proper authentication process between tags and readers; (4) setting up proper security at wireless access points; (5) strict physical access control to the company's buildings; (6) installing surveillance to monitor merchandise tagged with RFID, (7) using rewritable tags only when appropriate; and (8) installing protection from Internet attacks using firewalls, intrusion detection systems, network sniffers, and better anti-collision protocols. Collisions can also be somewhat solved with TDMA (time division multiple access) algorithms, which instructs each reader to read at different times or intervals (Lahiri, 2005). However, this would also require an intelligent

filtering system to prevent tags from being read more than once.

The RFID service bus is another area susceptible to attacks. The service bus contains all middleware components such as the object naming device, EPC event manager, EPCIS server, and the RFID integration server. Middleware essentially allows communication between the data being read and the corporate information system. Threats to this area would most likely be in the form of corporate spies, espionage agents, and intruders. With the right tools, they could gain access to key company information, trade secrets, and other private data that could potentially cause harm. To solve RFID service bus security problems, companies need to seriously consider controlling access to the network using firewalls, intrusion detection systems, and network sniffers. It would also be a good idea to set up a security infrastructure that will define which network users will be authenticated.

Additional help in providing the needed security infrastructure can be provided in the future by standards organizations. For example, EPCglobal, an international standards organization, maintains an EPC database, which identifies manufacturer, product, version, and serial number. Other functions performed by EPCglobal include providing middleware specifications for data exchange and administering the object name service for matching an EPC to information about the associated item. EPCglobal is currently working on specifications to secure EPCIS communications as well (Claburn & Hulme, 2004).

Finally, EIS (enterprise information system) security flaws have to be addressed. This system includes corporate assets such as the directory, identity management, access control, messaging systems, and a database that uses RFID data. RFID systems generate large amounts of transaction data. Companies utilizing RFID will be storing large volumes of potentially sensitive information that could overwhelm the existing network. As a result, this leaves the system open to intruders,

corporate spies, and pranksters. For example, if business sales and or inventory information was stolen it could result in huge financial losses. Plausible solutions include adequate network access control and physical access control to corporate premises. As RFID technology continues to improve, prices will probably drop allowing security methods to become more affordable.

Privacy Issues

Privacy is the right to be left alone when you want to be (Warren & Brandeis, 1890), to have control over you own personal possessions, and not to be observed without your consent (Haag, Baltsman, & Phillips, 2005). Certain types and uses of RFID tags definitely impact privacy (Peslak, 2005). The Pentagon, for example, plans to use RFID to track physical objects; such use raises relatively modest privacy concerns. The San Francisco Library would like to put RFID chips in its books, raising the specter of third parties being able to track our reading choices.

Even more troubling are proposals to put RFID chips into government issued identity documents (RFID Technology, 2004). The main concern is that this new technology will lead to the tracking of consumers and possible exposure of private information. Consumer information could be queried by marketers for the purpose of delivering personalized ads.

Further along the continuum of privacy concerns would be thieves using RFID technology to commit identity theft. Eventually, everyday products could be numbered, identified, cataloged, and tracked wherever readers are present (Flint, 2006). RFID tags could also end up inside many types of personal documents like driver's licenses, passports, diplomas, and similar documents (Granneman, 2003). Currently, there is no law requiring that product labels indicate the presence of an RFID tag. The current privacy gap with RFID tags exists because market penetration is moving faster than policy (Kuchinskas, 2006). Those who purchase RFID tagged merchandise, have RFID implants, or other tagged items could

Table 1. RFID privacy concerns (Glover & Bhatt, 2006, p 202)

RFID Characteristic	Privacy Concerns
<ul style="list-style-type: none"> No line of sight RFID tag is read just by being in close proximity to reader 	<ul style="list-style-type: none"> Unauthorized person can read your RFID-tagged items from safe distance Most consumers will not be aware of the tags or that the items are being tracked
<ul style="list-style-type: none"> Item-level tracking RFID tags have higher information storage capacities than most bar codes RFID tags may include a serial number Manufacturers and retailers can track items at an instance level Provides companies with a valuable tool for tracking and managing inventories, sales data, and other product information 	<ul style="list-style-type: none"> Can potentially be used to identify unique individuals with the objects purchased The capability to track goods at item level, associate them with individuals, and then be able to automatically locate them in public places causes the most concern among privacy advocates

be unknowingly exposed to readers, identified, and singled-out. Table 1 summarizes some RFID privacy concerns.

Many steps are being taken to protect consumer privacy. However, there is a delicate balance between satisfying the privacy-rights advocates and meeting the needs of the business world trying to fully benefit from RFID technology.

In the United States, government legislation regarding RFID privacy has been introduced in many states, but has failed in the majority of cases. Most of these bills will almost certainly be revised and reintroduced in the near future. Two notable bills were the RFID Right to Know Act of 2004, introduced by Missouri Senator Maida Coleman, and a California bill known as SB1834. The RFID Right to Know Act requires that any items with RFID tags have to be packaged with a clearly visible label notifying customers of the tag. SB1834 restricted the use of RFID tags and readers to relating only to product information; thus, customer identification is not utilized. SB1834 required that RFID be studied more carefully before being used in government issued ID cards (Torrieri, 2006).

The E.U. data protection laws require any data that can be directly identified to an individual be subject to Data Protection Directive (95/46). This directive includes several requirements: collection when only necessary and relevant; retention for only as long as necessary; and informed consent, which means a label must include details of how the information in the RFID tag will be used and instructions to the consumer how to disable or remove the tag. (Archer & Salazar, 2005).

There have also been numerous RFID privacy guidelines released by various organizations. For example EPCglobal has set the following guidelines (Glover & Bhatt, 2006, p 205-206):

- **Consumer Notice:** This guideline requires that consumers be given a clear notice of the

presence of EPC tags on products or their packaging. This notice will be given through the use of an EPC logo or identifier on the products or packaging.

- **Consumer Choice:** This guideline requires that consumers be informed of their choices to discard, remove, or disable EPC tags from the products they acquire. It is anticipated that for most products, the EPC tags will be part of disposable packaging or will otherwise be discardable.
- **Consumer Education:** Consumer education is key to dispelling some of the myths about RFID's benefits, capabilities, and limitations. EPCGlobal, working along with its member companies, will strive to provide consumers with the opportunity to obtain accurate information about RFID and its applications, as well as information about advances in the technology.
- **Record Use, Retention, and Security:** The EPC should not contain, collect, or store any personally identifying information. As with conventional bar code technology, data associated with an EPC will be collected, used, maintained, stored, and protected by the EPCGlobal member companies in compliance with applicable laws. Companies will publish, in compliance with all applicable laws, information on their policies regarding the retention, use, and protection of any personally identifying information associated with their use of EPC.

Dr. Garfinkel, of MIT, introduced a set of RFID privacy policies in 2002 to protect consumers, which he titled the "RFID Bill of Rights" (Glover & Bhatt, 2006). In the bill, he outlined several guidelines similar to those released by EPCglobal. Well-established organizations, such as CASPIAN (Consumers Against Supermarket Privacy Invasion), the ACLU (American Civil Liberties Union), Privacy International, METI (Ministry of Economy, Trade, and Industry), and

EPIC (Electronic Privacy Information Center), among others, have all played a part in attempting to enact legislation regarding RFID technology.

Measures to protect privacy can also be implemented by companies themselves by taking advantage of technological advancements. The simplest and most appealing way is to use kill commands or killer tags introduced by EPCglobal. They allow customers to request that RFID tags on purchased items be disabled or killed by the retailer before leaving the store or business location. Basically, a command is sent to the tag ordering it to render itself useless, thereby protecting consumers from unauthorized identification or tracking. On the other hand, this limits the usefulness of the technology to the point of sale and it could mean longer waiting times if customers decided to have all purchased items disabled. Another method is to use blocker tags developed by RSA Security. A blocker tag is a special type of RFID tag that prevents unwanted scanning of tags (Juels, 2005). Blocker tags work by passively jamming RFID readers, thus preventing other tags from being read. A potential drawback is that blocker tags could cause problems with individuals attempting to commit robberies by hiding products at check-out lines. Screaming tags could also be used by consumers which send out a strong signal burst to prevent other tags from being read.

Technology Issues

Several problems exist with the actual RFID technology. It is still an immature technology that is in the early adopters phase. Rapid upgrades are occurring, but this can also act as an inconvenience to businesses. Tags can be damaged or destroyed under current handling techniques; defective tag rates can be as high as 20 percent (Lahiri, 2005). RF-opaque and RF-absorbent materials can cause the technology to fail. For instance, if an RF-absorbent substance like water interferes with a tag or if an RF-opaque material, such as metal is tagged, a reader may fail to read the

tags. Radio frequencies also cannot pass through another human, which could create problems in high traffic areas. Another limitation for tags is they can easily be affected by environmental factors and surrounding conditions. If RFID tags get wet, they could be disabled or at least have their functionality damaged. UHF tags are currently being used mostly for warehouse supply-chain tracking and HF tags are used for item-level tracking (Schuman, 2006). UHF will start to replace HF tags at item-level, but if they continue to experience error rates a seesaw effect could be created between the usage rates of UHF and HF RFID tags.

RFID readers can be affected by the presence of an additional wireless network or by noise created from nearby electric motors. Incorrect hardware setup such as a wrong antenna placement could cause failure as well (Lahiri, 2005). Only a few tags can be read per second and, as mentioned earlier, readers can experience collisions. Universal RFID technology standards are not in place; therefore, you can have the same type of tags from different vendors perform differently. There does not seem to be a reliable timetable for when the standards issue will be resolved. It is a learning process and there are still not many RFID experts. Business owners should stay patient and when necessary, seek the guidance of consultants that have experience with RFID systems.

Presently, old-fashioned barcodes continue to provide greater stability to businesses. About five billion barcodes are scanned everyday and, with more than 50 existing standards, barcoding is the most widely deployed technology in the world (Lahiri, 2005). Furthermore barcodes cost less, have better accuracy rates, can be placed on almost any material, do not threaten privacy, and are secure. Nevertheless, as RFID technology continues to evolve, business people can research the benefits that an RFID system could provide and determine the technology that works best for a particular application.

Cost is usually the most common reason cited for not using RFID technology. Tags are priced around 20 cents or more depending on the type and features. This price must drop below five cents and in most cases as low as one cent before most businesses will accept it. When comparing the cost of RFID with barcodes, there are many significant differences. Barcode readers generally cost less than \$400, while RFID readers can sometimes exceed \$800. Installing an RFID system would also involve the time consuming and costly tasks of restructuring the IT infrastructure, training personnel, and educating customers. A survey conducted by AMR Research has shown that RFID in 2005 had an average budget of more than \$548K and could increase to \$771K by 2007 (Reilly, 2005). Furthermore, RFID systems are very complex to design and implement. As RFID technology improves, prices should continue to drop. Business managers should set a price threshold at which RFID becomes a realistic technological solution; next, they should reevaluate the current situation when this price threshold is reached.

FUTURE OUTLOOK

The major push towards adopting RFID technology came when both Wal-Mart and the Department of Defense issued mandates requiring that their top 100 suppliers begin using RFID tags in shipments (Brewin, 2003). Wal-Mart underestimated many of the problems with RFID, such as the cost, and as a result deadlines were not met (Feder, 2004). Wal-Mart and other corporations continue to test various RFID tracking systems. Examples of these trials include Benetton tracking apparel, Gillette tracking consumer packaged goods, Michelin tracking tires, the European Central Bank tracking paper currency, hospitals tracking patients and personnel, and payment systems like Exxon Mobil's SpeedPass™ (Electronic Privacy Information Center, 2006). Ford Motor Company's use of RFID in their Dearborn plant was very successful. Ford is currently planning to implement RFID technology in four additional plants (Hamblen, 2006).

Eventually RFID tags will be placed in objects not just to store and track information, but to

Figure 1. RFID deployment survey (Reilly, 2005)

Q. Which of the following best describes your state of RFID technology deployment? (n=496)

make those objects smart, more useful, easier to maintain, and easier to recycle (Roberti, 2006b). Thus, as new applications for RFID are created, new business opportunities will flourish. These types of applications could be smart shelves that know all of their contents courtesy of internal RFID readers or smart refrigerators that work in a similar fashion.

Over the next year or two we can probably expect to see key advancements being made in RFID technology, falling prices, and agreeable standards and protocols being passed. As that happens, RFID's place in our society will start to take shape. Research has indicated that some companies are re-examining the use of barcodes and may implement RFID tags where they are cost-effective and make the most sense (Eschinger, 2005; Reilly, 2005; Roberti, 2006a). AMR Research surveyed 500 companies in order to assess the RFID market from 2005 through 2007 (Reilly, 2005). At the time of the AMR Research survey, 31 percent of the respondents were in full deployment or in pilot use of RFID. Twelve percent responded that their company planned to implement RFID in 2005; 26 percent said their company would evaluate RFID in 2005; and 12

percent said their company would evaluate RFID in 2006. The results of the AMR Research survey are presented in Figure 1. A Gartner research reports states that in 2007 there will be a 50 percent annual growth in RFID sales (Eschinger, 2005). This is illustrated in Figure 2.

IMPLICATIONS FOR EDUCATORS

Because of the high cost of deployment and the impact on existing IT infrastructures, it seems that in the past users have been reluctant to adopt RFID (Webster, 2006). Even though RFID still has many limitations to be addressed, some have predicted that 2007 will be the year that RFID technology takes off (Eschinger, 2005b; Roberti, 2006).

Recently Comp TIA (Computer Technology Industry Association) announced a RFID certification in an effort to develop the workforce and provide the industry with a standard for measuring employee competency in RFID technology (Certification Magazine, 2006). IT certifications, such as RFID certification, typically developed and administered by a manufacturer or a profes-

Figure 2. RFID, worldwide size and growth (Eschinger, 2005)

sional organization can have numerous benefits. Some of advantages include: acquiring knowledge and skills that allow individuals to move into a new area; gaining exposure to the latest software or technology; increasing an individuals level of expertise; and gaining the ability to contact and network with world-wide top-performing professionals in the field (Al-Rawi, Lansari, & Bouslama, 2005).

One of the hardest things for IT educators to do is to it stay current with evolving technology. As we examine and develop our curriculum and course content, we may find that it is time to integrate topics pertaining to RFID technology within the various technology courses we teach. Some universities have incorporated RFID into their curriculum with support from business while others will need to do this on their own (SAP Gift to IU Kelley School of Business enables hands-on experiences, 2004). Some universities may want to develop a stand alone RFID course. Such courses could be centered on concepts such as RFID's use in the supply chain or RFID's application in manufacturing systems. If the curriculum does not have room for a stand alone course in RFID, these topics can be incorporated into such courses as the introductory or an intermediate computer information systems course or a telecom course.

Teaching Resources

Educators need to learn more about this technology and develop teaching materials. Currently most of the available teaching reference material for RFID is in the form of (1) professional organizations, (2) books, (3) journals, and (4) Internet resources.

- **Professional Organizations:** The Wireless Communications Alliance has a special interest group for those interested in RFID and is located at http://www.wca.org/RFID_info.htm. The Colorado RFID Alliance is a non-profit organization dedicated to bringing together the RFID community in the eastern part of Colorado and is located at <http://corfida.org/>.
- **Books:** Numerous books were found on the topic of RFID. Information on these books is given in Table 2.
- **Journals:** There is only one refereed journal, The International Journal of Radio Frequency Identification Technology and Applications, which began in 2007 according to Ulrich's Periodical Directory.
- **Internet Resources:** While one has to be cautious about the credibility of the Internet resources, there are some excellent Internet sources on RFID. They are primarily tar-

Table 2. Books relevant to RFID

Authors	Title	Year	Publisher
Bhuptani, Manish & Moradpour, Shahram	RFID Field Guide: Deploying Radio Frequency Identification Systems	2005	Prentice Hall
Glover, Bill & Bhatt, Himanshu	RFID Essentials (Theory in Practice)	2006	O'Reilly
Graafstra, Amal	RFID Toys: 11 Cool Projects for Home, Office and Entertainment	2006	ExtremeTech
Garfinkel, Simson & Rosenberg, Beth	RFID: Applications, Security, and Privacy	2005	Addison-Wesley Professional
Sweeney, Patrick J.	RFID for Dummies	2005	Wiley

geted to business and industry professionals. Some of the more noteworthy are:

1. RFID Journal—<http://www.rfid-journal.com/>. Highlights of this online journal are useful in preparing to teach topics related to RFID. Those most notable for educators include: glossary of terms, global news articles, case studies, white papers, and Webinars. Numerous parts of the journal are open to non-subscribers; there are some items that are available only to fee paying subscribers.
2. RFID product news—<http://www.rfid-productnews.com/>. Includes feature articles, information on new products, whitepapers, information on current events, and case studies.
3. RFID directory, UK—<http://www.rfid.uk.com/>. Contains directories of RFID companies, manufacturers and suppliers.
4. RFID 101.com—Info guide to radio frequency identification (RFID) technology — <http://www.rfid-101.com/>. An online guide to selecting and purchasing RFID technology products.

Teaching Objectives and Suggestions

Lectures utilizing material obtained through professional organizations, books, journals, and the Internet can be utilized to assist in building a framework of understanding that will enhance the students' understanding of assigned readings and projects. The course syllabus should include the objectives and detailed assignment guidelines for course projects; a description of the course deliverables; and the course evaluation criteria. Some suggested course objectives include:

- Types of RFID technology
- How RFID is being utilized today

- Security and privacy issues with RFID
- Future of RFID technology

In addition to lectures, three specific course activities can be considered: (1) an individual research project; (2) a group research project; and (3) a hands-on project.

It is recommended that the performance of research projects be monitored by requiring the students to turn in two or three interim deliverables at predefined points in the research project. The deliverables from the research projects should be evaluated on content, format, style, and other predefined criteria.

- **Individual research project:** The instructor should provide the students with a list of possible research topics from which each student selects a topic of interest. These topics should coincide with current issues pertaining to RFID. To aid the undergraduate students in the literature search necessary for their research, it is suggested that a professional librarian from the university library be invited to class to provide a tutorial on utilizing research databases.
- **Group research project:** Group research projects can be assigned to groups of three or four students. The group research project will be useful in stimulating the students' learning of new and interdisciplinary concepts in the more flexible and comfortable learning environment of the peer education process. This will also provide students with experience in working in teams, a skill that they need to further develop and practice before entering the workplace.

It is recommended that the group research topic be based on a real world business utilizing RFID. Using real world cases in the group research projects will afford students the opportunity to experience first hand things such as realistic content, real world business objectives,

organizational impacts, social values, and ethical issues (Gendron & Jarmoszko, 2003; Hackney, McMaster, & Harris, 2003). The professor will need to guide the students in the selection of a real world case. The students can be asked to complete their group research project as follows:

1. Describe in detail a specific real world company's application of RFID.
2. Survey the existing literature regarding the specific company's application of RFID and summarize the literature related to that application.
3. If possible, describe the company's future plans regarding RFID.

At the completion of the projects, each group can present the results of their final group research project to the entire class. In addition to a class presentation utilizing presentation software such as Microsoft PowerPoint™, the students can provide the professor with a presentation file, a written project report, and a few test questions the group feels the class could answer after listening to the formal presentation. The questions collected from all the groups may be used on an exam to test the level of understanding of all students on all research project presentations. Such a procedure can be very useful in garnering student attentiveness during all group presentations. The instructor and all class members may evaluate each of the group research presentations based on pre-arranged guidelines.

- **Hands-on practice using RFID:** To enhance the students understanding of technology and its application in the real world, it is important to give students hands-on experience with technology in a lab environment (Greca, Cook, & Harris, 2004). Robert Yoder (2006) utilizes an inexpensive RFID reader and tags in a university lab setting to teach a variety of basic principles. Hands-on

practice opportunities, in which the students actually work with RFID components, will be beneficial in enhancing the students' understanding of the course's technical components. Depending upon the learning environment desired by the professor, the hands-on practice opportunities can be offered as lab sessions or as individual take-home assignments.

SUMMARY

Since RFID has the potential to have an impact on information systems in businesses as well as in our lives, it is important that we incorporate topics pertaining to RFID into existing courses and, where applicable, develop in-depth, stand-alone courses on RFID.

The overview of RFID and implications for teaching should be of interest to several groups of readers. Researchers in academic communities should be aware of the important role of RFID in industry and the resulting implications for needed IT research. Second, IT curriculum planners will find this information helpful as they strive to keep the curriculum in tune with the needs of business and industry. Third, IT professors need to be aware of the importance of RFID. Hopefully, IT professors can benefit from the teaching resources and teaching suggestions presented.

Chapter 8.9

Games and Advertisement: Beyond Banners and Billboards

David B. Nieborg

University of Amsterdam, The Netherlands

ABSTRACT

The use of digital games for the promotion of goods and services is becoming more popular with the maturing and penetration of the medium. This chapter analyzes the use of advertisement in games and seeks to answer in which way brands are integrated in interactive play. The branding of virtual worlds offers a completely new range of opportunities for advertisers to create a web of brands, and it is the usage of marketing through games that differs considerably. This chapter offers a categorization of advergames and will address the use of advergames from a developmental perspective, differing between commercial games with in-game advertisement and dedicated advergames. Where TV commercials, print ads, and the World Wide Web rely on representation for the conveying of their message, advergames are able to add the extra dimension of simulation as a mode of representation, resulting in various interesting game designs.

INTRODUCTION

The increasing sociocultural and economic importance of digital games not only caught the attention of politicians, academics, and journalists but advertisers as well. Modern day gamers complement their use of the television screen with playing games, and use their PCs for Web browsing and buying books online as well as gaming. Marketers may have found their way around in the cinema and the television set; but the virtual world has yet to be fully explored. Slowly but steadily, the adaptive character of advertisement is spilling over to digital games. Besides money earned from the original purchase and subscriptions another revenue stream may become equally important for game publishers and developers. Why have digital games become such an interesting medium for advertisers? And in which way are brands integrated in interactive play? This chapter seeks an answer to both questions.

Digital play on its part can no longer be seen as child's play. The question is, if games ever have

been child's play. Due to the graphic nature, but also the complexity and sophistication of many contemporary PC games, children are not by default the primary target group of game publishers. As stated elsewhere in this volume, the average age of a gamer is not 13, not even 20, but 29, while 59% percent of the players are male. A significant number (43%) of all of all U.S. gamers play online and the gender breakdown of online players is similar to the overall demographics (ESA, 2004). And when gamers do play, they take their time. They have to, as contemporary console games for the big three—Xbox, PlayStation 2, and GameCube—as well as the majority of PC games, allow gamers to invest dozens of hours of their free time.

Single-player, narrative-driven role playing games such as the Final Fantasy series can take hours to complete, more open ended simulation games such as The Sims series or the Rollercoaster Tycoon series can grip the short attention span of Generation Y even longer, and online multi-player games can in theory be played indefinitely, for those considering playing games as an essential part of their lives. For the “hardcore” gamers, gaming is part of their lifestyle. The complex social worlds online multi-player games have become, makes playing such games even more rewarding from a sociocultural perspective, as discussed by Sal Humphreys elsewhere in this volume (Chapter IV). Spending 5 hours a day—on average—playing Counter-Strike with friends or clan mates, or playing 6 hours a day—role playing as a level 60 Night Elf Rogue in World of Warcraft with guild mates—is not an uncommon activity at all.

The Online Games White Paper 2003 by the International Game Developers Association (2003) estimates the U.S. market size of PC CD-based online games at less than 5 million gamers, and the PC Web-based category at 50 million (or more) gamers. The growing broadband penetration in the United States, Europe, and parts of Asia proves to be invaluable for the distribution of all sorts of digital content, and games are no exception to

these advancements. As game technology gets cheaper and more pervasive, the group of online PC gamers is projected to steadily grow over the coming years. The introduction of massive multiplayer online role playing game (MMORPG) such as World of Warcraft, showed the remarkable smooth distribution of a subscription-based game among millions. Only a month after the games' introduction on the Chinese market, the Warcraft population increased with 1 million new gamers, surpassing the 4 million player limit worldwide (Schiesel, 2005). Counter-Strike and Counter-Strike: Source, the most played, online first-person-shooter games, facilitate online game play for 2.4 million players every month.¹

As such, digital games are arguably the most influential product of contemporary computer technology. Many aspects of the omnipresent and growing cyber culture are surfacing in this new form of digital amusement and profound questions regarding the complex interplay of marketing, technology, and culture are yet to be addressed. Kline, Dyer-Witford, and de Peuter (2003) gave their take on the interaction among game technology, game culture, and marketing and argue that game culture has become part of “a web of synergistic advertising, branding and licensing practices spreading through contemporary popular culture” (p. 21). The commodification of digital play is commonplace and games as “the ideal commodity in the post-Fordist society” are natural inhabitants of this new high-technology capitalistic society. The post-Fordist society, also dubbed “post-industrial capitalism” and “information capitalism,” signals “changes in the workplace, in patterns of consumption, in media of communication and in the role of government” (Kline et al., p. 64). It is a move towards perpetual innovation, from material to experiential commodities and towards the development of media, information, and digitization. This society seems to welcome the synergy of advertisement and games with arms wide open.

The “eyeball” time of gamers is worth billions of dollars. Game technology enables developers to develop true-to-life simulations and as a result games steadily move outside their role of entertainment technology. Games are increasingly used for education, testing of (military) technology, and propaganda. Games have become more than just mere entertainment (Nieborg, 2004, 2005). And because of the interactive and configurative nature of game technology, advertisement in games can go far beyond static in-game banners, posters, and billboards.

Consider the horrifying First Person Shooter game *Doom 3*. The in-game personal digital assistant (PDA) of the player provides vital clues as how to navigate through the Mars base where the main character is trapped. During the game, dozens of e-mail messages become available on the PDA, some of which praise the fictive company *Martian Buddy*—“the latest interstellar marketing venture” (*Martian Buddy*, n.d.). As it turns out, investigative players, such as the author of this chapter, find out that surfing to *martianbuddy.com* provides a code to unlock a weapons locker. With an unforeseen wink to the subject matter at hand, the Web site explains its purpose: “*Martian Buddy* represents the best in direct marketing advertisements” (*Martian Buddy*, n.d.). The game developers are not far from the truth—the semi-annoying spam e-mails evidently did their work as the *Martian Buddy* Web site had more than 470,000 unique visits within 3 weeks after the release of the game. Naturally, the imaginary *Martian Buddy* brand is easily replaced by a global brand of choice.

The example of the fake *Martian Buddy* brand helps to pinpoint several essential elements in discussing games and advertising. The starting point of any analysis on games should always be the emphasis on its ludological nature, as games are systems “in which players engage in an artificial conflict, defined by rules, that results in a quantifiable outcome” (Salen & Zimmerman,

2004, p. 80). Static in-game advertising may seem like a viable way to market a product or service, and in many ways it is, but games as rule-bound, interactive texts favor more than just an interpretive reading practice. Gaming is at the same time a configurative practice, combining “ends, means, rules, equipment and manipulative actions” (Eskelinen, 2001). The PDA in *Doom 3* is not merely encountered during a play session, it is operated by the player and a player cannot progress without using the device. Playing games involves engaging with the game’s simulation model in a creative fashion. In this way, the process of “reconfiguration,” creatively repurposing the rules of a game, could complement configurative gaming practices (Raessens, 2005, p. 380). It is my belief that the forward leaning (inter)active nature of game play, whether or not they enable a reconfigurative mode of participatory media culture, should always be considered by those including marketing messages in digital play.

Today, the implementation of branded game designs takes various forms and shapes. In the following section the distinction between different sorts of *advergames* will be fleshed out after which a detailed case study of the PC game *America’s Army*, will focus on the most elaborate form of *advergaming*, as it is wholly designed as a branded game experience.

UNDERSTANDING ADVERGAMES

The number as well as the sophistication and implementation of game-based advertisement (or *advergames*) are becoming more popular with the maturing and penetration of the medium. An *advergame* could be defined as the integration of advertising messages in an online game and is increasingly used as an integral part of Internet marketing and advertising strategies to promote goods and services to potential consumers (Buckner, Fang, & Qiao, 2002). Chen and Ringel (2001)

distinguish three ways in which messages can be incorporated in games. The first is associative advergaming, that is, driving brand awareness “by associating the product with the lifestyle or activity featured in the game” (p. 3), the second illustrative advergaming, in this way the product is heavily featured in the game, and a third way is demonstrative advergaming, featuring “the product or brand name in incidental ways” (p. 4). In addition, advergaming can also serve as online tracking tools. By both active and passive data gathering, advertisers can learn from customers and collect all sorts of demographic data, e-mail addresses, and data on online behavior. The topology of Chen and Ringel offers a starting point to discuss the use of games for marketing purposes. But as they ignore the interactive nature of games, a different categorization will be proposed to deepen the understanding of both games and advertisement.

As the various examples in this chapter will make clear, game technology enables developers to incorporate the modes discussed by Chen and Ringel (2001) in more than one way in a single game. This chapter offers a different categorization of advergaming and will address the use of advergaming from a developmental perspective. There are considerable differences between simple tennis games featuring a company’s logo and slogan, a high-profile commercial release developed for profit showing in-game ads, and state-of-the-art simulations offering immersive marketing experiences. In this chapter two main categories of advergaming are proposed based on the rationale of a game, that is, advertisement in commercial games, hereafter in-game advertisement, versus dedicated advergaming. The former category consists of commercially developed games, aimed to sell as many units as possible to profit both the developers and publisher. The latter category games are solely made to advertise. Both categories are inhabited by subcategories. These subcategories focus on the formal aspects of games, distinguishing be-

tween non-game-play integrated advertisement (logo’s, slogans, banners, and billboards) versus game-play integrated advertisement. This second subcategory consists of advertisement integrated into the game’s ruleset.

ADVERTISEMENT IN COMMERCIAL GAMES

The first category of games featuring in-game ads holds games containing some sort of brand placement. Similar to movies and television series, advertisers can insert praise for their goods in a commercial game in two ways. On the one hand, developers can choose to insert static advertisement, similar to a banner on a Web site or a billboard on the background in a movie or television series. The exploratory research of Chaney, Lin, and Chaney (2004) found that first-person-shooter players, regardless of their experience with the genre, did recall encountering static advertisement in the form of billboards during game play, but did not recall a brand’s name 15 minutes after. In this particular study, gamers were focused on playing the game, rather than paying attention to the (branded) environment.

On the other hand, developers can harness the interactive nature of games and blend an advertisement message into the game play. The moving picture equivalent of game-play integrated advertisement would be the cars of James Bond—for example, the BMW Z8 or the Aston Martin V12 Vanquish. Bond’s use of his specially prepared and luxurious cars, bear direct relevance to the movie’s plot. After all, a master spy needs a fast and powerful car to impress his opponents or in order to escape after a successful mission. It should be noted that the distinction between game play and non-game-play integrated ads is to a certain extent a theoretical one, many games have incorporated both mechanisms.

Let us now take a closer look as to how the two forms of in-game advertisement function in

today's for-profit games. The popular and much debated game *Grand Theft Auto: San Andreas* is an interesting example in this respect. Albeit the game has no real world in-game advertisement, it could be regarded as a proof of concept as to how to use interactive play for marketing purposes. As it happens, the game does show a great range of fake advertisement—ranging from promiscuous sex jokes to nods at previous games in the franchise. *Grand Theft Auto: San Andreas* is available for the PlayStation 2, Xbox, and the PC and is best described as an urban simulation game. The player navigates the Afro-American avatar Carl “CJ” Johnson through the state of San Andreas, modeled after the state of California. At the beginning of the game CJ arrives at his mother's home in the city of Los Santos, where he meets his old “homies” and the games' mission structure sets off. The player can freely explore the enormous virtual world of San Andreas by foot or by using various vehicles, for example, trains, planes, automobiles, golf carts, and forklifts.

The game space is modeled after three real world cities—Los Angeles, Las Vegas, and San Francisco with similar architecture and atmosphere. Because of its plentiful real world references, there are numerous opportunities to advertise various goods or services. It is likely that the controversial character of the game made many advertisers hesitant to put up a signpost in San Andreas. The inclusion of a brand without prior consent can lead to difficulties as shown in the PlayStation 2 game *The Getaway*. This game contains 50 square kilometers of virtual London where gamers have to fulfill all sorts of driving missions. The game pictured a scene where a criminal was dressed up as a British Telecom technician, after which British Telecom protested, resulting in the subsequent removal of the “advertisement” in future versions.

The easiest way to advertise goods in San Andreas is through the use of billboards alongside the road—a clear form of non-game-play integrated advertisement. To achieve missions in

the game, players have to cover great amounts of terrain and road signs, and billboards are already a natural part of the game space. However, gamers do not have to interact with the billboards in any way. For instance, the billboards do not offer any secret codes to unlock doors. An opportunity to add game-play integrated advertising would be branding clothing of the main character. It is possible to completely customize the appearance of CJ, ranging from various outfits (e.g., police uniforms, country or medic clothes), to watches and sun glasses. As new clothes make CJ look “cool” and improve his “appearance,” it also positively influences his “respect” and thus clothes become integrated into the overall game play. Designers could go as far as to let the computer-controlled characters make positive remarks about certain brands—encouraging a certain outfit.

Similarly, the game features various unbranded cars which will take the player to the gym to build muscles or to one of the fast food restaurants, such as Cluckin' Bell Happy Chicken (a Taco Bell/KFC parody) where the player can eat a Cluckin' Big Meal and have a glass of Sprunk (a parody of the soft drink Sprite). Nelson (2002) found that when brands are integrated into the game play: “for example, the car selection in a racing game—short term recall is enhanced” (p. 89). And while driving their randomly picked cars, the players of San Andreas can visit Well Stacked Pizza Co. or Burger Shot. Similar to the fake ads of Martian Buddy in *Doom 3*, Cluckin' Bell has a Web site at cluckinbellhappychicken.com, including the Cluckin' Bell Happy Chicken theme song and a list of the menus. Despite these various marketing opportunities, all these brands still are self-referential and they are part of the appeal of the game series—that is, the fake brands consist of typical *Grand Theft Auto* humor.

The games' soundtrack is one of the few in-game real world references in *Grand Theft Auto*. The moment the player gets into a (stolen) car, he can opt for one of the nine radio stations, ranging from a modern rock station to a country channel.

A month after the release of the PlayStation 2 version of the game, an 8-CD, stand-alone version of the soundtrack box set hit the market, featuring all in-game radio stations. The box is clearly primarily meant as a collector's item rather than a marketing opportunity. Games do however prove to be a valuable medium to market (new) music or bands. Rapper Snoop Dog for example, let his single Riders on the Storm debut in the race game Need For Speed Underground 2. The Need For Speed Underground 2 soundtrack is part of the EA TRAX initiative. The game industry's biggest publisher Electronic Arts (EA) teamed up with several record companies and started TRAX to promote new music in their sports games:

Record labels partner with EA because they understand videogames are a powerful channel for exposing new music to a large core of young opinion leaders. Record companies also realize the valuable demographics of gaming; its "cool" factor; the buzz and the size of the interactive entertainment industry have put videogames at the center of mainstream entertainment.²

In this way gamers might find their way to the latest hits via their games, rather than via their peers, p2p software, or the radio. In the same way that publishers put out press releases for movies and games, they put out independent press releases for a games' soundtrack.

For a long time, games have been part of the complex intertextual web of popular culture (cf. Marshall, 2002). Initial research points to the direction that gamers do not object to the use of in-game advertisement, arguing that (fake) advertisement makes the game space more "real" (Hernandez, Chapa, Minor, Maldonado, & Baranzuela, 2004; Molesworth, 2003; Nelson, 2002; Nelson, Keum, & Yaros, 2004;), whether this (perceived) additional realism is effective has yet to be seen (cf. Chaney et al., 2004). An expressive example of the "need" for advertisement and the idea it increases a virtual world's authenticity, is a

free downloadable user-made modification (mod) redecorating the virtual landscape of Grand Theft Auto III. The mod, ironically dubbed RealGTA3 (or RGTA), is assembled and partly developed by a Czech modder, and contains a collection of many Grand Theft Auto 3 modifications "trying to make GTA3 more realistic by adding real cars, buildings or advertisements all over Liberty City."³ The mod could as well be named the best of international brands mod with in-game advertisement for McDonalds, Pepsi, Coca-Cola, IKEA, Media Market, Pizza Hut, and the inevitable Czech beer brand Pilsner Urquell. The long list of mod developers from all over the world who contributed to RGTA suggests the willingness of amateur software developers to take part in the voluntarily act of branding virtual worlds.

FROM BANNERS TO POWER-UPS

The willingness to consume, to experience, or even to co-develop advertisement is shown in a number of today's persistent MMOGs, such as There and Second Life. These worlds as well show a mixture of both game-play and non-game-play integrated in-game advertising. In the virtual playgrounds, such the one of There, users are able to produce their own (noncorporate) brands and use the same branding techniques as clothing companies to market their goods. With the use of time, money, and technical skill, users are able to rival with corporate branded goods in regards of reputation within the virtual world (Book, 2004). Advertisement in MMOGs shows the active appropriation of brands used in the social and economic interests of gamers.

Some players actively choose to incorporate brands into their game experience to construct their online personae. In this way, the game world becomes an index of consumers rather than products, signifying consumers as cultural entities (Pennington, 2001). By a carefully constructed web of brands, consumers can market themselves

within chaotic online worlds deprived of the necessary signifiers to construct one's identity. That a personality can be defined by naming a number of brands shows the former Web site Branddating.nl. Here visitors associated themselves with several brands to distinguish themselves from other daters, in addition with their gender, age, and place of residence. Research into MMOGs suggests that younger age groups have a more positive attitude towards advertisement and branding in virtual worlds than adolescents and adults (Book, 2004). This fits with the demographics from the Branddating.nl Web site where a majority of the daters were fairly young as well.

As said, the technological and innovative character of game technology can open up a window of opportunity for innovative and daring marketers. The tactical first-person-shooter game SWAT 4 introduced customized in-game ads in their first (mandatory) patch. The marketing firm Massive Incorporated specializes in technology-linking ads with specific game audiences and already has some major game publishers among their clientele. When gamers play SWAT 4 they will randomly encounter in-game ads such as Coca-Cola or Gamefly.com posters and data is sent back to the Massive Incorporated ad servers detailing which ads are looked at by gamers and for how long. In this way the advertisers can specifically target online gamers with ads of their taste, thereby changing static, hard coded, in-game product placement into truly interactive dynamic advertisement, although still not game-play integrated. It is even possible, as is done in the MMOG Anarchy Online, to include full-motion video and audio ads.

Soft drink company Red Bull has integrated its product in the platform game Worms 3D where it serves as a power-up. A clever integration, oddly shaped power-ups with ever weirder results are part of all games in the Worms series. In the game a can of Red Bull serves as a powerful simulation of the Red Bull slogan "Red Bull gives you wings." In a similar way game publisher Ubisoft and Sony

Ericsson Mobile Communications made a deal to include the Sony Ericsson P900 and the T637 camera phone in the stealth game Tom Clancy's Splinter Cell Pandora Tomorrow. The phones are integrated in the game play, similar to Doom 3's PDA, as gamers have to use the mobile phone to receive messages from headquarters and to locate their position. And during hour-long single player game sessions, gamers are continually exposed to Sony Ericsson's technology up to a point where they have to make a photo of an opponent with the T637 camera phone.

Big corporations, such as McDonalds, already invest in branding online worlds. In The Sims Online users can purchase a McDonald's food kiosk, an element deliberately integrated into the game play. Book (2004, p. 13) demonstrates that the McDonald's food kiosks "function more as billboards than anything, they do not live up to their interactive potential." Pointing out that game-play integrated advertisement is not necessarily more successful than the non-game-play integrated subcategory. While both modes of in-game advertisement may become more ubiquitous, the sociocultural, political-economic, and technological characteristics of digital play facilitate yet another form of commodified game play, games focused on one product or service; the dedicated adverggame.

DEDICATED ADVERGAMES

The category of dedicated adverggames inhabits a wide array of games, ranging from simple Internet adverggames, mostly using Macromedia Flash technology, to sophisticated online worlds. A distinction can be made between three subcategories of dedicated adverggames. First, there consists a wide range of singular dedicated adverggames. Secondly, there are transferal dedicated adverggames, and thirdly there is the subcategory of experiential dedicated adverggames.

The first subcategory of simple nonpersistent advergaming are probably the widest employed subcategory of dedicated advergaming, for its low costs and simple development cycle. The notion of singularity derives from the games' focus on single-style game play. A singular advergame only has one core game-play element, such as games focusing on motor skills or (e.g., a race game), problem solving (e.g., a puzzle game). Many of these games are modeled on the classic games of yesteryear, such as Pacman or Tetris. A puzzle game with Tetris-style game play could be turned into a dedicated advergame by making it appear on a specific Web site in a pop-up window. Gamers who are interested can play the game on the spot or sometimes download it to play on a moment of choice. Other advergaming offer a new but familiar design. Car manufacturer Jaguar promoted their new S-type R model with a Flash game offering an online Urban Golf course.⁴ The car in the back of the game had nothing to do with the actual game play. A player has to finish a Golf course in central London and the hole is replaced by a red postbox. Players who supply their e-mail address can win golf lessons from a pro.

These simple advergaming arguably lack the game play to engender immersive play and are primarily used to raise brand awareness and direct visitors to the various Web sites for more information. The games have their own Web sites or may pop up when visiting a random Web site and cannot be saved to one's computer, thus the game becomes a random encounter and in many cases the nonpersistent achievements—that is, points—do not encourage gamers to play the game again. Making the game available off-line, on the other hand, can aid the viral distribution of a game and thus its marketing message. In the Jaguar advergame example, players may send the Web site's URL to their "mates" via the Web site and can compete to beat the top scores. The International Game Developers Association (IGDA) in their Online Games Whitepaper promote these kinds of advergaming as "a powerful and effective tool

for delivering branding and advertising messages" as these games tend to be "sticky," nonintrusive and able to generate various demographic data of consumers (2003, p. 35). As said, small PC Web-based advergaming can tap into a large group of 50 million U.S. gamers, whereas PC CD-based games, such as *The Sims* or *Rollercoaster Tycoon 3*, have a much smaller potential market of less than 5 million U.S. consumers.

A more sophisticated form of dedicated advergaming are games offering a transferring experience, or what Chen and Ringel (2001, p. 3) would call "associative advergaming." Here brand awareness is raised through lifestyle association. The subcategory of transferal advergaming may also feature the advertised product and thus can be seen as an illustrative advergame—offering as much in-game product exposure as possible. The sole intent of these kinds of advergaming is to put users into contact with its brand and harness a positive game experience within a controlled and branded (persistent) online world. The games in this subcategory may or may not contain any links to external Web sites of the advertised service or product and does not enable gamers to actually experience a particular product or service.

A successful example, in terms of the amount of visitors and time spent on the Web site is the online world of Coke Music, developed by order of Coca-Cola.⁵ Coke Music has all the elements of an MMOG and contains all kinds of simple social activities, which can be very time consuming, ranging from chat to the production of simple music compositions. The technology is completely Web based and gamers can only play online. Established in 2002, this Web site counted "over a million views a day, the number of new visitors increases monthly with 200,000, and people spend about 25 minutes on the site" (Van der Graaf, 2004). Additional gain for Coca-Cola is added through putting out surveys to collect various gamer data. The Coca-Cola brand is omnipresent and many ad campaigns in other media slip into Coke Music—and vice versa.

The example of the branded world of Coke Music shows how existing game genres can be repurposed to fit the advertisers need. Built upon the template of the commercial game/chat environment of Habbo Hotel, Coca-Cola successfully appropriated the game mechanics of a proven game concept and offers a free branded alternative. Habbo Hotel, developed by the Finnish company Sulake Labs, is a moderated, Web-based chat environment with many franchises all over the world. It is a huge success among young children and has 3 million unique users visiting virtual hotels within 16 countries on four continents. As both Habbo Hotel and Coke Music are free games, the choice between both games may be somewhat arbitrary and has a social dimension. In a way Coca-Cola's virtual world is more than a game; it is a social structure:

(...) based on the constant negotiation of cliques, inner circles, in-crowds and social drama that is enacted throughout a variety of settings. The corporate sponsor is just as likely to be completely ignored in the pursuit of these activities, especially when more powerful metaphors can be found. (Book, 2004, p. 21)

This observation shows that the complexity or sophistication of an advergaming does not equal (instant) success for the advertised product or service. There is always such a thing as good game design. A brand may be cleverly integrated into the game play or to put in the words of Hernandez et al. (2004) a brand may be congruent and thus less intrusive, creating meaningful play is an art in itself (cf. Salen & Zimmerman, 2004). Young gamers may freely wander through the branded world of Coke Music, whether or not they will associate their own lifestyle with the soft drink's brand is a question certainly worth further analysis. Next, the third subcategory of dedicated advergaming will be discussed—experiential advergaming.

EXPERIMENTAL MARKETING

Games add the representational mode of simulation to the marketing mix. In games, brands can be shown repeatedly and through carefully branded simulations, games enable consumers to “transfer meaning to themselves, defining themselves as cultural entities” (Pennington, 2001, p. 50). But the gift of interactivity adds a significant “bonus level,” through game-play products or services can be experienced. The intangible and arbitrary associations evoked by brands as symbols, become tangible, allowing gamers to experience what it is like to drive a car or being a soldier by immersing themselves into carefully constructed virtual simulations. Economists Pine and Gilmore (1999) offer a useful concept to understand this new marketing paradigm: “Cyberspace is a great place for escapist experiences” (p. 34) and the game can stage such memorable experiences, situating itself within existing community structures and design conventions in order to offer a “show.” This shift is in line with the notion of “the experience economy,” where the former offerings of the commodity economy are replaced by an economy relying on staging memorable and personal experiences.

The branding of virtual worlds offers a complete new range of opportunities for advertisers to create a web of brands. Brands get their meaning partly through opposition (Pennington, 2001) and the previous example of RealGTA shows the low technical, social, and virtual barriers of the branding of virtual worlds. Major global brands such as Microsoft, IBM, General Electric, and Intel do not have the advantage of being able to create experiential branded simulations. Computer software and hardware and consumer appliances seem to miss a central point to create meaningful play. Coca-Cola bypassed this problem by facilitating social interaction in a branded virtual world where teenagers can chat and come together within a branded community. Car manufacturers are

arguably one of the other few major brand holders being able to tap into existing game genres and develop engaging experiential simulations, that is, a racing game rather than a branded simulation, for example, a puzzle game sponsored by a car brand.

An interesting example of a successful experiential dedicated advergame, from an economic perspective, is the PC game *America's Army*.⁶ This game goes beyond a transferal experience as it is a game that relies mainly on the simulation of combat. The state-of-the-art game facilitates rich and immersive virtual experiences, showing consumers virtual insights in an interactive world previously not accessible to the general public. "By creating leads and traffic through *America's Army's* design and characteristics, the Army's brand is not about 'just a logo. It is much more, namely, it is the experience that occurs when a gamer comes into contact with the Army's game'" (Van der Graaf & Nieborg 2003, p. 329).

For most players *America's Army* is first and foremost an online multi-player-tactical, first-person-shooter PC game. Developed by the U.S. Army, the game is freely available on various Web sites and the game's design is inspired by other popular first-person-shooter games such as *Counter-Strike* and *Tom Clancy's Rainbow Six*. In *America's Army* the player takes the role of a U.S. Army soldier and engages in man-to-man combat against human opponents in authentic environments by using a range of real-life weaponry in order to complete a mission or objective. *America's Army* is primarily a multi-player game. The single player part entails several training missions, which need to be completed in order to unlock certain roles, such as a medic or a sniper.

America's Army could be seen as a simulation of the U.S. Army, many unrealistic elements from the first-person-shooter genre are changed. For realism's sake, the game play is much more structured and bound by the rules of physics and warfare. Players become soldiers with a persistent record. Shooting team members is ruled out and

maps, weapons, and roles cannot be changed. In *America's Army* you will always be put in the boots of a U.S. Army soldier. Through the use of a software trick every gamer sees himself and his team as U.S. soldiers and the other team as the Opposing Forces (OpFor) and vice versa.

America's Army is not the only advergame issued by the U.S. military to promote its services. There is the free downloadable real-time strategy game *Guard Force* to aid recruitment for the U.S. Army National Guard. While the U.S. Marine Corps was heavily involved in the development of the first-person-shooter, training tool spin-off *Close Combat: First to Fight*, this game is a commercial game with game-play integrated advertisement. Gamers have to buy the game and its primary goal is to sell as many copies as possible. The U.S. Navy issued the action game *Navy Training Exercise (NTE): Strike & Retrieve*. This game however is a transferal-dedicated advergame as the game play does not directly simulate the activities of Navy recruits. *America's Army* then is marketed as a combat experience, and by simulating U.S. Army values through a true-to-life infantry combat experience, the Army educates gamers about soldiering. How *America's Army* works as a dedicated advergame and an experiential marketing tool, will be explored more in depth in the following analysis.

MILITARY ADVERTISEMENT

With the end in 1973 of the mandatory military service, better known as the draft, the U.S. military had to rely on its recruiting efforts to enlist personnel for its new All-Volunteer-Force. Over three decades later, the U.S. military has to persuade more than 200,000 recruits annually to fill its ranks, but one of the biggest problems facing contemporary recruiting efforts still is its effectiveness. Today, the U.S. armed forces rely on three pillars for their recruiting efforts. First, there is a 15,000 strong force of recruiters. Second, various

(financial) incentives are available upon joining and in order to raise awareness, and third, to help recruiters reach their target groups, the military invests heavily in advertisement. From 1998-2003, the total advertising budget for military recruiting almost doubled from \$299-\$592 million while the total recruiting budget approached \$4 billion (General Accounting Office, 2003). In order to keep up with contemporary marketing, the U.S. Army created the “U.S. Army: An Army of One” brand.

As any other brand, the U.S. Army brand needs constant expansion—a process taking up enormous amounts of financial resources. To expand the Army brand, the U.S. Army sponsors a NASCAR (National Association for Stock Car Auto Racing) racing team, a NHRA (National Hot Rod Association) Top Fuel team, and a NHRA Pro Stock Bike team. And in line with the ubiquitous transgressive character of brands (Pennington, 2001), there are three (official) Web stores offering licensed material with the “U.S. Army of One” logo and slogan on it, ranging from clothing to mugs, playing cards to key rings, and other knickknacks.⁷ With half of the military advertising funding going to the Army and the constant need to reinvent and explore new advertisement platforms, there is room to experiment and try new initiatives to reach the core group of 18- to 24-year-olds. Probably the most high profile advertising experiment of all, could well be America’s Army.

It was the advergame dimension, the Army’s goal of attracting more recruits, that became at the conception of the project, the guiding design rationale. The U.S. Army does not label America’s Army as a recruiting tool or an advergame, but as a strategic communication tool (e.g., Davis, 2004). The goal of the game is to inform popular culture rather than to persuade and to raise awareness rather than directly recruit, which is done by U.S. Army recruiters. Raising both the awareness of the U.S. Army brand and the U.S. Army as a possible career are central to the design of the

game and its community. With less influencers, people with a positive attitude towards the Army and a willingness to communicate this attitude present in the U.S. society (e.g., former soldiers), the Army has to rely on other mechanisms to enter the “consideration set” of America’s youth. “So when a young person turns 18—17, 18—and they start to think about what their options are for the future, what does that list look like? Go to college? Get a job? Hang out with my friends? We want ‘join the Army’ to be one of those lists of options” (Department of Defense, 2001). With this statement, the former Secretary of the Army, Louis Caldera, articulated one of the main goals of the “Army of One” campaign.

What makes America’s Army fairly unique is that it could be considered one of the first multidimensional games (Nieborg, 2004, 2005). Analysis shows that the game has more than an advergame dimension. It is used to train U.S. Army soldiers as well as to educate gamers about the U.S. Army the edugame dimension. Through off-line PowerPoint lectures followed by multiple choice tests and through online game play, gamers may learn what it takes to be part of the “Army of One.” The games’ third dimension is its use as a test tool. New military technologies are carefully modeled in the game, allowing military experts and soldiers to test these future weapon systems in the virtual world, after which they can be easily incorporated into the edugame dimension. Gamers can be tested as well. Similar to off-line test tools, such as the Armed Services Vocational Aptitude Battery (ASVAB) freely available at U.S. high schools, the U.S. Army is able to virtually test the aptitude of potential Army recruits. The fourth and last dimension of America’s Army is its propaganda dimension. The game is both an example of a public affairs instrument, as an instrument of public diplomacy, as it shares many of the same goals and characteristic of both strategic communication tools. However, it is the role of America’s Army as a tool of public diplomacy that signals a shift away from the advergame di-

mension towards the propagame dimension. Both dimensions still interact and reinforce rather than replace each other. The initial goal of a recruitment aid and raising the brand awareness of the U.S. Army is partly bypassed when looked at the global use of the game, thereby giving way to the propagame dimension.

Encapsulated in the first-person-shooter genre are several key features ready to be appropriated for (successful) digital marketing. The U.S. Army as a brand transformed into the America's Army brand and appears able to tap seamlessly into existing game community frameworks. Kierzkowski, McQuade, Waitman, and Zeisser (1996) provide five distinct recommendations for success in digital marketing, all of which are present in the production, distribution, and consumption of the official U.S. Army game. First, there is the advertisement on and alliances with gaming Web sites such as GameSpy.com and Gigex.com. Second, providing participants with a stimulating and motivating game is evident in America's Army's much acclaimed realism. Third, participants are instantly rewarded and have the prospect of beating top scores. This is constructed by the extensive and persistent honor system which gives a gamer certain credits and acknowledgement among peers as well as goals to aim at (e.g., getting more honor points than a peer). Fourth is the identification of user preferences by providing choices within the game. In America's Army players can play in theatres of operation all over the (virtual) world, playing different rolls and familiarizing themselves with a plethora of weapons. And the fifth and final aspect is retaining users which is partly taken care of by the community, which consists of the official homepage with its message boards, several (semi-professional) affiliates and fan sites and several IRC channels. Game communities are known for their collaborative and peer-supporting character (Jenkins, 2002; Newman, 2004) and America's Army is no exception to this rule.

One of the questions asked by every journalist and academic unfamiliar with America's Army is: "is the game effective and do you have figures showing how many people joined?" Such figures are nonexistent and the design of both the game and the community are not set up in a way that such data can easily be obtained. One thing about America's Army as an adverggame is clear; the game is extremely cost effective. The game cost \$4 million a year from 2000-2003. With a breakdown of \$2 million in wages, \$300,000 for game engine costs, and \$1.5 million in operational costs (Zyda, Mayberry, McCree, & Davis, 2004). In the upcoming years, staffing costs and licensing fees are likely to grow. The \$20 million spent on the game pales into insignificance considering the following remark: "The Army estimates America's Army has the potential to save some \$700M-\$4B per year" (Zyda, 2002, p. 9).

CONCLUSION

In a society where even sand can be branded, the competition for attention is enormous (cf. Klein, 1999). Advertisement in our post-modern, media-saturated world is omnipresent but at the same time extremely fragmentary. The eyeball time of young people has become a commodity in itself, with every medium fighting for attention trying to sell audiences to a growing pool of companies and brand owners. Over the years and with the maturing of the medium, children's play has become heavily commodified (Kline et al., 2003). Product placement in digital games is ubiquitous and gamers seem to praise the efforts of game designers to include their favorite brands in a game to make the game space more "real." The console hardware developers have become established brands themselves, up to a point where gamers identify themselves with the hardware. Gamers even have names for such aficionados: "fanboys." As a result "The industry

has come full circle: conditions for its spectacular growth were set in existing youth-oriented media niches; now for gaming is itself poised to create marketing opportunities for other corporations that are seeking to target the youth audience” (Kline et al., 2003, p. 236). The multiple identities of gamers as both fans and consumers are not without consequences, the voluntary activity of play becomes intertwined with the discourses of a commodified game culture.

Where TV commercials, print ads, and the World Wide Web rely on representation for the conveying of their message, dedicated advergimes add the extra dimension of simulation. The ever-rising processing power of computer chips, doubling every 18 months according to Moore’s law, enables rich and immersive virtual experiences, showing consumers virtual insights in interactive worlds previously not accessible for the general public. It is the usage of marketing through games that differs considerably. Commercial games increasingly include some sort of marketing message. Increasingly, dedicated advergimes are used to advertise, varying from singular advergimes which may be freely distributed via popular Web sites or on a company’s homepage, to the more sophisticated experiential advergimes, which encompass elaborate, persistent, virtual worlds. As the early abstract games of Pong, Spacewar, and Tetris turned into lifelike and realistic simulations, developers are now able to turn their intertextual references into commercial representations and simulations. Games as one of the new intertextual commodities have to:

... posses the elasticity to incorporate the imaginary reconfigurations of its images, stories and products by users. Although corporations protect their trademarks and images, they have also developed sophisticated structures and architectures that allow certain images of their film or game to float freely across the Internet as promotional

sirens of their cultural commodity. (Marshall, 2002, p. 76)

America’s Army is a successful example of such a cultural commodity, marketed as a simulation of the U.S. Army. Game-play-integrated advertisement seems to be favored by gamers over non-game-play integrated forms—a cleverly integrated branded car of PDA adds flavor to a game and aids brand recall. Advergimes can move beyond in-game banners and billboards. However, while the goal of brand placement is raising brand awareness (Nelson, 2002), interactive entertainment is able to move beyond this marketing model as well. America’s Army shows that gamers are able to learn (U.S. Army) values, basic skills, and a considerable amount of knowledge and information, just by playing the game. Gamers willfully subject themselves to minute long PowerPoint lectures to advance in the game. A career in the U.S. Army is literally played out. In America’s Army, the U.S. Army brand is ubiquitous and encompasses all modes of advergaming.

The game constantly supports brand awareness, for the brand and its simulation are interchangeable. By using various new media technologies, the U.S. Army is able to directly reach their target group in an active and engaging manner that corresponds with the media use of today’s youth. Being able to simulate conflict by using existing game design conventions, the U.S. Army both redefines elements within the first-person-shooter genre and taps directly into the very fabric of popular culture. In a similar way Coke Music is based on the popular format of Habbo Hotel. The question would then be if the designers and publishers of future advergimes are willing to leave existing game genres behind and if, through innovative game design, they not only will profit from game technology and culture, but contribute to it as well.

Chapter 8.10

Believe It or Not: Virtual Religion in the 21st Century

Susan E. George

University of South Australia, Australia

ABSTRACT

This paper considers the development of virtual communities focusing upon virtual religion and its impact on humanity. It is important that religion is expressed communally and socially, and the Internet has provided a new community context for religiosity, linking people from geographically, socially, and culturally disparate backgrounds, facilitating interactivity as never before in an intriguing anthropological development. We find examples of “online religion” that are already occurring and see technology as playing a crucial positive role in humanity in the 21st century. While there are limitations with virtual interaction compared to face-to-face engagement, there are benefits, primarily that such technology starts to answer the deeper philosophical questions associated with technology, especially the question of how technology cannot rob people of the essence of what it is to be human. By facilitating virtual religion, technology assists the uniquely human pursuit of religiosity, and merely provides a new “meeting place” for exchange.

INTRODUCTION

The Internet has created new human communities linking people from geographically, socially, culturally, and otherwise disparate backgrounds. Such virtual communities may be defined as

a collection of people sharing common interests, ideas, and feelings over the Internet or other collaborative networks. Web-based virtual communities have been defined as social aggregations that emerge from the Net when enough people carry on public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace. These communities are becoming increasing[ly] important forums for individuals and groups that share a professional interest or share common activities. (call for papers for the forthcoming Encyclopaedia of Virtual Communities and Technologies, editor Subhasish Dasgupta, Idea Group Reference)

Virtual communities may be considered an outcome of the recent developments in com-

munications technologies and a natural anthropological consequence for humanity embracing communications technology. They are found in realms as diverse as education and health, recreation and science.

One of the most important human realms in which virtual communities are found is that of religion. The technology underlying “virtual religion” is essentially the communication technology provided by computer science through the Internet. While the original computer networks were never designed as a human communication medium, they have come to penetrate society for communication purposes in many ways — from mobile phones to Internet banking, handheld computers to “intelligent” agents and voice recognition at human-machine interfaces. The Internet has particularly brought people together from all over the world in various online communities and virtual worlds in the new “meeting place” of cyberspace.

The remainder of this paper explores the development of virtual religion and its impact on humanity. First we consider the nature of religion and note that a social and communal expression is vital. As humanity embraces new modes of interaction, we recognize virtual religion as an anthropological consequence of the new technologies. Second, we explore ways that technology is facilitating religious expression, noting it is both supporting conventional practice and enabling new. We pose some questions that have been raised about the validity of virtual religious expression and consider who is interacting in this forum and why.

Third, we move to consider technology in context, noting how it is ideally the application of science for the benefit of humanity, although many people have identified negatives of technology including its power to rob humanity of the essence of what it is to be human. One of the key questions of the generation is how technology can have a positive role in lives. In conclusion, the development of virtual religion is seen as the means

by which technology may play a positive role in lives, facilitating as it does virtual communities and religious expression in a new anthropological context, and promoting, not stifling, the questions that are at the essence of what it is to be human.

RELIGION: REAL AND VIRTUAL

Religion has proved very hard to define. Definitions of religion are often too narrow and exclude many of the belief systems which most people will agree are religious, or they are too vague and ambiguous, leading one to conclude that just about any and everything is actually a religion. Some of the more successful attempts identify a set of markers such as practical and ritual, experiential and emotional, narrative and mythical, doctrinal and philosophical, ethical and legal, social and institutional, and the material (Smart, 1992). The more markers present, the more “religious-like” the belief system is. Sometimes religion is regarded as subjective, designating the feelings and acts of people that specifically relate to God and is distinguished from theology. From this subjective perspective, religion may be defined by the benefits it offers: the inclusion in a social community, the accompanying rights and responsibilities, personal fulfillment, spiritual and emotional benefits from that, and other assets.

One important element of religion is its communal and social expression. In fact, religion is often distinguished from spirituality, which is used to refer to devotional aspects of faith and interior individual experiences (McGrath, 2001). In a Christian context, the “body of believers” has a special significance as the church. The faithful are invited to gather and not cease to meet together, whether that is in a physical church building, or other! The synagogue as a Jewish place of worship literally means a meeting place where people would come together. For Islam, one of the five pillars entails the giving of alms as if all are brother and sister in the same family. For

these major world religions, and for many others, the social dimension may be regarded as one of its distinguishing marks, and meeting together is a crucial component.

When we use the term virtual religion, we are speaking of interactions within cyberspace. Many theorists have divided communications history into three main epochs: the oral tradition, the literary tradition, and the visual tradition (Postman, 1985). Each of these traditions provides ways of knowing what is true and what is not. Summitt (1993) suggests that society is entering a fourth tradition, that of interactivity where the locus of interaction is cyberspace. This is where virtual religion is happening. The interactivity facilitated by the Internet means that those in geographically or otherwise isolated areas may (in some capacity) participate in corporate expression of religion, cutting across cultural, social, economic, linguistic, and other borders in a way never previously possible. Importantly, there is a two-way communication in the interaction — in the exchange that makes virtual religion so unique and a very real component of life at the start of the 21st century.

The anthropological implications of such a society are fascinating. That component of anthropology that is interested in the different environments in which people are found, the social relationships and the language within them, their evolution, and customs will find Internet religious-expression fascinating. Some branches of anthropology being particularly concerned with the nature and substance of people from a religious perspective (<http://mountainretreat.org/glossary.html>) and some religions, such as Christianity, may argue that the human can only be understood in the context of God. Virtual religion certainly provides a stimulus for anthropological study in the online, interactive, global, virtual communities that have come into being with communications technologies.

We find virtual religion a natural anthropological consequence for humanity as it utilizes this

enabling technology — in a way unimagined by its inventors. Hurd (2001) sees technology itself as a consequence of humanity; the act of creating and using tools for present and future use is part of what it is to be human. Taking that a step further, having created those tools, humanity will naturally use them to further its own quest. The deepest questions that humanity asks are philosophical and religious: questions about identity, significance, and purpose. A part of what it is to be human will be to continue to ask those questions through the technologies that emerge as consequences of humanity.

TECHNOLOGY AND RELIGIOUS EXPRESSION

Supporting the Old, Facilitating the New

George (2004) examines the information technology (IT) revolution in the specific context of technology applied to Western Christianity, discussing how technology has supported conventional church life and mission through church management and administration. There are excellent study resources and a wealth of electronic aids and software resources, often interactive in nature, engaging the learner; worship can also be supported with technology and made relevant to a multimedia-experience generation. Such IT systems undoubtedly (at the best of times) benefit church life with improved efficiency, accuracy, ease of communicating information, reliability, and so forth. Drawbacks are obvious when the system fails and when IT detracts more subtly from the relational community of a church.

In terms of facilitating the new in religiosity, George Barna (1998), in his book *The Second Coming of the Church*, argues that most Christian churches are operating on outdated models of authority, leadership, and congregational structure, failing to meet the needs of a changing culture.

He believes that in this decade “millions of people will never travel physically to a church, but will instead roam the Internet in search of meaningful spiritual experiences.” Using a computer for online religious activity could become the dominant form of religion and religious experience. Soukup (2000) also believes that it is vital to understand the media in reaching the culture with natural implications for the religious expression in online communities.

However, online communities are not the prerogative of the religious. Online learning is another forum where face-to-face gatherings are replaced by electronic interaction. Many students still prefer face-to-face learning situations compared to online collaboration, often because online interaction is used when it is inappropriate for the learning objectives and there is a mismatch that hinders rather than supports the educational purpose. See, for example, Carnegie Mellon’s guidelines for facilitating online collaborative learning and interaction (<http://www.cmu.edu/teaching/technology/collab.html>). Also, for many religious adherents, a remote community would be a poor substitute for a physical gathering, yet it is certainly gaining some adherents as will be discussed shortly.

Internet church is essentially an online community that includes the normal components of church in an electronic forum. There may be archived addresses, liturgies, prayers, and meditations, even video and audio recordings of actual gatherings. A bulletin board may be used for prayer or as a discussion forum to enable members to engage with each other. Members may keep in touch with electronic mailing lists and/or SMS messages and mobile phones. All manners of Internet churches have sprung up with this form of alternative worship originating in the UK in the late 1980s.

Wilson (2000) describes Internet church as an opportunity to change the history of Christianity, comparing the information superhighway to the Roman roads built almost two millennia ago that

facilitated the spread of Christianity. For example, one initiative in virtual church recognizes that younger people are attracted to online communities through games (e.g., <http://www.waltemathe.org/virtkirch/>) and a gaming strategy may be the way that inhabitants of cyberspace are drawn into deeper discussions in the marketplace. A UK-based organisation has recently (May 2004) developed a three-month Web-based pilot of a 3D virtual church (<http://shipoffools.com/church/>). It consists of a chat room with participants embodied as characters in the space; there is a virtual building where religious expression can be made and online services complete with a religious message and music.

Brenda Brasher’s book *Give me that Online Religion* (2001) broadens from Christianity to describe online religious communities and practices in general. It is one of the earliest sources that address the practical outworkings of religion through technology. Bell (2004) observes that new technologies, “technologies of enlightenment,” are delivering religious experiences in new mediums and creating new possibilities and opportunities for spiritual and religious life — everything from cyber seders, the papal SMS service, Mecca finding mobile phones, Buddhist blessings of the Internet, and the ngonli almanac online. While examples of online religion can be found, the question remains of just how they relate to the conventional expression of religion.

Virtual Religion in Question

The Catholic Church has faced particular questions relating to its worship and liturgy in light of virtual and remote communication possibilities. In particular, it has had to address the question of whether sacraments can be administered over the Internet where normally the celebration depends “on the physical presence of the gathered faithful.” The ruling of the U.S. bishops’ secretariat for the liturgy was that no sacrament can be received by electronic communication. The same ruling

was found for the ritual involving “adoration of the cross,” which was not permitted to be done via a Webcam without physically being in the church building (<http://www.monksofadoration.org/webadore.html>). This has implications for all remote links—live telecast, Internet transmissions, Webcams, and video links — since technology cannot replace the physical presence among gathered people.

Theological rulings are not the only reasons why online communities are not desirable. If people engage solely in online social groups, friendships and other intimates in the real world can be put on hold. The technology can be adopted uncritically without discerning the options and setting appropriate limits. A new sort of addiction can grow among those who have tasted the Internet and replace the real-world interactions with a virtual world. While examples of online communities can be found, some questions that remains are who uses them, how, when, why, and where.

Who is Interacting and How

The Internet shrouds the user in anonymity, and some of Goffman’s (1982) principles for face-to-face interaction just do not hold. Goffman’s theory provides an explanation on how people interact with one another in day-to-day life. He sees two regions in which people perform. The first is the front region where our activities embody certain standards, such as politeness, where the individual is socially accepted within society. In contrast, the backstage or back region is where suppressed feelings make an appearance and contradict the actions carried out in the front region. When analyzing Goffman’s theory relative to cyberspace communication, we see that the lines between the front stage and backstage are blurred through anonymity, creating issues in “flaming” (insulting or argumentative replies), all the while keeping privacy.

In terms of using computer technology, there are some trends already observable. Gender has for a long time been recognized as a factor influencing interest (or disinterest) in computer science, with the female traditionally being adverse to using the technology. At the start of the IT revolution, age was traditionally a factor influencing uptake, but not so much as the decades pass. When natural communication needs to be and can be supported because of disability, there may also be a gravitation towards the use of technology. Personality may also be a factor in uptake of online communities, where in accordance with Goffman’s interactive principles, the normal rules of communication face to face are broken with the anonymity that Internet technology affords.

Careaga (1999) reports that “one out of every four Internet users has sought religious or spiritual information at one point or another in their virtual travels, and on a daily basis, more people use the Internet for spiritual purposes than for gambling, banking, finding a date, trading stocks, or buying and selling at web auction sites like eBay combined.” Cyberspace is regarded as a new marketplace where people meet together, and hand in hand with everyday business, will discuss politics, religion, and philosophy, and ask those questions that traditional religion has conventionally answered in churches, synagogues, mosques, and other religious meeting places. People are going to the Internet more than they are to any organized religious meeting place.

This paper finds the interactivity of online environments to be the place where virtual religion is happening. The About forum is just one discussion group (<http://forums.about.com>) where atheists and agnostics, Islamics, Christians, and many others from all over the world are meeting 24 hours a day, seven days a week, and engaging in the deepest religious and philosophical questions ever asked. The interactions occurring in such online environments may be labeled virtual religion, just as real as any debate that might take

place in the actual world in forums more recognizably identified as religious. Using technology to continue the religious quest of humanity is seen as a natural anthropological consequence for humanity at the threshold of the 21st century, given communications technology has enabled such interactivity and repositories of information in every language, in various media, unparalleled in human history. Virtual religion is a natural anthropological consequence for humanity.

TECHNOLOGICAL DEVELOPMENT IN CONTEXT

Science Applied to Benefit Daily Life

It is surprising how many definitions see technology as not only the application of science, but an application designed to benefit humanity. However, clearly, the ramifications of a certain piece of technology in terms of benefit or harm may not always be apparent at the outset. For example, definitions include, “the application of scientific advances to benefit humanity” (<http://sln.fi.edu/franklin/glossary.html>), and, “The creation of products and processes for the purpose of improving human chances for survival, comfort level, and quality of life” ([http://www.geog.ouc.bc.ca/conted/online courses/enviroglos/t.html](http://www.geog.ouc.bc.ca/conted/online%20courses/enviroglos/t.html)). In terms of benefits to humanity, we may look to how technology might be applied to clinical health care practice (Gastmans, 2002), how to develop (and fund) more technologies that will serve social human needs (Steffan, 2004), or how technology intersects with social enterprise (Fruchterman, 2004). We may consider how technology has benefited and served humanity in what many would regard as one of its deepest and most distinguishing capacities, that is, in its capacity for religiosity.

Other definitions of technology also embody expectations that technology will influence every aspect of existence—from education to

health care, recreation to international politics. Technology is science applied to daily life, with applications as diverse as genetically modified food and intelligent washing machines. Many definitions focus particularly upon commerce or industry (“the practical application of science to commerce or industry”; <http://www.cogsci.princeton.edu/cgi-bin/webwn>), or engineering (“The practical application of knowledge, especially in a particular area such as engineering”; <http://www.projectauditors.com/Dictionary/T.html>). And while definitions may emphasize a certain component of daily life, technology undeniably touches every facet and excludes none, not even religiosity.

Since technology does apply science to daily life, a need is found for monitoring the ethical questions and vital issues of the use of technology to judge whether it is good or bad. Science in its purest form is not concerned with moral judgment, or with purpose or teleology (and while social sciences may ask why about a particular phenomenon, they still remain silent on the deepest questions of human existence). Groups that do monitor the application of science typically have a religious affiliation. For example, the Institute for Religion, Technology, and Culture (<http://www.religion-research.org/irtc/irtc.htm>) aims to promote discussion and reflection on technology from a theological and philosophical perspective. They see technology as impinging upon how people understand themselves, the world, and God. The science, religion, and technology group of the Church of Scotland (<http://www.srtp.org.uk/srtpage3.shtml>) was set up to monitor unexpected risks and side effects, unintended social consequences, and changes in moral outlook arising from technology. Sometimes these groups are seen in negative terms, representing people who are resistant to change, reinforcing the false dichotomy of science versus religion rather than presenting a body reflecting upon the application of science.

The Uptake of Technology

The Western Judeo-Christian culture of the previous century has shown an extraordinary obsession with technology in its application of science to daily life. While a residual of technophobia can be found, the widespread uptake of technology is largely continuing unabated in the Western world. In some instances, technology and its products are rejected; for example, the increased interest in “natural” products is seen as an example of shunning technology (Carson, 2002). Yet, largely, the Western world embraces technology. Noble (1977) finds the theme of transcendence as explanation for technological obsession in a Judeo-Christian culture; both science and religion promise to transcend mortal life — nature, our bodies, humanity, and the world.

Yet at the same time the Western world embraces technology, Western culture enters into a post-Christian society, rejecting the Judeo-Christian culture of the past two millennia. In particular, it witnesses the end of Christendom (Hall, 2002). An increase in technology has apparently occurred hand in hand with a decrease in religiosity — at least a decline in the participation in organized, traditional religion. Whether people are any less religious remains a question. The Closer to Truth forum discusses this question, noting the intriguing paradox that as the world becomes more scientific, extreme religions are gaining ground (Kuhn Foundation, 2003). Others point out that technology has replaced religion and become a god of society (Strong, 1991).

Technology: Negative or Positive?

Many have reflected on technology in its most general terms and found it both changing humanity and having some negative consequences. Shelly’s *Frankenstein* is a fictional story meant as a cautionary tale to warn us that technology could eventually destroy us. Technological disas-

ters undoubtedly occur. Works such as *Inviting Disasters: Lessons from the Edge of Technology* (Chiles, 2002) discuss major accidents from space exploration to aircraft- and chemical-processing plants, seeking to determine why they happen. Yet the primary difficulties of technology are more profound than simple catastrophes.

The philosopher Heidegger (1977b) finds that technology is changing society and is relentlessly overtaking and transforming the entire world into raw materials mobilized in technical processes. Heidegger (1977a) explained that “[o]nly a god can save us” from the juggernaut of progress. The issue is not that machines are evil or that they have taken over, but that in constantly choosing to use them over every other alternative, we make many other unwitting choices that confuses our nature. Heidegger’s goal is to find a way of living with technology that does not allow it to “warp, confuse, and lay waste our nature.”

Other philosophers such as Borgmann (1993) also see technology (in a modern and postmodern world) to include a waning recognition of the possibility of any substantial spiritual existence. It is as if technology destroys that component of humanity. Dreyfus and Spinoza (1997) ask how we can relate ourselves to technology in a way that not only resists this devastation, but that also gives it a positive role in our lives. This is marked as the key question for our generation.

Other negatives of technology have been identified from a specifically religious perspective. The education and training accompanying science and technology has been directly linked to a decline in participation of organized religion. While education is obviously not wrong in itself, the underlying rationalism placing reason over faith has been identified as a factor increasing religious scepticism and atheism (Lecky & Edward, 1946). In fact, education now explicitly recommends that atheism be taught as part of the religious education curriculum in British schools (Cassidy, 2004), reflecting a society that values

rationalism, inclusiveness of all worldviews, and postmodern correctness over values of a previously Christian Western society.

From a religious perspective, there is also the observation that technology breeds a sense of empowerment and self-sufficiency. With appropriate technology, the human can control many facets of the world, removing the need for God, at least fostering a reliance on technology rather than anything supernatural. A Catholic religious address half a century ago warns of the dangers of technology in terms of “exalting technology” and “blinding intelligence” (Pius, 1953/2000). The address points out that technology can beautifully reveal God, but also cause humanity to once again sink itself into the first sin of self-sufficiency and independence. Berger’s *The Precarious Vision* (1961) is one of the earliest works that describe why it is difficult for a fully contemporary person to maintain a Christian view of reality that is not in some way precarious, once again pointing to the way technology — from a religious perspective — may be having a negative impact.

CONCLUSION

Going back to the key question of our generation asked by Dreyfus and Spinoza (1997) — that of how we can relate ourselves to technology in a way that resists its devastation and also gives it a positive role in our lives — it would seem natural to relate the answer, or at least a component of the answer, to the observations made previously about virtual religion: that humanity is utilizing technology for the purposes of furthering answers to its own deepest questions. Far from stifling this exploration and investigation, technology is facilitating a renaissance in interactivity, enquiry, and communication among people from all walks of life in virtual communities. There may be drawbacks in the depth of interaction possible, for example, that could be seen as negative for human-

ity in contrast to face-to-face communal religious expression, yet, in that it facilitates communities that promote and do not stifle the questions that are at the essence of what it is to be human, virtual religion makes one of the most positive contributions to that key question: How can technology play a positive role in humanity?

Chapter 8.11

Changing Technological Trends in the Travel Behaviour of Older Tourists

Ian Patterson

University of Queensland, Australia

ABSTRACT

This chapter examines the growth in usage of information technology and the Internet by older adults. We are becoming an ageing society with seniors and baby boomers now responsible for a larger share of all holiday spending. The Internet provides a perfect vehicle for the travel industry however, many seniors are still fearful about using the Internet, and perceived problems still exist with credit card security, quality control and privacy issues. In the future, Internet travel bookings are likely to increase with the growth in baby boomers who generally prefer to use the Internet. This will further encourage the use of discount fares however it will place increased pressure on the future role of the travel agent. Furthermore the authors hope that through an understanding of the technological needs of older

adults, it will inform tourism providers about the best ways to attract older people to use Internet sites for all aspects of their travel needs.

INTRODUCTION

We are becoming an ageing society. The United Nations has recognised the fact that the older generation are growing rapidly, and has estimated that over two billion people will be aged 60 years and over by the year 2050, and this will account for 22% (or one out of five) of the world's population compared to 10% in 2000. These demographic shifts will be seen across all continents (United Nations, 2000). For example, McNeil (1991) stated that, "... as amazing as it seems, over one-third of all Americans were born between 1946 and 1964" (p. 22). Australia's ageing population also is

increasing, from around 12% in 1999 to between 24% and 26% by 2051, or one in four people (Australian Bureau of Statistics, 1999).

On a global scale, the world is becoming increasingly aware of the significant impact that older adults (and in particular, baby boomers) will have on the tourism industry in the decades ahead (Goeldner, 1992). The direct consequence of this ageing pattern is that in the future, seniors will be responsible for a larger share of all holiday spending. For example, in 1999 over 593 million international travellers were aged 60 years and over. This accounted for around a third of all holiday spending by this segment. By 2050 this figure is projected to be greater than 2 billion trips (World Tourism Organisation, 2001).

As a result of this change in the demographic profile, the tourism and leisure industry is increasingly targeting the 65 years and over market because older adults generally are regarded as having greater amounts of free time and discretionary income to spend on travel, and as a result have become a significant growth market (Javalgi, Thomas, & Rao, 1992). This is because many baby boomers perceive themselves to be younger in age and in outlook, more in control of their lives, and increasingly more self-reliant. Baby boomers typically feel a decade younger (average of 10.2 years) than what their actual age is, and as a result often prefer to spend their holiday activities with younger people (Clever & Muller, 2002). They often seek out new and different leisure experiences that are often challenging and soft adventure activities, as well as being skillful and knowledgeable consumers that are generally satisfied with their lives (Patterson, 2002).

Today, the Internet has provided a perfect vehicle for the travel industry, as online travel Web sites have allowed consumers to have increased power over their travel planning, as well as providing them with a quick, easy and cheaper way of booking holiday travel. Traditionally, older consumers have been slower to embrace new technologies such as computers and the Internet in comparison

to younger people. Many seniors are still fearful of using the Internet, and a widespread belief exists that information and communication technologies (ICT) are only for the young. This attitude is slowly changing as more baby boomers are approaching the retirement age.

AIMS OF THE CHAPTER

This chapter will discuss the use of information technology and the Internet by older adults, to assist them in making more informed decisions about future tourist destinations, and provide cheaper travel bookings. Some of the important research questions that will be asked in this chapter are:

1. Are older adults still reliant on travel agents to help make travel decisions for them?
2. Do older adults feel confident that they can use computers and the Internet to gather travel information?
3. In the future, will older adults use the Internet to plan and make their own travel bookings?

THE TRADITIONAL ROLE OF TRAVEL AGENTS

In the past, travel agents have served as both information providers and planning/booking providers for a large number of travellers, particularly when planning international overseas travel (Oppermann, 1997). In the 1990s travel agencies emerged as one of the top three information sources used by tourists for overseas travel, as well as the means to arrange travel to destinations that people had not previously visited (Duke & Persia, 1993; Mihalik, Uysal, & Pan, 1995).

The first serious attempts at research focussing on the role of the travel agent began in the 1980s. These studies set out to discover how consum-

ers perceived the role of the travel agent, and the reasons why people chose a specific agency to make travel bookings. Bitner and Booms (1982) were quick to predict that the role of the travel agent needed to change in the future—from the traditional role of a clerk, to a salesperson, and ultimately to a travel councillor. They suggested that if travel agents were to survive in the future, they needed to adopt the following radical changes to the way they do business:

- To use more aggressive marketing techniques to segment the market and to better communicate with their clients
- To have a better command of product line and profitability analysis
- To expand their use of highly sophisticated information systems and equipment
- To gain a thorough knowledge of travel destinations and requirements for each of the market segments
- To develop an understanding of how to interact and to successfully negotiate with suppliers

Sheldon (1986) examined the role of the travel agent from an economic perspective. The author affirmed that the main function of a travel agent was to reduce the time and money spent on information and transaction costs for consumers, as well as providing promotional expenditure for suppliers. Sheldon found that basic package tours provided a bigger discount to the consumer (15%) than all-inclusive tours (-3%) in his study.

Kendall and Booms (1989) investigated the way that consumers chose, used, and reacted to communications from retail travel agencies. They administered a questionnaire to 660 respondents in the Seattle region using a random digit dialling technique, as well as conducting several focus group workshops to discuss issues that were associated with people's views about travel agencies. The authors found that word of mouth communication was heavily relied upon,

and as a result many travel agencies developed many loyal clients. The researchers found that consumers will sometimes call a travel agency that is listed in an advertisement to compare basic information and prices, but will always go back to their regular agency for the actual bookings and payments.

Kendall and Booms (1989) concluded that if travel agents were to survive, they needed to develop greater knowledge about the specific needs and expectations of their clients. This included information about the types of restaurants they preferred; local attractions or side trips they wanted to go on; leisure activities that they liked to participate in; and the destinations and types of hotels, resorts, and transportation they preferred. Consumers rated the importance of gaining knowledge from all types of information sources higher than their own physical comfort when visiting an agency. In regard to their physical needs, some clients were particularly attracted by the specific location of the retail travel agency operation and the pleasantness of the office décor, while others preferred to use the telephone when dealing with the agency. Kendall and Booms (1989) concluded that travel agents needed to develop more sophisticated marketing techniques and to have a thorough understanding of consumer needs so as they could effectively compete in the travel marketplace.

Richards (1995) was interested in discovering whether travel agents were able to provide customers with travel information by helping them to bridge the information gap. This was because many consumers were becoming more skilled in accessing specialised product knowledge through their own sources, and as a result were increasingly becoming more advanced in their means of information retrieval than travel agents themselves. With this in mind, Oppermann (1997) focused his research on resident's perceptions of travel agency service attributes and compared them to travel agents beliefs about what customers found to be important. He collected responses from 266

travel agencies and 400 New Zealand residents, and found that there was a wide gap between resident's perceptions and the travel agent's actual beliefs. He argued that travel agents needed to be more aware of their client needs in order to remain competitive, and thereby to ensure long-term viability. Oppermann (1997) concluded that travel agents needed to lift their current performance because they were being placed under increasing pressure from other competitors in the travel industry. For example, the increased availability of tourist information on the Internet combined with direct booking and payment facilities were now seen as detrimental to travel agencies.

Oppermann cited several authors who also had forecast the demise of travel agencies because of the increasing competition from the Internet. Lewis, Semeijn, and Talalayevsky (1998) for example, expressed concern about the future of travel agents, given the increased trend toward information technology. The researchers noted that there had been a significant reduction in agency commissions paid by airlines to travel agencies, due to the increasing use of the Internet by consumers that had enabled them to obtain current travel information and to make direct airline reservations more easily. Because of these changing customer demands and travel patterns of senior customers, this has resulted in increased expectations in relation to value and convenience, as well as the emergence of increasingly knowledgeable consumers who were quickly becoming more proficient users of information technology.

As noted previously, the traditional travel industry structure consisted of a huge network of travel agencies that had a complete monopoly on information, prices and bookings. However, this is now changing and increasingly being challenged by travel providers who have direct access to customers through Web sites provided through the Internet. This has particularly become evident in the airline industry where carriers such as Virgin Airlines in Australia and Southwest Airlines in the U.S. sell most of their cheaper tickets on the

Internet without the use of travel agents. Even the established airlines such as American and United are now using direct channels such as line services, the Internet, and toll-free telephone numbers to reach their customers. Eliminating the human aspect has minimised costs for the airlines and as a result they can now offer discount fares that are exclusively available to online users as well as promoting the use of electronic ticketing (Lewis et al., 1998).

However, although they are increasingly becoming under threat from new technological advances, travel agents are still performing many important services for their travel consumers. Some still act as information brokers by passing on information from suppliers of travel products to consumers. They process transactions of printing tickets or forwarding money and often act as advisers to travellers. Aspects such as trust and social contact are still important to some consumers particularly when planning leisure travel, as well as face-to-face communication with an agent at a physical retail location is still seen as important for many older travellers. In the future, the highly competitive nature of the travel industry and the declining commissions paid by airlines may lead to the widespread consolidation of some smaller travel agencies. The success of travel agents will depend entirely on their ability to, "... capture the market's loyalty, ensure access to travel information while providing value-added services, and develop winning product strategies supported by information technology" (Lewis et al., 1998, p. 25).

In Scotland, one travel agency, Stewart Travel Centre, has responded to Internet travel companies cutting into their business by refocusing their strategic direction (Edry & Sennott, 2004). Stewart had noticed that there was a large number of cruise ships launched in the 1990s and decided to concentrate on advertising cruise packages. By 1999, he had created Scotland's Cruise Centre which became the largest in the country with nearly half of his 5,000 annual customers book-

ing cruises. Stewart also has moved into other profitable niche areas such as gay and senior travel, adventure vacations, and even pet travel. In the future he felt that travel agents needed to embrace the Internet more, and help customers to sort through the information overload on the Web. Although the Internet may be cheaper and easier for simple trips, travel agents are still needed to sort out difficult itineraries and complex long-haul travel. Their skills and experience will still be needed to sort out such problems as arranging connecting flights, and to inform travellers about the plethora of rules and regulations that apply to travel within different overseas countries. Many older clients in particular like to spend time talking over their travel plans in person, therefore they prefer to book through a travel agent rather than through the Internet (Edry & Sennott, 2004).

THE USE OF COMPUTERS AND THE INTERNET BY OLDER PEOPLE

In the later part of the 20th century, a technological revolution began to occur with the development and mass production of the personal computer (PC), video games, cable TV, and mobile telephones. In addition, the Internet soon became available and started to form a link between the multiple forms of information and communication technologies (ICT).

In the 21st century, increasingly larger numbers of older people are learning to use a computer and the Internet. For example, only about 30% of Americans aged 55 and over owned a computer in 1996. By 2001 these figures had increased to 37.1% (Adler, 2002). However, the majority of older people aged 65 years and older still do not have any Internet access. In the United Kingdom, although there has been a huge increase in the use of the Internet to 62% of the British population, the usage rate dropped to 33% for the 55 to 64 year age group, and to just 6% for those over 75

years of age (National Statistics Survey, 2003). This has been attributed to the lack of adequate training, unfamiliarity with computer technology, or uncertainty about how the Internet can be used as a useful resource for them. Others are disadvantaged because of their low income, poorer education and/or lower social class status (Castells, 1998). As a result, Internet usage is mainly concentrated in the younger end of the over 50 age group. However, baby boomers who are presently aged between 42 and 60 years of age will rapidly increase the percentage of computer users as they become older. This is because many baby boomers are well educated and wealthy and because of this, have favourable attitudes toward the use of computers (Kawamoto, 2003).

In Australia, the Australian Bureau of Statistics (2002) found that around one in five older people used a computer in 2002 which is slightly lower than the American figures (ABS, 2002). That is, only 21% of older people aged 65 years and older used a computer compared to 89% of persons aged 18 to 24 years (see Figure 1).

Older people who use computers were more likely to use them at home for personal and private purposes (92%). Other uses were for educational purposes (19%), work or business (16%) and voluntary or community work (13%). Only 13% of older people aged 65 years and older used the Internet, with 4% using it to pay their bills such as their car registration or local government rate payments. Over a third of older people (36%) stated that they had no need to order goods and services via the Internet, or had not bothered to try.

A recent study in the United States by the Kaiser Family Foundation (2004) specifically looked at the use of the Internet for informing decisions about health and health care options. The foundation found that less than a third (31%) of Americans aged 65 years and older had used the Internet. However, they noted that 70% of the next generation of seniors who are presently aged 50 to 64 year age group were regular users of the Internet. These differences in usage figures

Changing Technological Trends in the Travel Behaviour of Older Tourists

Figure 1. Computer usage across different age groups between 1998-2002 (Source: Household Use of Information Technology, Australia [8146.0])

Note: (a) Data for 2001 not available for persons aged 65 years and over

were quite striking with only 21% of older adults going online to access health resources compared to 53% of the 50 to 64 year olds. The foundation concluded that there was a “digital divide” between the two age groups and this placed older people who were most in need with limited access to information on which to base important health care decisions.

A report titled “Older Americans and the Internet” reinforced the findings of the Kaiser Foundation. They stated that despite the significant gains among seniors, “... most Americans aged 65 and older live lives far removed from the Internet, know few people who use e-mail or surf the Web, and cannot imagine why they would spend money and time learning how to use the computer” (AScribe Health News Services, 2004, p. 2). However this is quickly changing as a growing group of younger baby boomers in the 50 to 60 year age group have become significantly more attached to the Internet. Lee Rainie, the author of this report, concluded, “Internet users are gaining momentum. Internet users in their 50’s

who work, shop, and keep in touch with friends and family online will age into, and transform the wired senior population” (AScribe Health News Services, 2004, p. 2).

Several studies have investigated the benefits of computer usage for older adults. A study by White, McConnell, Clipp, and Bynum (1999) at Duke University concluded that teaching older adults to use computers to access the Internet and e-mail has resulted in a trend toward reduced loneliness. White et al. (1999) found that computers had a beneficial effect on older people’s psychosocial wellbeing as well as expanding their social support network. White and his colleagues also noted that involvement in a network of online support and chat groups, helped older people to feel connected to society, and was a strong predictor of lower levels of perceived life stress. The Kaiser Foundation (2004) reinforced this, with their study findings that 34% of seniors considered e-mail and the Internet as an important part of their lives that they did not want to do without. Furthermore, over half (56%) of seniors who used

e-mail stated that it made it a lot easier for them to stay in touch with family and friends.

The importance of social support networks has been emphasised in other studies of older adults. Wright (2000) found that older adults were able to meet a diverse group of individuals not only from the same cohort group but also to make intergenerational contacts. Wright concluded that these online support groups helped older adults to feel more connected to society, as sharing one's life with others helps to validate their experiences as human beings. This is especially true for individuals who spend a great deal of time on the Internet, and generally results in relatively strong relationships beginning to form. For a number of people, their relationships with Internet friends were regarded as similar to a surrogate family, even though they had met online and were complete strangers beforehand. Furthermore, Antonucci (1990) and Wright (2000) noted that greater involvement with Internet support networks was a better predictive of lower perceived life stress than age or the number of hours per week communicating on the Internet.

Morrell, Mayhorn, and Bennett (2000) conducted a study to document the use of the World Wide Web among a sample of 381 (151 men and 230 women) in different age groups in South Eastern Michigan. The breakdown in age groups were 108 middle-aged (aged 40-59), 181 were young-old adults (aged 60-74), and 92 were old-older adults (aged 75-92). Two versions of a World Wide Web questionnaire were mailed to respondents, one directed at current users of the Web while the other directed at nonusers. The researchers found that only nine of the 92 old-older adults indicated that they were current Web users. Users were found to be younger, better educated, more likely to own a computer, have a higher household income, and lived with someone who was a nonuser. The authors concluded that age was a good predictor of Web use, and the reason that the old-older age group did not use the Web was because of a lack of computer access and knowledge.

Sourbati (2002) conducted focus group and individual interviews with 18 older tenants and six care staff in sheltered accommodation schemes in North London. This accommodation service employed care staff on a 24-hour basis and provided a communal Internet facility and free Internet sessions. Sourbati (2002) wanted to ascertain what benefits were provided by Internet access for older people living in sheltered accommodation. Firstly, she found that encouragement that was provided by family, social networks, and care staff generated a lot of interest about using the Internet among older people. Several saw it as a way of providing opportunities to engage in constructive leisure activities and hobbies, find companionship, communicate with others, and keep in contact with modern society.

One retired tenant stated "... I would love to be able to use the Internet. Because that's tomorrow, I mean if I had a few bob and I wanted to buy something I'd buy the Internet ... I'd use it for entertainment, I could tap into information, companionship" (Sourbati, 2002, p. 2).

Secondly, she found that there were barriers and obstacles to their use of the Internet. These included physical disabilities such as arthritis, dexterity problems, or declining vision had caused problems. Lack of technical support and assistance by community support officers who also lacked basic Internet skills were issues that also needed to be dealt with. Such computer devices as the mouse could cause difficulties for older adults when performing such skills such as dragging, clicking, or fine positioning. "The only thing I find hard now which I have only ever used once is what do you call it ... the mouse, you know, it kept going here, there and everywhere" (Sourbati, 2002, p. 2). Older adults also may become confused and frustrated by the unfriendliness of interface designs such as small font sizes, using pull-up or drop-down menus, or having a poor colour contrast background (Lee, Godbey, & Sawyer, 2003). Although these barriers exist, several organisations such as the University of

the Third Age, ElderHostel, and SeniorNet are helping older adults to gain computer knowledge through a wide range of educational programs and training.

Elderhostel (www.elderhostel.org)

In 1999, Elderhostel was one of the Internet winners at the annual CIO Web Business Magazine awards. Elderhostel began with a very basic site in 1995 however in 1997, the president of Elderhostel, Bill Berkeley, decided to expand of this site as one of his major objectives. Among the changes that occurred, the customer mailing list was expanded by 25% and online registrations were encouraged. This saved the organisation \$87,000 as Elderhostel promoted an appeal to save the environment resulted in a growing number of clients who no longer received paper catalogues. Instead, regular customers received e-mail notification when a new catalogue went online. The online catalogue was improved by including details about accommodations and information of special interest to those with physical limitations. The site allows customers to register, check their status, cancel or transfer courses, go on a mailing list, change their information, send e-mails, and make donations. In fact, online donations have outpaced mail contributions, and the average gift has been 30% higher than donations that are made through the mail. The site also supported meaningful surveys and experimental programs. Future plans include peer program reviews and a discussion forum. Elderhostel has attributed their success to design that is tailored to suit over 55-year olds, such as readable print, minimal graphics and allowance for small screens (www.cio.com/archive/Web-business/070199_interwinners.html).

SeniorNet as an Educational Provider (www.seniornet.org)

SeniorNet was established to provide education for older adults so as to enable them to gain greater

access to computer technology (Grotsky & Gilbert, 1998). SeniorNet began in 1986 as a research study that was aimed at encouraging seniors to use a computer. The study found that under the right conditions, older adults adapted well to using digital technology. Over time, SeniorNet soon established an infrastructure of learning centres specifically designed to cater for older adults which has now grown into a national network of 128 learning centres covering 35 states in the United States. Adults who are 50 years and older can enrol in an inexpensive eight week class ranging from an introduction to computers, to creating your own Web page. These classes are peer taught by more than 1800 older adult volunteers who have previously taught more than 120,000 older adults to use computers and the Internet.

The mission of SeniorNet is centred on inclusion and independence, and classes are places where comfort and community are stressed, and older students are encouraged to ask questions and work at their own pace. By going online, older adults can also locate new friends and gain support in difficult times. For example, SeniorNet has established a grief support discussion group where people can find comfort and support when necessary. Other intergenerational projects such as "Living Archives" were launched in 1993 and this has enabled school students to electronically connect and interact with seniors, and at the same time to encourage participation by older adults in this form of electronic classroom. The project focuses on such specific topics as World War II, the 1950s, the civil rights movement, space travel, and women's liberation. This has enabled a high school student in Alabama for example, to communicate with a Holocaust survivor in Arizona, or a senior citizen who marched with Dr Martin Luther King Jr. to share that experience with students across the country (Grotsky & Gilbert, 1998).

Adler (2002) stated that in the future, the widespread availability of broadband networks will play a major role in supporting and enhancing

the lives of older adults. High-speed broadband networks offer several important advantages over slower narrowband networks: first, they make it possible to add high-quality two-way video to today's voice and text communications. Second, they provide instant access to rich multimedia content. Third, broadband's "always on" feature makes communications more convenient and supports a broad range of continuous, unobtrusive monitoring services. Finally, once broadband networks, both wired and wireless, become ubiquitous, users will be able to access any content from anywhere at any time.

While broadband applications will be of value to many segments of society, some applications will be of special importance to seniors. Among the key benefits that ubiquitous broadband networks offer to older adults are:

- **Enhancing communications with family and friends:** High-speed, always-on networks will dramatically enhance the ways in which people communicate and share their lives on an on-going basis. High quality video will be added to today's voice and text communications providing opportunities for richer interactions.
- **Expanding opportunities for lifelong learning:** Current experiments with "e-learning" have demonstrated the potential of online education for older adults, particularly for those with limited mobility. Online "classrooms without walls" will bring engaging educational experiences to seniors at home, and will help prolong the careers of older workers by providing instant access to continued training in the workplace.
- **Improving the delivery of health care services:** Broadband technology may have the greatest impact on the lives of seniors in the area of health. As people get older, the cost of the medical services they use also increases. One promising approach to improving health care delivery is a greater

use of "tele-medicine" services. Broadband networks will make it possible to deliver high quality medical services to older adults, including remote diagnoses and continuous health monitoring in ways that are convenient for both patients and providers.

- **Supporting independent living:** One of the most innovative uses of broadband networks will be to help people remain independent as they age and become more frail. Research is currently underway to develop an "aware home" that will unobtrusively track the behaviour of residents, automatically provide needed services, and call for help when needed.
- **Creating new options for entertainment:** As broadband access grows, so will the range of entertainment options available to everyone, including older adults. Greater bandwidth will expand the opportunities to provide content designed for specific audiences and give individuals the ability to customise the programming available to them.

For these benefits to be realised, a number of barriers will have to be overcome. These include ensuring that new services are easy for older adults to learn and use, guaranteeing that online applications are private and secure, and creating a legal and regulatory environment favourable to the rapid deployment of broadband networks (Adler, 2002).

Adler (2002) presents the following future scenario of Madge Gunderson, 88 years old, and the year is 2012:

Madge is able to keep in close contact with her family thanks to a constant stream of communication back and forth. As she sits down to breakfast she picks up a wireless tablet about the size of a pad of paper and scans a list of half a dozen messages that have arrived overnight. She sees that a video e-mail message has arrived from her 21-year old grandson who is teaching

English in Japan. She could play the message on her handheld tablet, but she decides to watch it on a larger flat screen that hangs on the wall of in her kitchen. The screen is in fact a normal digital television set containing some additional circuitry that allows it to connect to and interact with other systems through a wireless home network. Using her tablet as a remote control, Madge turns on the wall screen and calls up the message. Madge is amused to see that the grandson wants to introduce one of his students named Toshio who wants to practice his English skills. His English is less than perfect, but she is able to follow his description of a kite-flying festival he had participated in. The message then cuts to a few seconds of video of brilliantly coloured kites flying in a clear blue sky. Madge likes the image of the kites so much that she replays this segment. She freezes the video of the kites and sends the image to an electronic picture frame that sits on the kitchen counter, replacing another picture that had been in the frame for the last few months. At the end of the message, Toshio asks Madge if she would be kind enough to send him a message back. She considers using a digital video camera in the room to create a video response, but decides that she doesn't look good enough at this hour of the day to be seen, even in an online message. So she records a short audio message politely thanking Toshio for his message and telling him how she enjoyed seeing the kites. When she is finished, she sends the message to her grandson for delivery to his student. As she scans the rest of her message list on her tablet, she sees one from her physical therapist who explains that he has some new exercises that he'd like Madge to try and asks her to schedule an appointment. She links to a calendar showing the therapist's schedule and sees that he has an open slot at the end of the morning. She taps on that time on the tablet's touch sensitive screen, and her name is automatically entered (the system recognises that it is Madge who is calling and knows that she is one on the therapist's patients). After going through her messages, Madge shifts to a display

of the front page of the *Washington Post* which remains a daily habit, even though she rarely reads the printed version of the paper. She scans the headlines and reads a few stories, then calls up a calendar of her activities for the day. She sees that she is scheduled to meet a friend for afternoon tea then tutor a group of second graders in a local after-school program which she does every week ... Since Madge no longer drives a car, her calendar automatically reserves a ride to her appointments through a local para-taxi ... As Madge drives to town she gets a call from her granddaughter in Boston who is eager to show her a drawing that she made that morning at school. As Madge only has her handheld phone with a small video display, she tells her granddaughter that she will look at the picture when she gets home where she will be able to see it on the big screen. As Madge arrives at the school she decides to turn off her pocket phone. All of this technology is helpful, she thinks, but sometimes it's a good idea not to be too connected! (pp. 8-9)

THE USE OF INTERNET TECHNOLOGY FOR TRAVEL BY OLDER ADULTS

The Internet is a technological innovation which is having a profound influence on all aspects of people's lives. The Internet is gaining rapidly on other forms of media such as television and newspapers in terms of time spent on these types of media (Heichler, 1997). The travel industry in particular has consistently been identified as one of the main industries that is most likely to be affected by the growth of the Internet. Machlis (1997) stated that travel was the single largest revenue generator among consumers on the Internet, totalling US\$800 million in 1997.

In 2005 the Travel and Tourism Industry (TIA) estimated that 56% of the 216.1 million adults in the U.S. currently use the Internet. This translates to over 120 million adults of which 84% state that

they are travellers, meaning that they have taken at least one trip of 50 miles or more away from their home in the past year. This translates to a market of 101.3 million online travellers. More frequent travellers who state that they have undertaken five or more trips annually, have an even greater likelihood of using the Internet with 75% indicating that they use it (Green & Cook, 2005).

Several studies have looked at the increased growth in Internet purchases for travel by older people. Age has been found to be an important demographic variable in terms of the likelihood of older adults using the Internet for a browsing search for travel information, purchasing, and perceptions about security. A study by GTRC (1998) found that mature individuals were less likely to use search engines to reach an Internet site than by traditional means such as through reading magazines and newspapers. This study also found a significant relationship between a traveller's age and the likelihood of making purchases over the Internet. This is because as people age, they appear to be more suspicious about the quality of products that are available, with almost 50% of potential travellers over 50 years of age citing the quality of the goods as a problem when making purchases over the Internet. Mature individuals also were less likely to admit that they would use their credit card over the Internet (GTRC, 1998).

Weber and Roehl (1999) provided a profile of consumers who purchased travel via the Internet. These researchers at Georgia Tech conducted a WWW survey in 1997 to track the growth and changes of the Web user base. The survey was conducted online with participants completing questionnaires that were posted on the Web. Their study found that age and education were significant variables, and that people who were younger (25 years or younger), or older (over 55 years of age) were less likely to purchase travel arrangements online than people in other age groups. Furthermore, respondents with four-year college degrees or postgraduate qualifications were more likely

to purchase travel online than people with lower educational levels. Travel purchasers also were more likely to have previously been online for a period of four or more years. The most frequently cited reasons for *not* purchasing products online were credit card fraud, no assessment of product quality, privacy issues, and the preference to purchase locally. The researchers concluded that the major challenges facing online travel retailers were to address the issues of credit card security and data access. They concluded that consumers must feel confident that the information being provided was safe and could be used ethically and appropriately (Weber & Roehl, 1999).

In a further study by Bonn, Furr and Hausman (2000), they interviewed a sample of almost 14,000 travellers during a recent trip to Tampa, Florida. The researchers divided the sample population into three representative age groups: Generation X'ers, Baby Boomers, and Mature Travellers. A small number of travellers from England, Canada, Germany, and Brazil (11.2%) completed the questionnaire, while 88.8 % of the total sample was residents of the United States. The authors found that the U.S. respondents, particularly Generation X'ers and Baby Boomers consistently stated that they were the most likely users of Internet services for travel purposes. Mature travellers were less likely to make use of the Internet to book a trip as the trend line in their study indicated nearly flat growth until 1999. However, future growth in Internet usage among mature travellers is likely to increase as a result of the continuing maturation of the baby boomer population, rather than any change in behaviour patterns of present-day mature travellers.

These latest figures are encouraging, with seniors who now use the Internet increasing by 47% between 2000 and 2004. In February 2004, a survey found that 22% of Americans aged 65 years or older had access to the Internet and this has increased from 15% in 2000. This translates to about 8 million Americans who are aged 65 years or older that presently use the Internet.

By contrast, 58% of Americans aged 50 to 64 years, 75% of 30 to 49-year-olds, and 77% 18 to 29-year-olds currently go online. In particular, 41% of the older age group 65 years and older have made travel reservations online at the end of 2003. This is a 16% increase since 2000 and showed a growth rate of 64% (AScribe Health News and Services, 2004).

Why is the Internet Becoming More Popular for Travel Bookings by Older Adults?

Several reasons have been suggested:

- Allows customers to shop around for the lowest fares for trips and accommodations
- Provides a more personalised service with large amounts of useful information available
- Helps consumers to better understand the products by using multimedia, such as fantasy vacations and 360 degree virtual tours
- Saving money in a paperless environment
- Increases the convenience of obtaining information at home, and supporting a customer focussed strategy
- The Web dramatically decreases the time it takes to make travel reservations and plans. (Turban, 2004)

Examples of Successful Travel Web Sites for Use by Older People

Travelocity (<http://www.travelocity.com>)

Regarded as the leader in the category of mega-travel sites, this is the third largest Web site on the Internet. This site provides consumers with a myriad of services, ranging from car rentals, train bookings, hotel reservations, and information on every conceivable destination and complete vacation packages. It maintains a user friendly

interface over which transactions are processed. The site is simple to use, and a consumer can literally book an airline ticket with 3 clicks. It also continues to add value to the site by introducing new personalised services to customers.

Wal-Mart (<http://www.walmart.com>)

Wal-Mart has moved into the booming and profitable world of Internet travel sites. In 2000 it launched its new site which offers airline tickets, car rentals, and hotel reservations to customers. The site is extremely simplistic and provides nothing other than the basics and is easy to use for older travellers.

United Airlines
(<http://www.shopzilla.com>)

In July 1999, United Airlines and Buy.com announced a strategic alliance between the two which capitalised on the booming online travel industry. Specifically, it was a strategic business move to get into the mega-travel site sector which had become very profitable. This site offers the typical array of hotel, car, and planning services. This idea was later modified to target college students CollegeTravelNetwork.com. In January 2000, United announced a partnership with Delta Airlines, Northwest Airlines, and Continental Airlines to develop a site devoted to airline travel that will offer fares that can be only found on the Internet.

REI Adventure Travel
(<http://www.rei.com>)

REI.com is one of the growing sites that specialises in adventure travel. REI has experienced a 22% increase in sales since 1998, and now offers around 4,000 trips each year. Adventure Travel has bought out Adventure Travel and this has allowed them to provide a dynamic Web wizard search engine that enables customers to plan an adventure trip

by searching its database based on parameters of destination and activity, and then narrows it down by price, and so on. REI also is the sole provider of adventure gear and other paraphernalia.

Suggestions for successful travel sites for older travellers:

- Focus on customer service.
- Keep the site as simple as possible and use larger print to make it easier to read for older people.
- Provide as many services as possible to create a one-stop shopping site for travel without sacrificing simplicity.
- Utilise java script and intelligent agents to further personalise the site for older visitors.
- Attempt to form strategic alliances with other companies with complimentary core competencies.
- Look to move into regions that are untapped and have a huge market potential such as Asia.

CONCLUSION

In 1998, people who were over 50 years of age and who were intent on travelling were more likely to use the traditional advertising media such as through travel agents, magazines, and/or newspapers. Travel agents in particular have, and still are providing an important service for older travellers especially if they are travelling overseas. Many older adults still prefer word of mouth communications with their travel agent, many of which have built up a loyal clientele of older people over the years that still rely on them for travel information, advice and personalised booking services. Several academics have challenged the traditional role of the travel agent stating that they need to change their mode of operations from a salesperson and clerical worker, to become a travel councillor if they want to remain competi-

tive with online booking and Internet services, especially in the airline and hospitality industries. That is, a good travel agent needs to develop more sophisticated marketing techniques and detailed information about travel destinations, as well as an understanding the specific travel needs of different segments of the older adult market if they wish to stay in business.

Many older people still lack knowledge about, and access to computers while others do not feel confident about using the Internet. However, there are many benefits of using the Internet such as developing an increased social support network, and improved contacts with friends, relatives, and family members through e-mail services. Furthermore, surfing the Web can increase a person's knowledge and skills and help to re-establish and maintain an older adult's sense of empowerment and confidence. Finally, cognitive improvements through the learning of new technologies also have been noted, and studies have shown that older adults have substantially increased their ability to feel mentally alert, challenged, and useful (Lee et al, 2003).

Recently, through such organisations as Senior Net and the University of the Third Age, older people are learning how to use computers in relaxed and comfortable settings close to their homes. This has encouraged the use of intergenerational projects with schoolchildren, who can now instantaneously interact with seniors through the use of electronic classrooms. Adler (2002) also stated that the widespread availability of broadband networks will play a major role in supporting and enhancing the lives of older adults. These benefits include enhancing communications with family and friends, expanding opportunities for lifelong learning, improving the delivery of health care services, supporting independent living, and creating new options for entertainment. For these benefits to be realised, a number of barriers will have to be overcome. These include ensuring that new services are easy for older adults to learn and use, guaranteeing that online applications

Changing Technological Trends in the Travel Behaviour of Older Tourists

are private and secure, and creating a legal and regulatory environment favourable to the rapid deployment of broadband networks.

Although younger consumers are more likely to make online bookings for travel purposes, older people are becoming increasingly more confident in the use of this form of information technology. Perceived problems still exist with such aspects as credit card security, quality control and privacy issues. However, the numbers of people aged 65 years and older in the United States who are using the Internet has increased from 15% in 2000, to 22% in 2004, an increase of eight million Americans. This will further increase with the growth in the number of baby boomers who are generally proficient in their use of the Internet, and prefer to take advantage of its services in relation to online purchases. This has encouraged the use of discount fares for international travel however it places greater pressure on the future role of the travel agent, as it may eventually eliminate them as a broker for travel transactions.

Chapter 8.12

New ICTs for Conflict Prevention and Management

Ángela-Jo Medina
ConcienciAcción.org, USA

ABSTRACT

This chapter introduces the impact of new information and communication technologies (nICTs), specifically the Internet, on national and international conflict prevention and management. This analysis provides case studies of the use and examples of the prospective use of nICTs to counteract conflict as it undermines social and economic structures and hinders regional development. This study reviews the specific application of nICT-related initiatives at the different phases of the conflict cycle: from addressing the root causes of conflict as a tool for prevention and management, through the reconciliation and reconstruction phase. The author intends this analysis to illustrate and contribute to the discussion of how the social and development-related application of nICTs can compliment existing conflict prevention and management reduction strategies.

INTRODUCTION

According to the United Nation's Development Program's Human Development Report the greater part of countries with limited human development, 22 of 32, have experienced violent conflict since 1990 (2005, pp. 149-179). Conflict undermines social and economic structures: public healthcare, education systems, employment, and so forth. Regional development is also one of its victims.

This chapter outlines the uses of new Information and Communication Technologies (nICTs) for the prevention and management of active and latent national and international conflicts. It will demonstrate the application and potential of nICTs to complement activities that are already being carried out in the field to address the root causes of conflict, its prevention and management, as well as the fomentation of reconstruction and reconciliation.

Some of the uses given within the structure of this analysis are the creation of a medium of coherent manifestation, the establishment of a basis for transparent governance, and the development of generic platforms of common interest. Case studies illustrate the actual and prospective use of nICTs in the different phases of the conflict cycle.

The term nICTs is used to designate the Internet individually and/or its conversion with other types of information communication technologies like community radios, television, mobile telephony, and so forth. In this case, however, for the most part, the Internet will be the focus. Nevertheless, later in the chapter, mobile telephony, another very important nICT, will be considered.

BACKGROUND

Differences of opinion are commonplace and conflict is natural; neither of them is necessarily negative. The crux of the issue is finding and applying methods to prevent and manage these conflicts in a peaceful manner.

Today's intra and inter state conflicts¹ are difficult to analyze, thus difficult to solve. Since the end of the Cold War, the nature of global conflicts has significantly changed². The ethno-political, structural, and social factors that cause and transform conflict constitute a complex, ever-changing web. The weakening and/or disintegration of state authority, the existence of third parties that benefit from strife and the many cases in which civilians are the target of violence are constants within this framework. As indicated by Timothy Shaw, "Prospects for regional development recede as conflicts both escalate and proliferate and 'off-budget' incomes and expenditures become priorities for regimes and leaders alike" (2003, p.7).

Society's evolution has expanded the variety of sources and scenarios of conflict and simultaneously increased the number of tools available to deal with them. New information and

communication technologies are among these. To date, non-military studies about the impact of nICTs on conflict situations have been few³. This possibility results from the Internet which evolved from ARPANET, a military command and control center dating back to the 1960s (Sequeira Bolaño, 2001).

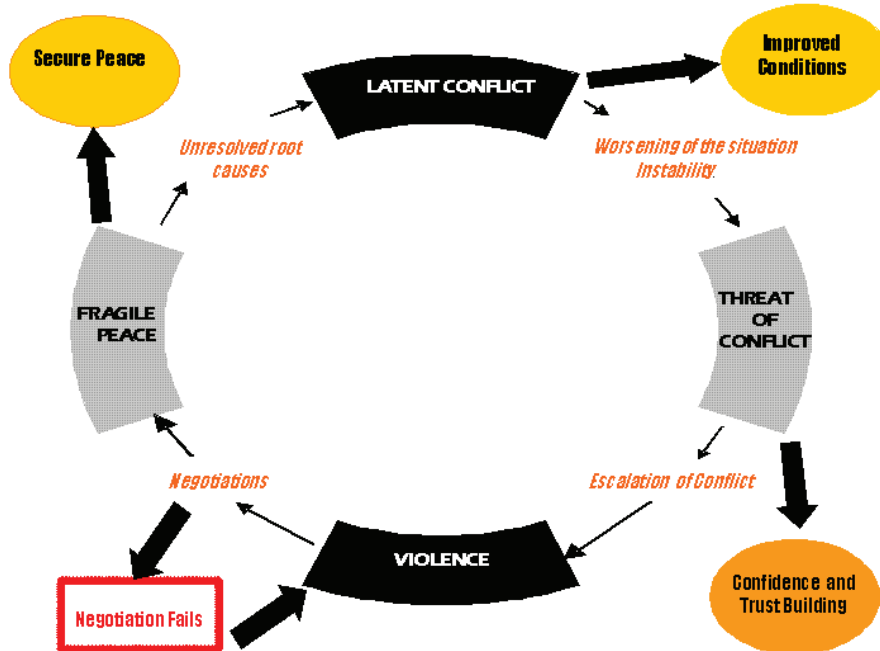

The public eye is quick to hone in on the dangers of the Internet: identity theft, digital crimes, child exploitation and pornography, as well as it being a potential virtual breeding ground for terrorists and insurgents, to name a few. Paradoxically, non-governmental organizations that address human rights, conflict transformation, governance, and development issues, however, have also been quick to adopt nICTs to support their work in the field (Naughton, 2001, pp. 147-168). Similarly, governments are increasingly sensitive to the possible importance of nICTs in official and grassroots interventions directed at preventing and managing ethno-political conflicts. Tony Rutkowsky, former senior Telecommunication Union Executive, has emphasized the potential of the Internet to compensate for many of the structural deficiencies within national and international governing bodies (1997). The Internet creates a common border-free information space where equality is inherent⁴.

ISSUES

For Carment and Schnabel (2003) conflict prevention includes, "institutional mechanisms that prevent tensions from escalating into violent conflict, to employ early warning mechanisms that allow the international community to monitor relations between and within states, and to facilitate capacity building within conflict-prone societies" (p. 1).

Conflict by nature is non-linear, yet in theory, the line between conflict prevention and conflict management is very distinct. In practice, however, and faithful to the fluctuating nature of conflict

Figure 1. The conflict cycle

itself, this distinction becomes blurred. Figure 1 depicts this reality through an illustration of the conflict cycle. The possibility of diffusing conflict is present at every stage, as is the possibility of escalation.

This difference is even more distorted in the case of the relationship between nICTs and conflict. The problems, actors, and interests change over time because of society’s changing dynamics, economies and policies (Vayrynen, 1991, p. 1-25). nICTs to be used in to assist both in the prevention of conflict as well as post-conflict reconstruction and reconciliation. The room for action for nICTs spans every nuance that affects the conflict cycle and its potential outcome. As Jan Berting notes, information systems penetrate modern societies in all spheres of life (Berting, 1990, pp. 33-36). The line between social structures and technological systems has become increasingly difficult to define.

Conflict Prevention

According to the European Commission, conflict prevention spans from initiatives directed at reacting rapidly to emerging conflicts to those aimed at projecting long-term stability. International cooperation and development initiatives, institution building, and rapid-reaction mechanisms fall under this category. Identifying and addressing the presence of factors that are a breeding ground for conflict—undemocratic political systems, ethnic, cultural and religious tensions, the presence of refugees, a weak or non-existent welfare state, and unequal distribution of resources—in a timely manner is essential.

nICTs are useful in responding to some of these structural—governmental, social, and economic—deficiencies because they serve as a bridge between developed and developing countries. They provide alternative solutions to existing

realities, act as a catalyst for social and economic change, and defy geographical limitations. The strategic use of nICTs can encourage existing relationships, foster subtle changes in existing paradigms and mobilize society to reinforce the social perspective towards a community goal or ideal. This approach enables opportunities for early alerts, and pre-emptive measures to deal with the potential sources of conflict.

Difficult socioeconomic conditions are among the root causes of conflict. UN Secretary General Kofi Annan has recognized that “peace and development remain inextricably linked—one feeding on the other, enabling the other and securing the other. The renunciation of violence as a means of gaining and holding power is only the beginning. Then must follow a renewed commitment to national development founded on sober, sound, and uncorrupted economic policies” (United Nations, 1998). The Secretary General says the proposal in his report on Africa requires new ways of thinking, of acting (1998, p. 3). The facts speak for themselves: 50% of the 45 poorest countries in the world have seen their social and economic foundations eroded by wars and other forms of violence (“Breaking the Conflict Trap,” 2003). Poverty itself does not generate conflict, but it does generate pressure for change in countries in which there is an unequal distribution of resources. Because of this, the Swedish Cooperation Agency has noted that when development is lacking, countries become more susceptible to conflict.

According to Nobel Prize winner, Amartya Sen, poverty is not limited to lack of income, but includes the lack of skills or capabilities needed to be more productive and obtain higher income (2000). Some of these are basic education, health services, food security, and so forth. nICTs are useful in the development process because they supplement existing development initiatives. They also open new routes to address inequities and existing sources of structural violence. Electronic

commerce (e-commerce) contributes to addressing these issues in many ways.

The Internet offers many possibilities for establishment of small and medium-sized businesses. The benefits it offers are immense, as it provides any business an avenue to enter into the global markets. Size and location have become issues of little relevance in finding markets that are receptive to the goods from any business (Heeks, 2002).

Ecosandals.com⁵, a cooperative based in the shantytown of Korogocho in Nairobi, Kenya, is a successful example of the use of e-commerce in poverty and violence-stricken areas. This international business is the product of the Wikyo Akala Project, which educates, trains, and provides employment for the inhabitants of Kogorocho. They do this through the production and sale of sandals made from recycled tires that are sold throughout the world from the project’s Web site.

PeopLink⁶, and Mercado Global⁷ are two nonprofit organizations that also seek to foment development and fair trade by helping artisans from remote areas around the world to sell their products via the Internet.

In these examples, e-commerce has dramatically reduced transaction costs, allowed artisans to reach larger numbers of customers, provided a means to build capacities in local communities and ensured the long-term sustainability of the projects. This approach has provided holistic solutions to development and poverty related dilemmas. Unfortunately, the digital divide related problems, such as infrastructure, access, and training (Bastos Tigre & O’Connor, 2002) as well as a lack of regulatory and legal frameworks have made banks and financial institutions reticent to assume a more active role in promoting e-commerce. Their participation, however, remains primordial in many countries to extend the reach and attractiveness of e-commerce and avoid fraud.

Another variable in the solution to the poverty problem is agriculture. It generates earnings for

governments by raising the per capita income, foments a more equal growth and, if necessary, provides reparations for the less-fortunate segments of the population particularly when dealing with issues relating to agricultural reform and access to natural resources (Addison, 2005).

Regardless of location, farmers need access to certain types of information to maximize productivity and comprehend and take advantage of market trends. The Food and Agriculture Organization (FAO) of the United Nations' Global Information and Early Warning System⁸ provides timely information on production, trade, stocks, food consumption, food aid requirements and the status thereof from each sub-region in the world. This enables governments, the international community, and other organizations to tailor their actions to existing situations and avoid potential crises.

Research has shown that wages increased by a worldwide average of 10% per year of schooling, and educated parents are more likely to have educated children. Education is an important key in breaking the inter-generational poverty cycle. Worldwide, there are one billion youth between the ages of 15-24, and 85% of them live in developing countries. Their unemployment and under-employment rates tend to be much higher than that of the average population. Young people with limited education and employment opportunities fall prey to groups involved in violent conflict that seek to increase their numbers. This is particularly disturbing since, according to UNESCO, over 27 million children and youth that are in the midst of, or recovering from, conflict lack access to formal schooling (Roberts, 2005). In this situation, e-learning can be found very useful in providing learning opportunities for young people because of its flexible delivery method and can be easily adapted to the demands of their day to day lives. In rural areas, lacking formal educational centers, ICT and nICTs have been proven successful in facilitating the educational process. Such is the

case of the African Virtual University⁹ (AVU) based in Nairobi, Kenya.

AVU has over 34 learning centers in 17 African countries. It educates and supports economic development through the network of African institutions that work with internationally recognized universities. Learning is done via online materials, CD-ROMs, DVDs, and realtime chat sessions. The exchange between student and instructor takes place, for the most part, by e-mail and online discussions forums.

The use of nICTs provides the combination of distance education with traditional learning methods and allows access to high quality teaching materials that support and/or substitute poorly qualified teachers. Furthermore, initiatives of this nature not only train future employees, but also create human capital that is prepared to contribute to and take a leadership role in the development process.

In these contexts, legitimate institutions, strong civil society, and good governance have been found to play a central role in conflict prevention. States in danger of, or affected by, conflict tend to suffer crisis of legitimacy. Then the state gradually adopts an oppressive and predatory attitude vis-à-vis society and is undermined by strife and its gradual inability to carry out its duties. Faced with "failed" statehood, governments cannot respond to the needs and demands of its citizens, and violence becomes almost inevitable. nICTs can be used to intervene in this dynamic and aid in the correction of these deficiencies.

Through e-government and e-governance initiatives, nICTs contribute to the relationship between government institutions and citizens. The Gyandoot Project—implemented in India, and winner of the Stockholm Challenge IT Award in Public Services and Democracy in 2000 (Stockholm, 2000)—for example, has established kiosks throughout the rural, poverty-stricken area of Madhya Pradesh. This has been done to facilitate access to information pertaining to agricultural

transactions, municipal affairs—such as the filing of complaints, registries and land titles—and governmental transparency¹⁰. The use of electronic media to complete public transactions has eliminated many of the economic, physical, and time constraints of traditional bureaucracy. Easy access to information and knowledge regarding political processes, services, and so forth, allows citizens to play a more active role in government, thus increasing government accountability, and promoting the open communication needed for state legitimacy. These are the mechanisms of democracy.

The manner in which the use of nICTs empowers citizens makes them a means for the poor, marginalized and disenfranchised to find their voice, organize grassroots movements, and demand governmental accountability. Such is the case of the ex-Yugoslavia in which local non-governmental organizations (NGOs) and student groups used the Internet and mailing lists to organize and overthrow Slobodan Milosevic (Cronnauer, 2004). Mailing lists of this nature often satisfy the psychological need for support that many individuals and groups who feel traditional media fails to provide. Through the movement's use of the Internet, they realized that they were not alone and that there were people throughout the country and world that shared their messages. These forms of large-scale virtual mobilizations often manage to gather traditional media attention, and influence public institutions through public opinion.

nICTs allow timely monitoring of conflict indicators and adoption of measures to address the root causes of conflicts. Human rights violations, for example, are not only indicators of the imminent threat of conflict and the possibility of violence, but also a root cause of conflict. Thereby, human rights violations lead to massive refugee movements, which, in turn, increase the socio-political tensions that ultimately result in the long-term threat of the eruption of violence.

The World Organization Against Torture (OMCT) is the largest coalition of NGOs fighting against all forms of malicious and demeaning treatment for the protection of human rights. It became fully active in February 1997, resulting from the need for more effective action and efficient means of transmitting information in cases of possible violations. The SOS Torture network has 250 NGOs at its disposal as sources of information and urgent intervention. Through these networks, urgent actions reach over 90,000 state and non-state institutions, associations, and pressure groups. Since the rapid transmission of information is essential, the OMCT counts on over 90,000 correspondents ready to intervene if required. This permits the network-based monitoring of information pertaining to existing and potential human rights violations. Simultaneously, the analysis of the information might be used to predict and prevent human rights violations that may aggravate already tense situations and result in further violence.

In "Information Technology and Human Rights," Metz (1996) emphasized the transnational nature of the relationship between human rights and the Internet by characterizing it as "having enormous consequences for the human rights movement as an aid to its efforts to collect, interpret, and disseminate information and to push for appropriate action in response to violations"¹¹ (p. 179). Here, digital technology plays a crucial role in developing issue networks that compel state and international actors to take action. In this way, digital networks remove national intermediary players that might otherwise hinder, censor, or conceal certain invaluable information. The Internet offers local occurrences and local groups the opportunity to gain the attention of the international transcendence that might have otherwise been denied. This often acts as a vital catalyst for action and essential to the spirit of their message. On Friday, March 9, 2001, Amnesty International¹² won the Revolution 2001 Award

for the best use of e-mail and the Internet for Stoptorture.org, (Amnesty International, 2001) which went live on Wednesday, October 18, 2000, to mark the launch of its global campaign against torture. The site received over 10,000 hits from people in 146 countries in the 48 hours following its publishing (Amnesty International, 2000).

Amnesty International has harnessed the power of the Internet to improve its traditional letter writing method of campaigning. Among these improvements one finds increased momentum in human rights emergencies. The (Amnesty International Urgent Action) network activates rapid action for those who are in imminent danger of grave human rights violations. Urgent Actions circulate by e-mail and fax to Amnesty International sections worldwide who then distribute them to members of the UA network asking them to send appeals through the fastest channels available. It has been found that e-mail through the UA network has facilitated networking at an international level, and each case sometimes generates between 3,000 and 5,000 appeals.

In any type of democracy, the Internet offers citizens and civil society an alternate source to obtain political legitimacy and at the same time strengthens the legitimacy of the system in which they operate. These opportunities are essential conduits for democracy and become vital when the plurality of opinions that circulate in a society can be channelled in a productive manner. However, their function and success are based on the normative commitment of the stakeholders towards the transformation of the existing system (Flichy, 2001).

Conflict Management

The independence of media from private and political interests is one of the important parameters among the European Commission's indicators for the prevention of conflict. This is clearly because they play an important role in the search

for freedom of speech, human development, and movements for peace. They are important tools for shaping public thought and perceptions. Media has the ability to polarize communities or unite them; consequently, nICTs harbour great potential in moments of crisis.

When used properly, the Internet is a tool that can offer a panoramic and simultaneous view of situations in conflict. The methodology used by the human rights organization, Equipo Nizkor¹³, facilitates this. The Vigía del Fuerte cases in Colombia demonstrates this perfectly (Equipo Nizkor, 2002).

As Diaz Dionis (2002) remarks on the FARC church incident that killed 90 people in which, official versions of the event omitted the action was intended to provoke the massive displacement of the population (p. 95). Twenty-four hours after the incident contact was re-established with clerics from the affected area through a religious group in Panama. They, in turn, transmitted information via the Internet every six hours. The official communiqués of the Archbishopship of Quibdo denouncing the incident were disseminated online in Spanish and English to over 18,000 human rights organizations, 5,000 activists and 40 list-serves, including a closed discussion list for jurists specialized in international tribunals. The information ultimately also reached 200 legal experts and the parliaments of 11 countries (Dionis, 2002, p. 96). The massive dissemination of information that Nizkor carried out, de-legitimized the official government version (Oficina en Colombia del Alto Comisionado de las Naciones Unidas para los Derechos Humanos, 2002) and forced the Colombian government to change from its position. Additionally, it enabled the application of the II Additional Protocol to the Geneva Conventions Relating to the Protection of Victims of Non-International Armed Conflicts ("Protocol Additional to the Geneva Conventions of 12 August 1949, and Relating to the Protection of Victims of Non-International

Armed Conflicts [Protocol II]”). Therefore, the documental treatment of information pertaining to human rights issues and the monitoring of the situation in a particular locality via the Internet can help manage an existing crisis.

Modern conflicts articulate themselves in the communicative realm. The “Internet, War, and Peace in Colombia,” project notes that “The narratives of war are strategies of the war itself, they are inscribed in its logic: lies and cover-ups are basic tactics to bring down the contenders” (Barón Porrás, Corredor & Mancera, 2002, pp. 6-7). The use of symbolic language, the environment, and the media produce the narrative of the war and create the discourse of public reality. During Colombia’s 40 years of strife, the war has not only taken place in rural and urban settings, it has been fought in the collective imagery of the population. Colombian media were critical at various levels of the conflict. It became yet another actor, responsible for the polarization of society and in many cases the escalation of conflict (Barón Porrás, et al., 2002).

In the past 10 years, along with the expansion of the use of nICTs around the country, “the citizen movement for peace,” organized by civil society, has emerged. This group uses new and old ICTs to reach its goals (Barón Porrás). Their use has had such a deep impact on the dynamics of the Colombian conflict that the belligerent parties—the government and the FARC—have favored nICTs to disseminate information, educate about the conflict, and involve civil society (Porrás, 2002). Web sites open the way for public discourse and allow the parties involved to create meaning for their actions and reality. The Internet is playing vital role in their legitimacy. It has opened direct channels of communication with the national and international public. The actors engage in the negotiation process through their participation in the narration of the Colombian people’s collective reality (Porrás, 2002). Contextualizing the conflict gives it a political meaning and supplies information that enables

actors to make informed decisions and join the peace process (Barón Porrás).

Similarly, electronic conferences allow users to share their points of view, publications, or commentaries so that other users can read them and respond. The first recorded electronic conference organized to seek a solution to a war took place in 1991 during the war in the former Yugoslavia. Sponsored by the Swedish Association for Peace and Arbitration and the Association for Progressive Communications, it contained 5,000 messages, ideas, opinions, calls for action, and information on disappearances. As the cyber-Balkan communication center with messages from Switzerland, United States, Croatia, the Netherlands, Australia, Bosnia-Herzegovina, Germany, Finland, and so forth, it was also used to coordinate the aid received (Walch, 1999).

nICTs permit the immediate dissemination of local information and provide informational and communicative infrastructure services to millions of users and organizations worldwide. These types of networks facilitate an exchange of information that is otherwise impossible through traditional media. In fact, traditional media strictly regulates the fixed roles of the content providers and audience. On the other hand, the roles adopted by participants in a virtual environment are more fluid and involve participants from any corner of the earth, in a variety of capacities. Online publications are a resource for journalists that attract a readership of millions, but refuse to conform to the constraints of mass media. These are the authentic voices of cyberspace.

The blog¹⁴ phenomenon which began circa 1994 is a recent, concrete example of this. Simply put, a blog is a journal that is updated periodically and is available on the Web. As Andrew Sullivan from Wired Magazine notes, “Blogs do two things that Web magazines like Slate and Salon simply cannot. First off, blogs are personal. Almost all of them are imbued with the temper of their writer. This personal touch is much more in tune with our current sensibility than were the

opinionated magazines and newsarticles of old” (2005). The impact of blogging is such that Reporters without Borders (2005) recently released a Handbook for Bloggers and Cyberdissidents, arguing that, “Bloggers are often the only real journalists in countries where the mainstream media is censored or under pressure” (Create your own blog, 2005).

nICTs form a decentralized system that can mobilize any amount of information in web-like fashion. This can be used to strengthen the articulation of networks and interest groups. Technology 4 Peace¹⁵ began its work in 1996 as a virtual based organization whose primary goal was to inform and recruit expatriate Greek and Turkish Cypriots to complement the need for structured, organized, and long lasting dialogue between the belligerent parties. As a focal point for information and peace-related activities, it fomented workshops, coordinated events, marches, and meetings between different bi-communal groups. In this context, the project designed and created a holistic infrastructure for individuals and groups interested in promoting peace.

Burmanet¹⁶ and the Free Burma Coalition¹⁷ have found nICTs to be the most important campaigning tool available. Thanks to the collaboration of international activists, they are able to coordinate activities beyond their national borders. Using the Internet, its members have created a virtual community that uses cyber diplomacy to pressure the State Law and Order Restoration Council peacefully. The Internet’s role was essential in getting legislation passed in the state of Massachusetts condemning companies that do business with or within Burma. This is particularly the case since Massachusetts does not have a large Burmese electorate. This illustrates how the Internet can be a peaceful alternative to the violent transformation of repressive regimes through the search for consensus and public debate, regardless of where it takes place.

Electoral violence biases and shapes the ethno-political factors that contribute to violent conflict.

In Sri Lanka, the Center for Monitoring Election Violence (CMEV) uses the Internet to hinder initiatives that intend to undermine the peaceful transformation of the conflict in Sri Lanka (Liyanaarachchi, 2003). It does this by releasing numerous updated reports daily on its Web site that publicly expose existing political violence and naming its perpetrators.

nICTs inform of events instantly as they occur. In May 19, 2002, Fiji suffered a *coup d’état* that brought on a political crisis. The Internet became an essential source of information during that crisis. Fijilive.com Web site was the first source to release news of the coup internationally (Baghwan Rolls, 2002). In fact, the BBC began its coverage of the event with a picture of the Web site because that was the only image available at that time.

Thus, the Internet empowers its users to partake in informational processes and the creation of public consciousness. It introduces new messages into the dominant message flow and creates alternative, horizontal means to reach people at large. It mobilizes the mind of the world.

Post-Conflict Reconstruction and Reconciliation

Although reconstruction may occur at different points during and after conflict, in general terms, it is characterized as taking place between the cessation of violent conflict and the return to normalization. Reconstruction provides an initial response as a tool for transformation, and fosters long-term sustainability through addressing the following issues: security; justice/reconciliation; social/economic well-being; and governance/participation (Center for Strategic and International Studies (CSIS) and the Association for the United States Army (AUSA), 2002).

Most of the time, violent confrontation destroys physical and social infrastructures, hinders development, and exacerbates already existing precarious conditions. Once violence

has ceased, unaddressed, unmanaged, unresolved conflicts continue to be fertile ground for future confrontations. Therefore, certain measures and conditions become imperative to establish the foundations necessary to move beyond conflict. These include, but are not limited to, measures involving the:

- Protection of victims and survivors
- Reform of political and legal institutions
- Revitalization, restructuring of social and economic structures
- Management and return of refugees and internally displaced persons
- Promotion of reconciliation and facilitation of political participation

As mentioned earlier, initiatives like addressing the reform of political and legal institutions, social and economic revitalization, and promoting political participation become invaluable in reconstruction and reconciliation processes. Addison (2001) argues that, “conflict resolution and prevention require economic reform— independently of the need for reform to raise growth, reduce poverty and safeguard the environment. And infrastructure reconstruction (e.g. in rural areas) is ineffective if policies that depress its values to livelihood are retained” (p. 2).

On the other hand, long-term solutions are required to avoid relapses. They must aim to heal (Øberg, 1996) the:

- Bodies and psyches of the victims
- Social and economic structures
- Environment
- Loss of trust

These are the reasons for using nICTs in the prevention of conflict and at the same time are equally applicable for post-conflict reconstruction and reconciliation.

Similarly, the concept of *human security* recognizes the notions of conflict, health and

their interdependence. It refers to the safety of individuals and groups to be freed from acts of violence. This includes human rights violations and terrorism, and non-violent threats, such as environmental degradation, economic crisis, infectious diseases, and natural disasters (Commission on Human Security, 2003). Apart from these, illnesses like tuberculosis, malaria, HIV/AIDS, and other sexually transmitted diseases affect and threaten the reality of the poverty and conflict-stricken.

Furthermore, extended periods of conflict not only undermine economic development, but also worsen the lack of sanitary measures. Humanitarian organizations often attempt to supplement this deficit with an influx of aid. In general, the main recipients of these services and goods are refugees, whose presence involuntarily increases the existing tensions in that area. The resentment of local residents may arise under these circumstances, but in situations like this, health services can mitigate the displacement of population (Bunde-Birouste, Eisenbruch, Grove, Humphrey, Silove, Waller, & Zwi, 2004).

More importantly, in times of peace the use of nICTs can provide indications for its potential uses in post-conflict scenarios.

E-health¹⁸ telemedicine and tele-health have an important impact on the supply of health services, knowledge sharing, access to medical information and research and training. Through an easy-access, combination of e-mail communication and Web-based medical databases can be made available to practitioners worldwide¹⁹. The India Health Project (Graves & Reddy, 2000) facilitates the work of rural health care providers by using nICTs to improve prevention programs and provide timely information to monitor, analyze, and plan urgent responses. Midwives, who are the primary care providers in India²⁰, use PDAs to process patient data, collect information, generate schedules, and so forth. Telemedicine is used in Ethiopia to connect rural clinics with the central hospital in Addis Ababa, and the Tigray

regional hospital with a mobile physician. This aids the decision making process by allowing medical professionals in remote areas access to the knowledge and experience of urban doctors through interactive audiovisual and data applications (Lemma, Atnaf & Kassegne, 2004).

Tools of this nature when applied to conflict-ridden or conflict-prone areas could ease the load of medical personnel, while improving the health of the general population.

In “Towards Conflict Transformation and a Just Peace,” Clements (2004) remarks that stable peace requires a deep analysis of the structural causes that underlie conflict. Determining the commonalities between traditional and budding social sources of power are complicated tasks, and that if not approached from an organic perspective they will worsen existing conditions or will create new confrontations. Thus, the task of promoting reconciliation is a multidimensional and extremely difficult challenge. This challenge can only be met if the warring factions can be moved beyond the confines of the reasoning and realities that led to the positions they adopted at the beginning of the conflict. Information and communication can act here as an essential element for dialogue initiation and confidence building.

Internet has minimized the distance factor and, despite the technological component, relationships do not cease to be human. According to Aguirre (1999), “behavioral sciences and, especially, psychological schools,” have demonstrated that “the initial ‘distance’ Internet places between people, enables individuals to know that there are others with similar affinities in a faster, simpler way than in normal relationships.”

Info-Share²¹ is interactive software developed by a group of peace promoters in response to the September 2003 dwindling of the Sri Lankan peace process. Its purpose is to develop networks between the stakeholders of the peace process, so that instant communication —via messenger or chat—is available at all times. The project, which is sponsored by Groove Networks, USAID and the

Academy for Educational Development, among others, is designed to be a platform that offers support for the creation of “shared spaces” in the public and private domain. V. Anandasangaree, the leader of the Tamil United Liberation Front commented that lapses in communication were extremely pernicious to the evolution of the peace process (Liyanaarachchi, 2003). Info-Share has bridged the communication gaps between the parties involved. For example, the tools available have assisted in finding the most appropriate strategic responses for the dissemination of information through early alert systems and other more appropriate networks. Info-Share’s Hattotuwa (2004) claims that the process of conflict transformation and management as well as peace-building are strengthened if the entities involved are connected through multi-sectoral networks and have open access to stored knowledge. The creation of this type of networks makes the positive impact of nICTs plausible and possible.

The importance of human contact in conflict transformation and peacebuilding should not be overlooked. It is essential to strengthen relationships and foment cooperation. The combinations of interpersonal communication and daily collaboration, however, have been proven to be the most appropriate and successful formal methods to reduce tension (Huntington, 1993).

Although the Israeli-Palestinian conflict has reached a new peak in terms of ethnic tensions and violence, the Project for Arab-Jewish Dialogue has made positive contributions to peace-building efforts in that area. Under the sponsorship of the Program in Conflict Resolution at Bar-Ilan University and its Palestinian counterpart, Al-Quds University in East Jerusalem, the project has organized virtual encounters between Israeli and Palestinian students. These virtual meetings are dialogues that revolve around finding the commonalities between Islam and Judaism. This is important because the religious element, considering the social structure of the communities involved, is essential to the characteriza-

tion of these collectives. These similarities are intended to be the basis of future relationships (Mollov & Lavie, 2000). This platform helps to establish bonds of trust that are favorable to the implementation of the political agreements that arise from formal negotiations. It helps advance beyond the stereotypes and labels to identify with the “other.”

A follow-up of these activities demonstrated that when face-to-face contact was complemented with virtual contact, it increased the level of intimacy and trust between both groups. It levelled the terrain for interaction on equal terms because both groups perceived they have something to teach and learn from each other. The success this project has had in meeting the objective of changing the perceptions and improving the quality of relationships between the groups indicates that the large scale implementation of these types of initiatives can facilitate negotiation, reconstruction, and reconciliation processes. The type of interpersonal exchanges and cultural respect promoted in this context is vital to reach a long-lasting peace.

RECOMMENDATIONS

Suggestions on the use of nICTs for conflict management and prevention in the future must first be pre-empted with a disclaimer of sorts regarding nICTs and their implications within the discourse of conflict. nICTs are by no means the end-all, be-all of conflict prevention and management.

The Internet offers the advantages of decentralization and participation, it merges the local with the global; it is a means to communicate and transmit information and empowers individuals who have access to it. Nevertheless, and due to great part of these same factors, the other side of the coin is as dangerous as the first one is full of advantages. Francisco Marín Calahorro (2004) notes both in times of peace and conflict the

dissemination of content is free, which is why the presence of information on crises, conflicts, subversive groups, and other types of national and international activities have proliferated (pp. 341-349). As per sociologist, Sherry Turkle, “the Internet is an ‘ideal medium’ to recruit small groups of people” (Guzman, 1997). Although this chapter has focused on the positive facets of nICTs in conflict situations, it is important to realize that in the same way that they empower citizens and assist in the promotion of the universal ideals of peace, human rights, equality, and social justice, Neo-Nazi and terrorist groups, like Al-Qaeda, also make use of nICTs to network, disseminate, and legitimize their messages.

From the communicative and informational perspective, the flux and immediacy of information through nICTs facilitates the transmission of reality as it occurs. One of the dangers or problems that arise when dealing with conflicts in a virtual setting is, however, the very characteristics of the medium itself: it is virtual and text-based. The lack of non-verbal cues might inhibit “speakers” from understanding the totality of the message being transmitted²². On one level, cyberspace requires a straightforward communicative style to determine the degree to which parties agree or disagree to avoid lapses and misunderstandings. On that same note, however, lack of tact or sensitivity could be lethal to the dialogue process. Since the Internet is a discursive medium, it is important to take into account the cultural and social context of the individuals who are communicating. This helps minimize the effect of the personal backgrounds of the negotiators or dialoguing parties that may contribute to the interaction. The goal is to avoid misunderstandings and maintain the fluidity and openness of the exchange.

Censorship and governmental monitoring are also issues that arise when discussing the application of nICTs for conflict prevention and management. Countries like China frequently restrict access to Web sites that are critical of

their government, speak of human rights abuses, or denounce corrupt behaviour²³. This content is considered subversive and illegal and is automatically blocked by governmental Internet filters (Zittrain & Edelman, 2003). These types of limitations inhibit the extent to which nICTs can be of use in many of the scenarios mentioned earlier in this chapter.

Additionally, the benefits that might arise from the use of nICTs are greatly hindered by the existence of the digital divide (The Economist, 2005). It is essential to realize that the advantages of the Internet can only be seen as such if one presupposes that this chapter relates specifically to individuals, populations, and countries that do not suffer, or suffer a lesser version of the digital divide. According to the Digital Divide Network, access to digital technology hinges on numerous factors: telecommunications infrastructure, national poverty index, the cost of the necessary technology, literacy rates and basic education. The digital divide and the development divide are practically the same. As Cynthia Hewitt de Alcántara (2001) notes:

The digital divide is an integral part of a much broader and more intractable development divide. The likelihood that people in low-income countries can improve their life chances is often sharply limited not only by their lack of access to modern means of communication and sources of information, but also by a complex network of constraints ranging from unresolved problems of poverty and injustice in their own societies to the structure and dynamics of the global economic system. (pp. 7, 30)

Populations that are on the losing end of the development divide will continue to have problems when it comes to using digital technology to improve their realities.

Furthermore, problems arise regarding the legal, fiscal, and regulatory frameworks of the

political and policy environments in which nICTs are used²⁴. It is because of this, that the role of nICTs in conflict is only complementary to other measures taken to prevent, manage, and bring conflict to a conclusion.

However, it is important to recognize that there are no solutions to the issue of the impact of nICTs on conflict prevention and management, but there are realities. Of those realities, only some of them, those relating to access, technology, infrastructure, and expertise can be addressed in a straightforward manner through policy and concrete national and international initiatives. For the other realities, which hinge on the nature of the medium itself and the content communicated, there are no quick fixes or easy solutions. They require an increased general awareness on the exchange of ideas and the potential for dialogue of the Internet, as well as knowledge to discern the quality and legitimacy of the information available.

In concluding this segment, in spite of limitations outlined, it is important for institutions addressing conflict prevention and management to incorporate the use of nICTs into the breadth of their work. Only then they will be able to take full advantage of the benefits and assistance they could afford from this technology.

FUTURE TRENDS

The opportunities that technology affords can be practically endless. In the same way that software can search databases worldwide to predict the number of military war casualties (The Economist, 2005), it may well be used to project and find ways to avoid loss of civilian life.

The future for the use of nICTs in conflict prevention and management does not limit itself to the evolution of the realities and possibilities outlined above, but encompasses a variety of other scenarios and uses. Governments, international

organizations, and financial institutions might consider investing increased time and funds in further studying their effects within this context. Also, it is important to extend research and foment the use of related indigenous innovations.

Unlike computer-based Internet and other more traditional ICTs, mobile telephony has the advantage that their use neither requires literacy nor a permanent electricity supply. Both on its own and merged with the Internet—mobile data services—mobile telephony has proven to be a useful political tool in the cases of Spain, the Philippines, the United States, India, and Hong Kong (Standage, 2001). In all these situations short message services have served as mediums to mobilize voters (Adelman, 2004). Furthermore, in terms of development, efforts such as the Grameen Bank's "telephone ladies" have proven their usefulness to the development cause (Buerk, 2005). Results in this respect have been such that it has been estimated that "that an extra ten phones per 100 people in a typical developing country increases GDP growth by 0.6 percentage points" (Bishop, 2005).

Attention should also be given to the use of nICTs to prevent the loss of life in road accidents, militia fights, kidnappings, ambushes, and so forth. The informational vacuum that exists between life in urban and rural areas, which often requires unprotected citizens to travel long distances on precarious roads, could be filled by providing information and news via mobile short message services, mobile data services and digital networks, where available. These tools would help maintain a functioning alternative back-end media infrastructure at times when traditional media collapses.

It would be extremely useful to compile information and centralize data repositories on the implementation of these mechanisms within different conflict contexts to determine typologies for action.

CONCLUSION

Conflict is a global phenomenon. Thanks to new and old ICTs, conflict now reaches beyond its immediate physical location and travels around the globe as information in the blink of an eye. The purpose of this article has been to explore the methods via which the nICTs can help to prevent and manage the globalized conflict. Within this framework, nICTs have been used to provide punctual specific, incidental sources of income generation and economic empowerment that compensate for deficits in social services, like health and education, and assist in local capacity building. Through initiatives and projects of this nature, international organizations, civil society, and governments can use nICTs to contribute to the correction of structural flaws that produce or aggravate some of the root causes of conflict.

From the communicative and informational perspective, nICTs can play as facilitators and catalysers of dialogue²⁵ is certain. Virtual communities have become one of the central axis of social mobilization in the information society. This confirms Wellman's affirmation regarding how computer networks unite individuals as much as they do machines and the manner in which this coincides with the emergence of social networks (1996). They emerge and develop in an environment that is very different from every day life: cyberspace (Tirado & Gálvez, 2002). Furthermore, they continue to be a forum for complete interaction. They create bridges between the parties involved in the conflict that complement the activities and negotiations taking place in situ. Foremost, they are important in the reconstruction of the communal concept of the "other" to overcome stereotypes and false assumptions.

These technologies have also proven valuable to:

- Predict and manage crises

- Create and manage solidarity of action networks
- Disseminate information.
- Plan and coordinate activities
- Mobilize citizens

In many cases, particularly relating to conflict management, one might argue that rather than offering any tangible support, messages are introduced into the flow of public discourse through the Internet. This newly integrated information then becomes a means to act on the imaginary collective of the conflict. Therefore, the communication process demands a collective course of action, but at the same time should invoke individual decision-making and enable contributions to the formation and revision of opinions.

In conclusion, it can be stated that the ultimate enduring success and sustainability of the effects of these initiatives are linked to the complementary use of nICTs processes that are already taking place in the field. They are meant to be another, but no less important, component of the holistic solutions that conflict—its causes and consequences—may require.

ENDNOTES

¹ The most common types of armed conflicts over the past 50 years have been liberation

wars, civil wars, minority conflicts (ethnic groups seek to end oppression), and border disputes.

² Of the 106 armed conflicts in the world that took place from 1989-1996, only six occurred between states. The remaining 86 were internal conflicts where over 80% of the directly affected populations were civilians.

³ For information regarding military studies see Boltz (2002). Since this chapter was written, the UNICTS Task force has also published *Information and Communication Technologies for Peace: The Role of ICT in Preventing, Responding to and Recovering from Conflict* by Stauffacher, Drake, Curriion, and Steinberger (2005).

¹⁰ The literacy threshold of the citizens in the area may, nevertheless, still be an important caveat to the total success of the Gyandoot Project as it may enable old gatekeepers to stay in control. The Organization for Economic Cooperation and Development's study on "Literacy in the Information Age" divides literacy into five levels. Level 1 (very easy text only) is the usual definition of literacy. Level 3 is needed to function within the Information Society, which includes the Internet. Level 3 approximately matches the skills acquired by completing second-

- ary education. This research evaluated the literacy of individuals ranging from ages 16-65 in industrialized countries, and found an astonishing amount of population below level 3, for example, more than 40% in the USA, and 85% in Chile. OECD (Literacy in the Information Age, 2001).
- ¹¹ nICTs are the tool of choice for disseminating information regarding human rights violations, torture, arbitrary detention, etc., that does not reach corporate media outlets.

Chapter 8.13

Crossing the Digital Divide and Putting ICT to Work to Improve People's Lives

Teresa Peters

Bridges.org, South Africa

INTRODUCTION

Information and communications technology (ICT) is a key weapon in the war against world poverty. When used effectively, it offers huge potential to empower people in developing countries to overcome development obstacles, address the most important social problems they face, and strengthen communities, democratic institutions, a free press, and local economies. But, a “digital divide” separates those who can access and use ICT to gain these benefits, and those who do not have access to technology or cannot use it for one reason or another.

Governments can play a fundamental role in creating an environment that will foster technology use and encourage investment in ICT infrastructure, development, and a skilled workforce. Government action is also important in spreading the benefits of technology throughout society, and governments have the power and mandate to balance the needs of their citizens for long-term

economic growth and social prosperity. However, translating a vision into practical steps that fit the local context is not a simple matter. Leaders need to have a realistic appreciation for what ICT can—and cannot—do for their countries and communities, and they must lead effectively and bolster public confidence in the path they take.

The digital divide is a complex problem, presenting both practical and policy challenges. And it is apparent that solutions, which work in developed countries, cannot simply be transplanted to developing country environments: solutions must be based on an understanding of local needs and conditions.

GOVERNMENT POLICY CAN HINDER EFFORTS TO TACKLE DIGITAL DIVIDES

A range of projects are underway in developing countries to integrate ICT in a number of critical

areas, including education, healthcare, government, trade, and small business support. However, these projects frequently encounter obstacles that directly or indirectly relate to the country's policy environment. One example involves projects that rely on technology or infrastructure use that is limited by current laws or regulations, such as laws that control or ban the use of satellite, wireless, or Voice over Internet Protocol (VoIP) technologies. Another example involves ICT projects that are hindered by a general law or regulation, such as fiscal or customs policies that limit cross-border trade in computing technologies. Another involves projects working in a particular subject area (such as healthcare) where current laws or regulations do not cover ICT use (such as privacy and data protection laws governing the handling of electronic health data).

To cross the digital divide and put ICT to effective use to improve people's lives, countries and communities must be "e-ready" in terms of infrastructure, access to ICT, training, and a legal and regulatory framework that will foster ICT use. If the digital divide is to be narrowed, these issues must be addressed in a coherent, achievable strategy that is tailored to meet local needs.

Many national leaders have embraced ICT and are ready to promote a legal and regulatory environment that will enable its widespread use. However, at the working level, many government officials do not understand the implications of existing policies that may hinder ICT use, nor the changes they need to create a more favourable environment. Although the development aid industry generates a tremendous volume of reports, advice, and analysis aimed at helping developing countries in the policy area, developing country governments frequently report that such recommendations do not show sufficient understanding of local needs and conditions. Some governments have subscribed to e-strategies promulgated by outsiders, but at a practical level they lack the political will to drive change because they do not enjoy widespread public support for

an ICT-focused approach. Often this is because government officials fail to engage stakeholders in framing the e-strategies, so they do not have public buy-in for their long-term plans. In some cases the government has partnered with the country's business and civil society sectors to promote ICT-enabled development at the ground level, but the various stakeholder groups lack the experience and resources to give effective input.

CITY OF CAPE TOWN: AN EXAMPLE OF BEST PRACTICE AT CITY LEVEL

Many of the policy issues related to ICT use are at the national level and include issues such as legal and regulatory frameworks and macro-economic policies. But there are other issues where city governments have a key role to play.

The City of Cape Town is an example of a local government committed to putting ICT to work for social and economic development, and driving the changes necessary to ensure ICT is used effectively. Cape Town's leaders have recognised that ICT is a powerful tool for transforming the way that people do business, communicate with each other, access information and, if used effectively, can help the City achieve its goals.

In January 2002, the City Council commissioned Bridges.org to undertake a pioneering assessment of the digital divide in Cape Town, in order to get a view of where its citizens, communities, and organisations stood in terms of current ICT use and the potential benefits of ICT use in the City. The study examined the access, use, and need for ICT in Cape Town, with a special focus on the millions of people who live in disadvantaged communities within the greater metropolitan area. The study helped City leaders to measure ICT integration, plan for expansion, focus their internal efforts, and to identify areas where external support was required. The study also provided benchmarks for external comparison and gauging

internal progress. Finally, the study served as a valuable part of a greater process to bring a wide range of stakeholders into the discussion about ICT and development in Cape Town.

National-level assessments of this nature commonly study e-readiness by compiling information from government agencies, big companies, business associations, and other secondary sources. This study started with such an approach. However, it then went further to collect direct input from communities, small businesses, and community organisations, to gauge the need for ICT service in the community and depict the real-life constraints—and opportunities—that people and institutions face as they work to harness ICT for local benefit. At the same time, the study assessed the interest and capacity of the City's communities, businesses, academic institutions, and government agencies to help 'bridge the divide'. Such an approach allowed this study to look ahead to the social appropriation of ICT for local benefit, so that practical options and recommendations could be framed to guide the City Council as it developed its own plans. Further, the processes used in the study helped the City better connect with its people and to gain widespread support for the e-strategies the process developed.

As a result, several public and private sector initiatives commenced in Cape Town with the related goals of (1) fostering the budding ICT sector and using ICT as an enabler for broader economic growth, and (2) tackling the problems of

the "digital divide" to maximise digital inclusion. Perhaps the most notable example was the City of Cape Town's Smart City Strategy, which won the African ICT Achievers Award for e-Government in 2002. This strategy aimed to put ICT to work in ways that would enable the government to transform itself to deliver more effective and efficient service to citizens. It also aimed to empower citizens to deal more effectively with the growing digital economy. The city envisions "a smart city populated by informed people, connected to the world and each other by the technology of the information age."

ABOUT BRIDGES.ORG

Bridges.org (<http://www.bridges.org>) is an international non-profit organisation based in South Africa with a mission to promote the effective use of ICT in developing countries to improve people's lives. One area of focus is in informing policy decisions that affect people's access to and use of ICT. Bridges.org also conducts technology research and provides social consulting services to ground level projects using ICT, helping with project planning and evaluation and relaying lessons learned. It brings an entrepreneurial attitude to its social mission, and is committed to working with, instead of against, government agencies and the business community.

Chapter 8.14

Creative London?

Investigating New Modalities of Work in the Cultural Industries

David Lee

Goldsmiths College, University of London, UK

ABSTRACT

This chapter considers the emergence of the discourse of creativity in contemporary economic, political, and social life, and the characteristics of emerging labour markets in the cultural industries. In particular it is concerned with analysing the working experiences of a number of individuals working in the cultural industries in London. Using a critical theoretical framework of understanding, it examines the importance of cultural capital, subjectivisation, governmentality, network sociality, and individualization as key concepts for understanding the experience of labour in the creative economy. This chapter considers how creative individuals negotiate the precarious, largely freelance, deregulated and de-unionised terrain of contemporary work. As the economic becomes increasingly inflected by the cultural in contemporary social life, the terrain of experience of individuals working in these expanding sectors has been neglected in cultural studies. This chapter seeks to critically intervene

in this area, arguing that the “creative” turn in contemporary discourse can be seen to mask emergent inequalities and exploitative practices in the post-industrial employment landscape.

INTRODUCTION

Everywhere we turn in contemporary society, we are being encouraged to be creative. In today’s “knowledge economy,” where we are told we are “living on thin air” (Leadbeater, 1999) the imperative to be creative has taken on the ideological force of a moral edict: something that we should all aspire to. Influential political literature tells us that we are living in the “Creative Age” (Bentley & Seltzer, 1999), commentators speak of the rise of the “creative class” (Florida, 2002) and businesses are told to display “creative leadership” (Guntern, 1998). Indeed creativity is no longer presented as a choice in such discourse; it becomes compulsory if one is to survive the vicissitudes of global capitalism. A vast plethora of books from

self-help literature to popular psychological literature as well as an extensive range of discursive political activity seeks to assure us that creativity is something that we can all achieve, if only we try. As Osborne (2003) argues, “in psychological vocabularies, in economic life, in education and beyond, the values of creativity have taken on the force of a moral agenda” (p. 507).

Creativity, as a key structural necessity of cultural production, has come to be seen as a constitutive element of the contemporary economy. One of the defining features of our times is the ever-increasing fusion of the cultural with the economic within society (see Jameson, 1991; Lash & Urry, 1994). Ours is an economy of “signs and spaces,” increasingly dominated by the media, by brands, by advertising, in short by signifying practices. As Lash and Urry (1994) argue “[e]conomic and symbolic processes are more than ever interlaced and interarticulated; that is...the economy is increasingly culturally inflected and ... culture is more and more economically inflected” (p. 64). The structural needs of late capitalism demand creative workers in a wide range of areas. The huge growth in the creative industries is concomitant with the emergence of the notion of the creative economy. As such, Wang (2004) claims that “[c]reativity’ is redefined as an enterprise sector, intrinsic, not external, to the contemporary technologically-accented knowledge economy” (p. 11). In contemporary society creativity becomes a central element of the discursive regime of the new economy, in which the demands on the individual to demonstrate flexibility, entrepreneurship, and innovation have taken on the hegemonic power of ideology.

In the United Kingdom, the ethos of creativity has become an integral part of the New Labour government. The overt fusion of culture with politics can be seen both as a rebranding exercise as evident in the Cool Britannia project and as a vital component of the bid to transform Britain into a leading global knowledge economy.¹ Yet the

creativity explosion is not one that emanates purely from the heavy hand of the state, it also becomes a matter of governmentality, in the Foucauldian sense,² one that encourages the development of techniques of the self,³ and is a discursive process that has become embedded within our very subjectivity. Subsequently, we live in a society where everyone not only wants to be creative but is told and believes that they can be.

This chapter considers the working experiences of a small group of cultural producers working in London’s creative economy as a way of exploring the sociological significance of the cultural economy within the context of late modernity. It investigates why creativity has become such a central component of the discourse of everyday life, and how it has become entwined with the social, the political, and the economic. Exploring the importance of identity, reflexivity, and individualization for these “cultural intermediaries,”⁴ I argue that the precarious routes that they are obliged to take through the spheres of employment within the creative economy are indicative of a radically transformed world of work. As the relationship between the cultural and the economic becomes ever more entwined in modern society, the question of how these cultural producers negotiate the terrain of the new economy is vital. The new modalities of work in the cultural industries, which are largely freelance, flexible, and entrepreneurial, can be seen as templates for how we are all increasingly having to negotiate our working lives in a state that is “permanently transitional” (McRobbie, 2004).

As today’s cultural producers make highly individualized pathways through their working lives, and as the notion of the “portfolio career” becomes more common place, we can see how the traditional notion of a career is radically altering; no longer a “job for life,” work becomes transitional and insecure. The increased individualization of late modern social life means that these knowledge workers must “seek personal solutions to systemic

Creative London?

contradictions” (Beck & Beck-Gernsheim, 2002, p. 22): they must live with the ever-present possibility of “the breakdown biography” (p. 3). It is clear from my research that the working lives of cultural producers are increasingly precarious. At the same time culture has been appropriated by the state and by transnational corporations for neo-liberal, free-market purposes. With this in mind, the fundamental and underlying questions driving my research for this chapter are: what purposes does the “creative turn” serve within contemporary society, and what are the subjective experiences of those individuals who are working inside the creative economy?

Structurally, the argument that follows is split into two key sections. The first section is a theoretical discussion that seeks to contextualize the cultural economy within the larger historical and social framework of late modernity. This will examine the key literature both in terms of theorizing the cultural economy and also more specifically the research that is available into the study of cultural production and the sociology of work. Through an examination of recent academic and political literature I will attempt to define the scope of the creative economy, and its political significance. Then I will explore the increasingly cultural nature of economic life, followed by an analysis of the inherent reflexivity and individualization in contemporary society and the significance of this for my research. This will be followed by a review of the literature within both media and cultural studies and sociology that helps us to understand the working lives of cultural producers, assessing the importance of subjectivity, discourse, and governmentality.

The second section is an analysis of interviews carried out between July and August 2004 with four individuals working within the creative industries in London. I will attempt to ground the theoretical discussion of the essay in the actual lived and situated experiences of these individuals. The subjects of this analysis come

from a variety of backgrounds and ages. All are working within the creative industries as defined by the Department of Culture Media and Sport (DCMS).⁵ They have a personal investment with the notion of being “creative” in terms of what they do. As such they fit the criteria of subjects for whom being creative is a deeply important aspect of their lives, and for whom, as Rose (1990) would suggest, “[w]ork is a essential element in the path to self-fulfilment” (p. 118).

THEORIZING THE CULTURAL ECONOMY

Worldwide, the creative industries sector has been among the fastest growing sectors of the global economy. (Cunningham, 2004, p. 110)

First let us turn to a consideration of what the creative industries actually are, and how we can assess their social, economic, and political significance. The cultural workers inside the creative economy are employed in a huge variety of different roles, within a rapidly transforming area. In recent years, creative industries have become the subject of intense promotion within political and economic discourse. In 1998 the British government defined the creative industries as being comprised of music, performing arts, publishing, software, TV and radio, film, designer fashion, advertising, arts and antiques, crafts, design, architecture, and interactive leisure software (DCMS, 1998). They are defined as “those industries which have their origin in individual creativity, skill and talent and which have a potential for wealth and job creation through the generation and exploitation of intellectual property” (DCMS, 2001, p. 5).

Concomitantly, in recent years creativity has been put at the top of the political and economic agenda on a global basis. Leadbeater (1999) has declared that “the real assets of the modern econ-

omy come out of our heads not out of the ground: ideas, knowledge, skills, talent and creativity” (p. 18). In the U.S., Florida (2002) has announced that there is a dominant new social group in society that he calls the “Creative Class”:

[i]f you are a scientist or engineer, an architect or designer, a writer, artist or musician, or if you use your creativity as a key factor in your work of business, education, health care, law or some other profession, you are a member. With 38 million members, more than 30 per cent of the nation’s workforce, the Creative Class has shaped and will continue to shape deep and profound shifts in the ways we work, in our values and desires, and in the very fabric of our everyday lives. (p. 9)

On the more local level that I am describing in London, creative industries have become central to regional policy to promote economic growth. A recent report on London’s creative industries, Creative London, shows the scale of growth of this sector in recent years (London Development Agency, 2004). According to this research, the creative industries contribute £21 billion to London’s gross domestic product; one in every five new jobs created in London is in the creative industries, and the sector as a whole now accounts for more than 500,000 jobs in the capital (London Development Agency, 2004). This makes the creative economy second only to financial services in terms of its economic significance in the capital.

CULTURAL CAPITALISM

The structural demands of late capitalism mean that increasing numbers of people are now making a living within the creative industries. Jameson (1984) detected the centrality of cultural production to the workings of advanced capitalist economies, asserting that post-modernism, both as a historical condition and as a new cultural

aesthetic marked by pastiche, irony, depthlessness, and heterogeneity, needs to be understood from a material, economic basis. Post-modernism occurs in a society where culture has become inextricably connected with the economy and where: “aesthetic production ... has become integrated into commodity production generally: the frantic economic urgency of producing fresh waves of ever more novel-seeming goods at ever greater rates of turnover, now assigns an increasingly essential structural function and position to aesthetic innovation and experimentation” (Jameson, 1991, pp. 4-5). This shift is also one away from an industrial society into a so-called post-industrial society, where services rather than manufacturing and industry have become the economic dominant (Bell, 1973). This supposedly “weightless” economy creates an increased need for cultural producers. In our consumer society, goods have a built in obsolescence and advertising and marketing become crucial. As such, culture becomes not only a major aesthetic consideration, but is also the major driving economic force within society.

More recently Lash and Urry (1994) have argued that we live in an economy of “signs and spaces.” By this they mean that business processes have become increasingly acculturated in modern social life, so that the value of a commodity, for example, is indissociable from the power and symbolic capital attached to its “brand.” As they note, “[w]hat is increasingly being produced are not material objects, but signs.” In this process, “goods often take on the properties of sign-value through the process of ‘branding,’ in which marketers and advertisers attach images to goods” (Lash & Urry, 1994, p. 15). Structurally, this means there are ever-greater numbers of people working to produce symbolic content. As Lash and Urry (1994) assert: “[w]e thus live in increasingly individuated and symbol-saturated societies in which the advanced-services middle class plays an increasing role in the accumulation process.

This class assumes a critical mass in the present restructuration: as symbol-processing producers and as consumers of processed symbols working and living in certain towns and cities” (p. 222).

REFLEXIVE MODERNIZATION

As the cultural has become fused with the economic, the ongoing processes of individualization and reflexive modernization provide a theoretical framework for understanding the new modalities of work for cultural producers. A number of commentators have examined the processes of detraditionalization that have occurred through modernization, and the impact of this on the individual where subjects become increasingly “reflexive” and are compelled to seek structure and meaning to their lives through a plethora of personal lifestyle choices (see Beck, Giddens, & Lash, 1994). Individualization has become a key trend in contemporary social life, occurring as people are disembedded from traditional social ties of kinship, class, and geography and become more fluid and mobile in their social relationships. As Lash (2002) writes, “individualism is a result of the retreat of the classic institutions: state, class, nuclear family, ethnic group” (pp. 9-10).

This process has profound consequences for the individual. Subjects in individualized societies must take responsibility for themselves. If things go wrong, the answer lies not with society, but with their own personal failings. Indeed, “‘individualization’ consists in transforming human ‘identity’ from a ‘given’ into a ‘task’—and charging the actors with the responsibility for performing that task and for the consequences (also the side-effects) of their performance” (Bauman, 2002, p. 15).

Explaining this dynamic, Giddens (1992) argues: “[t]he self today is for everyone a reflexive project—a more or less continuous interrogation of past, present and future. It is a project carried

on amid a profusion of reflexive resources: therapy and self-help manuals of all kinds, television programmes and magazine articles” (p. 30). This is certainly evident for my interviewees, who are self-monitoring and order their identities through personal narratives which present themselves as life choices. The “creative” turn which I have described can be seen as a key element of the ongoing process of individualization within late modernity, something for the self to aspire to, that which will bring self-fulfillment. As such it becomes part of the “lifestyle” culture of contemporary society, an individual route to potentially transform one’s domestic life, relationship—even one’s identity.

RESEARCHING CONTEMPORARY CULTURAL PRODUCTION: THE MISSING LINK

Why has the study into the working lives of cultural producers been so neglected in recent years by academics? Firstly, such work is “production heavy,” and “requires intense periods of immersion in the field of study” (Schudson, 2000, p. 257). Access is also a central issue. Although academics have some contact with media professionals and cultural intermediaries, in order to do valid research in this field one needs to have very strong contacts, as gaining access to busy media and creative professionals is a painstaking and time-consuming process. Furthermore, production research has been seen by some as overly celebratory of the industries it studies, in that it “succumbs to the superficial glamour” of the world it attempts to study (Garnham, 1990, p. 11). Critics have also questioned the validity of the methodology of ethnographic research in media and cultural studies, claiming that the interview technique misses the larger questions of power, decision making, and economics within media organizations (Garnham, 1990).

THEORIZING WORK IN THE NEW CULTURAL ECONOMY

In recent years, however, a number of writers have attempted to make sense of the transformed working landscape of contemporary cultural producers. For example, McRobbie's (2000) engagement with recent social theories of reflexivity, network cultures, governmentality, and individualization has produced some crucial insights into modalities of work within the cultural economy. Addressing Garnham's (1990) point, she acknowledges that there is always the fear that "this kind of work can often convey the field of study as being more autonomous and more cut off from the network of powerful institutions that are its conditions of existence" (McRobbie, 2000, p. 258). However, drawing on the insights of theorists such as Rose (1990, 1999), she argues that the self-promotional strategies used by creative workers that emphasize the glamour of what they do are in fact critical factors in the study of this field: "I would propose that it is precisely the creative dimension, the dynamics of self-promotion and also the sociological nature of 'the glamour' that now ought to be the focus of attention in studies of cultural workers" (McRobbie, 2000, p. 258). Of course, such rewards are only available to a tiny elite of cultural workers, and following this path comes at the expense of job security, decent pay, and a whole array of worker's rights, which are sacrificed on the altar of creativity.

Discourse analysis also provides a convincing means of understanding the role of creativity as a loaded signifier involved in the formation of work-based identities. For example, Du Gay's research (1996, 1997) investigates how workers come to identity with beliefs that closely echo the needs and normative demands imposed on them by capitalism and by the companies that they work for. Du Gay's research exposes the centrality of culture within the contemporary workplace. His insights are essential for understanding the

discursive power of creativity for those employed within the cultural industries, as a way of creating "better" contemporary workers. Du Gay suggests that there is a clear reason for this turn to culture in the workplace—profit—in which, "[c]ulture' is accorded a privileged position ... because it is seen to structure the way people think, feel and act in organizations. The aim is to produce the sort of meanings that will enable people to make the right and necessary contribution to the success of the organization for which they work" (1996, p. 41). Equally, Miller and Rose (1990) argue that economic governance operates through subjects, and so needs to connect with an individual's subjectivity in order to be effective. As they explain, there is an economic rationale for this process: "[g]overnment ... is a 'personal' matter, and many programmes have sought the key to their effectiveness in enrolling individuals as allies in the pursuit of political, economic and social objectives" (Miller & Rose, 1990, pp. 327-328). The promotion of creativity can be interpreted as a fundamental part of economic discourse and governmentality, one in which the creative lifestyle as an individual choice has a wider economic and political purpose. As they suggest: "[o]rganizations are to get the most out of their employees ... by releasing the psychological strivings of individuals for autonomy and creativity and channelling them into the search of the firm for excellence and success" (Miller & Rose, 1990, p. 330). These processes play a vital role in the formation of identity for cultural producers, as we shall now see.

THE CULTURAL PRODUCERS

I have chosen to separate the analysis of my interviews into three central themes. Firstly, I will examine the economic realities of making a living in the cultural industries. Secondly, I will explore the importance of creativity to my interviewees.

Creative London?

Finally, I will analyse the emergence of cultural individualization within the creative economy, through my participants' experiences. Work for these individuals has become a site of intense flux, compelling them to be entrepreneurial and to sell themselves on the labour market on a constant basis. This has had a negative impact on their personal lives in some cases. Yet for all this, these cultural producers loved their work, and the "freedom" that their creative labour gave them. As such, work for them has become a terrain of great risk but also of opportunity and great satisfaction. In the pages that follow I will try to make sense of the complex and often contradictory evidence that I have amassed from my research.

A RISKY BUSINESS: MAKING A LIVING IN THE CULTURAL ECONOMY

The working lives that I describe illustrate a shift in which the traditional notion of a career or job for life is disappearing; instead people are more likely to be in a state of semi-employment or multi-activity work. As Beck (2000) argues: "[t]he normal work situation ... has begun to break down, and a political economy of insecurity and differentiation has developed in place of an economy of state-guaranteed social security" (p. 53). For growing numbers of people the "portfolio career" is emerging, filling the vacuum left by the permanent job. This is certainly the pattern of work as experienced by my interviewees. For example, Mark (personal communication, August 2004), the co-founder of a small advertising firm, described the lack of security that he experiences in work:

It's not particularly secure. I mean we constantly have conversations about it, will we be able to continue, have we got enough money? It's hard to say, I've only ever got about 30 days where I'm certain [of work].

Similarly, Catherine (personal communication, August 2004), a television producer/director working in the independent television sector, finds her working life highly precarious at times. When asked about the average length of a contract, Catherine replied:

I've got a long one at the moment, 8 months. But I've had a weekly contract before ... that's about as bad as it gets! Three months is very common for a documentary. I've never had anything longer than 8 months.

Catherine described the tension between managing a creative career in a self-entrepreneurial way and the impact that it can have on your emotional life:

At times I feel incredibly insecure ... The positive way of trying to look at the career is always looking for new skills and new challenges and just keeping moving, taking the work that comes my way. But the actual feeling, what it's actually like to work really, really hard and be off to Africa one week talking your way into a jail cell and then fly back and the project is over and you're unemployed again and all your contacts say that there is no work about, can be very harsh really. Hard on yourself.

Daniela is an established freelance journalist, who has worked for a large number of national newspapers and magazines over the course of her career. Because of this, she has very good contacts in the business, and finds work more easily than most in her field. But she is still prone to the fluctuations of fashion and of the market, and has experienced the insecurity of creative work the hard way. When working for a national newspaper she told me how suddenly they terminated her contract when it became financially necessary:

When they had a budget overspend they had to get rid of me and bring the job in-house because that's

how they were going to save £11,000 a year ... they just phoned up and said 'Could you file your copy? Oh and by the way we don't need you any more.' (personal communication, August 2004)

“DUCKING AND DIVING”: THE PORTFOLIO CAREER

A significant trend that my analysis shows is the emerging “portfolio career” pattern for those employed in cultural production. As the “job-for-life” disappears, and the insecurity of project-based work increases, subjects in the cultural economy are compelled to find a number of ways to make a living. It quickly became clear that in addition to the attendant insecurity of creative work, my participants have to juggle any number of different projects at a given time. They are forced to become highly entrepreneurial, commodifying themselves on the labour market, always on the lookout for the next project. According to Catharine:

As a researcher or assistant producer most people spend the last few weeks of their contract looking around for work, because when people want to hire you they want you the next Monday.

Daniela provided particularly telling evidence of the portfolio career pattern.

When the Internet came up British Airways head-hunted me, At this point I was working at The Times two days a week, I was doing my television critic stuff for the Daily Mail and I was doing other freelance stuff—so I had like an office job a steady contract and other bits and pieces, and then British Airways wanted me to set up their internet site ... so I've got a little portfolio. Then I've got this rock festival that I'm setting up in Nebraska which is something completely different.

Daniela is performing a juggling act to ensure a steady flow of capital. She was an exemplary

case study of a creative worker for whom “[t]he norm now is a kind of middle class ‘ducking and diving’” (McRobbie, 2002a, p. 525).

Ellie also finds it necessary to combine a number of jobs to make a living as an artist. Insecurity and transition form a staple feature of her working life. She makes very little money from her artistic practice and sees it as an investment in her future career. In order to survive she teaches sculpture part-time on an art foundation course and does occasional telesales work to supplement her income. She has little security in her teaching work and no formal contract in her telesales work.

NETWORKING: A CLUB CULTURE

To survive in such a precarious, flexible situation, where one goes from project to project at a dizzying pace, the ability to network becomes crucial. Daniela states:

I think you do have to network and I think a lot of people do it and I think there's a lot of brown-nosing going on. You have to rely on contacts, you have your favourite commissioning editors who you actually socialize with ... you become friends with the people who commission you and you almost expect them to hand you pieces like you're their favourite pet.

How can we understand the emergence of the network as the dominant paradigm of contemporary social and economic life? Castells (1996) argues that fundamental changes in communications technology, most importantly the development of the Internet and instantaneous global communications systems, mean that we have entered the age of the “network society.” In this emergent society, labour markets have undergone intense changes. As Castells (1996) suggests: “[c]apitalism itself has undergone a process of profound restructuring, characterized

Creative London?

by greater flexibility in management; decentralization and networking of firms both internally and in their relationships to other firms; considerable empowering of capital vis-à-vis labour, with the concomitant decline of influence of the labor movement; increasing individualization and diversification of working relationships” (p. 1). As creative workers are increasingly freelance, mobile, and have no fixed stable workplace, the network becomes increasingly important in terms of finding work, socializing, sharing information, and learning new skills.

Taking this into account, interestingly my analysis shows that most of my participants had an ambivalent relationship to the networking culture that they operated in. While admitting its centrality to success, it was also seen as something potentially vulgar, not something that they overtly associated themselves with doing. It seemed that there was a code to “correct” networking.

THE CENTRALITY OF “CULTURAL CAPITAL”

If networking is the new paradigm for finding work and maintaining a career in the new cultural economy, then a critical question arises: who has the skills to get on in this “club culture” and who does not? Clearly, successful networking in London’s creative economy can be seen to take place in a rigid hierarchy of taste, with definite social codes and norms. Navigating this terrain successfully requires high levels of “cultural capital” in order to facilitate access to the network and to provide an individual with the communicative and cognitive skills to succeed in this environment (Bourdieu, 1984).

All of my interviewees can be said to possess high levels of cultural capital. Middle-class, university-educated, they epitomize Bourdieu’s definition of “cultural intermediary,” a group that: “comes into its own in all the occupations involving presentation and representation (sales,

marketing, advertising, public relations, fashion, decoration and so forth) and in all the institutions providing symbolic goods and services. These include the various jobs ... in cultural production and organization which have expanded considerably in recent years” (Bourdieu, 1984, p. 359). My interviewees instinctively knew how to behave in the closed worlds of their professions and how to work the cultural economy to their advantage, where networking is so vital. Evidence of their skills can be seen in these comments:

Mark: You’ve got to have the interpersonal skills—they are the most important things. (personal communication, August 2004)

Catherine: How do I network? Just pop an e-mail, make a call, be charming. (personal communication, August 2004)

The networked economy becomes increasingly discriminatory in terms of who has access and who does not while hard-fought battles over workers’ rights and antidiscrimination laws are sidelined. As McRobbie (2002) argues, networked labour markets in the creative industries are far more open to subtle forms of discrimination and exclusion: “[w]hat we see ... is the emergence of working practices which reproduce older patterns of marginalization (of women and people from different ethnic backgrounds), while also disallowing any space or time for such issues to reach articulation. In this case the club culture question of ‘are you on the guest list?’ is extended to recruitment and personnel, so that getting an interview for contract creative work depends on informal knowledge and contacts, often friendships” (p. 533).

CULTURAL INDIVIDUALIZATION

The working lives of this group of cultural producers are acted out against the backdrop of an ac-

celerated individualization within contemporary society. My analysis suggests that the creative economy is peopled by atomized workers, who connect through networks but have lost a wider sense of workplace politics and labor solidarity. Because they have no fixed communal workplace, their experience of work is innately individual, as they move with such speed from project to project and place to place. For Daniela, modern technology exacerbates the atomizing process:

When you're freelance you've got the Internet and everything, you can do your shopping on the Internet there becomes very little reason for you to walk out of your front door. I could be here for a whole week and never go out.

FINDING "PLEASURE IN WORK"

Despite the pains that they feel at such precarious working lives, my participants were all at pains to stress how much they love their jobs, and the sense of freedom and fulfillment it gives them. They expressed a deep ambivalence towards their working lives. As seen previously, they were open about their concerns at the insecurities and the stresses of individualization, of living and working in a culture requiring constant risk taking. Yet at the same time they emphasized their great personal satisfaction in being creative, and in the pleasure they derive from their work. In central ways, "creativity" acted as a panacea for the structural pains of making a living under such pressures:

Daniela: I love the fact that I can come up with an idea, and have the freedom to turn it into a story that lots of people then enjoy reading. I'm lucky to have that, so many jobs are really boring.

Mark: It's a way of expressing yourself, of doing work that doesn't necessarily feel like work, you know?

In particular, my participants all stressed the satisfaction they derived from "doing their own thing," and of escaping the dull confines of a nine-to-five office job, which they associated with tradition and a lack of autonomy and fulfillment.

Ellie: I think it's about freedom maybe, having freedom about choices I make, in terms of what I do and what I think about.

Daniela: I know for a fact that I really need to believe in what I'm doing. I can't just do it for the money.

As Ursell (2000) suggests, for creative workers "pleasure derives from the scope they are finding for aesthetic self-expression" (p. 819). This helps to explain why contemporary cultural producers actively choose their occupations and sometimes work for very little money or even for nothing, even though they experience insecurity and exploitation. The pleasure and satisfaction that these workers derive from their jobs, even in the face of deeply (self) exploitative working practices, serves a structural function that legitimizes the workings of late capitalism. The individualized pleasure in work that my participants feel can be understood in terms of how the discourse of creativity has a disciplinary effect on workers. In a culture where creativity is prized as an "inner quality" that will bring self-fulfillment, it becomes a discursive regime: "regimes of power all the more effective since they are connected with freedom and self-realization" (McRobbie, 2002b, p. 104). As Ursell (2000) suggests, in the creative economy, "one constructs one's self with a view to marketability and value-adding propensities" (p. 810). Thus commercial consumption regimes and lifestyle politics so evident in contemporary society act as potent technologies of the self, creating individuals who are "seeking identity in work, whose subjective desires for self-actualiza-

Creative London?

tion are to be harnessed to the firm's aspiration for productivity" (Rose, 1990, p. 244).

CONCLUSION

My research into the rapidly evolving and amorphous creative industries signals a number of trends, each of which would provide fertile ground for further research. In examining the personal implications of the creative economy focusing on the experiences of my respondents, I have only been able to sketch out some preliminary and tentative shifts. However, the results are striking, and if they can be said to be indicative of wider developments in this field, and indeed in the economy at large, they signal a significant transition in contemporary labour markets.

My analysis suggests that creative workers are compelled to find new ways of managing their careers in increasingly individualized ways; in the absence of a job-for-life, and with the need to juggle a variety of projects in their attempts to work the cultural economy, these knowledge workers are having to find complex pathways through their working lives, routes which insist that they become reflexive, adaptive, and in the absence of workplace politics that they become their own support structures. They are truly "entrepreneurs of the self" (Du Gay, 1997, pp. 301-303).

Creative workers are at the vanguard of the new economy model of work in terms of how they experience flexible capitalism, freelance economies, networking, and work that is defined by mobility, atomisation, rapid deskilling, self-exploitation, multiple sites, insecurity, entrepreneurialism, and flux. In their biographies we can begin to understand the logical progression of neo-liberal values, the fusion of the cultural with the economic and the impact of the network society on work in the age of "soft capitalism." Cast adrift in the flows of the creative economy, my interviewees all exist in a constant state of risk at work, yet the rewards are deeply uncertain for as Sennett

(1998) argues, "new market conditions oblige large numbers of people to take quite demanding risks even though the gamblers know the possibilities of reward are slight" (p. 88).

A future world of work characterized by semi-employment, risk, and insecurity is the logical conclusion of the neo-liberal winner-take-all market. Such a breakdown of certainty and meaning can be glimpsed in my participants' working lives. As Sennett (1998) asks, "How can long-term purposes be pursued in a short-term society? How can durable social relationships be sustained? How can a human being develop a narrative of identity and life history in a society composed of episodes and fragments?" (pp. 26-27). This is the dilemma for my participants working in the creative economy of London. And as Beck (2000) suggests, it may be one that will face us all: "[t]he high-wire balancing act is becoming the paradigm for individual biography and social normality. Become a life-artist or go under: such is the alternative that is posed everywhere" (p. 118).

ENDNOTES

- 1 "Cool Britannia" was New Labour's strategy on coming to power in 1997 to promote the UK as a cultural powerhouse and as a world leader in the creative industries.
- 2 "Governmentality" relates to Michel Foucault's theory of power. The term refers to the techniques that exist to encourage individuals to act upon themselves in ways that serve particular ends (see Burchell, Gordon, & Miller, 1991).
- 3 Techniques of the self are those practices which "permit individuals to effect by their own means or with the help of others, a certain number of operations on their own bodies and souls, thoughts, conduct and ways of being, so as to transform themselves in order to attain a certain state of happiness, purity, wisdom, perfection or immortality" (Foucault, 1988, p. 18).
- 4 The notion of the "cultural intermediary" derives from the work of French sociologist Pierre Bourdieu. Bourdieu (1984) argues that the cultural intermediaries are a new economic class, who work in the culture industries, serving the needs of an economy characterized by a massive expansion of the cultural sphere.
- 5 The DCMS definition of the creative industries includes music, performing arts, publishing, software, TV and radio, film, designer fashion, advertising, arts and antiques, crafts, design, architecture (DCMS, 2001).

Chapter 8.15

Information–Communications Systems Convergence Paradigm: Invisible E–Culture and E–Technologies

Fjodor Ruzic

Institute for Informatics, Croatia

ABSTRACT

This chapter is on cultural aspects of information-communications systems embedded into new media environment and invisible e-technologies, and on a new age of social responsibility for information technology professionals. Besides the key issues in information technology development that create smart environment and ambient intelligence, the chapter also discusses digital e-culture and the new media role in cultural heritage. From the viewpoint of information technology, the current information-communications systems converge with media. This convergence is about tools-services-content triangle. Thus, we are confronted with a new form of media mostly presented with the term digital, reshaping not only media industry but also a cultural milieu of an entire nation on a regional and global basis. The discussion follows on the World Library idea that

is rebuilding with new form of World Memory (World Brain), the shift from visible culture domination to the domination of invisible culture in the world of e-technologies predominance. From this scenario, information technology professionals coping with information systems projects, e-services development, and e-content design have more cultural responsibility than in the past when they worked within closer and inner cultural horizons and when their misuse of technologies had no influence on culture as a whole.

INTRODUCTORY REMARKS

The information society is, above all, an economic concept but with important social and cultural implications. The new forms of direct access to information and knowledge create new forms of e-culture. E-culture is a part of a culture. It not

only concerns users but the community of information professionals as well. When one speaks of information technology, it is always from the Western point of view, whereas e-technology (especially its applications) takes place throughout the world, and every culture has a different understanding of it. The shift to an e-culture at the level of society in general is translated to the individual level, enabling cultural change to be described empirically. The term *e-culture* refers to the diffusion of new technology, its application for various purposes (especially information and communication), and shifts in related attitudes, values, and norms. E-technology may not be gnawing at the roots of our culture, but those roots are gradually absorbing it. As with all innovation, cultural or otherwise, this technology will reinvigorate, transform, and inspire older cultural forms. We are living in the era of globalization, the information economy, with borderless communities and multiple citizenships. E-culture literacy and attainment will require serious attention to new infrastructure, to the building blocks and platforms for e-culture. These are critical issues for the pursuit of information professionals' excellence, for creativity in an information society, as well as for fundamental imperatives for commerce and trade in a new media environment.

The main notion of the following text is on cultural aspects of information-communications systems embedded into a new media environment, on invisible technologies, and on a new age of cultural responsibility for information technology professionals. The key issues in information technology development that create invisible e-technologies and smart environments are under e-culture influence. From the viewpoint of information technology, the current information-communications systems converge with media. This convergence is about tools-services-content triangle. Thus, we are accepting a new form of media mostly presented with the term *digital*, reshaping not only media industry but also a cul-

tural milieu of an entire nation on a regional and global basis. The discussion follows on the new e-technology and information-communications systems convergence as the basis for defining pervasive computing and positive e-technologies. The findings at the end of this chapter explain the process of a fundamental cultural shift from the computer-based information technology to the computerless (invisible) e-technologies in which the e-culture is the essential factor of the success. The discussion section is about the role of information technology professionals coping with information systems projects, e-services development, and e-content design. They have more social responsibility than in the past when they worked within closer and inner cultural horizons and when their misuse of technologies had no influence on culture as a whole.

BACKGROUND ON INFORMATION COMMUNICATIONS SYSTEMS AND NEW MEDIA

One of the most valuable and essential processes that humanity can engage in and which is, therefore, essential to look at in terms of information technologies, is the process of self-determination. The principal of self-determination of people was embodied as a central purpose of the United Nations in its 1945 charter. The purposes of the United Nations are to develop friendly relations among nations based on respect for the principle of equal rights and self-determination of nations, and to take other appropriate measures to strengthen universal peace. Resolution 1514 (XV) of December 14, 1960, containing the Declaration on the Granting of Independence to Colonial Countries and Peoples, stated that all nations have the right to self-determination; by virtue of that right, they freely determine their political status and freely pursue their economic, social, and cultural development (United Nations, 1960). In the 1990s,

these issues continued to be highly relevant as numerous people around the world strove for the fulfillment of this basic right of self-determination. The UN General Assembly in 1995 again adopted a resolution regarding the universal realization of the right of nations to self-determination. Thus, the General Assembly reaffirmed the importance for the effective guarantee and observance of human rights and of the universal realization of the right of nations to self-determination (United Nations, 1995). By this, we see that self-determination is tied to all aspects of life: political, economic, social, and cultural. It is ultimately about how we choose to live and allow others to live together on this planet. Furthermore, information technology plays a key role in current economic and social affairs, so the information technology specialists/professionals have much more social responsibility than other professions. Information and communication technologies and networking infrastructures are playing an expanding role in supporting the self-determination of people and emergent nations. Access to information and the facilitation of communication provides new and enhanced opportunities for participation in the process of self-determination. It gives the potential to enhance political, economic, social, educational, and cultural advancement beyond the scope of traditional institutions and forms of governance.

The next step in recognizing cultural and social dimensions of information technology on the international scene is regarding the Council of Europe document, Declaration of the Committee of Ministers on human rights and the rule of law in the information society (Council of Europe, 2005). The Declaration recognizes that information and communication technologies are a driving force in building the information society with the convergence of different communication media. It also stressed that building societies should be based on the values of human rights, democracy, rule of law, social cohesion, respect for cultural

diversity, and trust between individuals and between nations, and their determination to continue honoring this commitment as their countries enter the Information Age.

Vannevar Bush (1945) predicted that the advanced arithmetical machines of the future would be (a) electrical in nature, (b) far more versatile than accounting machines, (c) readily adapted for a wide variety of operations, (d) controlled by instructions, (e) exceedingly fast in complex computation, and (f) capable of recording results in reusable form. The new computer devices as smart devices, linked through communications systems, are creating new forms of information-communications systems. Thus, the new form of information appliances and ubiquitous information technology creates the basis for the concept of an information-processing utility. Based on interactive and ubiquitous carriers of information, the first generation of new information systems evolved to provide easy communication over time and space barriers. Thus, the new information systems are media. They are virtual communication spaces for communities of agents interested in the exchange of goods and knowledge in a global environment. Further promising technologies are pervasive computing and augmented reality. The vision of pervasive computing is, to some extent, a projection of the future fusion of two phenomena of today: the Internet and mobile telephony. The emergence of large networks of communicating smart devices means that computing no longer will be performed by just traditional computers but rather by all manners of smart devices. From these notions, it is evident that information-communications systems open the way to information society development. The information society is based on the new (digital) media that provides vast opportunities for information/content networking. New organizational networks are built, cutting across national borders and interests. The networks themselves increasingly may take precedence over nation-states as the driving factor

in domestic and foreign affairs. At the same time, native communities have been actively engaged in creating and utilizing such networks with increasing participation and sophistication.

We are entering the era of new media. New media are tools that transform our perception of the world and, in turn, render it invisible or visible. Information technology (IT) professionals must understand new problems, considering the role of e-technologies in the integration and interaction between cultures. It is apparently true with tera architecture of the sensor networks that will transform business, healthcare, media, and e-culture itself. A new form of information-communications systems boosts intelligent networks with the majority of computers that are invisible and disposable. The IT professionals have the challenge in turning all that data into useful and meaningful information and in resolving cultural and privacy issues that accompany pervasive networked computing and ambient intelligence. IT professionals are confronted with the stage when e-technologies extract analytic values from social networks turning information issued by sensors and other data sources into knowledge management systems.

Defining new media is hard work. If we begin to use voice or books in an innovative fashion, we have just made old media into new media. Whatever we define as new media now would be old media as soon as we add innovations. We cannot define new media strictly based on the use of new technology for distance communication, since technology is always changing. What is new media today will be passé tomorrow. If we try to define new media by process rather than by structure, we are still in trouble. Whatever we define new media as today no longer will be valid tomorrow as technology changes the structures and processes. Trying to define the limits of change is a futile effort due to the very nature of change. This means that the regulation of new media is also an exercise in utility. The experiences with first-generation media platforms showed that in order

to take advantage of the potentials and chances offered by new media, we need to explore their features and learn how to use them effectively and to build them efficiently. In short, we need to develop innovative concepts, frameworks, and methodologies for the design, realization, and management of the new media. The new media offer unprecedented opportunities and potentials for positively changing almost any aspect of our lives. The growing importance of new media and the demand for appropriate platforms have given rise to the development of innovative technologies and components for such media. Consequently, we can now observe the first generation of media platforms and the first management approaches for such platforms.

The evolution in convenient, high-capacity storage of digital information is one of the enabling technologies for new media. Disk drives that allow local storage, retrieval, and manipulation of digital content are increasing in capacity and falling in price. The current TV experience will evolve into a highly personalized process. Consumers have access to content from a wide variety of sources tailored to their needs and personal preferences. New business models and opportunities for the various providers in the value chain will evolve in an organic market focused on addressing individuals directly with new services. This will allow content providers to respond more effectively to audience needs. Digital media and the emerging communication technologies have created an overabundance of programs and information available from which each consumer can choose. The consumer will need new solutions enabling smart and active decision making over viewing preferences, such as a personal filter for the multitude of choices, dynamically adapting to changing needs and preferences.

Communications technology is available for the support of highly complex interenterprise service networks that support new services (Nergoponte, 1996). Altogether, this creates a new view on the product, emphasizing the utility of

the package (product and services) instead of the product itself. Analyzing the lifecycle of a product is crucial for synthesizing and specifying new types of benefits for a customer. Therefore, modern manufacturers have to provide benefits to customers. Questions are what could be the benefits and what kind of utility may be beneficial for the customer. Based on that exercise, they have to come up with appropriate business concepts based on new media e-culture.

THE CULTURE AND INVISIBLE CULTURE

To cope with the new culture space in the context of information-communications systems embedded into new media environment, there is a need for basic definitions on culture, new media, and digital e-technologies. The great advances in culture come not when people tried to impose the values of one culture to the exclusion of all others, but rather when modern individuals try to create structures that are more exciting by combining elements from different cultures. The current information technology is capable of recording universal standards and particulars around the world, and it opens new ways and sources for creativity and global cultural heritage. Hence, information technology must reflect the full range of human existence, the values, the culture, and the entire knowledge. At the same time, the new e-culture is born interacting with e-technologies, and it exists in new cultural ecology. This new cultural ecology stimulates the development of a new trio (triple convergence) consisting of e-technologies, e-culture, and e-society.

The culture is a shared set of manifest and latent beliefs and values (Sackmann, 1991). It helps people to categorize and predict their world by teaching them about habits, rules, and expectations from the behaviors of others. Culture also molds the way people think—what their motivations are, how they categorize things, what inference

and decision procedures they use, and the basis on which they evaluate themselves. Most of other definitions are too narrow. Sociologists have focused on behaviorist definitions of culture as the ultimate system of social control. In this system, people act appropriately and monitor their own standards and behaviors. Thus, the culture consists of the learned ways of group living and group responses to various stimuli; sociologists describe the content of the culture as the values, attitudes, beliefs, and customs of a society. Media theorists have explored the interplay of culture and technology, which has led to an emphasis on some aspects of culture. The new approaches are considering cultural ecology as consisting of new media in which various types of media are translated into a common digital form that is accessible within a single framework.

Today's networked media allow each user to participate actively in the creation of cultural expressions, which we perceive simultaneously and with immediate proximity. The new culture is emerging due to the use of digital technology (e-technology). At the same time, there is a strong relation between values promoted by the new digital e-culture and the traditional moral values created by the major world cultures. These notions open the new contextual approaches on culture in the information society. The culture related to the information society is about three contextual elements (Figure 1).

The forces of globalization and technology development are paradoxical by nature, offering both threats and opportunities for cultural diversity. Yet, the information society is currently perceived only as an economic imperative in a new environment shaped by rapid information technology developments, based on visions shaped primarily by technologist and business concerns and priorities. The prevailing options embedded in these visions, such as globalization based on cultural homogenization, are questionable not only from a political and social standpoint but also in economic terms. Citizens around the world

Figure 1. Triple context of culture in information society

are becoming increasingly concerned about the way accelerating processes of globalization and technological innovation are leading to cultural homogenization and immense concentrations of financial power. Globalization generally is seen to be a phenomenon driven primarily by economic interests. As such, it has neither moral content nor values. Therefore, it could be independent from culture.

Cultural Diversity and the Information Society

Cultural diversity potentially can become a key asset in the information society, despite the fact that the culture could be defined as an obstacle. It is clear from the previous discussion on glo-

balization that the economic forces of globalization pose a serious threat to cultural identity. Information technologies are not only the tools that accelerate the pace of globalization, but they are also becoming the key means of access to any good or service. One could thus argue that cultural diversity is an obstacle. Cultural diversity is essentially a question of communication, both internally to one’s own culture and externally with distributed cultures. Thus, one of the central issues is not only access to new e-technologies but also the capability of manipulating new media in order to participate actively in communicational exchanges.

Technology literacy is needed to operate IT effectively. Cultural literacy refers to the ability of an individual (or community) to relate to the

Figure 2. Tools-services-content triangle as the basis for information society

services made by one's own cultural heritage and with access to another culture in a positive way. This means learning from both similarities and differences, being able to reject some aspects, and accepting others. Cultural literacy thus lies at the heart of the possibility of communication in a context of cultural diversity. Content is about Creativity. Creativity is the factor lying at the intersection of motivation and competence, and it covers both the individual and the collective levels. Collective creativity is of greater importance if we are aiming for a shift toward an information society in which a given community will depend on the collective creativity of its social and economic individuals and organizations (with accepting collective memory and brain).

Visible Culture

Western culture has had a strong bias toward the so-called fine arts, such as painting and sculpture. These expressions of culture, which are continuously visible, were more significant than the performance arts (theatre, film, music), which are only visible when they are being played. One of the key elements of great visible culture is uniqueness. Thus, the challenge of universal standards has brought the question of uniqueness back to the fore. To communicate internationally, we need global standards that bring the risk of reducing everything to one mode of expression.

The world of telephony offers an interesting case in point. We clearly need standards and uniform rules for telephones, yet every conversation on those telephones still can be different (Veltman, 1997). In this imperative to record the particular as well as the universal, creativity is only one essential element. The major cultures of the world owe much of their greatness to the fact that they have a recorded tradition, which stabilizes the corpus but also ensures the possibility of a cumulative dimension, which is reflected in terms such as cultural heritage. Even so, there

are many skills in the craft tradition relating to culture that remain oral and invisible.

Invisible Culture

Many people favor material culture because it is visible and easily recognized. Culture is about more than objects in visible and tangible places. For example, many computer users are accustomed to thinking of computers as tools for answering questions. We need to think of them as tools for helping us to understand which questions can be asked, to learn about contexts when and where questions are not asked, of knowing that there are very different ways of asking the same thing. If software continues to be dominated by one country and if the so-called wizards of those programs all rely on the questions of that single country, then many potential users of computers inevitably will be offended, and it is likely that they will not use the programs.

The base assumption is that culture for us is invisible (invisible culture). As workers do not know that they are participants accepting entire organization values, the culture of an organization is invisible (Cooke & Lafferty, 1989). Yet, it is all-powerful. Therefore, this assumption is important for invisible e-culture. We are working in organizations that actually drive our behavior and performance in a way that most of the time is not visible to us. A definition of culture includes the way we do things.

A way to look at culture is actually to have some outside expert or outside person come in and question the way things are going, which can begin to give some insight to the people inside the organization about their own culture (Cleary & Packard, 1992). However, the culture is also considering exchange of ideas, thoughts, and beliefs, and it helps people realize that things can be done differently somewhere else. The success in one culture does not mean success in another culture, and there are actually many ways to suc-

ceed, change, and live. People realize that they can act on some other level of culture and act on their own culture.

E-Culture

We could define culture as the beliefs, behaviors, languages, and entire way of life of a particular time or group of people. Culture includes customs, ceremonies, art, inventions, technology, and traditions. The term also may have a more specific aesthetic definition and can describe the intellectual and artistic achievements of a society. The new world economy develops in e-culture and characterizes with the fast, open access to information and the ability to communicate directly with nearly anyone anywhere (Kanter, 2001). This sets e-culture apart from traditional environments.

In a first approximation, one could say that an e-culture is emerging from the convergence of communication and computing along with globalization and the penetration of e-technology in the smallest corners of our lives. The advent of information and communication technology goes hand in hand with changes in attitudes, skills, and behaviors that play a central role in daily life. The advent of an e-culture is correlated with terms of a broad definition of culture. This concerns the culture of a society with both invisible and material characteristics. E-technology as a part of the cultural information may be classified as e-invisible culture, but the outputs of that technology (information appliances) may range among the material (visible) cultural products.

The shift to an e-culture at the level of society is translated to the individual level enabling cultural change to be empirically described. The term *e-culture* refers to the diffusion of new technology; its application for various purposes (especially information and communication); and shifts in related attitudes, values, and norms. The human thinking and behavior are changing gradually by

information and communication technology. E-technology may not be gnawing at the roots of our culture, but those roots gradually are absorbing it. As with all innovation, cultural or otherwise, this technology will reinvigorate, transform, and inspire older cultural forms. We are living in the era of globalization, the information economy, with borderless communities and multiple residencies. E-culture literacy and attainment will require serious attention to new infrastructure and to the building blocks and platforms for e-culture. These are critical issues for the pursuit of information professionals' excellence, for creativity in an information society, as well as for fundamental imperatives for commerce and trade in new media environments.

E-TECHNOLOGIES AND UBIQUITOUS INFORMATION (DIGITAL) APPLIANCES

The Internet is without precedent because of two key features: its interactive and communicative natures. It is not a commodity in the sense that you can go out and buy a TV. You cannot go out and buy a net. The key word here is interactivity. Interactivity implies a dialogue of some kind, a changing response based on changing stimuli. There is much talk of interactive Web sites, but even the best of these choose from a preprogrammed set of possibilities in order to give the illusion of being interactive. You have interactivity over the telephone, and you have interactivity in a face-to-face dialogue. However, you do not have interactivity in traditional analogue television. The prosperity of the net is that it permits simultaneous interactivity with thousands and, perhaps, millions of people worldwide. This is a first in the history of humankind.

With the new and upcoming information-communications systems with pervasive and personal appliances, there will be a huge number

Figure 3. Scenario of universal personal information appliance

of networked intelligent devices and information appliances functioning as self-organizing and managed networks (Figure 3).

In the near future, information communications systems with invisible networked devices, sensors, and appliances will transform businesses, public administration, public services, and the way we communicate within digital networks. Digital networks through the new form of information transport by ultra wideband and WiMax technologies will boost the intelligent networks development around the entire globe. The computer is becoming invisible and everywhere simultaneously. This is the beginning of the invisible computer era.

Parallel to this development is that of networking, which conceivably could result in all the invisible computers in the world being networked into a single virtual computer. This would lead to the evolution of a computer that

would be everywhere and nowhere at the same time. Technology itself and on its own is not a cultural determinant. Technology is the invention of a particular culture—a cultural expression. The relationship between culture and technology is not linear and monodirectional but rather multidimensional and hyperspatial. Ten years from now, the computer as we know it today will be an anachronism, a device consigned to museums. Instead, the digital information and services once delivered via conventional computers will be available through almost everything we touch. At the heart of this next generation of computing is the network. It will be pervasive and personal. Looking out a decade or two, every person and thing could be instrumented with sensors that feed data into the content base and take actions on behalf of the client.

The new term, *speckled computing*, goes in that way. It offers a radically new concept in

information technology that has the potential to revolutionize the way we communicate and exchange information (Arvind, 2005). Computing with Specknets will enable linkages between the material and digital worlds, and it is the beginning of truly ubiquitous computing. As the once-separate worlds of computing and wireless communications collide, a new class of information appliances will emerge. Where once they are used regularly, the post-modern equivalent might not be explicit after all. Rather, data sensing and information processing capabilities will fragment and disappear into everyday objects and the living environment. At present, there are sharp dislocations in information processing capability—the computer on a desk, the PDA/laptop, the mobile phone, smart cards, and smart appliances. However, Speckled Computing, the sensing and processing of information, will be highly diffused. The person, the artifacts, and the surrounding space become computational resources and interfaces to those resources. Surfaces, walls, floors, ceilings, articles, and clothes will be invested with a computational activity for rich interactions with the computational resources.

The information appliance is the natural outcome in the evolution of information processing. That is why they were foreseen a long time ago. Digital computers started out as expensive mainframes accessible to a few. The next step was the personal computer that individuals could own, and it was incorporated into everyday human activities. Thus, it was essential to have as much functionality in the personal computer as possible. Information technology is making feasible small and inexpensive devices that are smart. This helps to push intelligence closer to the people, the ultimate customers of information technology that accept some of the hidden cultural attributes of the entire community.

In a smart environment, the interaction endpoints simply could not be cognitively or physically visible. In essence, the user may have no idea that they are engaging in a computer-mediated

communication. A smart environment is a composite space made from many individual objects. These objects are either fixed or mobile. The term *invisible* means that a technology has become so natural (common) and so comfortable that we use it all the time without ever thinking of it as a technology or a number of linked technologies. These invisible technologies are taken for granted. Since they are no longer technological, we can afford to think of them as customary, as the day-to-day workings of our world. As it continues to become more acceptable and as people come into the any-information system more proficient with these new tools, computer technologies will become increasingly invisible.

The exact example of the ubiquitous e-technologies environment is under way through the ubiquitous city in South Korea. New Songdo City (U-city), being built on a manmade island, will feature pervasive computer technology throughout, driven by RFID tags and CDMA wireless communication. Although many Western observers would find the lack of privacy disquieting, Asian countries are more interested in the technological potential of such environments. U-life will become its own brand, its own lifestyle. Residents will enjoy full videoconferencing calls between neighbors, video on demand, and wireless access to their digital content and property from anywhere in Songdo. At the same time, privacy is also encountered: all information services will be anonymous, and they will not be linked to user identity.

INVISIBLE E-TECHNOLOGIES' INTERACTION WITH INVISIBLE E-CULTURE

Our relationship with the manmade world is dominated by the paradigm of the device. This paradigm creates an illusory separation between the technological means (the machinery, the medium) and the technological ends (the commodity,

the message). Technological progress generally is devoted to increasing the availability of technological goods, to make them everywhere available instantly without risk or hassle. At the same time, we want the machinery to become invisible. For various reasons, we repress ourselves from seeing the machinery and our dependence upon it. Our conscious awareness focuses on the message, and we refuse to acknowledge the medium (Pribram, 1971). Our perception of the world and our place in it are inextricably mediated through technology and the device paradigm. Our discovery of ourselves (identity through self-determination) is technical and complicated.

We are entering a new era of computing, often referred to as ubiquitous or pervasive computing. Ubiquitous computing consists of information appliances, specialized and easy-to-use devices that avoid the complexity of the computer. The future belongs to information appliances. When technology changes rapidly, greater ease of use serves to attract more users and developers, creating new frustrations. The most we can do is ameliorate the spread of the information appliance products and services. To do this, it appears necessary to recognize that flexibility and ease of use are in an unavoidable conflict and that the optimal balance between those two factors differs among users. Therefore, systems should be designed to have degrees of flexibility that can be customized for different people. Information appliances will be popular, since they will provide many new services for which the desktop computer is ill-suited and will do so in user-friendly ways. However, they will introduce their own complexity, and the level of frustration with information technology will not decrease. This is a result of the conflict between usability and flexibility. The information appliance market will be anything but mature for a long time to come. The emphasis in information processing has been and is likely to continue to be on development of novel applications. When the available information is stored on computers, it is important

for information management applications to be able to model users' interpretations of their data and to capture the possibly different meanings, semantics links, and relationships with which users associate the information units available. This is in correlation to one's personal culture. For this purpose, various Personal Information Management tools are being developed to assist the user with navigation/browsing over various forms of personal digital data. As an example of capturing, organization, and archiving new media content, the MyLifeBits project is very explanatory. MyLifeBits has the aim to store in digital form everything related to the activities of an individual, providing full-text search, text and media annotations, and hyperlinks to personal data (Gemmell, Aris, & Lueder, 2005).

Information technology should mature to the humane technology of appliances in which the technology of the computer disappears behind the scenes into task-specific devices that maintain all the power without the difficulties. This could be explained by the technology of radio. Thus, computers should evolve the way radio receivers did (Norman, 1998). However, there is a problem of motivation, beliefs, knowledge, and frustration dealing with the information technology. This is considering culture (dominantly invisible culture). The problem is that with information appliances and by invisible technologies, we are confronted with the services that must be well-understood and stable. We will not see this scenario with information appliances, not for a long time. In a world with a huge potential in services, content, and navigation, we cannot know how people will want to use information appliances.

Careful design that is focused on human factors and incorporates powerful processors and software can provide information appliances that are a delight to use. However, once the number of devices to be connected increases and wireless communication with WiFi networks expands, the difficulties will increase. Building complicated systems that work is hard. Building ones

that work and are user-friendly is much harder. Further, it is necessary to balance the demand for user friendliness with the demand for more features. A tradeoff between flexibility and ease of use is unavoidable. The problem is that we should not be thinking just of individual information appliances. We have to be concerned with the whole system, which is likely to be complex. The problem is also how to balance flexibility and ease of use in a way that can be customized for people with different needs. This problem is especially focused on multimedia home systems. The home information appliance environment is likely to be more complicated than the office environment today. In addition, many users will be less knowledgeable about information technology than the typical office worker will (Ronfeldt, 1992). Therefore, it will be essential to outsource the setup and maintenance of home computing and electronics to experts. This notion opens new ways for information technology professionals that are accessing information appliances environment (this environment asks for new interface design, navigation methods, and computational power over networked appliances). Hence, there is convergence of culture and technology in use, be they visible or invisible.

Positive E-Technologies

Rheingold (2000) argues that the technology that makes virtual communities possible has the potential to empower ordinary citizens at a relatively small cost. E-technology potentially can provide citizens and professionals advantage and power, which is intellectual, social, commercial, and political. At the same time, civil and informed people must understand the advantages that e-technology provides. They must learn to use it wisely and constructively, as it cannot fulfill its positive potential by itself. Thus, the positive e-technologies should be developed as reduction technologies that make target behaviors easier by

reducing a complex activity to a few simple steps. One of the most explicit theories that attempts to describe our natural inclination to do a cost/benefit assessment is expectancy theory. This theory posits that behavior results from expectations about what alternatives will maximize pleasure and minimize pain. E-technologies also should be self-monitoring technologies to perform tedious calculations or measurements, helping people achieve goals or outcomes. Ideally, these technologies work in real time, giving users immediate feedback on a performance or status. When people can take immediate action on a persuasive message, psychologists have found the message more persuasive than when presented at other times. The recent effort on real-time speech translation is an obvious example of these notions. Researchers from the International Center for Advanced Communication Technologies (interACT), a joint venture of Carnegie Mellon and the University of Karlsruhe, have developed a wearable system that allows real-time speech translation. The system consists of sensors that detect mouth muscle movements, translates that to a spoken language, and then retranslates that into other languages. It will make communication and cultural learning more likely, since people using this technology will be empowered to come together when they otherwise would not interact.

Culture is omnipresent in all technological advancements over the course of history, whether it is the result of intrinsic societal dynamics or the extrinsic factors of the environment. As history clearly documents, whenever technology changes, some pressing force of culture has had an effect on it. Moreover, there is a sort of invisible complimentary system between culture and technology; that is, whenever technology changes, the culture will adapt its way of life to fit the technology. For example, with the invention of the technology necessary for agriculture, cultures worldwide changed their hunting and gathering way of life in order to use the new technology

and expand its horizons. This would be expected with the information technology, too. In essence, culture indeed influences human technology, but technology also simultaneously molds the way in which cultures function.

PERSUASIVE AGENDA

Like human persuaders, persuasive interactive technologies can bring about positive changes in many domains, including health, business, safety, and education (Dillard & Pfau, 2002). With such ends in mind, the new area of information technology development is created under the term *captology*. Captology focuses on the design, research, and analysis of interactive computing products created for the purpose of changing people's attitudes and behaviors. The fact that people respond socially to computer products has significant implications for persuasion. It opens the door for computers to apply a host of persuasion dynamics that are described collectively as social influence. These dynamics include normative influence and social comparison as well as less familiar dynamics such as group polarization and social facilitation.

Just as the term *software* shifts the emphasis from media/text to the user, the term *information behavior* also can help us to think about the dimensions of cultural communication, which previously went unnoticed. These dimensions always have been there, but in an information society, they have rapidly become prominent in our lives and, thus, intellectually visible. Today, our daily life consists of information activities in the most literal way: checking e-mail and responding to e-mail, checking phone messages, organizing computer files, using search engines, and so forth. In the simplest way, the particular way people organize their computer files, use search engines, or interact on the phone can be thought of as information behavior. Of course,

according to a cognitive science paradigm, human perception and cognition, in general, can be thought of as information processing. While every act of visual perception or memory recall can be understood in information processing terms, today there is much more to see, filter, recall, sort through, prioritize, and plan. In other words, in our society, daily life and work largely revolve around new types of behavior activities that involve seeking, extracting, processing, and communicating large amounts of information. Information behaviors of an individual form an essential part of individual identity. They are particular tactics adopted by an individual or a group to survive in information society. Just as our nervous system has evolved to filter information existing in the environment in a particular way that is suitable for information capacity of a human brain, so we evolve particular information behaviors in order to survive and prosper in an information society. In today's world of information, people suddenly are shifting their attention to the Web for their computing needs.

Levy (1998) contends that communication in the virtual world can cultivate collective intelligence, which can encourage the development of intelligent communities. He states that sharing of information, knowledge, and expertise in e-communities can promote a kind of dynamic, collective intelligence, which can affect all spheres of our lives. He contends that the virtual world can foster positive connections, cooperation, bonds, and civil interactions. In e-groups or e-communities, which are flexible, democratic, reciprocal, respectful, and civil, this collective intelligence can be enhanced continually. Researchers in science, education, business, and industry are pooling their collective intelligence, knowledge, and data in collaborative memories. These are virtual centers in which people in different locations work together in real time, as if they were all in the same place. Science, education, commerce, and industry have become increasingly global.

Collaboration, which is efficient, maximizing, and timesaving among distance researchers in these fields, has become more critical.

This new e-culture paradigm within the Web users' community opens the ways for Web 2.0 e-technologies platform comprising the set of principles and practices based dominantly on the user behavior and cultural values of collaboration. Most users find that Web 2.0 sites are extremely useful, because they are always available (whenever they need it and anywhere they go) with their information. Web 2.0 is the network as platform, spanning all connected devices. Web 2.0 applications are those that make the most of the intrinsic advantages of that platform:

- Delivering software as a continually updated service that gets better, the more people use it.
- Consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others.
- Creating network effects through architecture of participation.
- Going beyond the page metaphor of Web 1.0 to deliver rich user experiences.

One of the key aspects of Web 2.0 is that it connects people so that they can participate effortlessly in fluid conversations and dynamic information sharing. At the same time, information appliances and computing devices are giving people permappresence on the Web. Before now, the user consciously had to go to cyberspace by sitting at a desktop computer and looking at it through a display. Web 2.0 applications will become invisible as they become more popular, and there also would not be such a phrase as "going on the Web." Moreover, if the network is omnipresent and invisible, we do not need the term *cyberspace* anymore. Web 2.0 is also more human and a social one labeled with social interactions like

conversation, sharing, collaboration, publishing, which could be supported by the corresponding processes (blogging, tagging, sharing, publishing, networking) and content formats (blogs, wikis, podcasts, folksonomies, social software). In addition, Johnson and Kaye (2004) stated that the Web would become a trustworthy place and the users would take it with much more reliance and credibility.

Computers Influence our Thoughts and Actions

Although culture is mostly learned, it is bound by necessity to a particular setting or context of its behavioral and material articulation. Culture is both conservative and adaptable. Culture is articulated symbolically and has the function of symbolically integrating the diverse moments and spaces of culture into a coherent sense of order. This format is emerging throughout the social field as a format of technology (the point-to-point Internet, file sharing, grid computing, blogs), and as a third mode of production producing hardware, software (often called open sources software) and intellectual and cultural resources (wetware) that are of great value to humanity (GNU/Linux, Wikipedia).

Cognitive scientist Clark (2003) believes that we are liberating our minds, thanks to our penchant for inventing tools that extend our abilities to think and communicate, starting with the basics of pen and paper and moving on to ever more sophisticated forms of computers and e-technologies. He declares that we are, in fact, human-technology symbionts, or natural-born cyborgs, always seeking ways to enhance our biological mental capacities through technology. The persuasive e-technologies are in front of us to solve the problem of difficulties in utilization of the computer, which complexity is fundamental to its nature. We have to start over again to develop information appliances that fit people's

needs and lives (Norman, 1998). In order to do this, companies must change the way they develop information system products. They need to start with an understanding of people: user needs first, technology last. Companies need a human-centered development process, even if it means reorganizing the entire company.

People are more readily persuaded by computing technology products that are similar to them in some way (Fogg, 2003). Although people respond socially to computer products that convey social cues, in order to be effective in persuasion, hardware and software designers must understand the appropriate use of those cues. If they succeed, they make a more powerful positive impact. If they fail, they make users irritated or angry. With that in mind, when is it appropriate to make the social quality of the product more explicit? In general, it is appropriate to enhance social cues in leisure, entertainment, and educational products, especially with smart mobile devices (Rheingold, 2002). Users of such applications are more likely to indulge, accept, and perhaps even embrace an explicit cyber social actor. When perceived as social actors, computer products can leverage these principles of social influence to motivate and persuade.

DISCUSSION ON NEW FORMS OF CULTURAL RESPONSIBILITY OF IT PROFESSIONALS

Culture and ethics are a very important part of our everyday life in information society. The invention of new e-technologies tends to bring many different dilemmas into the lives of the creators and the people who use them. Some technologies have been created without choice, and we must make sure we fully understand how to use them properly. The introduction and use of new technologies require a check against the moral structure of the society and the ethical beliefs of

the individuals that will feel the effects of such an addition to their lives (Postman, 1992). This belief should be the foundation of innovation so that members of the society can have a strong, viable, and ethical solution to satisfy their wants and needs and to extend their capabilities. Ubiquitous computing and smart environments will be characterized by massive numbers of almost invisible miniature sensing devices that potentially can observe and store information about our most personal and intimate experiences. The new forms of direct access to information and knowledge create new forms of e-culture. It concerns not only users but the community of information professionals as well.

Technology can be a powerful tool for change, especially when used responsibly. Responsible IT management should be an important part of any socially responsible enterprise's strategies, policies, and practices. Users should have information technology choices that can and should reflect organizational, community, and national values and social responsibility. These notions are considering IT professionals' activities; they should create applications that guarantee accessibility. Accessibility to information via the information-communications systems should not be inhibited by disability or resource limitations, and the design solutions should be for the user experience. Usability of information technology solutions requires attention to the needs of the user (information consumer). The information-communications systems create new psychological demands from human. They ask us to bring a greater capacity for innovation, self-management, and personal responsibility. They also demand social responsibility of information technology professionals. Information technology is the wave of today and the future. Society must adapt to it by creating responsible rules, norms, ethics, and knowledge workers that will enhance its rapid growth.

Many firms acting on the global scene via information-communications systems are committed to incorporating socially responsible projects into their policies and activities. Corporate social responsibility is a development that is here to stay for the long term as a part of corporate policy influencing the company's involvement in the well being or development of local as well as global communities (Furnham & Gunter, 1993). Information technology firms are in a unique position to distribute their high-tech expertise and cultural values in development projects. The new information society environment poses a new relation between values promoted by the new digital civilization and the traditional moral and cultural values created by the major world civilizations. Computer technology and ethical egoism are the products of secular research within a free market capitalist society. The majority of non-Western societies and some Western, as well, follow ethical rules created within traditional culture. These rules are centered on guiding the individual in properly fulfilling his or her role within the society, which means the superiority of the society over the individual. The changes that information technology is bringing to people's lives are revolutionary, and one of the features of every revolution is that it is at the same time both a process of creation and of destruction. The revolutionary process itself is a very rapid one, which means that there is little or no time for a methodical and deep reflection on it while the process is actually in progress. These points ask for more attention from information technology professionals to cope with the culture exposed through the visible objects. They also should implement invisible culture elements when designing new information services. One possible way of minimizing the harm could be through incorporating the experiences of the process of intercultural dialogue into the process of creating a global e-culture of the information society.
