Suggestions for Teaching with *Principles of Electric Circuits*

Selected Course Emphasis and Flexibility of the Text   This textbook is designed primarily for use in a two-term course sequence in which dc topics (Chapters 1 through 10) are covered in the first term and ac topics (Chapters 11 through 21) are covered in the second term. A one-term course covering dc and ac topics is possible but would require very selective and abbreviated coverage of many topics.

If time limitations or course emphasis restrict the topics that can be covered, as is usually the case, there are several options for selective coverage. The following suggestions for light treatment or omission do not necessarily imply that a certain topic is less important than others but that, in the context of a specific program, the topic may not require the emphasis that the more fundamental topics do. Because course emphasis, level, and available time vary from one program to another, the omission or abbreviated treatment of selected topics must be made on an individual basis. Therefore, the following suggestions are intended only as a general guide.

1. Chapters that may be considered for omission or selective coverage:

   ◆ Chapter 8, Circuit Theorems and Conversions

   ◆ Chapter 9, Branch, Loop, and Node Analyses

   ◆ Chapter 10, Magnetism and Electromagnetism

   ◆ Chapter 18, Passive Filters

   ◆ Chapter 19, Circuit Theorems in AC Analysis

   ◆ Chapter 20, Time Response of Reactive Circuits

   ◆ Chapter 21, Three-Phase Systems in Power Applications

2. *Application Activity* features and troubleshooting sections can be omitted without affecting other material.

3. Other specific topics may be omitted or covered lightly on a section-by-section basis at the discretion of the instructor.

The order in which certain topics appear in the text can be altered at the instructor's discretion. For example, the topics of capacitors and inductors (Chapters 12 and 13) can be covered at the end of the dc course in the first term by delaying coverage of the ac topics in Sections 12–6, 12–7, 13–5, and 13–6 until the ac course in the second term. Another possibility is to cover Chapters 12 and 13 in the second term but cover Chapter 15 (*RC* Circuits) immediately after Chapter 12 (Capacitors) and cover Chapter 16 (*RL* Circuits) immediately after Chapter 13 (Inductors).

Application Activity   These features are useful for motivation and for introducing applications of basic concepts and components. Suggestions for using these sections are:

   ◆ As an integral part of the chapter to illustrate how the concepts and components can be applied in a practical situation. The activities can be assigned for homework.

   ◆ As extra credit assignments.

   ◆ As in-class activities to promote discussion and interaction and to help students understand why they need to know the material.

Coverage of Reactive Circuits   Chapters 15, 16, and 17 have been designed to provide two approaches to teaching these topics on reactive circuits.

The first option is to cover the topics on the basis of components. That is, first cover all of Chapter 15 (*RC* Circuits), then all of Chapter 16 (*RL* Circuits), and, finally, all of Chapter 17 (*RLC* Circuits and Resonance).

The second option is to cover the topics on the basis of circuit type. That is, first cover all topics related to series reactive circuits, then all topics related to parallel reactive circuits, and finally, all topics related to series-parallel reactive circuits. To facilitate this second approach, each of the chapters has been divided into the following parts: *Part 1: Series Circuits, Part 2: Parallel Circuits, Part 3: Series-Parallel Circuits,* and *Part 4: Special Topics.* So, for series reactive circuits, cover Part 1 of all three chapters in sequence. For parallel reactive circuits, cover Part 2 of all three chapters in sequence. For series-parallel reactive circuits, cover Part 3 of all three chapters in sequence. Finally, cover Part 4 of all three chapters.

To the Student

Any career training requires effort, and the electrical/electronics field is no exception. The best way to learn new material is by reading, thinking, and doing. This text is designed to help you along the way.

Read each section of the text carefully and think about what you have read. Sometimes you may need to read the section more than once. Work through each example problem step by step before you try the related problem that goes with the example. After each section, answer the checkup questions. Answers to the related problems and the section checkup questions are at the end of the chapter.

Review the chapter summary, the key term definitions, and the formula list. Take the true/false quiz, the multiple choice self-test, and the Circuit Dynamics Quiz. Check your answers against those at the end of the chapter. Finally, work the problems and verify your answers to the odd-numbered problems with those provided at the end of the book.

The importance of obtaining a thorough understanding of the basic principles contained in this text cannot be overemphasized. Most employers prefer to hire people who have both a thorough grounding in the basics and the ability and eagerness to grasp new concepts and techniques. If you have a good training in the basics, an employer will train you in the specifics of the job to which you are assigned.

Careers in Electronics

The fields of electricity and electronics are very diverse, and career opportunities are available in many areas. There are many types of job classifications for which a person with training in electricity and electronics technology may qualify. A few of the most common job functions are discussed briefly in the following paragraphs.

Service Shop Technician Technical personnel in this category are involved in the repair or adjustment of both commercial and consumer electronic equipment that is returned to the dealer or manufacturer for service. Specific areas include consumer electronics and computers. This area also offers opportunities for self-employment.

Industrial Manufacturing Technician Manufacturing personnel are involved in the testing of electrical and electronic products at the assembly-line level or in the maintenance and troubleshooting of electrical, electronic, and electromechanical systems used in the testing and manufacturing of products. Virtually every type of manufacturing plant, regardless of its product, uses automated equipment that is electronically controlled.

Laboratory Technician These technicians are involved in breadboarding, prototyping, and testing new or modified electronic systems in research and development laboratories. They generally work closely with engineers during the development phase of a product.

Field Service Technician Field service personnel service and repair electronic equipment—for example, computer systems, radar installations, automatic banking equipment, and security systems—at the user's location.

Engineering Assistant/Associate Engineer Personnel in this category work closely with engineers in the implementation of a concept and in the basic design and development

of electrical and electronic systems. Engineering assistants are frequently involved in a project from its initial design through the early manufacturing stages.

Technical Writer   Technical writers compile technical information and then use the information to write and produce manuals and audiovisual materials. A broad knowledge of a particular system and the ability to clearly explain its principles and operation are essential.

Technical Sales   Technically trained people are in demand as sales representatives for high-technology products. The ability both to understand technical concepts and to communicate the technical aspects of a product to a potential customer is very valuable. In this area, as in technical writing, competency in expressing yourself orally and in writing is essential. Actually, being able to communicate well is very important in any technical job category because you must be able to record data clearly and explain procedures, conclusions, and actions taken so that others can readily understand what you are doing.

Milestones in Electronics

Let's briefly look at some of the important developments that led to the electronics technology we have today. The names of many of the early pioneers in electricity and electromagnetics still live on in terms of familiar units and quantities. Names such as Ohm, Ampere, Volta, Farad, Henry, Coulomb, Oersted, and Hertz are some of the better known examples. More widely known names such as Franklin and Edison are also significant in the history of electricity and electronics because of their tremendous contributions. Short biographies of some of these pioneers are located throughout the text in History Notes.

The Beginning of Electronics   Early experiments with electronics involved electric currents in vacuum tubes. Heinrich Geissler (1814–1879) removed most of the air from a glass tube and found that the tube glowed when there was current through it. Later, Sir William Crookes (1832–1919) found the current in vacuum tubes seemed to consist of particles. Thomas Edison (1847–1931) experimented with carbon filament bulbs with plates and discovered that there was a current from the hot filament to a positively charged plate. He patented the idea but never used it.

Other early experimenters measured the properties of the particles that flowed in vacuum tubes. Sir Joseph Thompson (1856–1940) measured properties of these particles, later called *electrons*.

Although wireless telegraphic communication dates back to 1844, electronics is basically a 20th century concept that began with the invention of the vacuum tube amplifier. An early vacuum tube that allowed current in only one direction was constructed by John A. Fleming in 1904. Called the Fleming valve, it was the forerunner of vacuum tube diodes. In 1907, Lee deForest added a grid to the vacuum tube. The new device, called the audiotron, could amplify a weak signal. By adding the control element, deForest ushered in the electronics revolution. It was with an improved version of his device that made transcontinental telephone service and radios possible. In 1912, a radio amateur in San Jose, California, was regularly broadcasting music!

In 1921, the secretary of commerce, Herbert Hoover, issued the first license to a broadcast radio station; within two years over 600 licenses were issued. By the end of the 1920s radios were in many homes. A new type of radio, the superheterodyne radio, invented by Edwin Armstrong, solved problems with high-frequency communication. In 1923, Vladimir Zworykin, an American researcher, invented the first television picture tube, and in 1927 Philo T. Farnsworth applied for a patent for a complete television system.

The 1930s saw many developments in radio, including metal tubes, automatic gain control, "midget sets," directional antennas, and more. Also started in this decade was the development of the first electronic computers. Modern computers trace their origins to the work of John Atanasoff at Iowa State University. Beginning in 1937, he envisioned a binary machine that could do complex mathematical work. By 1939, he and graduate student Clifford Berry had constructed a binary machine called ABC, (for Atanasoff-Berry Computer)

that used vacuum tubes for logic and condensers (capacitors) for memory. In 1939, the magnetron, a microwave oscillator, was invented in Britain by Henry Boot and John Randall. In the same year, the klystron microwave tube was invented in America by Russell and Sigurd Varian.

During World War II, electronics developed rapidly. Radar and very high-frequency communication were made possible by the magnetron and klystron. Cathode ray tubes were improved for use in radar. Computer work continued during the war. By 1946, John von Neumann had developed the first stored program computer, the Eniac, at the University of Pennsylvania. The decade ended with one of the most important inventions ever, the transistor.

Solid-State Electronics The crystal detectors used in early radios were the forerunners of modern solid-state devices. However, the era of solid-state electronics began with the invention of the transistor in 1947 at Bell Labs. The inventors were Walter Brattain, John Bardeen, and William Shockley. PC (printed circuit) boards were introduced in 1947, the year the transistor was invented. Commercial manufacturing of transistors began in Allentown, Pennsylvania, in 1951.

The most important invention of the 1950s was the integrated circuit. On September 12, 1958, Jack Kilby, at Texas Instruments, made the first integrated circuit. This invention literally created the modern computer age and brought about sweeping changes in medicine, communication, manufacturing, and the entertainment industry. Many billions of "chips"—as integrated circuits came to be called—have since been manufactured.

The 1960s saw the space race begin and spurred work on miniaturization and computers. The space race was the driving force behind the rapid changes in electronics that followed. The first successful "op-amp" was designed by Bob Widlar at Fairchild Semiconductor in 1965. Called the µA709, it was very successful but suffered from "latch-up" and other problems. Later, the most popular op-amp ever, the 741, was taking shape at Fairchild. This op-amp became the industry standard and influenced design of op-amps for years to come.

By 1971, a new company that had been formed by a group from Fairchild introduced the first microprocessor. The company was Intel and the product was the 4004 chip, which had the same processing power as the Eniac computer. Later in the same year, Intel announced the first 8-bit processor, the 8008. In 1975, the first personal computer was introduced by Altair, and Popular Science magazine featured it on the cover of the January, 1975, issue. The 1970s also saw the introduction of the pocket calculator and new developments in optical integrated circuits.

By the 1980s, half of all U.S. homes were using cable hookups instead of television antennas. The reliability, speed, and miniaturization of electronics continued throughout the 1980s, including automated testing and calibrating of PC boards. The computer became a part of instrumentation and the virtual instrument was created. Computers became a standard tool on the workbench.

The 1990s saw a widespread application of the Internet. In 1993, there were 130 websites, and now there are millions. Companies scrambled to establish a home page and many of the early developments of radio broadcasting had parallels with the Internet. In 1995, the FCC allocated spectrum space for a new service called Digital Audio Radio Service. Digital television standards were adopted in 1996 by the FCC for the nation's next generation of broadcast television.

The 21st century dawned in January 2001. One of the major technology stories has been the continuous and explosive growth of the Internet. Wireless broadband access has helped fuel the growth tremendously. The processing speed of computers is increasing at a steady rate and data storage media capacity is increasing at an amazing pace. Carbon nanotubes are seen to be the next step forward for computer chips, eventually replacing transistor technology.

In recent years, the search for alternative sources of energy has led to intensive research and development in the areas of batteries, solar cells, fuel cells, wind energy, and others.

INTRODUCTION

You must be familiar with the units used in electronics and know how to express electrical quantities in various ways using metric prefixes. Scientific notation and engineering notation are indispensable tools whether you use a computer, a calculator, or do computations the old-fashioned way.

⚡ SAFETY NOTE

When you work with electricity, you must always consider safety first. Safety notes throughout the book remind you of the importance of safety and provide tips for a safe workplace. Basic safety precautions are introduced in Chapter 2.

1–1 UNITS OF MEASUREMENT

In the 19th century, the principal weight and measurement units dealt with commerce. As technology advanced, scientists and engineers saw the need for international standard measurement units. In 1875, at a conference called by the French, representatives from eighteen nations signed a treaty that established international standards. Today, all engineering and scientific work use an improved international system of units, Le Système International d'Unités, abbreviated **SI***.

After completing this section, you should be able to

◆ **Discuss the SI standard**

   ◆ Specify the fundamental SI units

   ◆ Specify the supplementary units

   ◆ Explain what derived units are

Fundamental and Derived Units

The SI system is based on seven fundamental units (sometimes called *base units*) and two supplementary units. All measurements can be expressed as some combination of fundamental and supplementary units. Table 1–1 lists the fundamental units, and Table 1–2 lists the supplementary units.

The fundamental electrical unit, the ampere, is the unit for electrical current. Current is abbreviated with the letter I (for intensity) and uses the symbol A (for ampere). The ampere is unique in that it uses the fundamental unit of time (t) in its definition (second). All other electrical and magnetic units (such as voltage, power, and magnetic flux) use various combinations of fundamental units in their definitions and are called *derived units*.

For example, the derived unit of voltage, which is the volt (V), is defined in terms of fundamental units as $m^2 \cdot kg \cdot s^{-3} \cdot A^{-1}$. As you can see, this combination of fundamental units is very cumbersome and impractical. Therefore, volt is used as the derived unit.

▶ **TABLE 1–2**

QUANTITY	UNIT	SYMBOL

Letter symbols are used to represent both quantities and their units. One symbol is used to represent the name of the quantity, and another symbol is used to represent the unit of measurement of that quantity. For example, italic *P* stands for *power,* and nonitalic W stands for *watt,* which is the unit of power. Another example is voltage, where the same letter stands for both the quantity and its unit. Italic *V* represents voltage and nonitalic V represents *volt,* which is the unit of voltage. As a rule, italic letters stand for the quantity and nonitalic (roman) letters represent the unit of that quantity.

Table 1–3 lists the most important electrical quantities, along with their derived SI units and symbols. Table 1–4 lists magnetic quantities, along with their derived SI units and symbols.

◄ **TABLE 1–4**

Magnetic quantities and derived units with SI symbols.

In addition to the common electrical units shown in Table 1–3, the SI system has many other units that are defined in terms of certain fundamental units. In 1954, by international agreement, *meter, kilogram, second, ampere, degree Kelvin,* and *candela* were adopted as the basic SI units (*degree Kelvin* was later changed to just *kelvin*). These units form the basis of the mks (for meter-kilogram-second) units that are used for derived quantities and have become the preferred units for nearly all scientific and engineering work. An older metric system, called the cgs system, was based on the centimeter, gram, and second as fundamental units. There are still a number of units in common use based on the cgs system; for example, the gauss is a magnetic flux unit in the cgs system and is still in common usage. In keeping with preferred practice, this text uses mks units, except when otherwise noted.

1. How does a fundamental unit differ from a derived unit?

2. What is the fundamental electrical unit?

3. What does *SI* stand for?

4. Without referring to Table 1–3, list as many electrical quantities as possible, including their symbols, units, and unit symbols.

5. Without referring to Table 1–4, list as many magnetic quantities as possible, including their symbols, units, and unit symbols.

1–2   SCIENTIFIC NOTATION

In electrical and electronics fields, both very small and very large quantities are commonly used. For example, it is common to have electrical current values of only a few thousandths or even a few millionths of an ampere and to have resistance values ranging up to several thousand or several million ohms.

After completing this section, you should be able to

◆ **Use scientific notation (powers of ten) to represent quantities**

    ◆ Express any number using a power of ten

    ◆ Perform calculations with powers of ten

Scientific notation provides a convenient method to represent large and small numbers and to perform calculations involving such numbers. In scientific notation, a quantity is expressed as a product of a number between 1 and 10 and a power of ten. For example, the quantity 150,000 is expressed in scientific notation as 1.5×10^5, and the quantity 0.00022 is expressed as 2.2×10^{-4}.

Powers of Ten

Table 1–5 lists some powers of ten, both positive and negative, and the corresponding decimal numbers. The **power of ten** is expressed as an exponent of the base 10 in each case (10^x). An **exponent** is a number to which a base number is raised. It indicates the number

▼ TABLE 1–5

Some positive and negative powers of ten.

$10^6 = 1,000,000$	$10^{-6} = 0.000001$
$10^5 = 100,000$	$10^{-5} = 0.00001$
$10^4 = 10,000$	$10^{-4} = 0.0001$
$10^3 = 1,000$	$10^{-3} = 0.001$

of places that the decimal point is moved to the right or left to produce the decimal number. For a positive power of ten, move the decimal point to the right to get the equivalent decimal number. For example, for an exponent of 4,

$$10^4 = 1 \times 10^4 = 1.0000. = 10,000$$

For a negative the power of ten, move the decimal point to the left to get the equivalent decimal number. For example, for an exponent of −4,

$$10^{-4} = 1 \times 10^{-4} = .0001. = 0.0001$$

EXAMPLE 1–1

Express each number in scientific notation.

(a) 200   (b) 5000   (c) 85,000   (d) 3,000,000

Solution   In each case, move the decimal point an appropriate number of places to the left to determine the positive power of ten. Notice that the result is always a number between 1 and 10 times a power of ten.

(a) $200 = 2 \times 10^2$ (b) $5000 = 5 \times 10^3$

(c) $85,000 = 8.5 \times 10^4$ (d) $3,000,000 = 3 \times 10^6$

Calculations with Powers of Ten

The advantage of scientific notation is in addition, subtraction, multiplication, and division of very small or very large numbers.

Addition   The steps for adding numbers in powers of ten are as follows:

1. Express the numbers to be added in the same power of ten.

2. Add the numbers without their powers of ten to get the sum.

3. Bring down the common power of ten, which is the power of ten of the sum.

EXAMPLE 1–4

Add 2×10^6 and 5×10^7 and express the result in scientific notation.

Solution

1. Express both numbers in the same power of ten: $(2 \times 10^6) + (50 \times 10^6)$.

2. Add $2 + 50 = 52$.

3. Bring down the common power of ten (10^6); the sum is $52 \times 10^6 = \mathbf{5.2 \times 10^7}$.

Related Problem   Add 3.1×10^3 and 5.5×10^4.

Subtraction   The steps for subtracting numbers in powers of ten are as follows:

1. Express the numbers to be subtracted in the same power of ten.

2. Subtract the numbers without their powers of ten to get the difference.

3. Bring down the common power of ten, which is the power of ten of the difference.

EXAMPLE 1–5

Subtract 2.5×10^{-12} from 7.5×10^{-11} and express the result in scientific notation.

Solution

1. Express each number in the same power of ten: $(7.5 \times 10^{-11}) - (0.25 \times 10^{-11})$.

2. Subtract $7.5 - 0.25 = 7.25$.

3. Bring down the common power of ten (10^{-11}); the difference is $\mathbf{7.25 \times 10^{-11}}$.

Related Problem   Subtract 3.5×10^{-6} from 2.2×10^{-5}.

Multiplication   The steps for multiplying numbers in powers of ten are as follows:

1. Multiply the numbers directly without their powers of ten.

2. Add the powers of ten algebraically (the exponents do not have to be the same).

EXAMPLE 1–6

Multiply 5×10^{12} and 3×10^{-6} and express the result in scientific notation.

Solution

Multiply the numbers, and algebraically add the powers.

$$(5 \times 10^{12})(3 \times 10^{-6}) = (5)(3) \times 10^{12+(-6)} = 15 \times 10^6 = \mathbf{1.5 \times 10^7}$$

Related Problem   Multiply 3.2×10^6 and 1.5×10^{-3}.

Division The steps for dividing numbers in powers of ten are as follows:

1. Divide the numbers directly without their powers of ten.
2. Subtract the power of ten in the denominator from the power of ten in the numerator (the powers do not have to be the same).

EXAMPLE 1–7

Divide 5.0×10^8 by 2.5×10^3 and express the result in scientific notation.

Solution Write the division problem with a numerator and denominator as

$$\frac{5.0 \times 10^8}{2.5 \times 10^3}$$

Divide the numbers and subtract the powers of ten (3 from 8).

$$\frac{5.0 \times 10^8}{2.5 \times 10^3} = 2 \times 10^{8-3} = \mathbf{2 \times 10^5}$$

1–3 ENGINEERING NOTATION AND METRIC PREFIXES

Engineering notation, a specialized form of scientific notation, is used widely in technical fields to represent large and small quantities. In electronics, engineering notation is used to represent values of voltage, current, power, resistance, capacitance, inductance, and time, to name a few. Metric prefixes are used in conjunction with engineering notation as a "short hand" for the certain powers of ten that are multiples of three.

After completing this section, you should be able to

◆ **Use engineering notation and metric prefixes to represent large and small quantities**

  ◆ List the metric prefixes

  ◆ Change a power of ten in engineering notation to a metric prefix

  ◆ Use metric prefixes to express electrical quantities

  ◆ Convert one metric prefix to another

Engineering Notation

Engineering notation is similar to scientific notation. However, in **engineering notation** a number can have from one to three digits to the left of the decimal point and the power-of-ten exponent must be a multiple of three. For example, the number 33,000 expressed in engineering notation is 33×10^3. In scientific notation, it is expressed as 3.3×10^4. As another example, the number 0.045 expressed in engineering notation is 45×10^{-3}. In scientific notation, it is expressed as 4.5×10^{-2}.

EXAMPLE 1–8

Express the following numbers in engineering notation:

(a) 82,000   (b) 243,000   (c) 1,956,000

Solution In engineering notation,

(a) 82,000 is expressed as **82 × 10³**.

(b) 243,000 is expressed as **243 × 10³**.

(c) 1,956,000 is expressed as **1.956 × 10⁶**.

(a) 0.0022   (b) 0.000000047   (c) 0.00033

Solution In engineering notation,

(a) 0.0022 is expressed as **2.2 × 10⁻³**.

(b) 0.000000047 is expressed as **47 × 10⁻⁹**.

(c) 0.00033 is expressed as **330 × 10⁻⁶**.

Related Problem Express 0.0000000000056 in engineering notation.

Metric Prefixes

In engineering notation **metric prefixes** represent each of the most commonly used powers of ten. These metric prefixes are listed in Table 1–6 with their symbols and corresponding powers of ten.

Metric prefixes are used only with numbers that have a unit of measure, such as volts, amperes, and ohms, and precede the unit symbol. For example, 0.025 amperes can be expressed in engineering notation as 25×10^{-3} A. This quantity expressed using a metric prefix is 25 mA, which is read 25 milliamps. Note that the metric prefix *milli* has replaced 10^{-3}. As another example, 100,000,000 ohms can be expressed as 100×10^6 Ω. This quantity expressed using a metric prefix is 100 MΩ, which is read 100 megohms. The metric prefix *mega* has replaced 10^6.

METRIC PREFIX	SYMBOL	POWER OF TEN	VALUE
femto	f	10^{-15}	one-quadrillionth
pico	p	10^{-12}	one-trillionth
nano	n	10^{-9}	one-billionth
micro	μ	10^{-6}	one-millionth
milli	m	10^{-3}	one-thousandth
kilo	k	10^3	one thousand

Calculator Tip

All scientific and graphing calculators provide features for entering and displaying numbers in various formats. Scientific and engineering notation are special cases of exponential (power of ten) notation. Most calculators have a key labeled EE (or EXP) that is used to enter the exponent of numbers. To enter a number in exponential notation, enter the base number first, including the sign, and then press the EE key, followed by the exponent, including the sign.

Scientific and graphing calculators have displays for showing the power of ten. Some calculators display the exponent as a small raised number on the right side of the display.

47.0 ⁰³

Other calculators display the number with a small E followed by the exponent.

47.0ᴇ03

Notice that the base 10 is not generally shown, but it is implied or represented by the E. When you write out the number, you need to include the base 10. The displayed number shown above is written out as 47.0×10^3 in engineering notation.

Some calculators are placed in the scientific or engineering notation mode using a secondary or tertiary function, such as SCI or ENG. Then numbers are entered in regular decimal form. The calculator automatically converts them to the proper format. Other calculators provide for mode selection using a menu.

Always check the owner's manual for your particular calculator to determine how to use the exponential notation features.

1–4 METRIC UNIT CONVERSIONS

It is sometimes necessary or convenient to convert a quantity from one unit with a metric prefix to another, such as from milliamperes (mA) to microamperes (μA). Moving the decimal point in the number an appropriate number of places to the left or to the right, depending on the particular conversion, results in a metric unit conversion.

After completing this section, you should be able to

◆ **Convert from one unit with a metric prefix to another**

  ◆ Convert between milli, micro, nano, and pico

  ◆ Convert between kilo and mega

The following rules apply to metric unit conversions:

1. When converting from a larger unit to a smaller unit, move the decimal point to the right.

2. When converting from a smaller unit to a larger unit, move the decimal point to the left.

3. Determine the number of places to move the decimal point by finding the difference in the powers of ten of the units being converted.

For example, when converting from milliamperes (mA) to microamperes (μA), move the decimal point three places to the right because there is a three-place difference between the two units (mA is 10^{-3} A and μA is 10^{-6} A). The following examples illustrate a few conversions.

EXAMPLE 1–11

Convert 0.15 milliampere (0.15 mA) to microamperes (μA).

Solution Move the decimal point three places to the right.

1–5 MEASURED NUMBERS

Whenever a quantity is measured, there is uncertainty in the result due to limitations of the instruments used. When a measured quantity contains approximate numbers, the digits known to be correct are called significant digits. When reporting measured quantities, the number of digits that should be retained are the significant digits and no more than one uncertain digit.

After completing this section, you should be able to

◆ **Express measured data with the proper number of significant digits**

  ◆ Define *accuracy, error,* and *precision*

  ◆ Round numbers properly

Error, Accuracy, and Precision

Data taken in experiments are not perfect because the accuracy of the data depends on the accuracy of the test equipment and the conditions under which the measurement was made. In order to properly report measured data, the error associated with the measurement should be taken into account. Experimental error should not be thought of as a mistake. All measurements that do not involve counting are approximations of the true value. The difference between the true or best-accepted value of some quantity and the measured value is the **error**. A measurement is said to be accurate if the error is small. **Accuracy** is an indication of the range of error in a measurement. For example, if you measure thickness of a 10.00 mm gauge block with a micrometer and find that it is 10.8 mm, the reading is not accurate because a gauge block is considered to be a working standard. If you measure 10.02 mm, the reading is accurate because it is in reasonable agreement with the standard.

Another term associated with the quality of a measurement is *precision*. **Precision** is a measure of the repeatability (or consistency) of a measurement of some quantity. It is possible to have a precise measurement in which a series of readings are not scattered, but each measurement is inaccurate because of an instrument error. For example, a meter may be out of calibration and produce inaccurate but consistent (precise) results. However, it is not possible to have an accurate instrument unless it is also precise.

Significant Digits

The digits in a measured number that are known to be correct are called **significant digits**. Most measuring instruments show the proper number of significant digits, but some instruments can show digits that are not significant, leaving it to the user to determine what should be reported. This may occur because of an effect called *loading*. A meter can change the actual reading in a circuit by its very presence. It is important to recognize when a reading may be inaccurate; you should not report digits that are known to be inaccurate.

Another problem with significant digits occurs when you perform mathematical operations with numbers. The number of significant digits should never exceed the number in the original measurement. For example, if 1.0 V is divided by 3.0 Ω, a calculator will show 0.33333333. Since the original numbers each contain 2 significant digits, the answer should be reported as 0.33 A, the same number of significant digits.

The rules for determining if a reported digit is significant are

1. Nonzero digits are always considered to be significant.

2. Zeros to the left of the first nonzero digit are never significant.

3. Zeros between nonzero digits are always significant.

4. Zeros to the right of the decimal point for a decimal number are significant.

5. Zeros to the left of the decimal point with a whole number may or may not be significant depending on the measurement. For example, the number 12,100 Ω can have 3, 4, or 5 significant digits. To clarify the significant digits, scientific notation (or a metric prefix) should be used. For example, 12.10 kΩ has 4 significant digits.

When a measured value is reported, one uncertain digit may be retained but other uncertain digits should be discarded. To find the number of significant digits in a number, ignore the decimal point, and count the number of digits from left to right starting with the first nonzero digit and ending with the last digit to the right. All of the digits counted are significant except zeros to the right end of the number, which may or may not be significant. In the absence of other information, the significance of the right-hand zeros is uncertain. Generally, zeros that are placeholders, and not part of a measurement, are considered to be not significant. To avoid confusion, numbers should be shown using scientific or engineering notation if it is necessary to show the significant zeros.

EXAMPLE 1–18

Express the measured number 4300 with 2, 3, and 4 significant digits.

Solution   Zeros to the right of the decimal point in a decimal number are significant. Therefore, to show two significant digits, write

$$4.3 \times 10^3$$

To show three significant digits, write

$$4.30 \times 10^3$$

To show four significant digits, write

$$4.300 \times 10^3$$

Related Problem   How would you show the number 10,000 showing three significant digits?

EXAMPLE 1–19

Underline the significant digits in each of the following measurements:

(a) 40.0   (b) 0.3040   (c) 1.20 × 10^5 (d) 120,000   (e) 0.00502

Solution   (a) <u>40.0</u> has three significant digits; see rule 4.

(b) 0.<u>3040</u> has four significant digits; see rules 2 and 3.

(c) <u>1.20</u> × 10^5 has three significant digits; see rule 4.

(d) <u>12</u>0,000 has at least two significant digits. Although the number has the same value as in (c), zeros in this example are uncertain; see rule 5. This is *not* a recommended method for reporting a measured quantity; use scientific notation or a metric prefix in this case. See Example 1–18.

(e) 0.00<u>502</u> has three significant digits; see rules 2 and 3.

Related Problem   What is the difference between a measured quantity of 10 and 10.0?

Rounding Off Numbers

Since they always contain approximate numbers, measurements should be shown only with those digits that are significant plus no more than one uncertain digit. The number of digits shown is indicative of the precision of the measurement. For this reason, you should

round off a number by dropping one or more digits to the right of the last significant digit. Use only the most significant dropped digit to decide how to round off. The rules for rounding off are

1. If the most significant digit dropped is greater than 5, increase the last retained digit by 1.

2. If the digit dropped is less than 5, do not change the last retained digit.

3. If the digit dropped is 5, increase the last retained digit *if* it makes it an even number, otherwise do not. This is called the "round-to-even" rule.

EXAMPLE 1–20

Round of the following numbers to three significant digits:

(a) 10.071 (b) 29.961 (c) 6.3948 (d) 123.52 (e) 122.52

Solution (a) 10.071 rounds to **10.1**. (b) 29.961 rounds to **30.0**.

(c) 6.3948 rounds to **6.39**. (d) 123.52 rounds to **124**.

(e) 122.52 round to **122**.

Related Problem Round 3.2850 to three significant digits using the round-to-even rule.

In most electrical and electronics work, components have tolerances greater than 1% (5% and 10% are common). Most measuring instruments have accuracy specifications better than this, but it is unusual for measurements to be made with higher accuracy than 1 part in 1000. For this reason, three significant digits are appropriate for numbers that represent measured quantities in all but the most exacting work. If you are working with a problem with several intermediate results, keep all digits in your calculator, but round the answers to three when reporting a result.

2. What is the round-to-even rule?

3. On schematics, you will frequently see a 1000 Ω resistor listed as 1.0 kΩ. What does this imply about the value of the resistor?

4. If a power supply is required to be set to 10.00 V, what does this imply about the accuracy needed for the measuring instrument?

5. How can scientific or engineering notation be used to show the correct number of significant digits in a measurement?

APPLICATION ACTIVITY PREVIEW

In this application activity, you will see how the theory presented in this chapter is applied to a practical circuit that simulates part of a car's instrument panel lighting system. An automobile's lights are examples of simple types of electric circuits. When you turn on the headlights and taillights, you are connecting the lamps to the battery, which provides the voltage and produces current through each lamp. The current causes the lamps to emit light. The lamps themselves have resistance that limits the amount of current. The instrument panel lamp in most cars can be adjusted for brightness. By turning a knob, you change the resistance in the circuit, thereby causing the current to change. The amount of current through the lamp determines its brightness.

INTRODUCTION

The theoretical concepts of electrical current, voltage, and resistance are introduced in this chapter. You will learn how to express each of these quantities in the proper units and how each quantity is measured. The essential elements that form a basic electric circuit and how they are put together are covered.

Types of devices that generate voltage and current are introduced. Also, you will see a variety of components that are used to introduce resistance into electric circuits. The operation of protective devices such as fuses and circuit breakers are discussed, and mechanical switches commonly used in electric circuits are introduced. You will learn how to control and measure voltage, current, and resistance using laboratory instruments.

Voltage is essential in any kind of electric circuit. Voltage is the potential energy of electrical charge required to make the circuit work. Current is also necessary for electric circuits to operate, but it takes voltage to produce the current. Current is the movement of electrons through a circuit. Resistance in a circuit limits the amount of current. A water system can be used as an analogy for a simple circuit. Voltage can be considered analogous to the pressure required to force water through the pipes. Current through wires can be thought of as analogous to the water moving through the pipes. Resistance can be thought of as analogous to the restriction on the water flow produced by adjusting a valve.

2–1 ATOMIC STRUCTURE

All matter is made of atoms; and all atoms consist of electrons, protons, and neutrons. In this section, you will learn about the structure of an atom, including electron shells and orbits, valence electrons, ions, and energy levels. The configuration of certain electrons in an atom is the key factor in determining how well a given conductive or semiconductive material conducts electric current.

After completing this section, you should be able to

- ◆ **Describe the basic structure of atoms**
  - ◆ Define *nucleus, proton, neutron,* and *electron*
  - ◆ Define *atomic number*
  - ◆ Define *shell*
  - ◆ Explain what a valence electron is
  - ◆ Describe ionization
  - ◆ Explain what a free electron is
  - ◆ Define *conductor, semiconductor,* and *insulator*

An **atom** is the smallest particle of an **element** that retains the characteristics of that element. Each of the known 110 elements has atoms that are different from the atoms of all other elements. This gives each element a unique atomic structure. According to the classic Bohr model, an atom is visualized as having a planetary type of structure that consists of a central nucleus surrounded by orbiting electrons, as illustrated in Figure 2–1. The **nucleus** consists of positively charged particles called **protons** and uncharged particles called **neutrons**. The basic particles of negative charge are called **electrons**, which orbit the nucleus.

Each type of atom has a certain number of protons that distinguishes it from the atoms of all other elements. For example, the simplest atom is that of hydrogen, which has one proton and one electron, as pictured in Figure 2–2(a). As another example, the helium atom, shown in Figure 2–2(b), has two protons and two neutrons in the nucleus and two electrons orbiting the nucleus.

(b) Helium atom

▲ **FIGURE 2–2**

The two simplest atoms, hydrogen and helium.

Atomic Number

All elements are arranged in the periodic table of the elements in order according to their **atomic number**. The atomic number equals the number of protons in the nucleus. For example, hydrogen has an atomic number of 1 and helium has an atomic number of 2. In their normal (or neutral) state, all atoms of a given element have the same number of electrons as protons; the positive charges cancel the negative charges, and the atom has a net charge of zero, making it electrically balanced.

Shells, Orbits, and Energy Levels

As you have seen in the Bohr model, electrons orbit the nucleus of an atom at certain distances from the nucleus and are restricted to these specific orbits. Each orbit corresponds to a different energy level within the atom known as a **shell**. The shells are designated 1, 2, 3, and so on, with 1 being closest to the nucleus. Electrons further from the nucleus are at higher energy levels.

The line spectrums of hydrogen from the Bohr model of the atom shows that the electrons can only absorb or emit a specific amount of energy that represents the exact difference between the levels. Figure 2–3 shows the energy levels within the hydrogen atom. The

▶ **FIGURE 2–3**

Energy levels in hydrogen.
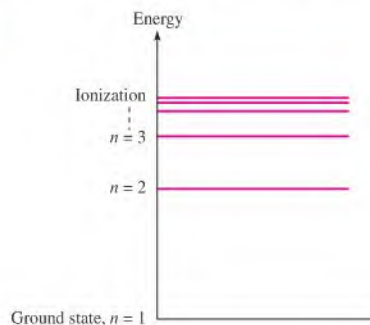

lowest level ($n = 1$) is called the *ground state* and represents the most stable atom with a single electron in the first shell. If this electron acquires a specific amount of energy by absorbing a photon, it can be raised to one of the higher energy levels. In this higher state, it can emit a photon with exactly the same energy and return to the ground state. Transitions between the levels account for various phenomena we see in electronics, such as the color of light from a light-emitting diode.

After Bohr's work, Erin Schroedinger (1887–1961) proposed a mathematical theory for the atom that explained more complicated atoms. He suggested that the electron has a wavelike property, and he considered the simplest case as having a three-dimensional standing wave pattern due to vibrations. Schroedinger theorized the standing wave of an electron with a spherical shape could have only certain wavelengths. This wave-mechanics model of the atom gave the same equation for the electron energy in hydrogen as Bohr's model, but in the wave-mechanics model, more complicated atoms could be explained by involving shapes other than spheres and adding a designation for the orientation of a given shape within the atom. In both models, electrons near the nucleus have less energy than those further out, which was the basic concept of the energy levels.

The idea of discrete energy levels within the atom is still a foundation for understanding the atom, and the wave-mechanics model has been very successful at predicting the energy levels for various atoms. The wave-mechanics model of the atom used the shell number, called the *principal quantum number,* in the energy equation. Three other quantum numbers describe each electron within the atom. All electrons in an atom have a unique set of quantum numbers.

When an atom is part of a large group, as in a crystal, the discrete energy levels broaden into energy bands, which is an important idea in solid-state electronics. The bands also differentiate between conductors, semiconductors, and insulators.

Valence Electrons

Electrons that are in orbits farther from the nucleus have higher energy and are less tightly bound to the atom than those closer to the nucleus. This is because the force of attraction between the positively charged nucleus and the negatively charged electron decreases with increasing distance from the nucleus. Electrons with the highest energy levels exist in the outermost shell of an atom and are relatively loosely bound to the atom. This outermost shell is known as the **valence** shell, and electrons in this shell are called **valence electrons**. These valence electrons contribute to chemical reactions and bonding within the structure of a material, and they determine the material's electrical properties.

Energy Levels and Ionization Energy

If an electron absorbs a photon with sufficient energy, it escapes from the atom and becomes a **free electron**. This is indicated by the ionization energy level in Figure 2–3. Any time an atom or group of atoms is left with a net charge, it is called an **ion**. When an electron escapes from the neutral hydrogen atom (designated H), the atom is left with a net positive charge and becomes a *positive ion* (designated H^+). In other cases, an atom or group of atoms can acquire an electron, in which case it is called a *negative ion*.

The Copper Atom

Copper is the most commonly used metal in **electrical** applications. The copper atom has 29 electrons that orbit the nucleus in four shells. The number of electrons in each shell follows a predictable pattern according to the formula, $2N^2$, where N is the number of the shell. The first shell of any atom can have up to two electrons, the second shell up to eight electrons, the third shell up to 18 electrons, and the fourth shell up to 32 electrons.

A copper atom is represented in Figure 2–4. Notice that the fourth or outermost shell, the valence shell, has only one valence electron. The inner shells are called the *core*. When the valence electron in the outer shell of the copper atom gains sufficient thermal energy, it

▶ **FIGURE 2–4**

The copper atom.
can break away from the parent atom and become a free electron. In a piece of copper at room temperature, a "sea" of these free electrons is present. These electrons are not bound to a given atom but are free to move in the copper material. Free electrons make copper an excellent conductor and make electrical current possible.

Categories of Materials

Three categories of materials are used in electronics: conductors, semiconductors, and insulators.

Conductors **Conductors** are materials that readily allow current. They have a large number of free electrons and are characterized by one to three valence electrons in their structure. Most metals are good conductors. Silver is the best conductor, and copper is next. Copper is the most widely used conductive material because it is less expensive than silver. Copper wire is commonly used as a conductor in electric circuits.

Semiconductors **Semiconductors** are classed below the conductors in their ability to carry current because they have fewer free electrons than do conductors. Semiconductors have four valence electrons in their atomic structures. However, because of their unique characteristics, certain semiconductor materials are the basis for **electronic** devices such as the diode, transistor, and integrated circuit. Silicon and germanium are common semiconductive materials.

Insulators **Insulators** are nonmetallic materials that are poor conductors of electric current; they are used to prevent current where it is not wanted. Insulators have no free electrons in their structure. The valence electrons are bound to the nucleus and not considered "free." Most practical insulators used in electrical and electronic applications are compounds such as glass, porcelain, teflon, and polyethylene, to name a few.

	2. Define *atom*.
	3. What does an atom consist of?
	4. Define *atomic number*.
	5. Do all elements have the same types of atoms?

2–2 ELECTRICAL CHARGE

As you know, an electron is the smallest particle that exhibits negative electrical charge. When an excess of electrons exists in a material, there is a net negative electrical charge. When a deficiency of electrons exists, there is a net positive electrical charge.

After completing this section, you should be able to

- ◆ **Explain the concept of electrical charge**
  - ◆ Name the unit of charge
  - ◆ Name the types of charge
  - ◆ Discuss attractive and repulsive forces
  - ◆ Determine the amount of charge on a given number of electrons

The charge of an electron and that of a proton are equal in magnitude. Electrical **charge** is an electrical property of matter that exists because of an excess or deficiency of electrons. Charge is symbolized by the letter Q. Static electricity is the presence of a net positive or negative charge in a material. Everyone has experienced the effects of static electricity from time to time, for example, when attempting to touch a metal surface or another person or when the clothes in a dryer cling together.

Materials with charges of opposite polarity are attracted to each other, and materials with charges of the same polarity are repelled, as indicated in Figure 2–5. A force acts between charges, as evidenced by the attraction or repulsion. This force, called an *electric field*, is represented by imaginary lines, as represented in Figure 2–6.

◀ **FIGURE 2–6**

Coulomb's law states

A force (F) exists between two point-source charges (Q_1, Q_2) that is directly proportional to the product of the two charges and inversely proportional to the square of the distance (d) between the charges.

Coulomb: The Unit of Charge

Electrical charge (Q) is measured in coulombs, symbolized by C.

One **coulomb** is the total charge possessed by 6.25×10^{18} electrons.

A single electron has a charge of 1.6×10^{-19} C. The total charge Q, expressed in coulombs, for a given number of electrons is stated in the following formula:

Equation 2–1

$$Q = \frac{\text{number of electrons}}{6.25 \times 10^{18} \text{ electrons/C}}$$

Positive and Negative Charge

Consider a neutral atom—that is, one that has the same number of electrons and protons and thus has no net charge. As you know, when a valence electron is pulled away from the atom by the application of energy, the atom is left with a net positive charge (more protons than electrons) and becomes a *positive ion*. If an atom acquires an extra electron in its outer shell, it has a net negative charge and becomes a *negative ion*.

The amount of energy required to free a valence electron is related to the number of electrons in the outer shell. An atom can have up to eight valence electrons. The more complete the outer shell, the more stable the atom and thus the more energy is required to remove an electron. Figure 2–7 illustrates the creation of a positive ion and a negative ion when a hydrogen atom gives up its single valence electron to a chlorine atom, forming gaseous hydrogen chloride (HCl). When the gaseous HCl is dissolved in water, hydrochloric acid is formed.

▶ **FIGURE 2–7**

Example of the formation of positive and negative ions.

(c) When dissolved in water, hydrogen chloride gas separates into positive hydrogen ions and negative chloride ions. The chlorine atom retains the electron given up by the hydrogen atom forming both positive and negative ions in the same solution.

EXAMPLE 2–1

How many coulombs do 93.8×10^{16} electrons represent?

Solution $Q = \dfrac{\text{number of electrons}}{6.25 \times 10^{18} \text{ electrons/C}} = \dfrac{93.8 \times 10^{16} \text{ electrons}}{6.25 \times 10^{18} \text{ electrons/C}} = 15 \times 10^{-2} \text{ C} = \mathbf{0.15\ C}$

*Related Problem** How many electrons does it take to have 3 C of charge?

*Answers are at the end of the chapter.

2–3 VOLTAGE

As you have seen, a force of attraction exists between a positive and a negative charge. A certain amount of energy must be exerted, in the form of work, to overcome the force and move the charges a given distance apart. All opposite charges possess a certain potential energy because of the separation between them. The difference in potential energy per charge is the potential difference or **voltage**. Voltage is the driving force, sometimes called electromotive force or emf, in electric circuits and is what establishes current.

After completing this section, you should be able to

- ◆ **Define *voltage* and discuss its characteristics**
  - ◆ State the formula for voltage
  - ◆ Name and define the unit of voltage
  - ◆ Describe the basic sources of voltage

Voltage, symbolized by V, is defined as energy or work per unit charge.

$$V = \frac{W}{Q}$$

Equation 2–2

where V is voltage in volts (V), W is energy in joules (J), and Q is charge in coulombs (C). Some sources use E instead of V to symbolize voltage, but V is used throughout this text.

As an analogy, consider a water tank that is supported several feet above the ground. A given amount of energy must be exerted in the form of work to pump water up to fill the tank. Once the water is stored in the tank, it has a certain potential energy which, if released, can be used to perform work.

The Volt

The unit of voltage is the volt, symbolized by V.

One volt is the potential difference (voltage) between two points when one joule of energy is used to move one coulomb of charge from one point to the other.

HISTORY NOTE

Alessandro Volta 1745–1827

Volta, an Italian, invented a device to generate static electricity and he also discovered methane gas. Volta investigated reactions between dissimilar metals and developed the first battery in 1800. Electrical potential, more commonly known as voltage, and the unit of voltage, the volt, are named in his honor. (Photo credit: AIP Emilio Segrè Visual Archives, Lande Collection.)

EXAMPLE 2–2

If 50 J of energy are required to move 10 C of charge, what is the voltage?

Solution

$$V = \frac{W}{Q} = \frac{50\,\text{J}}{10\,\text{C}} = \textbf{5 V}$$

How much energy is required to move 50 C from one point to another when the voltage between the two points is 12 V?

The Voltage Source

A **voltage source** provides electrical energy or electromotive force (emf), more commonly known as *voltage*. Voltage is produced by means of chemical energy, light energy, and magnetic energy combined with mechanical motion.

The Ideal Voltage Source   An ideal voltage source can provide a constant voltage for any current required by a circuit. The ideal voltage source does not exist but can be closely approximated in practice. For purposes of analysis the ideal source is assumed unless otherwise specified.

   Voltage sources can be either dc or ac. A common symbol for a dc voltage source is shown in Figure 2–8(a) and one for an ac voltage source is shown in part (b). AC voltage sources will be used later in the book.

▶ **FIGURE 2–8**

Symbols for voltage sources.

(a) DC voltage source   (b) AC voltage source
   A graph showing voltage versus current for an ideal dc voltage source is illustrated in Figure 2–9. As you can see, the voltage is constant for any current (within limits) from the source. For a practical voltage source connected in a circuit, the voltage decreases slightly as the current increases, as shown by the dashed curve. Current is always drawn from a voltage source when a load such as a resistance is connected to it.

Types of DC Voltage Sources

Batteries   A **battery** is a type of voltage source that converts chemical energy directly into electrical energy. As you know, work (or energy) per charge is the basic unit for voltage, and a battery adds energy to each unit of charge. It is something of a misnomer to talk about "charging a battery" because a battery does not store charge but rather stores chemical potential energy. All batteries use a specific type of chemical reaction called an *oxidation-reduction reaction*. In this type of reaction, electrons are transferred from one reactant to the other. If the chemicals used in the reaction are separated, it is possible to cause the electrons to travel in the external circuit, creating current. As long as there is an external path for the electrons, the reaction can proceed, and stored chemical energy is converted to electrical current. If the path is broken, the reaction stops and the battery is said to be in equilibrium. In a battery, the terminal that supplies electrons has a surplus of electrons and is the negative electrode or **anode**. The electrode that acquires electrons has a positive potential and is the **cathode**.
▲ **FIGURE 2–10**

A copper-zinc battery. The reaction can only occur if an external path is provided for the electrons. As the reaction proceeds, the Zn anode is eaten away and Cu^{2+} ions combine with electrons to form copper metal on the cathode.

Figure 2–10 shows a nonrechargeable single-cell copper-zinc battery that we will use for illustration of battery operation. The copper-zinc cell is simple to construct and illustrates concepts common to all nonrechargeable batteries. A zinc electrode and a copper electrode are immersed in solutions of zinc sulfate ($ZnSO_4$) and copper sulfate ($CuSO_4$), which are separated by a salt bridge that prevents the Cu^{2+} ions from reacting directly with the Zn metal. The zinc metal electrode supplies Zn^{2+} ions to the solution and electrons to the external circuit, so this electrode is constantly eaten away as the reaction proceeds. The salt bridge allows ions to pass through it to maintain charge balance in the cell. There are no free electrons in the solutions, so an external path for electrons is provided through an ammeter (in our case) or other load. On the cathode side, the electrons that were given up by the zinc combine with copper ions from the solution to form copper metal, which deposits on the copper electrode. The chemical reactions (shown in the diagram) occur at the electrode. Different types of batteries have different reactions, but all involve transfer of electrons in the external circuit.

A single cell will have a certain fixed voltage. In the copper-zinc cell, the voltage is 1.1 V. In a lead-acid cell, the kind used in car batteries, a potential difference of about 2.1 V is between the anode and cathode. The voltage of any cell depends on the cell chemistry. Nickel-cadmium cells are about 1.2 V and lithium cells can be as high as almost 4 V. Cell chemistry also determines the shelf life and discharge characteristics for a battery. For example, a lithium-MnO_2 battery typically has five times the shelf life of a comparable carbon-zinc battery.

Although the voltage of a battery cell is fixed by its chemistry, the capacity is variable and depends on the quantity of materials in the cell. Essentially, the *capacity* of a cell is the number of electrons that can be obtained from it and is measured by the amount of current that can be supplied over time.

Batteries normally consist of multiple cells that are electrically connected together internally. The way that the cells are connected and the type of cells determine the voltage and current capacity of the battery. If the positive electrode of one cell is connected to the negative electrode of the next and so on, as illustrated in Figure 2–11(a), the battery voltage is the sum of the individual cell voltages. This is called a series connection. To increase battery current capacity, the positive electrodes of several cells are connected together and all the negative electrodes are connected together, as illustrated in Figure 2–11(b). This is called a parallel connection. Also, by using larger cells, which have a greater quantity of material, the ability to supply current can be increased but the voltage is not affected.

Cells connected to form batteries.
(a) Series-connected cells increase voltage.

(b) Parallel-connected cells increase current capacity.

Batteries are divided into two major classes, *primary* and *secondary*. Primary batteries are used once and discarded because their chemical reactions are irreversible. Secondary batteries can be recharged and reused many times because they are characterized by reversible chemical reactions.

Primary and secondary batteries are available in a variety of shapes and sizes. Some of the sizes that you are most familiar with are AAA, AA, C, D, and 9 V but there are many others that are less common. Batteries are also typed according to their chemical makeup. A few common types of primary and secondary batteries are listed below.

◆ *Alkaline-MnO$_2$*   This is a primary battery that is commonly used in palm-type computers, photographic equipment, toys, radios, and recorders.

◆ *Carbon-zinc*   This is a primary battery used in flashlights and small appliances.

◆ *Lead-acid*   This is a secondary (rechargable) battery that is commonly used in automotive, marine, and other similar applications.

◆ *Lithium-ion*   This is a secondary battery that is commonly used in all types of portable electronics. This type of battery is increasingly being used in defense, aerospace, and automotive applications.

◆ *Lithium-MnO$_2$*   This is a primary battery that is commonly used in photographic and electronic equipment, smoke alarms, personal organizers, memory backup, and communications equipment.

◆ *Nickel-metal hydride*   This is a secondary (rechargable) battery that is commonly used in portable computers, cell phones, camcorders, and other portable consumer electronics.

◆ *Silver oxide*   This is a primary battery that is commonly used in watches, photographic equipment, hearing aids, and electronics requiring high-capacity batteries.

◆ *Zinc air*   This is a primary battery that is commonly used in hearing aids, medical monitoring instruments, pagers, and other frequency-use applications.

Fuel Cells   A **fuel cell** is a device that converts electrochemical energy into dc voltage directly. Fuel cells combine a fuel (usually hydrogen) with an oxidizing agent (usually oxygen). In the hydrogen fuel cell, hydrogen and oxygen react to form water, which is the only by-product. The process is clean, quiet, and more efficient than burning. Fuel cells and batteries are similar in that they both are electrochemical devices that produce electricity using an oxidation-reduction reaction. However, a battery is a closed system with all its chemicals stored inside, whereas in a fuel cell, the chemicals (hydrogen and oxygen) constantly flow into the cell where they combine and produce electricity.

Hydrogen fuel cells are usually classified by their operating temperature and the type of electrolyte they use. Some types work well for use in stationary power generation plants. Others may be useful for small portable applications or for powering cars. For example, the
▲ FIGURE 2–12

Simplified diagram of a fuel cell.

type that holds the most promise for automotive applications is the polymer exchange membrane fuel cell (PEMFC), which is a type of hydrogen fuel cell. A simplified diagram is shown in Figure 2–12 to illustrate the basic operation.

The channels disperse pressurized hydrogen gas and oxygen gas equally over the surface of the catalyst, which facilitates the reaction of the hydrogen and oxygen. When an H_2 molecule comes in contact with the platinum catalyst on the anode side of the fuel cell, it splits into two H^+ ions and two electrons (e^-). The hydrogen ions are passed through the polymer electrolyte membrane (PEM) onto the cathode. The electrons pass through the anode and into the external circuit to create current.

When an O_2 molecule comes in contact with the catalyst on the cathode side, it breaks apart, forming two oxygen ions. The negative charge of these ions attracts two H^+ ions through the electrolyte membrane and together they combine with electrons from the external circuit to form a water molecule (H_2O), which is passed from the cell as a by-product. In a single fuel cell, this reaction produces only about 0.7 V. To get higher voltages, multiple fuel cells are connected in series.

Current research on fuel cells is ongoing and is focused on developing reliable, smaller, and cost-effective components for vehicles and other applications. The conversion to fuel cells also requires research on how best to obtain and provide hydrogen fuel where it is needed. Potential sources for hydrogen include using solar, geothermal, or wind energy to break apart water. Hydrogen can also be obtained by breaking down coal or natural gas molecules, which are rich in hydrogen.

Solar Cells   The operation of solar cells is based on the **photovoltaic effect**, which is the process whereby light energy is converted directly into electrical energy. A basic solar cell consists of two layers of different types of semiconductive materials joined together to form a junction. When one layer is exposed to light, many electrons acquire enough energy to break away from their parent atoms and cross the junction. This process forms negative ions on one side of the junction and positive ions on the other, and thus a potential difference (voltage) is developed. Figure 2–13 shows the construction of a basic solar cell.

▶ FIGURE 2–13

Construction of a basic solar cell.
Although solar cells can be used in room light for powering a calculator, research is focusing more on converting sunlight to electricity. There is considerable research in increasing the efficiency of solar cells and photovoltaic (PV) modules today because they are a very clean source of energy using sunlight. A complete system for continuous power generally requires a battery backup to provide energy when the sun is not shining. Solar cells are well suited for remote locations where energy sources are unavailable and are used in providing power to satellites.

DC Generator   Electrical **generators** convert mechanical energy into electrical energy using a principle called *electromagnetic induction* (see Chapter 10). A conductor is rotated through a magnetic field, and a voltage is produced across the conductor. A typical generator is pictured in Figure 2–14.

▶ FIGURE 2–14

Cutaway view of a dc voltage generator.
The Electronic Power Supply   Electronic **power supplies** convert the ac voltage from a wall outlet to a dc voltage that can be varied over a specified range. Typical laboratory power supplies are shown in Figure 2–15.

Thermocouples   The **thermocouple** is a thermoelectric type of voltage source that is commonly used to sense temperature. A thermocouple is formed by the junction of two dissimilar metals, and its operation is based on the **Seebeck effect** that describes the voltage generated at the junction of the metals as a function of temperature.

Standard types of thermocouple are characterized by the specific metals used. These standard thermocouples produce predictable output voltages for a range of temperatures. The most common is type K, made of chromel and alumel. Other types are also designated by letters as E, J, N, B, R, and S. Most thermocouples are available in wire or probe form.

Piezoelectric Sensors   These sensors act as voltage sources and are based on the **piezo-electric effect** where a voltage is generated when a piezoelectric material is mechanically

deformed by an external force. Quartz and ceramic are two types of piezoelectric material. Piezoelectric sensors are used in applications such as pressure sensors, force sensors, accelerometers, microphones, ultrasonic devices, and many others.

2–4   CURRENT

Voltage provides energy to electrons, allowing them to move through a circuit. This movement of electrons is the current, which results in work being done in an electrical circuit.

After completing this section, you should be able to

♦ **Define *current* and discuss its characteristics**

　♦ Explain the movement of electrons

　♦ State the formula for current

　♦ Name and define the unit of current

As you have learned, free electrons are available in all conductive and semiconductive materials. These outer-shell electrons drift randomly in all directions, from atom to atom, within the structure of the material, as indicated in Figure 2–16. These electrons are loosely bound to the positive metal ions in the material, but because of thermal energy, they are free to move about the crystalline structure of the metal.

▶ **FIGURE 2–16**

Random motion of free electrons in a material.
If a voltage is placed across a conductive or semiconductive material, one end becomes positive and the other negative, as indicated in Figure 2–17. The repulsive force produced by the negative voltage at the left end causes the free electrons (negative charges) to move toward the right. The attractive force produced by the positive voltage at the right end pulls the free electrons to the right. The result is a net movement of the free electrons from the negative end of the material to the positive end, as shown in Figure 2–17.

▶ **FIGURE 2–17**

Electrons flow from negative to positive when a voltage is applied across a conductive or semiconductive material.

Voltage
The movement of these free electrons from the negative end of the material to the positive end is the electrical current, symbolized by I.

Electrical current is the rate of flow of charge.

Current in a conductive material is determined by the number of electrons (amount of charge) that flow past a point in a unit of time.

Equation 2–3

$$I = \frac{Q}{t}$$

where I is current in amperes (A), Q is charge in coulombs (C), and t is time in seconds (s).

One ampere (1 A) is the amount of current that exists when a number of electrons having a total charge of one coulomb (1 C) move through a given cross-sectional area in one second (1 s).

See Figure 2–18. Remember, one coulomb is the charge carried by 6.25×10^{18} electrons.

HISTORY NOTE

Ampère
1775–1836

In 1820 Ampère, a Frenchman, developed a theory of electricity and magnetism that was fundamental for 19th century developments in the field. He was the first to build an instrument to measure charge flow (current). The unit of electrical current is named in his honor. (Photo credit: AIP Emilio Segrè Visual Archives.)
When a number of electrons having a total charge of 1 C pass through a cross-sectional area in 1 s, there is 1 A of current.

EXAMPLE 2–3

Solution

$$I = \frac{Q}{t} = \frac{10\,\text{C}}{2\,\text{s}} = 5\,\text{A}$$

Related Problem If there are 8 A of current through the filament of a lamp, how many coulombs of charge move through the filament in 1.5 s?

The Current Source

The Ideal Current Source   As you know, an ideal voltage source can provide a constant voltage for any load. An ideal **current source** can provide a constant current in any load. Just as in the case of a voltage source, the ideal current source does not exist but can be approximated in practice. We will assume ideal unless otherwise specified.

The symbol for a current source is shown in Figure 2–19(a). The graph for an ideal current source is a horizontal line as illustrated in Figure 2–19(b). This is called the *IV* characteristic. Notice that the current is constant for any voltage across the current source. In a practical current source, the current decreases slightly with voltage, as shown by the dashed line.

(a) Symbol   (b) *IV* characteristic
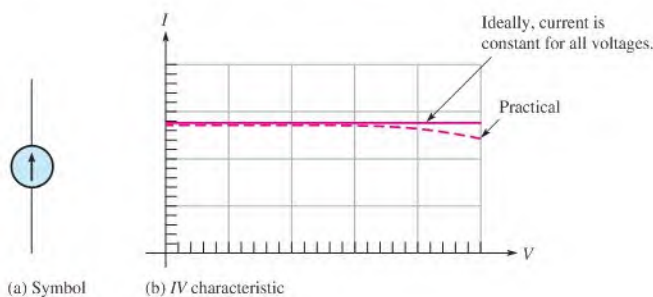

▲ **FIGURE 2–19**

The current source.

SAFETY NOTE

Current sources change the output voltage in order to supply a constant current to the load. For example, a meter calibrator can have a different output voltage that depends on the meter under test. You should never touch the leads from a current source; the voltage can be high, and a shock will result, particularly if the load is a high resistance load or the load is disconnected when the current source is turned on.

Practical Current Sources   Power supplies are normally thought of as voltage sources because they are the most common type of source in the laboratory. However, current sources are another type of energy source. Current sources may be "stand-alone" instruments or may be combined with other instruments, such as a voltage source, DMM, or function generator. Examples of combination instruments are the source-measurement units shown in Figure 2–20.

◄ **FIGURE 2–20**

Typical source-measurement instruments. (Courtesy of Keithley Instruments).

These units can be set up as voltage or current sources and include a built-in DMM, as well as other instruments. They are used primarily for testing transistors and other semiconductors.

In most transistor circuits, the transistor acts as a current source because part of the *IV* characteristic curve is a horizontal line as shown by the transistor characteristic in Figure 2–21. The flat part of the graph indicates where the transistor current is constant over a range of voltages. The constant-current region is used to form a constant-current source.

3. What is the current in amperes when 20 C flow past a point in a wire in 4 s?

2–5   RESISTANCE

When there is current through a material, the free electrons move through the material and occasionally collide with atoms. These collisions cause the electrons to lose some of their energy, and thus their movement is restricted. The more collisions, the more the flow of electrons is restricted. This restriction varies and is determined by the type of material. The property of a material that restricts the flow of electrons is called *resistance*, designated with an *R*.

After completing this section, you should be able to

◆ **Define *resistance* and discuss its characteristics**

   ◆ Name and define the unit of resistance
   ◆ Describe the basic types of resistors
   ◆ Determine resistance value by color code or labeling

These collisions cause the electrons to lose some of their energy, thus restricting their movement. The more collisions, the more the flow of electrons is restricted. This restriction varies and is determined by the type of material. The property of a material to restrict or oppose the flow of electrons is called resistance, *R*.

Resistance is the opposition to current.

Resistance is expressed in ohms, symbolized by the Greek letter omega (Ω).

One ohm (1 Ω) of resistance exists if there is one ampere (1 A) of current in a material when one volt (1 V) is applied across the material.

R

▲ **FIGURE 2–22**

Resistance symbol.

The schematic symbol for resistance is shown in Figure 2–22.

Conductance   The reciprocal of resistance is **conductance**, symbolized by *G*. It is a measure of the ease with which current is established. The formula is

$$G = \frac{1}{R}$$

The unit of conductance is the **siemens**, abbreviated S. For example, the conductance of a 22 kΩ resistor is

$$G = \frac{1}{22 \text{ k}\Omega} = 45.5 \text{ } \mu\text{S}$$

The obsolete unit of *mho* (ohm spelled backwards) was previously used for conductance.

Resistors

A component that is specifically designed to have a certain amount of resistance is called a **resistor**. The principal applications of resistors are to limit current in a circuit, to divide voltage, and, in certain cases, to generate heat. Although resistors come in many shapes and sizes, they can all be placed in one of two main categories: fixed or variable.

Fixed Resistors   Fixed resistors are available with a large selection of resistance values that are set during manufacturing and cannot be changed easily. They are constructed using various methods and materials. Figure 2–23 shows several common types.

(a) Carbon-composition resistors with various power ratings

(c) Chip resistor array

(e) Resistor network (surface mount)

(f) Radial-lead for PC board insertion
▲ **FIGURE 2–23**

Typical fixed resistors.

One common fixed resistor is the carbon-composition type, which is made with a mixture of finely ground carbon, insulating filler, and a resin binder. The ratio of carbon to insulating filler sets the resistance value. The mixture is formed into rods, and conductive lead connections are made. The entire resistor is then encapsulated in an insulated coating for protection. Figure 2–24(a) shows the construction of a typical carbon-composition resistor.

(b) Cutaway view of a tiny chip resistor

▲ FIGURE 2–24

Two types of fixed resistors (not to scale).

The chip resistor is another type of fixed resistor and is in the category of SMT (surface mount technology) components. It has the advantage of a very small size for compact assemblies. Figure 2–24(b) shows the construction of a chip resistor.

Other types of fixed resistors include carbon film, metal film, and wirewound. In film resistors, a resistive material is deposited evenly onto a high-grade ceramic rod. The resistive film may be carbon (carbon film) or nickel chromium (metal film). In these types of resistors, the desired resistance value is obtained by removing part of the resistive material in a helical pattern along the rod using a spiraling technique, as shown in Figure 2–25(a). Very close **tolerance** can be achieved with this method. Film resistors are also available in the form of resistor networks, as shown in Figure 2–25(b).

Wirewound resistors are constructed with resistive wire wound around an insulating rod and then sealed. Normally, wirewound resistors are used in applications that require higher power ratings. Since they are constructed with a coil of wire, wirewound resistors have significant inductance and are not used at higher frequencies. Some typical wirewound resistors are shown in Figure 2–26.

Resistor Color Codes Fixed resistors with value tolerances of 5% or 10% are color coded with four bands to indicate the resistance value and the tolerance. This color-code band system is shown in Figure 2–27, and the color code is listed in Table 2–1. The bands are always closer to one end.
◀ **FIGURE 2–27**

Color-code bands on a 4-band resistor.
The color code is read as follows:

1. Start with the band closest to one end of the resistor. The first band is the first digit of the resistance value. If it is not clear which is the banded end, start from the end that does not begin with a gold or silver band.

2. The second band is the second digit of the resistance value.

3. The third band is the number of zeros following the second digit, or the multiplier.

4. The fourth band indicates the percent tolerance and is usually gold or silver.

For example, a 5% tolerance means that the *actual* resistance value is within ±5% of the color-coded value. Thus, a 100 Ω resistor with a tolerance of ±5% can have an acceptable range of values from a minimum of 95 Ω to a maximum of 105 Ω.

For example, a color code of red, violet, gold, and silver represents 2.7 Ω with a tolerance of $\pm 10\%$. A table of standard resistance values is in Appendix A.

Resistor Label Codes Not all types of resistors are color coded. Many, including surface-mount resistors, use typographical marking to indicate the resistance value and tolerance. These label codes consist of either all numbers (numeric) or a combination of numbers and letters (alphanumeric). In some cases when the body of the resistor is large enough, the entire resistance value and tolerance are stamped on it in standard form.

Numeric labeling uses three digits to indicate the resistance value, as shown in Figure 2–31 using a specific example. The first two digits give the first two digits of the resistance value, and the third digit gives the multiplier or number of zeros that follow the first two digits. This code is limited to values of 10 Ω or greater.

▶ **FIGURE 2–31**

Example of three-digit labeling for a resistor.
Another common type of marking is a three- or four-character label that uses both digits and letters. An alphanumeric label typically consists of only three digits or two or three digits and one of the letters R, K, or M. The letter is used to indicate the multiplier, and the position of the letter indicates the decimal point placement. The letter R indicates a multiplier of 1 (no zeros after the digits), the K indicates a multiplier of 1000 (three zeros after the digits), and the M indicates a multiplier of 1,000,000 (six zeros after the digits). In this format, values from 100 to 999 consist of three digits and no letter to represent the three digits in the resistance value. Figure 2–32 shows three examples of this type of resistor label.

Related Problem   What is the resistance indicated by 1K25?

One system of labels for resistance tolerance values uses the letters F, G, and J:

$$F = \pm 1\% \qquad G = \pm 2\% \qquad J = \pm 5\%$$

For example, 620F indicates a 620 Ω resistor with a tolerance of $\pm 1\%$, 4R6G is a 4.6 Ω $\pm 2\%$ resistor, and 56KJ is a 56 kΩ $\pm 5\%$ resistor.

Variable Resistors   Variable resistors are designed so that their resistance values can be changed easily. Two basic uses for variable resistors are to divide voltage and to control current. The variable resistor used to divide voltage is called a **potentiometer**. The variable resistor used to control current is called a **rheostat**. Schematic symbols for these types are shown in Figure 2–33. The potentiometer is a three-terminal device, as indicated in part (a). Terminals 1 and 2 have a fixed resistance between them, which is the total resistance. Terminal 3 is connected to a moving contact (**wiper**). You can vary the resistance between 3 and 1 or between 3 and 2 by moving the contact.

Figure 2–33(b) shows the rheostat as a two-terminal variable resistor. Part (c) shows how you can use a potentiometer as a rheostat by connecting terminal 3 to either terminal 1 or terminal 2. Parts (b) and (c) are equivalent symbols. Some typical potentiometers are pictured in Figure 2–34.
▲ **FIGURE 2–34**

Typical potentiometers and construction views.

Potentiometers and rheostats can be classified as linear or tapered, as shown in Figure 2–35, where a potentiometer with a total resistance of 100 Ω is used as an example. As shown in part (a), in a linear potentiometer, the resistance between either terminal and the moving contact

(a) Linear

(b) Tapered (nonlinear)
▲ **FIGURE 2–35**

Examples of linear and tapered potentiometers.

varies linearly with the position of the moving contact. For example, one-half of the total contact movement results in one-half the total resistance. Three-quarters of the total movement results in three-quarters of the total resistance between the moving contact and one terminal, or one-quarter of the total resistance between the other terminal and the moving contact.

In the **tapered** potentiometer, the resistance varies nonlinearly with the position of the moving contact, so that one-half of a turn does not necessarily result in one-half the total resistance. This concept is illustrated in Figure 2–35(b), where the nonlinear values are arbitrary.

The potentiometer is used as a voltage-control device because when a fixed voltage is applied across the end terminals, a variable voltage is obtained at the wiper contact with respect to either end terminal. The rheostat is used as a current-control device because the current can be changed by changing the wiper position.

Variable Resistance Sensors Many sensors operate on the concept of a variable resistance, in which a physical quantity alters the electrical resistance. Depending on the sensor and the measurement requirements, the change in resistance may be determined directly or indirectly using the resistance change to alter a voltage or current.

Examples of resistance sensors include **thermistors** that change resistance as a function of temperature, **photoconductive cells** that change resistance as a function of light, and strain gauges that change resistance when a force is applied to them. Strain gauges are widely used in scales and applications where mechanical motion needs to be sensed. The measuring instruments need to be very sensitive because the change in resistance is very small. Figure 2–36 shows symbols for these various resistance sensors.

2–6   THE ELECTRIC CIRCUIT

A basic electric circuit is an arrangement of physical components that use voltage, current, and resistance to perform some useful function.

After completing this section, you should be able to

◆ **Describe a basic electric circuit**
   ◆ Relate a schematic to a physical circuit
   ◆ Define *open circuit* and *closed circuit*

◆ Describe various types of protective devices

◆ Describe various types of switches

◆ Explain how wire sizes are related to gauge numbers

◆ Define *ground* or *common*

Direction of Current

For a few years after the discovery of electricity, people assumed all current consisted of moving positive charges. However, in the 1890s, the electron was identified as the charge carrier in solid conductors.

Today, there are two accepted conventions for the direction of electrical current. *Electron flow direction*, preferred by many in the fields of electrical and electronics technology, assumes for analysis purposes that current is out of the negative terminal of a voltage source, through the circuit, and into the positive terminal of the source. *Conventional current direction* assumes for analysis purposes that current is out of the positive terminal of a voltage source, through the circuit, and into the negative terminal of the source.

Since you cannot actually see current, only its effects, it actually makes no difference which direction of current is assumed as long as it is used *consistently*. The results of electric circuit analysis are not affected by the direction of current that is assumed for analytical purposes. The direction used for analysis is largely a matter of preference, and there are many proponents for each approach.

Electron flow direction is used throughout this text. An alternate version of this text that uses conventional current direction is also available.

⚠ **SAFETY NOTE**

To avoid electrical shock, never touch a circuit while it is connected to a voltage source. If you need to handle a circuit, remove a component, or change a component, first make sure the voltage source is disconnected.

The Basic Circuit

Basically, an electric **circuit** consists of a voltage source, a load, and a path for current between the source and the load. Figure 2–37 shows in pictorial form an example of a simple electric circuit: a battery connected to a lamp with two conductors (wires). The battery is the voltage source, the lamp is the **load** on the battery because it draws current from the battery, and the two wires provide the current path from the negative terminal of the battery to the lamp and back to the positive terminal of the battery. Current goes through the filament of the lamp (which has a resistance), causing it to emit visible light. Current through the battery occurs by chemical action.

▲ **FIGURE 2–37**

A simple electric circuit.

In many practical cases, one terminal of the battery is connected to a common or ground point. For example, in most automobiles, the negative battery terminal is connected to the metal chassis of the car. The chassis is the ground for the automobile electrical system and acts as a conductor that completes the circuit.

The Electric Circuit Schematic   An electric circuit can be represented by a **schematic** using standard symbols for each element, as shown in Figure 2–38 for the simple circuit in Figure 2–37. A schematic, in an organized manner, shows how the various components in a given circuit are interconnected so that the operation of the circuit can be determined.

▲ FIGURE 2–38

Schematic for the circuit in Figure 2–37.

Current Control and Protection

The example circuit in Figure 2–37 illustrated a **closed circuit**—that is, a circuit in which the current has a complete path. When the current path is broken, the circuit is called an **open circuit**.

Mechanical Switches   Switches are commonly used for controlling the opening or clos-ing of circuits. For example, a switch is used to turn a lamp on or off, as illustrated in Figure 2–39. Each circuit pictorial is shown with its associated schematic. The type of switch in-dicated is a single-pole–single-throw (SPST) toggle switch. The term *pole* refers to the movable arm in a switch, and the term *throw* indicates the number of contacts that are af-fected (either opened or closed) by a single switch action (a single movement of a pole).

(a) There is current in a *closed* circuit because there is a complete current path (switch is ON or in the *closed* position). Current is almost always indicated by a red arrow in this text.

(b) There is no current in an *open* circuit because the path is broken (switch is OFF or in the *open* position).
▲ FIGURE 2–39

Figure 2–40 shows a somewhat more complicated circuit using a single-pole–double-throw (SPDT) type of switch to control the current to two different lamps. When one lamp is on, the other is off, and vice versa, as illustrated by the two schematics in parts (b) and (c), which represent each of the switch positions.

Switch symbols.

In addition to the SPST and the SPDT switches (symbols are shown in Figure 2–41(a) and (b)), the following other types are important:

- *Double-pole–single-throw (DPST)* The DPST switch permits simultaneous opening or closing of two sets of contacts. The symbol is shown in Figure 2–41(c). The dashed line indicates that the contact arms are mechanically linked so that both move with a single switch action.

- *Double-pole–double-throw (DPDT)* The DPDT switch provides connection from one set of contacts to either of two other sets. The schematic symbol is shown in Figure 2–41(d).

- *Push-button (PB)* In the normally open push-button switch (NOPB), shown in Figure 2–41(e), connection is made between two contacts when the button is depressed, and connection is broken when the button is released. In the normally closed push-button switch (NCPB), shown in Figure 2–41(f), connection between the two contacts is broken when the button is depressed.

- *Rotary* In a rotary switch, connection between one contact and any one of several others is made by turning a knob. A symbol for a simple six-position rotary switch is shown in Figure 2–41(g).

Figure 2–42 shows several varieties of mechanical switches, and Figure 2–43 shows the construction view of a typical toggle switch.

TECH NOTE

Small electronic parts can be damaged easily if you apply too much heat to them when soldering. Small switches frequently are constructed with plastic that can melt and render the switch useless. Manufacturers usually supply a maximum time and temperature that can be applied to a part without damage. A small heat sink can be temporarily connected between the point where solder is applied and the sensitive region of the component.

Semiconductor Switches Transistors are widely used as switches in many applications. The transistor can be used as the equivalent of a single-pole–single-throw switch. You can open and close a circuit path by controlling the state of the transistor. Two types of transistor symbols are shown in Figure 2–44 with their mechanical switch equivalents.

Transistor switches.

Current creates a closed switch.
No current creates an open switch.
(a) Bipolar transistor

Voltage creates a closed switch.
No voltage creates an open switch.
(b) Field-effect transistor
Here is a greatly simplified description of operation. One type, called the *bipolar transistor*, is controlled by current. When there is current at a specific terminal, the transistor acts as a closed switch; when there is no current at that terminal, the transistor acts as an open switch, as illustrated in Figure 2–44(a). Another type, called the *field-effect transistor*, is controlled by voltage. When there is voltage at a specific terminal, the transistor acts as a closed switch; when there is no voltage at that terminal, the transistor acts as an open switch, as illustrated in part (b).

Protective Devices **Fuses** and **circuit breakers** are used to deliberately create an open circuit when the current exceeds a specified number of amperes due to a malfunction or other abnormal condition in a circuit. For example, a 20 A fuse or circuit breaker will open a circuit when the current exceeds 20 A.

The basic difference between a fuse and a circuit breaker is that when a fuse is "blown," it must be replaced; but when a circuit breaker opens, it can be reset and reused repeatedly. Both of these devices protect against damage to a circuit due to excess current or prevent a hazardous condition created by the overheating of wires and other components when the current is too great. Several typical fuses and circuit breakers, along with their schematic symbols, are shown in Figure 2–45.

Two basic categories of fuses in terms of their physical configuration are cartridge type and plug type (screw in). Cartridge-type fuses have various-shaped housings with leads or other types of contacts, as shown in Figure 2–45(a). A typical plug-type fuse is shown in part (b). Fuse operation is based on the melting temperature of a wire or other metal element. As current increases, the fuse element heats up and when the rated current is exceeded, the element reaches its melting temperature and opens, thus removing power from the circuit.

Two common types of fuses are the fast-acting and the time-delay (slow-blow). Fast-acting fuses are type F and time-delay fuses are type T. In normal operation, fuses are often subjected to intermittent current surges that may exceed the rated current, such as when power to a circuit is turned on. Over time, this reduces the fuse's ability to withstand short surges or even current at the rated value. A slow-blow fuse can tolerate greater and longer duration surges of current than the typical fast-acting fuse. A fuse symbol is shown in Figure 2–45(d).

⚡ SAFETY NOTE

Always use fully insulated fuse pullers to remove and replace fuses in an electrical box. Even if the disconnect switch is in the off position, line voltage is still present in the box. Never use metal tools to remove and replace fuses.

(b) Plug fuse   (c) Circuit breakers   (d) Fuse symbol   (e) Circuit breaker symbol
▲ FIGURE 2–45

Typical fuses and circuit breakers and their symbols.

Typical circuit breakers are shown in Figure 2–45(c) and the symbol is shown in part (e). Generally, a circuit breaker detects excess current either by the heating effect of the current or by the magnetic field it creates. In a circuit breaker based on the heating effect, a bimetallic spring opens the contacts when the rated current is exceeded. Once opened, the contact is held open by mechanical means until manually reset. In a circuit breaker based on a magnetic field, the contacts are opened by a sufficient magnetic force created by excess current and must be mechanically reset.

Wires

Wires are the most common form of conductive material used in electrical applications. They vary in diameter and are arranged according to standard gauge numbers, called **AWG** (American Wire Gauge) sizes. As the gauge number increases, the wire diameter decreases. The size of a wire is also specified in terms of its cross-sectional area, as illustrated in Figure 2–46. A unit of cross-sectional area used for wires is the **circular mil**, abbreviated CM. One circular mil is the area of a wire with a diameter of 0.001 inch (1 mil). You can find the cross-sectional area by expressing the diameter in thousandths of an inch (mils) and squaring it, as follows:

$$A = d^2$$

where A is the cross-sectional area in circular mils and d is the diameter in mils. Table 2–3 lists the AWG sizes with their corresponding cross-sectional area and resistance in ohms per 1000 ft at 20°C.

EXAMPLE 2–7

What is the cross-sectional area of a wire with a diameter of 0.005 inch?

Solution

$$d = 0.005 \text{ in.} = 5 \text{ mils}$$
$$A = d^2 = 5^2 = \mathbf{25\ CM}$$

Related Problem What is the cross-sectional area of a 0.0015 in. diameter wire?

Wire Resistance Although copper wire conducts electricity extremely well, it still has some resistance, as do all conductors. The resistance of a wire depends on three physical characteristics: (a) type of material, (b) length of wire, and (c) cross-sectional area. In addition, temperature can also affect the resistance.

Each type of conductive material has a characteristic called its *resistivity, ρ*. For each material, ρ is a constant value at a given temperature. The formula for the resistance of a wire of length l and cross-sectional area A is

Equation 2–6

$$R = \frac{\rho l}{A}$$

This formula shows that resistance increases with an increase in resistivity and length and decreases with an increase in cross-sectional area. For resistance to be calculated in ohms, the length must be in feet, the cross-sectional area in circular mils, and the resistivity in CM-Ω/ft.

EXAMPLE 2–8   Find the resistance of a 100 ft length of copper wire with a cross-sectional area of 810.1 CM. The resistivity of copper is 10.37 CM-Ω/ft.

Solution

$$R = \frac{\rho l}{A} = \frac{(10.37 \text{ CM-}\Omega/\text{ft})(100 \text{ ft})}{810.1 \text{ CM}} = \textbf{1.280 } \Omega$$

Related Problem   Use Table 2–3 to determine the resistance of 100 ft of copper wire with a cross-sectional area of 810.1 CM. Compare with the calculated result.

As mentioned, Table 2–3 lists the resistance of the various standard wire sizes in ohms per 1000 feet at 20°C. For example, a 1000 ft length of 14 gauge copper wire has a resistance of 2.525 Ω. A 1000 ft length of 22 gauge wire has a resistance of 16.14 Ω. For a given length, the smaller wire has more resistance. Thus, for a given voltage, larger wires can carry more current than smaller ones.

Ground

Ground is the reference point in electric circuits. The term *ground* originated from the fact that one conductor of a circuit was typically connected with an 8-foot long metal rod driven into the earth itself. Today, this type of connection is referred to as an *earth ground*. In household wiring, earth ground is indicated with a green or bare copper wire. Earth ground is normally connected to the metal chassis of an appliance or a metal electrical box for safety. Unfortunately, there have been exceptions to this rule, which can present a safety hazard if a metal chassis is not at earth ground. It is a good idea to confirm that a metal chassis is actually at earth ground potential before doing any work on an instrument or appliance.

Another type of ground is called a *reference ground*. Voltages are always specified with respect to another point. If that point is not stated explicitly, the reference ground is understood. Reference ground defines 0 V for the circuit. The reference ground can be at a completely different potential than the earth ground. Reference ground is also called **common** and labeled COM or COMM because it represents a common conductor. When you are wiring a protoboard in the laboratory, you will normally reserve one of the bus strips (a long line along the length of the board) for this common conductor.

Three ground symbols are shown in Figure 2–47. Unfortunately, there is not a separate symbol to distinguish between earth ground and reference ground. The symbol in (a) represents either an earth ground or a reference ground, (b) shows a chassis ground, and (c) is an alternate reference symbol typically used when there is more than one common connection (such as analog and digital ground in the same circuit). In this book, the symbol in part (a) will be used throughout.

Figure 2–48 illustrates a simple circuit with ground connections. The current is from the negative terminal of the 12 V source, through the ground connection, through the lamp, and back to the positive terminal of the source. Ground provides a path for the current back to the source because all of the ground points are electrically the same point. The voltage at the top of the circuit is +12 V with respect to ground.

2–7 BASIC CIRCUIT MEASUREMENTS

In working on electrical or electronic circuits, you will frequently need to measure voltage, current, or resistance using meters safely and correctly.

After completing this section, you should be able to

♦ **Make basic circuit measurements**
  ♦ Properly measure voltage in a circuit
  ♦ Properly measure current in a circuit
  ♦ Properly measure resistance
  ♦ Set up and read basic meters

Voltage, current, and resistance measurements are commonly required in electronics work. The instrument used to measure voltage is a **voltmeter**, the instrument used to measure current is an **ammeter**, and the instrument used to measure resistance is an **ohmmeter**. Commonly, all three instruments are combined into a single instrument called a **multimeter**, in which you can choose what specific quantity to measure by selecting the appropriate function with a switch.

Meter Symbols

Throughout this book, certain symbols will be used in circuits to represent meters, as shown in Figure 2–49. You may see any of four types of symbols for voltmeters, ammeters, or ohmmeters, depending on which symbol most effectively conveys the information required. The digital meter symbol is used when specific values are to be indicated in a circuit. The bar graph meter symbol and sometimes the analog meter symbol are used to illustrate the operation of a circuit when *relative* measurements or changes in quantities, rather than specific values, need to be depicted. A changing quantity may be indicated by an arrow in the display showing an increase or decrease. The generic symbol is used to indicate placement of meters in a circuit when no values or value changes need to be shown.

▲ FIGURE 2–49

Examples of meter symbols used in this book. Each of the symbols can be used to represent either an ammeter (A), a voltmeter (V), or an ohmmeter (Ω).

Measuring Current

Figure 2–50 illustrates how to measure current with an ammeter. Part (a) shows a simple circuit in which the current through the resistor is to be measured. First make sure the range setting of the ammeter is greater than the expected current and then connect the ammeter in the current path by first opening the circuit, as shown in part (b). Then insert the meter as shown in part (c). Such a connection is a series connection. The polarity of the meter must be such that the current is in at the negative terminal and out at the positive terminal.

(a) Circuit in which the current is to be measured

(b) Open the circuit either between the resistor and the positive terminal or between the resistor and the negative terminal of source.

(c) Install the ammeter in the current path with polarity as shown (negative to negative, positive to positive).
▲ FIGURE 2–50

Example of an ammeter connection in a simple circuit to measure current.

Measuring Voltage

To measure voltage, connect the voltmeter across the component for which the voltage is to be found. Such a connection is a parallel connection. The negative terminal of the meter must be connected to the negative side of the circuit, and the positive terminal of the meter must be connected to the positive side of the circuit. Figure 2–51 shows a voltmeter connected to measure the voltage across the resistor.

⚡ **SAFETY NOTE**

Never wear rings or any type of metallic jewelry while working on a circuit. These items may accidentally come in contact with the circuit, causing shock and/or damage to the circuit. With high-energy sources, such as a car battery, a short across jewelry (watch or ring) can become hot instantly, causing severe burns.
▲ FIGURE 2–51

Example of a voltmeter connection in a simple circuit to measure voltage.

Measuring Resistance

To measure resistance, first turn off the power and disconnect one end or both ends of the resistor from the circuit; then connect the ohmmeter across the resistor. This procedure is shown in Figure 2–52.

Example of using an ohmmeter to measure resistance.

(a) Disconnect the resistor from the circuit to avoid damage to the meter and/or incorrect measurement.

(b) Measure the resistance. (Polarity is not important.)
Digital Multimeters

A **DMM** (digital multimeter) is a multifunction electronic instrument that can measure voltage, current, and resistance. DMMs are the most widely used type of electronic measuring instrument. Generally, DMMs provide more functions, better accuracy, greater ease of reading, and greater reliability than do many analog meters. Analog meters have at least one advantage over DMMs, however. They can track short-term variations and trends in a measured quantity that many DMMs are too slow to respond to. Figure 2–53 shows typical DMMs.

Typical digital multimeters (DMMs). (Courtesy of B+K Precision)

(a)

(b)

DMM Functions The basic functions found on most DMMs include the following:

- ◆ Ohms
- ◆ DC voltage and current
- ◆ AC voltage and current

Some DMMs provide special functions such as transistor or diode tests, power measurement, and decibel measurement for audio amplifier tests. Some meters require manual selection of the ranges for the functions. Many meters provide automatic range selection and are called *autoranging.*

DMM Displays DMMs are available with either LCD (liquid-crystal display) or LED (light-emitting diode) readouts. The LCD is the most commonly used readout in battery-powered instruments because it requires only very small amounts of current. A typical battery-powered DMM with an LCD readout operates on a 9 V battery that will last from a few hundred hours to 2000 hours and more. The disadvantages of LCD readouts are that (a) they are difficult or impossible to see in low-light conditions and (b) they are relatively slow to respond to measurement changes. LEDs, on the other hand, can be seen in the dark and respond quickly to changes in measured values. LED displays require much more current than LCDs, and, therefore, battery life is shortened when LEDs are used in portable equipment.

Both LCD and LED DMM displays are in a 7-segment format. Each digit in a display consists of seven separate segments as shown in Figure 2–54(a). Each of the ten decimal digits is formed by the activation of appropriate segments, as illustrated in Figure 2–54(b). In addition to the seven segments, there is also a decimal point.

(a)   (b)

▲ **FIGURE 2–54**

Seven-segment display.

Resolution The **resolution** of a DMM is the smallest increment of a quantity that the meter can measure. The smaller the increment, the better the resolution. One factor that determines the resolution of a meter is the number of digits in the display.

Because many DMMs have 3½ digits in their display, we will use this case for illustration. A 3½-digit multimeter has three digit positions that can indicate from 0 through 9, and one digit position that can indicate only a value of 0 or 1. This latter digit, called the *half-digit,* is always the most significant digit in the display. For example, suppose that a DMM is reading 0.999 V, as shown in Figure 2–55(a). If the voltage increases by 0.001 V to 1 V, the display correctly shows 1.000 V, as shown in part (b). The "1" is the half-digit. Thus, with 3½ digits, a variation of 0.001 V, which is the resolution, can be observed.

Now, suppose that the voltage increases to 1.999 V. This value is indicated on the meter as shown in Figure 2–55(c). If the voltage increases by 0.001 V to 2 V, the half-digit cannot display the "2," so the display shows 2.00. The half-digit is blanked and only three digits are active, as indicated in part (d). With only three digits active, the resolution is 0.01 V rather than 0.001 V as it is with 3½ active digits. The resolution remains 0.01 V up to 19.99 V. The resolution goes to 0.1 V for readings of 20.0 V to 199.9 V. At 200 V, the resolution goes to 1 V, and so on.

The resolution capability of a DMM is also determined by the internal circuitry and the rate at which the measured quantity is sampled. DMMs with displays of 4½ through 8½ digits are also available.

Accuracy The **accuracy** is the degree to which a measured value represents the true or accepted value of a quantity. The accuracy of a DMM is established strictly by its internal circuitry and calibration. For typical DMMs, accuracies range from 0.01% to 0.5%, with some precision laboratory-grade DMMs going to 0.002%.

Reading Analog Multimeters

Although the DMM is the predominate type of multimeter, you may occasionally have to use an analog meter. A representation of a typical analog multimeter is shown in Figure 2–56. This particular instrument can be used to measure both direct current (dc) and alternating current (ac) quantities as well as resistance values. It has four selectable functions: dc volts (DC VOLTS), dc milliamperes (DC mA), ac volts (AC VOLTS), and OHMS. Most analog multimeters are similar to this one.

▶ FIGURE 2–56

A typical analog multimeter.
Within each function there are several ranges, as indicated by the brackets around the selector switch. For example, the DC VOLTS function has 0.3 V, 3 V, 12 V, 60 V, 300 V, and 600 V ranges. Thus, dc voltages from 0.3 V full-scale to 600 V full-scale can be measured. On the DC mA function, direct currents from 0.06 mA full-scale to 120 mA full-scale can be measured. On the ohm scale, the settings are ×1, ×10, ×100, ×1000, and ×100,000.

The Ohm Scale   Ohms are read on the top scale of the meter. This scale is nonlinear; that is, the values represented by each division (large or small) vary as you go across the scale. In Figure 2–56, notice how the scale becomes more compressed as you go from right to left.

To read the actual value in ohms, multiply the number on the scale as indicated by the pointer by the factor selected by the switch. For example, when the switch is set at ×100 and the pointer is at 20, the reading is 20 × 100 = 2000 Ω.

As another example, assume that the switch is at ×10 and the pointer is at the seventh small division between the 1 and 2 marks, indicating 17 Ω (1.7 × 10). Now, if the meter remains connected to the same resistance and the switch setting is changed to ×1, the pointer will move to the second small division between the 15 and 20 marks. This, of course, is also a 17 Ω reading, illustrating that a given resistance value can often be read at more than one range switch setting. However, the meter should be *zeroed* each time the range is changed by touching the leads together and adjusting the needle.

The AC-DC and DC mA Scales   The second, third, and fourth scales from the top, labeled "AC" and "DC," are used in conjunction with the DC VOLTS and AC VOLTS functions. The upper ac-dc scale ends at the 300 mark and is used with range settings, such as 0.3, 3, and 300. For example, when the switch is at 3 on the DC VOLTS function, the 300 scale has a full-scale value of 3 V; at the range setting of 300, the full-scale value is 300 V. The middle ac-dc scale ends at 60. This scale is used in conjunction with range settings, such as 0.06, 60, and 600. For example, when the switch is at 60 on the DC VOLTS function, the full-scale value is 60 V. The lower ac-dc scale ends at 12 and is used in conjunction with switch settings, such as 1.2, 12, and 120. The three DC mA scales are used in a similar way to measure current.

EXAMPLE 2–9

Determine the quantity (voltage, current, or resistance) that is being measured and its value for each specified switch setting on the meter in Figure 2–57.

(a) The switch is set on the DC VOLTS function and the 60 V range.

(b) The switch is set on the DC mA function and the 12 mA range.

(c) The switch is set on the OHMS function and the ×1K range.

Solution   **(a)** The reading taken from the middle AC-DC scale is **18 V**.

(b) The reading taken from the lower AC-DC scale is **3.8 mA**.

(c) The reading taken from the ohms scale (top) is **10 kΩ**.

Related Problem   In Figure 2–57 the switch is moved to the ×100 ohms setting. Assuming that the same resistance is being measured as in part (c), what will the needle do?

2–8 ELECTRICAL SAFETY

Safety is a major concern when working with electricity. The possibility of an electric shock or a burn is always present, so caution should always be used. You provide a current path when voltage is applied across two points on your body, and current produces electrical shock. Electrical components often operate at high temperatures, so you can sustain skin burns when you come in contact with them. Also, the presence of electricity creates a potential fire hazard.

After completing this section, you should be able to

◆ **Recognize electrical hazards and practice proper safety procedures**

  ◆ Describe the cause of electrical shock

  ◆ List the groups of current paths through the body

  ◆ Discuss the effects of current on the human body

  ◆ List the safety precautions that you should observe when you work with electricity

Electric Shock

Current through your body, not the voltage, is the cause of **electrical shock**. Of course, it takes voltage across a resistance to produce current. When a point on your body comes in contact with a voltage and another point comes in contact with a different voltage or with ground, such as a metal chassis, there will be current through your body from one point to the other. The path of the current depends on the points across which the voltage occurs. The severity of the resulting electrical shock depends on the amount of voltage and the path that the current takes through your body. The current path through the body determines which tissues and organs will be affected.

Effects of Current on the Human Body The amount of current is dependent on voltage and resistance. The human body has resistance that depends on many factors, which include body mass, skin moisture, and points of contact of the body with a voltage potential. Table 2–4 shows the effects for various values of current in milliamperes.

Body Resistance Resistance of the human body is typically between $10 \text{ k}\Omega$ and $50 \text{ k}\Omega$ and depends on the two points between which it is measured. The moisture of the skin also affects the resistance between two points. The resistance determines the amount of voltage

CURRENT (mA)	PHYSICAL EFFECT
0.4	Slight sensation
1.1	Perception threshold
1.8	Shock, no pain, no loss of muscular control
9	Painful shock, no loss of muscular control
16	Painful shock, let-go threshold
23	Severe painful shock, muscular contractions, breathing difficulty
75	Ventricular fibrillation, threshold
235	Ventricular fibrillation, usually fatal for duration of 5 seconds or more
4,000	Heart paralysis (no ventricular fibrillation)
5,000	Tissue burn

◄ **TABLE 2–4**

Physical effects of electrical current. Values vary depending on body mass.

required to produce each of the effects listed in Table 2–4. For example, if you have a resistance of $10\,k\Omega$ between two given points on your body, 90 V across those two points will produce enough current (9 mA) to cause painful shock.

Utility Voltages

We tend to take utility voltages for granted, but they can be and have been lethal. It is best to be careful around any source of voltage (even low voltages can present a serious burn hazard). As a general rule, you should avoid working on any energized circuit, and check that the power is off with a known good meter. Most work in educational labs uses low voltages, but you should still avoid touching any energized circuit. If you are working on a circuit that is connected to utility voltages, the service should be disconnected, a notice should be placed on the equipment or place where the service is disconnected, and a padlock should be used to prevent someone from accidentally turning on the power. This procedure is called *lockout/tagout* and is widely used in industry. There are specific OSHA and industry standards for lockout/tagout.

Most laboratory equipment is connected to the utility line ("ac") and in North America, this is 120 Vrms (rms is discussed in Section 11–3). A faulty piece of equipment can cause the "hot" lead to inadvertently become exposed. You should inspect cords for exposed wires and check equipment for missing covers or other potential safety problems. The single-phase utility lines in homes and electrical laboratories use three insulated wires that are referred to as the "hot" (black or red wire), neutral (white wire), and safety ground (green wire). The hot and neutral wires will have current, but the green safety line should never have current in normal operation. The safety wire is connected to the metal exterior of encased equipment and is also connected to conduit and the metal boxes for housing receptacles. Figure 2–58(a) shows the location of these conductors on a standard receptacle. Notice that the neutral line is larger than the hot line.

The safety ground should be connected to the neutral at the service panel. The metal chassis of an instrument or appliance is also connected to ground. In the event that the hot wire is accidentally in contact with ground, the resulting high current should trip the circuit breaker or open a fuse to remove the hazard. However, a broken or missing ground lead may not have high current until it is contacted by a person. This danger is one obvious reason for ensuring that line cords have not been altered by removing the ground pin.

Many circuits are further protected with a special device called a ground-fault circuit interrupter (GFCI, which is sometimes called just GFI). If a fault occurs in a GFCI circuit, a sensor detects that the current in the hot line and the neutral line are not equal as they should be and trips the circuit breaker. The GFCI breaker is very fast acting and can trip faster than the breaker on the main panel. GFCI breakers are required in areas where a
(a) Standard receptacle
   and connections

(b) GFCI receptacle

SAFETY NOTE

A GFCI outlet does not prevent shock or injury in all cases. If you are touching the hot and neutral wires without being grounded, no ground fault is detected and the GFCI breaker will not trip. In another case, the GFCI may prevent electrocution but not the initial electric shock before it interrupts the circuit. The initial shock could cause a secondary injury, such as a fall.

shock hazard exists such as wherever there is water or moisture. Pools, bathrooms, kitchens, basements, and garages should all have GFCI outlets. Figure 2–58(b) shows a ground-fault receptacle with reset and test buttons. When the test button is pressed, the circuit should immediately be opened. The reset button restores power.

Safety Precautions

There are many practical things that you should do when you work with electrical and electronic equipment. Some important precautions are listed here.

◆ Avoid contact with any voltage source. Turn power off before you work on circuits when touching circuit parts is required.

◆ Do not work alone. A telephone should be available for emergencies.

◆ Do not work when tired or taking medications that make you drowsy.

◆ Remove rings, watches, and other metallic jewelry when you work on circuits.

◆ Do not work on equipment until you know proper procedures and are aware of potential hazards.

◆ Make sure power cords are in good condition and grounding pins are not missing or bent.

◆ Keep your tools properly maintained. Make sure the insulation on metal tool handles is in good condition.

◆ Handle tools properly and maintain a neat work area.

◆ Wear safety glasses when appropriate, particularly when soldering and clipping wires.

◆ Always shut off power and discharge capacitors before you touch any part of a circuit with your hands.

◆ Know the location of the emergency power-off switch and emergency exits.

◆ Never try to override or tamper with safety devices such as an interlock switch.

◆ Always wear shoes and keep them dry. Do not stand on metal or wet floors when working on electrical circuits.

◆ Never handle instruments when your hands are wet.

◆ Never assume that a circuit is off. Double-check it with a reliable meter before handling.

◆ Set the limiter on electronic power supplies to prevent currents larger than necessary to supply the circuit under test.

+ Some devices such as capacitors can store a lethal charge for long periods after power is removed. They must be properly discharged before you work with them.

+ When making circuit connections, always make the connection to the point with the highest voltage as your last step.

+ Avoid contact with the terminals of power supplies.

+ Always use wires with insulation and connectors or clips with insulating shrouds.

+ Keep cables and wires as short as possible. Connect polarized components properly.

+ Be aware of and follow all workplace and laboratory rules. Do not have drinks or food near equipment.

+ If another person cannot let go of an energized conductor, switch the power off immediately. If that is not possible, use any available nonconductive material to try to separate the body from the contact.

+ Use a lockout/tagout procedure to avoid someone turning power on while you are working on a circuit.

Application Activity

In this application activity, a dc voltage is applied to a circuit in order to produce current through a lamp to provide light. You will see how the current is controlled by resistance. The circuit simulates an instrument panel illumination circuit, which allows you to increase or decrease the amount of light on the instruments.

The instrument panel illumination circuit operates from a 12 V battery that is the voltage source for the circuit. The circuit uses a potentiometer connected as a rheostat, controlled by a knob on the instrument panel, which is used to set the amount of current through the lamp to back-light the instruments. The brightness of the lamp is proportional to the amount of current through the lamp. The switch used to turn the lamp on and off is the same one used for the headlights. There is a fuse for circuit protection in case of a short circuit.

Figure 2–59 shows the schematic for the illumination circuit, and Figure 2–60 shows the breadboarded circuit. A laboratory dc power supply is used in the place of an actual battery. The protoboard in Figure 2–60 is a type that is commonly used for constructing circuits on the test bench.

outer edges of the board are typically connected together as shown.

INTRODUCTION

In Chapter 2, you studied the concepts of voltage, current, and resistance. You also were introduced to a basic electric circuit. In this chapter, you will learn how voltage, current, and resistance are interrelated. You will also learn how to analyze a simple electric circuit.

Ohm's law is perhaps the single most important tool for the analysis of electric circuits, and you *must* know how to apply it.

In 1826 Georg Simon Ohm found that current, voltage, and resistance are related in a specific and predictable way. Ohm expressed this relationship with a formula that is known today as Ohm's law. In this chapter, you will learn Ohm's law and how to use it in solving circuit problems. A general approach to troubleshooting using an *analysis*, *planning*, and *measurement* (APM) approach is also introduced.

3–1   THE RELATIONSHIP OF CURRENT, VOLTAGE, AND RESISTANCE

Ohm's law describes mathematically how voltage, current, and resistance in a circuit are related. Ohm's law is expressed in three equivalent forms depending on which quantity you need to determine. As you will learn, current and voltage are linearly proportional. However, current and resistance are inversely proportional.

After completing this section, you should be able to

◆ **Explain Ohm's law**

 ◆ Describe how V, I, and R are related

 ◆ Express I as a function of V and R

 ◆ Express V as a function of I and R

 ◆ Express R as a function of V and I

 ◆ Show graphically that I and V are directly proportional

 ◆ Show graphically that I and R are inversely proportional

 ◆ Explain why I and V are linearly proportional

Ohm determined experimentally that if the voltage across a resistor is increased, the current through the resistor will also increase; and, likewise, if the voltage is decreased, the current will decrease. For example, if the voltage is doubled, the current will double. If the voltage is halved, the current will also be halved. This relationship is illustrated in Figure 3–1, with relative meter indications of voltage and current.

Effect on the current of changing the voltage with the resistance at a constant value.

(a) Less V, less I (b) More V, more I
Ohm also determined that if the voltage is held constant, less resistance results in more current, and, also, more resistance results in less current. For example, if the resistance is halved, the current doubles. If the resistance is doubled, the current is halved. This concept is illustrated by the meter indications in Figure 3–2, where the resistance is increased and the voltage is held constant.

Ohm's law states that current is directly proportional to voltage and inversely proportional to resistance. The circuits in Figures 3–1 and 3–2 illustrate Ohm's law, which is given in the following formula:

$$I = \frac{V}{R}$$

<div align="right">Equation 3–1</div>

where I is current in amperes (A), V is voltage in volts (V), and R is resistance in ohms (Ω). For a constant value of R, if the value of V is increased, the value of I increases; if V is decreased, I decreases. If V is constant and R is increased, I decreases. Similarly, if V is constant and R is decreased, I increases.

Using Equation 3–1, you can calculate the current if you know the values of voltage and resistance. By manipulating Equation 3–1, you can obtain expressions for voltage and resistance.

$$V = IR$$

<div align="right">Equation 3–2</div>

$$R = \frac{V}{I}$$

<div align="right">Equation 3–3</div>

With Equation 3–2, you can calculate voltage if you know the values of current and resistance. With Equation 3–3, you can calculate resistance if you know the values of voltage and current.

The three expressions—Equations 3–1, 3–2 and 3–3—are all equivalent. They are simply three ways of stating Ohm's law.

The Linear Relationship of Current and Voltage

In resistive circuits, current and voltage are linearly proportional. **Linear** means that if one of the quantities is increased or decreased by a certain percentage, the other will increase or decrease by the same percentage, assuming that the resistance is constant in value. For example, if the voltage across a resistor is tripled, the current will triple.

EXAMPLE 3–1

Show that if the voltage in the circuit of Figure 3–3 is increased to three times its present value, the current will triple in value.

▶ **FIGURE 3–3**
Solution   With 10 V, the current is

$$I = \frac{V}{R} = \frac{10\,\text{V}}{4.7\,\text{k}\Omega} = \textbf{2.13 mA}$$

If the voltage is increased to 30 V, the current will be

$$I = \frac{V}{R} = \frac{30\,\text{V}}{4.7\,\text{k}\Omega} = \textbf{6.38 mA}$$

The current went from 2.13 mA to 6.38 mA when the voltage was tripled to 30 V.

Related Problem[*]   If the voltage in Figure 3–3 is quadrupled, will the current also quadruple?

*Answers are at the end of the chapter.

Let's take a constant value of resistance, for example, 10Ω, and calculate the current for several values of voltage ranging from 10 V to 100 V in the circuit in Figure 3–4(a). The current values obtained are shown in Figure 3–4(b). The graph of the *I* values versus the *V* values is shown in Figure 3–4(c). Note that it is a straight line graph. This graph tells us that a change in voltage results in a linearly proportional change in current. No matter what value *R* is, assuming that *R* is constant, the graph of *I* versus *V* will always be a straight line.
▲ FIGURE 3–4

Graph of current versus voltage for the circuit in part (a).

EXAMPLE 3–2

Assume that you are measuring the current in a circuit that is operating with 25 V. The ammeter reads 50 mA. Later, you notice that the current has dropped to 40 mA. Assuming that the resistance did not change, you must conclude that the voltage source has changed. How much has the voltage changed, and what is its new value?

Solution The current has dropped from 50 mA to 40 mA, which is a decrease of 20%. Since the voltage is linearly proportional to the current, the voltage has decreased by the same percentage that the current did. Taking 20% of 25 V, you get

$$\text{Change in voltage} = (0.2)(25 \text{ V}) = \mathbf{5 \text{ V}}$$

Subtract this change from the original voltage to get the new voltage.

$$\text{New voltage} = 25 \text{ V} - 5 \text{ V} = \mathbf{20 \text{ V}}$$

Notice that you did not need the resistance value in order to find the new voltage.

Related Problem If the current drops to 0 A under the same conditions stated in the example, what is the voltage?

The Inverse Relationship of Current and Resistance

As you have seen, current varies inversely with resistance as expressed by Ohm's law, $I = V/R$. When the resistance is reduced, the current goes up; when the resistance is increased, the current goes down. For example, if the source voltage is held constant and the resistance is halved, the current doubles in value; when the resistance is doubled, the current is reduced by half.

Let's take a constant value of voltage, for example, 10 V, and calculate the current for several values of resistance ranging from 10 Ω to 100 Ω in the circuit in Figure 3–5(a). The

3–2 CURRENT CALCULATIONS

Examples in this section illustrate the Ohm's law formula $I = V/R$.

After completing this section, you should be able to

◆ **Calculate current in a circuit**

◆ Use Ohm's law to find current when you know voltage and resistance values

◆ Use voltage and resistance values expressed with metric prefixes

The following examples use the formula $I = V/R$. In order to get current in amperes, you must express the value of voltage in volts and the value of resistance in ohms.

EXAMPLE 3–3

How many amperes of current are in the circuit of Figure 3–6?

▶ **FIGURE 3–6**

Solution   Use the formula $I = V/R$, and substitute 100 V for V and 22 kΩ for R.

$$I = \frac{V}{R} = \frac{100\ V}{22\ k\Omega} = \mathbf{4.55\ mA}$$

Related Problem   If R is changed to 33 kΩ in Figure 3–6, what is the current?

Use Multisim file E03-03 to verify the calculated results in this example and your calculation for the related problem.

EXAMPLE 3–4

If the resistance in Figure 3–6 is changed to 47 Ω and the voltage to 50 V, what is the new value of current?

Solution   Substitute $V = 50$ V and $R = 47$ Ω into the formula $I = V/R$.

$$I = \frac{V}{R} = \frac{50\ V}{47\ \Omega} = \mathbf{1.06\ A}$$

Related Problem   If $V = 5$ V and $R = 1000$ Ω, what is the current?

Units with Metric Prefixes

In electronics, resistance values of thousands of ohms or even millions of ohms are common. The metric prefixes *kilo* (k) and *mega* (M) are used to indicate large values. Thus, thousands of ohms are expressed in kilohms (kΩ), and millions of ohms are expressed in megohms (MΩ). The following four examples illustrate how to use kilohms and megohms to calculate current. Volts (V) divided by kilohms (kΩ) results in milliamperes (mA). Volts (V) divided by megohms (MΩ) results in microamperes (μA).

EXAMPLE 3–5

Calculate the current in Figure 3–7.

▶ **FIGURE 3–7**
Solution   Remember that $1.0\,k\Omega$ is the same as $1 \times 10^3\,\Omega$. Use the formula $I = V/R$ and substitute 50 V for V and $1 \times 10^3\,\Omega$ for R.

$$I = \frac{V}{R} = \frac{50\,V}{1.0\,k\Omega} = \frac{50\,V}{1 \times 10^3\,\Omega} = 50 \times 10^{-3}\,A = \textbf{50 mA}$$

Related Problem   Calculate the current in Figure 3–7 if R is changed to $10\,k\Omega$.

In Example 3–5, 50×10^{-3} A is expressed as 50 milliamperes (50 mA). This can be used to advantage when you divide volts by kilohms. The current will be in milliamperes, as Example 3–6 illustrates.

EXAMPLE 3–6   How many milliamperes are in the circuit of Figure 3–8?

▶ **FIGURE 3–8**

Solution   When you divide volts by kilohms, you get current in milliamperes.

$$I = \frac{V}{R} = \frac{30\,V}{5.6\,k\Omega} = \textbf{5.36 mA}$$

Related Problem   What is the current in milliamperes if R is changed to $2.2\,k\Omega$?

Use Multisim file E03-06 to verify the calculated results in this example and to confirm your calculation for the related problem.

If you apply volts when resistance values are in megohms, the current is in microamperes (μA), as Examples 3–5 and 3–6 show.

EXAMPLE 3–7   Determine the amount of current in the circuit of Figure 3–9.

▶ **FIGURE 3–9**
Solution   Recall that $4.7\,M\Omega$ equals $4.7 \times 10^6\,\Omega$. Substitute 25 V for V and $4.7 \times 10^6\,\Omega$ for R.

$$I = \frac{V}{R} = \frac{25\,V}{4.7\,M\Omega} = \frac{25\,V}{4.7 \times 10^6\,\Omega} = 5.32 \times 10^{-6}\,A = \textbf{5.32 } \boldsymbol{\mu}\textbf{A}$$

Related Problem   What is the current if V is increased to 100 V in Figure 3–6?

EXAMPLE 3–8

Change the value of R in Figure 3–9 to $1.8\,\text{M}\Omega$. What is the new value of current?

Solution When you divide volts by megohms, you get current in microamperes.

$$I = \frac{V}{R} = \frac{25\,\text{V}}{1.8\,\text{M}\Omega} = \mathbf{13.9\,\mu A}$$

Related Problem If R is doubled in the circuit of Figure 3–6, what is the new value of current?

Small voltages, usually less than 50 V are common in semiconductor circuits. Occasionally, however, large voltages are encountered. For example, the high-voltage supply in some television receivers is around 20,000 V (20 kilovolts, or 20 kV), and transmission voltages generated by the power companies may be as high as 345,000 V (345 kV). The following two examples illustrate how to use voltage values in the kilovolt range to calculate current.

EXAMPLE 3–9

How much current is produced by a voltage of 24 kV across a $12\,\text{k}\Omega$ resistor?

Solution Since kilovolts are divided by kilohms, the prefixes cancel; therefore, the current is in amperes.

$$I = \frac{V}{R} = \frac{24\,\text{kV}}{12\,\text{k}\Omega} = \frac{24 \times 10^3\,\text{V}}{12 \times 10^3\,\Omega} = \mathbf{2\,A}$$

Related Problem What is the current in mA produced by 1 kV across a $27\,\text{k}\Omega$ resistor?

EXAMPLE 3–10

How much current is there through a $100\,\text{M}\Omega$ resistor when 50 kV are applied?

Solution In this case, divide 50 kV by $100\,\text{M}\Omega$ to get the current. Substitute 50×10^3 V for 50 kV and $100 \times 10^6\,\Omega$ for $100\,\text{M}\Omega$.

$$I = \frac{V}{R} = \frac{50\,\text{kV}}{100\,\text{M}\Omega} = \frac{50 \times 10^3\,\text{V}}{100 \times 10^6\,\Omega} = 0.5 \times 10^{-3}\,\text{A} = \mathbf{0.5\,mA}$$

Remember that the power of ten in the denominator is subtracted from the power of ten in the numerator. So 50 was divided by 100, giving 0.5, and 6 was subtracted from 3, giving 10^{-3}.

Related Problem How much current is there through a $6.8\,\text{M}\Omega$ resistor when 10 kV are applied?

SECTION 3–2 CHECKUP

In Problems 1–4, calculate I.
1. $V = 10\,\text{V}$ and $R = 5.6\,\Omega$.
2. $V = 100\,\text{V}$ and $R = 560\,\Omega$.
3. $V = 5\,\text{V}$ and $R = 2.2\,\text{k}\Omega$.
4. $V = 15\,\text{V}$ and $R = 4.7\,\text{M}\Omega$.
5. If a $4.7\,\text{M}\Omega$ resistor has 20 kV across it, how much current is there?
6. How much current will 10 kV across a $2.2\,\text{M}\Omega$ resistor produce?

3–3   VOLTAGE CALCULATIONS

Examples in this section illustrate the Ohm's law expression $V = IR$.

After completing this section, you should be able to

◆ **Calculate voltage in a circuit**

  ◆ Use Ohm's law to find voltage when you know current and resistance values

  ◆ Use current and resistance values expressed with metric prefixes

The following examples use the formula $V = IR$. To obtain voltage in volts, you must express the value of I in amperes and the value of R in ohms.

EXAMPLE 3–11

In the circuit of Figure 3–10, how much voltage is needed to produce 5 A of current?

▶ **FIGURE 3–10**
Solution   Substitute 5 A for I and 100 Ω for R into the formula $V = IR$.

$$V = IR = (5\,\text{A})(100\,\Omega) = \mathbf{500\,V}$$

Thus, 500 V are required to produce 5 A of current through a 100 Ω resistor.

Related Problem   In Figure 3–10, how much voltage is required to produce 12 A of current?

Units with Metric Prefixes

The following two examples illustrate how to use current values in the milliampere (mA) and microampere (μA) ranges to calculate voltage.

EXAMPLE 3–12

How much voltage will be measured across the resistor in Figure 3–11?

▶ **FIGURE 3–11**
Solution   Five milliamperes equals 5×10^{-3} A. Substitute the values for I and R into the formula $V = IR$.

$$V = IR = (5\,\text{mA})(56\,\Omega) = (5 \times 10^{-3}\,\text{A})(56\,\Omega) = 280 \times 10^{-3}\,\text{V} = \mathbf{280\,mV}$$

Related Problem   How much voltage is measured across R if $R = 33\ \Omega$ and $I = 1.5$ mA in Figure 3–11?

Use Multisim file E03-12 to verify the calculated results in this example and to confirm your calculation for the related problem.

EXAMPLE 3–13

Suppose that a solar cell produces a current of 180 μA through a 100 Ω resistor. How much voltage is across the resistor?

Solution   180 microamperes equals 180×10^{-6} A. Substitute the values for I and R into the formula $V = IR$.

$$V = IR = (180\ \mu\text{A})(100\ \Omega) = (180 \times 10^{-6}\text{A})(100\ \Omega) = 18 \times 10^{-3}\ \text{V} = \textbf{18 mV}$$

*Related Problem*   If there are 3.2 μA through a 47 Ω resistor, what is the voltage across the resistor?

The following two examples illustrate how to use resistance values in the kilohm (kΩ) and megohm (MΩ) ranges to calculate voltage.

EXAMPLE 3–14

The circuit in Figure 3–12 has a current of 10 mA. What is the voltage?

▶ **FIGURE 3–12**

Solution   Ten milliamperes equals 10×10^{-3} A and 3.3 kΩ equals $3.3 \times 10^{3}\ \Omega$. Substitute these values into the formula $V = IR$.

$$V = IR = (10\ \text{mA})(3.3\ \text{k}\Omega) = (10 \times 10^{-3}\text{A})(3.3 \times 10^{3}\ \Omega) = \textbf{33 V}$$

Notice that 10^{-3} and 10^{3} cancel. Therefore, milliamperes cancel kilohms when multiplied, and the result is volts.

EXAMPLE 3–15

If there is a current of 50 μA through a 4.7 MΩ resistor, what is the voltage?

Solution   Fifty microamperes equals 50×10^{-6} A and 4.7 MΩ is $4.7 \times 10^{6}\ \Omega$. Substitute these values into the formula $V = IR$.

$$V = IR = (50\ \mu\text{A})(4.7\ \text{M}\Omega) = (50 \times 10^{-6}\text{A})(4.7 \times 10^{6}\ \Omega) = \textbf{235 V}$$

Notice that 10^{-6} and 10^6 cancel. Therefore, microamperes cancel megohms when multiplied, and the result is volts.

▶ **FIGURE 3–13**
Solution   Substitute 12 V for V and 3.08 A for I into the formula $R = V/I$.

$$R = \frac{V}{I} = \frac{12\ \text{V}}{3.08\ \text{A}} = \mathbf{3.90\ \Omega}$$

EXAMPLE 3–18

Suppose that the ammeter in Figure 3–14 indicates 4.55 mA of current and the voltmeter reads 150 V. What is the value of R?

▶ **FIGURE 3–14**
Solution

4.55 mA equals 4.55×10^{-3} A. Substitute the voltage and current values into the formula $R = V/I$.

$$R = \frac{V}{I} = \frac{150 \text{ V}}{4.55 \text{ mA}} = \frac{150 \text{ V}}{4.55 \times 10^{-3} \text{ A}} = 33 \times 10^3 \ \Omega = \textbf{33 k}\boldsymbol{\Omega}$$

When volts are divided by milliamperes, the resistance is in kilohms.

EXAMPLE 3–19

Suppose that the value of the resistor in Figure 3–14 is changed. If the battery voltage is still 150 V and the ammeter reads 68.2 μA, what is the new resistor value?

Solution

68.2 μA equals 68.2×10^{-6} A. Substitute V and I values into the equation for R.

$$R = \frac{V}{I} = \frac{150 \text{ V}}{68.2 \ \mu\text{A}} = \frac{150 \text{ V}}{68.2 \times 10^{-6} \text{ A}} = 2.2 \times 10^6 \ \Omega = \textbf{2.2 M}\boldsymbol{\Omega}$$

3–5   INTRODUCTION TO TROUBLESHOOTING

Technicians must be able to diagnose and repair malfunctioning circuits and systems. In this section, you learn a general approach to troubleshooting using a simple example. Troubleshooting coverage is an important part of this textbook, so you will find a troubleshooting section in many of the chapters and troubleshooting problems, including Multisim circuits, for skill building.

After completing this section, you should be able to

◆ **Describe a basic approach to troubleshooting**

  ◆ List three steps in troubleshooting

  ◆ Explain what is meant by half-splitting

  ◆ Discuss and compare the three basic measurements of voltage, current, and resistance

Troubleshooting is the application of logical thinking combined with a thorough knowledge of circuit or system operation to correct a malfunction. The basic approach to troubleshooting consists of three steps: *analysis, planning,* and *measuring.* We will refer to this 3–step approach as APM.

Analysis

The first step in troubleshooting a circuit is to analyze clues or symptoms of the failure. The analysis can begin by determining the answer to certain questions:

1. Has the circuit ever worked?

2. If the circuit once worked, under what conditions did it fail?

3. What are the symptoms of the failure?

4. What are the possible causes of failure?

Planning

The second step in the troubleshooting process, after analyzing the clues, is formulating a logical plan of attack. Much time can be saved by proper planning. A working knowledge of the circuit is a prerequisite to a plan for troubleshooting. If you are not certain how the circuit is supposed to operate, take time to review circuit diagrams (schematics), operating instructions, and other pertinent information. A schematic with proper voltages marked at various test points is particularly useful. Although logical thinking is perhaps the most important tool in troubleshooting, it rarely can solve the problem by itself.

Measuring

The third step is to narrow the possible failures by making carefully thought out measurements. These measurements usually confirm the direction you are taking in solving the problem, or they may point to a new direction that you should take. Occasionally, you may find a totally unexpected result.

An APM Example

The thought process that is part of the APM approach can be illustrated with a simple example. Suppose you have a string of 8 decorative 12 V bulbs connected in series to a 120 V source V_S, as shown in Figure 3–15. Assume that this circuit worked properly at one time but stopped working after it was moved to a new location. When plugged in at the new location, the lamps fail to turn on. How do you go about finding the trouble?

A string of bulbs connected to a voltage source.
The Analysis Thought Process   You may think like this as you proceed to analyze the situation:

- Since the circuit worked before it was moved, the problem could be that there is no voltage at the new location.

- Perhaps the wiring was loose and pulled apart when moved.

- It is possible that a bulb is burned out or loose in its socket.

With this reasoning, you have considered possible causes and failures that may have occurred. The thought process continues:

- The fact that the circuit once worked eliminates the possibility that the original circuit was improperly wired.

- If the fault is due to an open path, it is unlikely that there is more than one break which could be either a bad connection or a burned out bulb.

You have now analyzed the problem and are ready to plan the process of finding the fault in the circuit.

The Planning Thought Process   The first part of your plan is to measure for voltage at the new location. If the voltage is present, then the problem is in the string of lights. If voltage is not present, check the circuit breaker at the distribution box in the house. Before resetting breakers, you should think about why a breaker may be tripped. Let's assume that you find the voltage is present. This means that the problem is in the string of lights.

The second part of your plan is to measure either the resistance in the string of lights or to measure voltages across the bulbs. The decision whether to measure resistance or voltage is a toss-up and can be made based on the ease of making the test. Seldom is a troubleshooting plan developed so completely that all possible contingencies are included. You will frequently need to modify the plan as you go along.

The Measurement Process   You proceed with the first part of your plan by using a multimeter to check the voltage at the new location. Assume the measurement shows a voltage

of 120 V. Now you have eliminated the possibility of no voltage. You know that, since you have voltage across the string and there is no current because no bulb is on, there must be an open in the current path. Either a bulb is burned out, a connection at the lamp socket is broken, or the wire is broken.

Next, you decide to locate the break by measuring resistance with your multimeter. Applying logical thinking, you decide to measure the resistance of each half of the string instead of measuring the resistance of each bulb. By measuring the resistance of half the bulbs at once, you can usually reduce the effort required to find the open. This technique is a type of troubleshooting procedure called **half-splitting**.

Once you have identified the half in which the open occurs, as indicated by an infinite resistance, you use half-splitting again on the faulty half and continue until you narrow the fault down to a faulty bulb or connection. This process is shown in Figure 3–16, assuming for purposes of illustration that the seventh bulb is burned out.
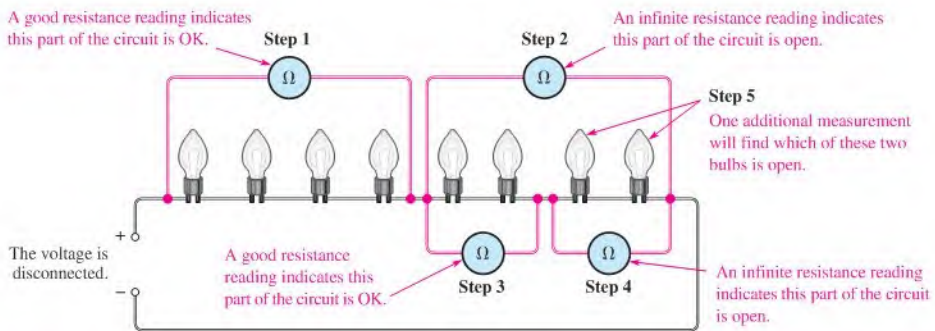

▲ **FIGURE 3–16**

Illustration of the half-splitting method of troubleshooting. The numbered steps indicate the sequence in which the multimeter is moved from one position to another.

As you can see in the figure, the half-splitting approach in this particular case takes a maximum of five measurements to identify the open bulb. If you had decided to measure each bulb individually and had started at the left, you would have needed seven measurements. Sometimes half-splitting saves steps; sometimes it doesn't. The number of steps required depends on where you make your measurements and in what sequence.

Unfortunately, most troubleshooting is more difficult than this example. However, analysis and planning are essential for effective troubleshooting in any situation. As measurements are made, the plan is often modified; the experienced troubleshooter narrows the search by fitting the symptoms and measurements into a probable cause. In some cases, low-cost equipment is simply discarded when troubleshooting and repair costs are comparable to replacement costs.

Comparison of *V*, *R*, and *I* Measurements

As you know from Section 2–7, you can measure voltage, current, or resistance in a circuit. To measure voltage, place the voltmeter in parallel across the component; that is, place one lead on each side of the component. This makes voltage measurements the easiest of the three types of measurements.

To measure resistance, connect the ohmmeter across a component; however, the voltage must be first disconnected, and sometimes the component itself must be removed from the circuit. Therefore, resistance measurements are generally more difficult than voltage measurements.

To measure current, place the ammeter in series with the component; that is, the ammeter must be in line with the current path. To do this you must disconnect a component lead or a wire before you connect the ammeter. This usually makes a current measurement the most difficult to perform.

SECTION 3–5 CHECKUP

1. Name the three steps in the APM approach to troubleshooting.
2. Explain the basic idea of the half-splitting technique.
3. Why are voltages easier to measure than currents in a circuit?

Application Activity

In this application, a resistive circuit is developed for controlling the speed of a small dc motor used to drive a fan for cooling electronic equipment mounted in a cabinet. One way to control the speed of a dc motor is to connect a resistor to the motor, as shown in Figure 3–17. The resistor reduces the current to the motor and therefore reduces its speed. This method is only recommended for small motors because energy is wasted in the resistance, and the overall efficiency is low.
▲ **FIGURE 3–17**

A circuit is required that will allow a selection of four motor speeds. The control circuit is to be mounted in a small box that will be attached to the equipment cabinet to control the fan motor speed, as shown in Figure 3–18.
The application requires four distinct switchable speeds. Your job is to develop a schematic, determine the values for the required resistors, and prepare a test procedure for the circuit. You will apply Ohm's law in order to complete the assignment. Motor data in graphical form is provided in Figure 3–19.
Specifications

◆ Each resistor is switch selectable from a rotary switch, so that only one resistor is connected to the motor at a time.

◆ The four approximate speed settings are 800 rpm, 600 rpm, 400 rpm, and 200 rpm.

◆ The motor is rated for a maximum of 12 V at 800 rpm.

◆ The circuit board is to be connected to a 12 V dc source and to the fan motor with wiring that is available inside the cabinet.
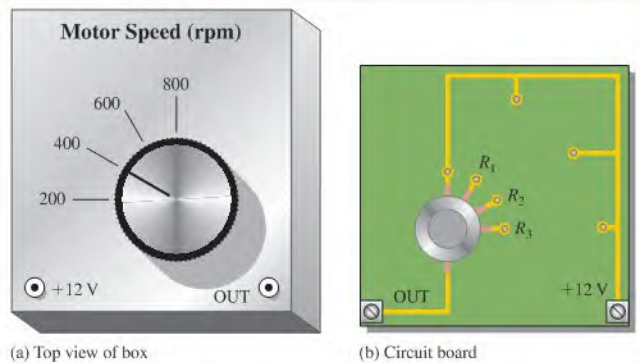

Resistance Calculations

The resistor box has been prepared with speed-value labels and the PC board has been prepared as shown in Figure 3–20.

1. Use the graphical motor data in Figure 3–19 and Ohm's law to determine the nearest standard resistor values needed for the project. *Hint:* To find the voltage across the resistor, V_R, subtract the motor voltage, V_M, from 12 V. This is based on a law introduced in Chapter 5 called Kirchhoff's law.

INTRODUCTION

From Chapter 3, you know the relationship of current, voltage, and resistance as stated by Ohm's law. The existence of these three quantities in an electric circuit results in the fourth basic quantity known as power. A specific relationship exists between power and I, V, and R.

Energy is the ability to do work, and power is the rate at which energy is used. Current carries electrical energy through a circuit. As the free electrons pass through the resistance of the circuit, they give up their energy when they collide with atoms in the resistive material. The electrical energy given up by the electrons is converted into heat energy. The rate at which the electrical energy is used is the power in the circuit.

4–1   ENERGY AND POWER

When there is current through a resistance, electrical energy is converted to heat or other form of energy, such as light. A common example of this is a light bulb that becomes too hot to touch. The current through the filament that produces light also produces unwanted heat because the filament has resistance. Electrical components must be able to dissipate a certain amount of energy in a given period of time.

After completing this section, you should be able to

◆ **Define** *energy* **and** *power*

   ◆ Express power in terms of energy

   ◆ State the unit of power

   ◆ State the common units of energy

   ◆ Perform energy and power calculations

Energy is the ability to do work, and power is the rate at which energy is used.

Power (P) is a certain amount of energy (W) used in a certain length of time (t), expressed as follows:

$$P = \frac{W}{t}$$

Equation 4–1

where P is power in watts (W), W is energy in joules (J), and t is time in seconds (s). Note that an italic W is used to represent energy in the form of work and a nonitalic W is used for watts, the unit of power. The **joule (J)** is the SI unit of energy.

Energy in joules divided by time in seconds gives power in watts. For example, if 50 J of energy are used in 2 s, the power is 50 J/2 s = 25 W. By definition,

One watt (W) is the amount of power when one joule of energy is used in one second.

Thus, the number of joules used in one second is always equal to the number of watts. For example, if 75 J are used in 1 s, the power is $P = W/t = $ 75 J/1 s = 75 W.

Amounts of power much less than one watt are common in certain areas of electronics. As with small current and voltage values, metric prefixes are used to designate small amounts of power. Thus, milliwatts (mW), microwatts (μW), and even picowatts (pW) are commonly found in some applications.

In the electrical utilities field, kilowatts (kW) and megawatts (MW) are common units. Radio and television stations also use large amounts of power to transmit signals. Electric motors are commonly rated in horsepower (hp) where 1 hp = 746 W.

Since power is the rate at which energy is used, as expressed in Equation 4–1, power utilized over a period of time represents energy consumption. If you multiply power in watts and time in seconds, you have energy in joules, symbolized by W.

$$W = Pt$$

EXAMPLE 4–1

An amount of energy equal to 100 J is used in 5 s. What is the power in watts?

Solution

$$P = \frac{\text{energy}}{\text{time}} = \frac{W}{t} = \frac{100\,\text{J}}{5\,\text{s}} = \textbf{20 W}$$

Related Problem*

If 100 W of power occurs for 30 s, how much energy, in joules, is used?

Solution

(a) 0.045 W = **45 mW**   **(b)** 0.000012 W = **12 μW**

(c) 3500 W = **3.5 kW**   **(d)** 10,000,000 W = **10 MW**

The Kilowatt-hour (kWh) Unit of Energy

The joule has been defined as a unit of energy. However, there is another way to express energy. Since power is expressed in watts and time in seconds, units of energy called the watt-second (Ws), watt-hour (Wh), and kilowatt-hour (kWh) can be used.

When you pay your electric bill, you are charged on the basis of the amount of energy you use, not the power. Because power companies deal in huge amounts of energy, the most practical unit is the kilowatt-hour. You use a **kilowatt-hour** of energy when you use one thousand watts of power for one hour. For example, a 100 W light bulb burning for 10 h uses 1 kWh of energy.

$$W = Pt = (100\,\text{W})(10\,\text{h}) = 1000\,\text{Wh} = 1\,\text{kWh}$$

EXAMPLE 4–3

Determine the number of kilowatt-hours (kWh) for each of the following energy consumptions:

(a) 1400 W for 1 h   **(b)** 2500 W for 2 h   **(c)** 100,000 W for 5 h

Solution

(a) 1400 W = 1.4 kW   **(b)** 2500 W = 2.5 kW

$W = Pt = (1.4\,\text{kW})(1\,\text{h}) = \textbf{1.4 kWh}$ $W = (2.5\,\text{kW})(2\,\text{h}) = \textbf{5 kWh}$

(c) 100,000 W = 100 kW

$W = (100\,\text{kW})(5\,\text{h}) = \textbf{500 kWh}$

4–2   POWER IN AN ELECTRIC CIRCUIT

The generation of heat, which occurs when electrical energy is converted to heat energy, in an electric circuit is often an unwanted by-product of current through the resistance in the circuit. In some cases, however, the generation of heat is the primary purpose of a circuit as, for example, in an electric resistive heater. In any case, you must frequently deal with power in electrical and electronic circuits.

After completing this section, you should be able to

◆ **Calculate power in a circuit**

  ◆ Determine power when you know I and R values

  ◆ Determine power when you know V and I values

  ◆ Determine power when you know V and R values

When there is current through resistance, the collisions of the electrons produce heat as a result of the conversion of electrical energy, as indicated in Figure 4–1. The amount of power dissipated in an electric circuit is dependent on the amount of resistance and on the amount of current, expressed as follows:

$$P = I^2R$$

Equation 4–2

where P is power in watts (W), I is current in amperes (A), and R is resistance in ohms (Ω). You can get an equivalent expression for power in terms of voltage and current by substituting V for IR (I^2 is $I \times I$).

$$P = I^2R = (I \times I)R = I(IR) = (IR)I$$

$$P = VI$$

Equation 4–3
▲ **FIGURE 4–1**

Power dissipation in an electric circuit results in heat energy given off by the resistance.

where P is in watts when V is in volts and I is in amperes. You can obtain another equivalent expression by substituting V/R for I (Ohm's law).

$$P = VI = V\left(\frac{V}{R}\right)$$

Equation 4–4

$$P = \frac{V^2}{R}$$

The relationships between power and current, voltage, and resistance expressed in the preceding formulas are known as **Watt's law**. In each case, I must be in amps, V in volts, and R in ohms. To calculate the power in a resistance, you can use any one of the three power formulas, depending on what information you have. For example, assume that you know the values of current and voltage. In this case calculate the power with the formula $P = VI$. If you know I and R, use the formula $P = I^2R$. If you know V and R, use the formula $P = V^2/R$.

EXAMPLE 4–4

Calculate the power in each of the three circuits of Figure 4–2.

◆ **FIGURE 4–2**

(a) 2 A 10 V R

(b) 2 A V 47 Ω

(c) 5 V 10 Ω
Solution

In circuit (a), you know V and I. Therefore, use Equation 4–3.

$$P = VI = (10\text{ V})(2\text{ A}) = \mathbf{20\text{ W}}$$

In circuit (b), you know I and R. Therefore, use Equation 4–2.

$$P = I^2R = (2\text{ A})^2(47\text{ Ω}) = \mathbf{188\text{ W}}$$

In circuit (c), you know V and R. Therefore, use Equation 4–4.

$$P = \frac{V^2}{R} = \frac{(5\text{ V})^2}{10\text{ Ω}} = \mathbf{2.5\text{ W}}$$

Related Problem

Determine P in each circuit of Figure 4–2 for the following changes:

Circuit (a): I doubled and V remains the same

Circuit (b): R doubled and I remains the same

Circuit (c): V halved and R remains the same

EXAMPLE 4–5

A 100 W light bulb operates on 120 V. How much current does it require?

Solution

Use the formula $P = VI$ and solve for I by first transposing the terms to get I on the left side in the equation.

$$VI = P$$

Rearranging,

$$I = \frac{P}{V}$$

Substituting 100 W for P and 120 V for V yields

$$I = \frac{P}{V} = \frac{100 \text{ W}}{120 \text{ V}} = 0.833 \text{ A} = \mathbf{833 \text{ mA}}$$

4–3 RESISTOR POWER RATINGS

As you know, a resistor gives off heat when there is current through it. The limit to the amount of heat that a resistor can give off is specified by its power rating.

After completing this section, you should be able to

◆ **Properly select resistors based on power consideration**

  ◆ Define *power rating*

  ◆ Explain how physical characteristics of resistors determine their power rating

  ◆ Check for resistor failure with an ohmmeter

The **power rating** is the maximum amount of power that a resistor can dissipate without being damaged by excessive heat buildup. The power rating is not related to the ohmic value (resistance) but rather is determined mainly by the physical composition, size, and shape of the resistor. All else being equal, the larger the surface area of a resistor, the more power it can dissipate. *The surface area of a cylindrically shaped resistor is equal to the length (l) times the circumference (c),* as indicated in Figure 4–4. The area of the ends is not included.

The power rating of a resistor is directly related to its surface area.

Surface area = $l \times c$
TECH NOTE

Sometimes an overheated resistor is due to another failure in the circuit. After replacing a heat-damaged resistor and before restoring power, check for visual faults that may cause excessive current, such as a short between two conductors.

Metal-film resistors are available in standard power ratings from $\frac{1}{8}$ W to 1 W, as shown in Figure 4–5. Available power ratings for other types of resistors vary. For example, wirewound resistors have ratings up to 225 W or greater. Figure 4–6 shows some of these resistors.

▶ FIGURE 4–5

Relative sizes of metal-film resistors with standard power ratings of $\frac{1}{8}$ W, $\frac{1}{4}$ W, $\frac{1}{2}$ W, and 1 W.

(a) Axial-lead wirewound   (b) Adjustable wirewound   (c) Radial-lead for PC board insertion

▲ FIGURE 4–6

Typical resistors with high power ratings.

When a resistor is used in a circuit, its power rating must be greater than the maximum power that it will have to handle. For example, if a resistor is to dissipate 0.75 W in a circuit application, its rating should be at least the next higher standard value which is 1 W. *A rating larger than the actual power should be used when possible as a safety margin.*

EXAMPLE 4–6

Choose an adequate power rating for each of the metal-film resistors in Figure 4–7 ($\frac{1}{8}$ W, $\frac{1}{4}$ W, $\frac{1}{2}$ W, or 1 W).

▶ FIGURE 4–7
Solution   In Figure 4–7(a), the actual power is

$$P = \frac{V^2}{R} = \frac{(10\text{ V})^2}{120\ \Omega} = \frac{100\text{ V}^2}{120\ \Omega} = 0.833\text{ W}$$

Select a resistor with a power rating higher than the actual power. In this case, a **1 W resistor** should be used.
  In Figure 4–7(b), the actual power is

$$P = I^2 R = (10\text{ mA})^2 (1000\ \Omega) = (10 \times 10^{-3}\text{ A})^2 (1000\ \Omega) = 0.1\text{ W}$$

At least a ⅛ **W (0.125 W) resistor** should be used in this case.

Related Problem   A certain resistor is required to dissipate 0.25 W. What standard rating should be used?

When the power in a resistor is greater than its rating, the resistor will become excessively hot. As a result, the resistor may burn open or its resistance value may change.

A resistor that has been damaged because of overheating can often be detected by the charred or altered appearance of its surface. If there is no visual evidence, a resistor that is suspected of being damaged can be checked with an ohmmeter for an open or incorrect resistance value. Recall that one or both leads of a resistor should be removed from a circuit to measure resistance.

Checking a Resistor with an Ohmmeter

A typical digital multimeter and an analog multimeter are shown in Figures 4–8(a) and 4–8(b), respectively. For the digital meter in Figure 4–8(a), you use the round function switch to select ohms (Ω). You do not have to manually select a range because this particular meter is autoranging and you have a direct digital readout of the resistance value. The large round switch on the analog meter is called a *range switch*. Notice the resistance (OHMS) settings on both meters.

For the analog meter in part (b), each setting indicates the amount by which the ohms scale (top scale) on the meter is to be multiplied. For example, if the pointer is at 50 on the

⚡ **SAFETY NOTE**

Some resistors can become very hot in normal operation. To avoid a burn, do not touch a circuit component while the power is connected to the circuit. After power has been turned off, allow time for the components to cool down.

ohms scale and the range switch is set at ×10, the resistance being measured is 50 × 10 Ω = 500 Ω. *If the resistor is open, the pointer will stay at full left scale (∞ means infinite) regardless of the range switch setting.*

EXAMPLE 4–7

Determine whether the resistor in each circuit of Figure 4–9 has possibly been damaged by overheating.

(a)   (b)   (c)
▲ **FIGURE 4–9**

Solution   In the circuit in Figure 4–9(a),

$$P = \frac{V^2}{R} = \frac{(9\,\text{V})^2}{100\,\Omega} = 0.810\,\text{W} = 810\,\text{mW}$$

The rating of the resistor is ¼ W (0.25 W), which is insufficient to handle the power. The resistor has been overheated and may be burned out, making it an open.
   In the circuit of Figure 4–9(b),

$$P = \frac{V^2}{R} = \frac{(24\,\text{V})^2}{1.5\,\text{k}\Omega} = 0.384\,\text{W} = 384\,\text{mW}$$

The rating of the resistor is ½ W (0.5 W), which is sufficient to handle the power.
   In the circuit of Figure 4–9(c),

$$P = \frac{V^2}{R} = \frac{(5\,\text{V})^2}{10\,\Omega} = 2.5\,\text{W}$$

The rating of the resistor is 1 W, which is insufficient to handle the power. The resistor has been overheated and may be burned out, making it an open.

Related Problem   A 0.25 W, 1.0 kΩ resistor is connected across a 12 V battery. Is the power rating adequate?

SECTION 4–3 CHECKUP

1. Name two important values associated with a resistor.
2. How does the physical size of a resistor determine the amount of power that it can handle?
3. List the standard power ratings of metal-film resistors.
4. A resistor must handle 0.3 W. What minimum power rating of a metal-film resistor should be used to dissipate the energy properly?
5. What is the maximum voltage that can be applied to a ¼ W 100 Ω resistor if the power rating is not to be exceeded?

4–4   ENERGY CONVERSION AND VOLTAGE DROP IN RESISTANCE

As you have learned, when there is current through a resistance, electrical energy is converted to heat energy. This heat is caused by collisions of the free electrons within the atomic structure of the resistive material. When a collision occurs, heat is given off; and the electron gives up some of its acquired energy as it moves through the material.

After completing this section, you should be able to

- ◆ **Explain energy conversion and voltage drop**
  - ◆ Discuss the cause of energy conversion in a circuit
  - ◆ Define *voltage drop*
  - ◆ Explain the relationship between energy conversion and voltage drop

Figure 4–10 illustrates charge in the form of electrons flowing from the negative terminal of a battery, through a circuit, and back to the positive terminal. As they emerge from the negative terminal, the electrons are at their highest energy level. The electrons flow through each of the resistors that are connected together to form a current path (this type of connection is called series, as you will learn in Chapter 5). As the electrons flow through each resistor, some of their energy is given up in the form of heat. Therefore, the electrons have more energy when they enter a resistor than when they exit the resistor, as illustrated in the figure by the decrease in the intensity of the red color. When they have traveled through the circuit back to the positive terminal of the battery, the electrons are at their lowest energy level.
◀ **FIGURE 4–10**

A loss of energy by electrons (charge) as they flow through a resistance creates a voltage drop because voltage equals energy divided by charge.

Recall that voltage equals energy per charge ($V = W/Q$) and charge is a property of electrons. Based on the voltage of the battery, a certain amount of energy is imparted to all of the electrons that flow out of the negative terminal. The same number of electrons flow at each point throughout the circuit, but their energy decreases as they move through the resistance of the circuit.

In Figure 4–10, the voltage at the left end of R_1 is equal to W_{enter}/Q, and the voltage at the right end of R_1 is equal to W_{exit}/Q. The same number of electrons that enter R_1 also exit R_1, so Q is constant. However, the energy W_{exit} is less than W_{enter}, so the voltage at the right end of R_1 is less than the voltage at the left end. This decrease in voltage across the resistor

due to a loss of energy is called a **voltage drop**. The voltage at the right end of R_1 is less negative (or more positive) than the voltage at the left end. The voltage drop is indicated by $-$ and $+$ signs (the $+$ implies a less negative or more positive voltage). For electron flow direction, a voltage drop is defined to be from negative ($-$) to positive ($+$), which is the opposite of that for conventional current.

The electrons have lost some energy in R_1 and now they enter R_2 with a reduced energy level. As they flow through R_2, they lose more energy, resulting in another voltage drop across R_2.

4–5   POWER SUPPLIES AND BATTERIES

Recall that power supplies and batteries were briefly introduced as types of voltage sources in Chapter 2. A *power supply* is generally defined as an electronic device that converts ac (alternating current) from the utility lines to a dc (direct current) voltage that virtually all electronic circuits and some transducers require. Batteries are also capable of supplying dc; in fact, many systems, such as laptop computers, can run from a power supply or internal battery. In this section, both types of voltage sources are described.

After completing this section, you should be able to

◆ **Discuss characteristics of power supplies and batteries**

 ◆ Describe controls on typical laboratory power supplies

 ◆ Determine the efficiency of a power supply given the input and output power

 ◆ Define ampere-hour rating of batteries

Utilities universally have adopted ac for transmitting electricity from the generating station to the user because it can be readily transformed to high voltages for transmission and low voltages for the end user. High voltages are much more efficient and cost-effective to transmit over long distances. In the United States, the standard voltage supplied to outlets is approximately 120 V or 240 V at 60 Hz, but in Europe and other countries, the outlet voltage is 240 V at 50 Hz.

Virtually all electronic systems require stable dc for the integrated circuits and other devices to work properly. Power supplies fulfill this function by converting ac to stable dc and are usually built into the product. Many electronic systems have a recessed and protected switch that allows the internal power supply to be set for either the 120 V standard or for the 240 V standard. That switch must be set correctly, or serious damage can occur to the equipment.

In the laboratory, circuits are developed and tested. The purpose of a laboratory power supply is to provide the required stable dc to the circuit under test. The test circuit can be anything from a simple resistive network to a complex amplifier or logic circuit. To meet the requirement for a constant voltage, with almost no noise or ripple, laboratory power supplies are **regulated**, meaning the output is constantly sensed and automatically adjusted if it tries to change because of a change in the line voltage or the load.

Many circuits require multiple voltages, as well as the ability to set the voltage to a precise value or change it a small amount for testing. For this reason, laboratory power supplies usually have two or three outputs that are independent of each other and can be controlled

separately. Output metering is normally part of a good laboratory power supply, in order to set and monitor the output voltage or current. Control may include fine and coarse controls or digital inputs to set precise voltages.

Figure 4–11 shows a triple output bench supply such as the type used in many electronic laboratories. The model shown has two 0–30 V independent supplies and a 4–6.5 V high current supply (commonly referred to a logic supply). Voltages can be precisely set using coarse and fine controls. The 0–30 V supplies have floating outputs, meaning they are not referenced to ground. This allows the user to set them up as a positive or negative supply or even connect them to another external supply. Another feature of this supply is that it can be set up as a current source, with a maximum voltage set for constant current applications.

A triple output power supply.
(Courtesy B+K Precision)

As in many power supplies, there are three output jacks for each of the 0–30 V supplies. The output is taken between the red (more positive) and black terminals. The green jack is referenced to the chassis, which is earth ground, and can be connected to either the red or black jacks. In addition, current and voltage can be monitored using the built-in digital meters.

The power delivered by a power supply is the product of the absolute voltage and current. For example, if a power supply is providing −15.0 V at 3.0 A, the supplied power is 45 W. For a triple output supply, the total power supplied by all three supplies is the sum of the power from each one individually.

EXAMPLE 4–8

What is the total power delivered by a triple output power supply if the output voltage and current are as follows?

Source 1: 18 V at 2.0 A

Source 2: −18 V at 1.5 A

Source 3: 5.0 V at 1.0 A

Solution   Power delivered from each supply is the product of voltage and current (ignoring the sign).

Source 1: $P_1 = V_1 I_1 = (18\ \text{V})(2.0\ \text{A}) = 36\ \text{W}$

Source 2: $P_2 = V_2 I_2 = (18\ \text{V})(1.5\ \text{A}) = 27\ \text{W}$

Source 3: $P_3 = V_3 I_3 = (5.0\ \text{V})(1.0\ \text{A}) = 5.0\ \text{W}$

The total power is

$$P_T = P_1 + P_2 + P_3 = 36\ \text{W} + 27\ \text{W} + 5.0\ \text{W} = \textbf{68 W}$$

Related Problem   How will the total power delivered change if the current from Source 1 increases to 2.5 A?

Power Supply Efficiency

An important characteristic of electronic power supplies is efficiency. **Efficiency** is the ratio of the output power delivered to a load to the input power to a circuit.

Equation 4–5

$$\text{Efficiency} = \frac{P_{OUT}}{P_{IN}}$$

Efficiency is often expressed as a percentage. For example, if the input power is 100 W and the output power is 50 W, the efficiency is (50 W/100 W) × 100% = 50%.

All electronic power supplies require that power be put into them. For example, an electronic power supply generally uses the ac power from a wall outlet as its input. Its output is usually a regulated dc voltage. The output power is *always* less than the input power because some of the total power must be used internally to operate the power supply circuitry. This internal power dissipation is normally called the *power loss*. The output power is the input power minus the power loss.

Equation 4–6

$$P_{OUT} = P_{IN} - P_{LOSS}$$

High efficiency means that very little power is dissipated in the power supply and there is a higher proportion of output power for a given input power.

EXAMPLE 4–9

A certain electronic power supply requires 25 W of input power. It can produce an output power of 20 W. What is its efficiency, and what is the power loss?

Solution

$$\text{Efficiency} = \frac{P_{OUT}}{P_{IN}} = \frac{20\text{ W}}{25\text{ W}} = \mathbf{0.8}$$

Expressed as a percentage,

$$\text{Efficiency} = \left(\frac{20\text{ W}}{25\text{ W}}\right)100\% = 80\%$$

The power loss is

$$P_{LOSS} = P_{IN} - P_{OUT} = 25\text{ W} - 20\text{ W} = \mathbf{5\text{ W}}$$

Related Problem   A power supply has an efficiency of 92%. If P_{IN} is 50 W, what is P_{OUT}?

Ampere-Hour Ratings of Batteries

Batteries convert stored chemical energy to electrical energy. They are widely used to power small systems, such as laptop computers and cell phones, to supply the stable dc required. The batteries used in these small systems are normally rechargeable, meaning that the chemical reaction can be reversed from an external source. The capacity for any battery is measured in ampere-hours (Ah). For a rechargeable battery, the Ah rating is the capacity before it needs to be recharged. The **ampere-hour rating** determines the length of time a battery can deliver a certain amount of current at the rated voltage.

A rating of one ampere-hour means that a battery can deliver an average of one ampere of current to a load for one hour at the rated voltage output. This same battery can deliver an average of two amperes for one-half hour. The more current the battery is required to deliver, the shorter the life of the battery. In practice, a battery usually is rated for a specified current level and output voltage. For example, a 12 V automobile battery may be rated for 70 Ah at 3.5 A. This means that it can produce an average of 3.5 A for 20 h at the rated voltage.

EXAMPLE 4–10

For how many hours can a battery deliver 2 A if it is rated at 70 Ah?

Solution The ampere-hour rating is the current times the number of hours (x).

$$70 \, \text{Ah} = (2 \, \text{A})(x \, \text{h})$$

Solving for the number of hours, x, yields

$$x = \frac{70 \, \text{Ah}}{2 \, \text{A}} = \textbf{35 h}$$

Related Problem A certain battery delivers 10 A for 6 h. What is its Ah rating?

INTRODUCTION

In Chapter 3 you learned about Ohm's law, and in Chapter 4 you learned about power in resistors. In this chapter, those concepts are applied to circuits in which resistors are connected in a series arrangement.

Resistive circuits can be of two basic forms: series and parallel. In this chapter, series circuits are studied. Parallel circuits are covered in Chapter 6, and combinations of series and parallel resistors are examined in Chapter 7. In this chapter, you will see how Ohm's law is used in series circuits; and you will learn another important circuit law, Kirchhoff's voltage law. Also, several applications of series circuits, including voltage dividers, are presented.

When resistors are connected in series and a voltage is applied across the series connection, there is only one path for current; therefore, each resistor in series has the same amount of current through it. All of the resistances in series add together to produce a total resistance. The voltage drops across each of the resistors add up to the voltage applied across the entire series connection.

5–1 RESISTORS IN SERIES

When connected in series, resistors form a "string" in which there is only one path for current.

After completing this section, you should be able to

◆ **Identify a series resistive circuit**

  ◆ Translate a physical arrangement of resistors into a schematic

The schematic in Figure 5–1(a) shows two resistors connected in series between point A and point B. Part (b) shows three resistors in series, and part (c) shows four in series. Of course, there can be any number of resistors in a series circuit.

(b)

(c)

▲ **FIGURE 5–1**

Resistors in series.

When a voltage source is connected between point A and B, the only way for current to get from one point to the other in any of the connections of Figure 5–1 is to go through each of the resistors. The following statement describes a series circuit:

A series circuit provides only one path for current between two points so that the current is the same through each series resistor.

In an actual circuit diagram, a series circuit may not always be as easy to visually identify as those in Figure 5–1. For example, Figure 5–2 shows series resistors drawn in other ways with voltage applied. Remember, if there is only one current path between two points, the resistors between those two points are in series, no matter how they appear in a diagram.

5–2   TOTAL SERIES RESISTANCE

The total resistance of a series circuit is equal to the sum of the resistances of each individual series resistor.

After completing this section, you should be able to

◆ **Determine total series resistance**

    ◆ Explain why resistance values add when resistors are connected in series

    ◆ Apply the series resistance formula

Series Resistor Values Add

When resistors are connected in series, the resistor values add because each resistor offers opposition to the current in direct proportion to its resistance. A greater number of resistors connected in series creates more opposition to current. More opposition to current implies a higher value of resistance. Thus, every time a resistor is added in series, the total resistance increases.

Figure 5–7 illustrates how series resistances add to increase the total resistance. Part (a) has a single 10 Ω resistor. Part (b) shows another 10 Ω resistor connected in series with the first one, making a total resistance of 20 Ω. If a third 10 Ω resistor is connected in series with the first two, as shown in part (c), the total resistance becomes 30 Ω.
▲ FIGURE 5–7

Total resistance increases with each additional series resistor.

Series Resistance Formula

For any number of individual resistors connected in series, the total resistance is the sum of each of the individual values.

Equation 5–1

$$R_T = R_1 + R_2 + R_3 + \cdots + R_n$$

where R_T is the total resistance and R_n is the last resistor in the series string (n can be any positive integer equal to the number of resistors in series). For example, if there are four resistors in series ($n = 4$), the total resistance formula is

$$R_T = R_1 + R_2 + R_3 + R_4$$

If there are six resistors in series ($n = 6$), the total resistance formula is

$$R_T = R_1 + R_2 + R_3 + R_4 + R_5 + R_6$$

To illustrate the calculation of total series resistance, let's determine R_T in the circuit of Figure 5–8, where V_S is the source voltage. The circuit has five resistors in series. To get the total resistance, simply add the values.

$$R_T = 56 \ \Omega + 100 \ \Omega + 27 \ \Omega + 10 \ \Omega + 47 \ \Omega = 240 \ \Omega$$

Note in Figure 5–8 that the order in which the resistances are added does not matter. You can physically change the positions of the resistors in the circuit without affecting the total resistance or the current.

$$R_T = R_1 + R_2 + R_3 + R_4 + R_5 = 33\ \Omega + 68\ \Omega + 100\ \Omega + 47\ \Omega + 10\ \Omega = \mathbf{258\ \Omega}$$

$$R_T = 39\ \Omega + 100\ \Omega + 47\ \Omega + 100\ \Omega + 180\ \Omega + 68\ \Omega = \mathbf{534\ \Omega}$$

Related Problem   What is the total resistance for the following series resistors: $1.0\ \mathrm{k}\Omega$, $2.2\ \mathrm{k}\Omega$, $3.3\ \mathrm{k}\Omega$, and $5.6\ \mathrm{k}\Omega$?

EXAMPLE 5–5

Determine the value of R_4 in the circuit of Figure 5–12.

▶ **FIGURE 5–12**
Solution　From the ohmmeter reading, $R_T = 17.9\,k\Omega$.

$$R_T = R_1 + R_2 + R_3 + R_4$$

Solving for R_4 yields

$$R_4 = R_T - (R_1 + R_2 + R_3) = 17.9\,k\Omega - (1.0\,k\Omega + 2.2\,k\Omega + 4.7\,k\Omega) = \mathbf{10\,k\Omega}$$

Related Problem　Determine the value of R_4 in Figure 5–12 if the ohmmeter reading is $14.7\,k\Omega$.

Equal-Value Series Resistors

When a circuit has more than one resistor of the same value in series, there is a shortcut method to obtain the total resistance: Simply multiply the resistance value by the number of equal-value resistors that are in series. This method is essentially the same as adding the values. For example, five $100\,\Omega$ resistors in series have an R_T of $5(100\,\Omega) = 500\,\Omega$. In general, the formula is expressed as

Equation 5–2

$$R_T = nR$$

where n is the number of equal-value resistors and R is the resistance value.

EXAMPLE 5–6

Find the R_T of eight $22\,\Omega$ resistors in series.

Solution　Find R_T by adding the values.

$$R_T = 22\,\Omega + 22\,\Omega + 22\,\Omega + 22\,\Omega + 22\,\Omega + 22\,\Omega + 22\,\Omega + 22\,\Omega = \mathbf{176\,\Omega}$$

However, it is much easier to multiply to get the same result.

$$R_T = 8(22\,\Omega) = \mathbf{176\,\Omega}$$

3. Suppose that you have one resistor each of the following values: 1.0 kΩ, 2.7 kΩ, 5.6 kΩ, and 560 kΩ. To get a total resistance of approximately 13.8 kΩ, you need one more resistor. What should its value be?

4. What is the R_T for twelve 56 Ω resistors in series?

5. What is the R_T for twenty 5.6 kΩ resistors and thirty 8.2 kΩ resistors in series?

5–3   CURRENT IN A SERIES CIRCUIT

The current is the same through all points in a series circuit. The current through each resistor in a series circuit is the same as the current through all the other resistors that are in series with it.

After completing this section, you should be able to

◆ **Determine the current throughout a series circuit**

   ◆ Show that the current is the same at all points in a series circuit

Figure 5–13 shows three resistors connected in series to a dc voltage source. *At any point in this circuit, the current into that point must equal the current out of that point,* as illustrated by the current directional arrows. Notice also that the current out of each resistor must equal the current into each resistor because there is no place where part of the current can branch off and go somewhere else. Therefore, the current in each section of the circuit is the same as the current in all other sections. It has only one path going from the negative ($-$) side of the source to the positive ($+$) side.

▲ **FIGURE 5–13**

Current into any point in a series circuit is the same as the current out of that point.

5–4   APPLICATION OF OHM'S LAW

The basic concepts of series circuits and Ohm's law can be applied to series circuit analysis.

After completing this section, you should be able to

◆ **Apply Ohm's law in series circuits**

  ◆ Find the current in a series circuit

  ◆ Find the voltage across each resistor in series

The following are key points to remember when you analyze series circuits:

1. Current through any of the series resistors is the same as the total current.

2. If you know the total applied voltage and the total resistance, you can determine the total current by Ohm's law.

$$I_T = \frac{V_T}{R_T}$$

3. If you know the voltage drop across one of the series resistors (R_x), you can determine the total current by Ohm's law.

$$I_T = \frac{V_x}{R_x}$$

4. If you know the total current, you can find the voltage drop across any of the series resistors by Ohm's law.

$$V_x = I_T R_x$$

5. The polarity of a voltage drop across a resistor is positive at the end of the resistor that is closest to the positive terminal of the voltage source.

6. The current through a resistor is defined to be in a direction from the negative end of the resistor to the positive end.

7. An open in a series circuit prevents current; and, therefore, there is zero voltage drop across each series resistor. The total voltage appears across the points between which there is an open.

Now let's look at several examples that use Ohm's law for series circuit analysis.

EXAMPLE 5–7   Find the current in the circuit of Figure 5–17.

▶ **FIGURE 5–17**

🌐 *This icon indicates selected websites for further information on topics in this section. See the Companion Website provided with this text.*
Solution The current is determined by the source voltage V_S and the total resistance R_T. First, calculate the total resistance.

$$R_T = R_1 + R_2 + R_3 + R_4 = 820\,\Omega + 220\,\Omega + 150\,\Omega + 100\,\Omega = 1.29\,k\Omega$$

Next, use Ohm's law to calculate the current.

$$I = \frac{V_S}{R_T} = \frac{25\,V}{1.29\,k\Omega} = 0.0194\,A = \mathbf{19.4\,mA}$$

where V_S is the total voltage and I is the total current. Remember, the same current exists at all points in the circuit. Thus, each resistor has 19.4 mA through it.

Related Problem What is the current in the circuit of Figure 5–17 if R_4 is changed to 200 Ω?

Use Multisim file E05–07 to verify the calculated results in this example and to confirm your calculation for the related problem.

EXAMPLE 5–8

The current in the circuit of Figure 5–18 is 1 mA. For this amount of current, what must the source voltage V_S be?

▶ **FIGURE 5–18**
Solution In order to calculate V_S, first determine R_T.

$$R_T = R_1 + R_2 + R_3 + R_4 = 1.2\,k\Omega + 5.6\,k\Omega + 1.2\,k\Omega + 1.5\,k\Omega = 9.5\,k\Omega$$

Next, use Ohm's law to determine V_S.

$$V_S = IR_T = (1\,mA)(9.5\,k\Omega) = \mathbf{9.5\,V}$$

Related Problem Calculate V_S if the 5.6 kΩ resistor is changed to 3.9 kΩ with the current the same.

Use Multisim file E05–08 to verify the calculated results in this example and to confirm your calculation for the related problem.

EXAMPLE 5–9

Calculate the voltage across each resistor in Figure 5–19, and find the value of V_S. To what maximum value can V_S be raised if the current is to be limited to 5 mA?

Solution By Ohm's law, the voltage across each resistor is equal to its resistance multiplied by the current through it. Use the Ohm's law formula $V = IR$ to determine the voltage

► FIGURE 5–19
across each of the resistors. Keep in mind that there is the same current through each series resistor. The voltage across R_1 (designated V_1) is

$$V_1 = IR_1 = (1\,\text{mA})(1.0\,\text{k}\Omega) = \mathbf{1\,V}$$

The voltage across R_2 is

$$V_2 = IR_2 = (1\,\text{mA})(3.3\,\text{k}\Omega) = \mathbf{3.3\,V}$$

The voltage across R_3 is

$$V_3 = IR_3 = (1\,\text{mA})(4.7\,\text{k}\Omega) = \mathbf{4.7\,V}$$

To find the value of V_S, first determine R_T.

$$R_T = 1.0\,\text{k}\Omega + 3.3\,\text{k}\Omega + 4.7\,\text{k}\Omega = 9\,\text{k}\Omega$$

The source voltage V_S is equal to the current times the total resistance.

$$V_S = IR_T = (1\,\text{mA})(9\,\text{k}\Omega) = \mathbf{9\,V}$$

Notice that if you add the voltage drops of the resistors, they total 9 V, which is the same as the source voltage.

V_S can be increased to a value where $I = 5$ mA. Calculate the maximum value of V_S as follows:

$$V_{S(\text{max})} = IR_T = (5\,\text{mA})(9\,\text{k}\Omega) = \mathbf{45\,V}$$

Related Problem Repeat the calculations for V_1, V_2, V_3, V_S, and $V_{S(\text{max})}$ if $R_3 = 2.2\,\text{k}\Omega$ and I is maintained at 1 mA.

Use Multisim files E05-09A, E05-09B, and E05-09C to verify the calculated results in this example and to confirm your calculations for the related problem.

EXAMPLE 5–10

Series connections often involve using resistance to limit current to some level. For example, it is necessary to limit current to a light-emitting diode (LED) to prevent the LED from burning out. The circuit in Figure 5–20 shows a basic application, where a red LED is used as an indicator as part of a more complicated circuit. The rheostat is included to dim the LED depending on ambient conditions. We will focus on these two current-limiting resistors.
A red LED will always have a voltage across it of about +1.7 V when it is on and working within its normal operating range. The remaining voltage from the power supply will be across the two series resistors. Together, the rheostat and the fixed resistor will have a total of 3.3 V across them.

Assume you want current in the LED to range from a minimum of 2.5 mA (dim) to a maximum of 10 mA (bright). What values of R_1 and R_2 would you choose to accomplish this?

Solution   Start with the brightest condition when the resistance of the rheostat is adjusted for 0 Ω. In this case, there will be no voltage across R_1 and 3.3 V will be across R_2. Because it is a series circuit, the same current is in R_2 as the LED. Therefore,

$$R_2 = \frac{V}{I} = \frac{3.3\,\text{V}}{10\,\text{mA}} = \textbf{330 Ω}$$

Now determine the total resistance required to limit the current to 2.5 mA. The total resistance is $R_T = R_1 + R_2$, and the voltage drop across R_T is 3.3 V. From Ohm's law,

$$R_T = \frac{V}{I} = \frac{3.3\,\text{V}}{2.5\,\text{mA}} = \textbf{1.32 kΩ}$$

To find R_1, subtract the value of R_2 from the total resistance.

$$R_1 = R_T - R_2 = 1.32\,\text{kΩ} - 330\,\text{Ω} = 990\,\text{Ω}$$

Choose a **1.0 kΩ** rheostat as the nearest standard value.

Related Problem   What is the value of R_2 if the highest current is 12 mA?

5–5   VOLTAGE SOURCES IN SERIES

Recall that an ideal voltage source is an energy source that provides a constant voltage to a load. Batteries and electronic power supplies are practical examples of dc voltage sources.

After completing this section, you should be able to

◆ **Determine the total effect of voltage sources connected in series**

    ◆ Determine the total voltage of series sources with the same polarities

    ◆ Determine the total voltage of series sources with opposite polarities

When two or more voltage sources are in series, the total voltage is equal to the algebraic sum of the individual source voltages. The algebraic sum means that the polarities of the sources must be included when the sources are combined in series. Sources with opposite polarities have voltages with opposite signs.

$$V_{S(tot)} = V_{S1} + V_{S2} + \cdots + V_{Sn}$$

When the voltage sources are all in the same direction in terms of their polarities, as in Figure 5–22(a), all of the voltages have the same sign when added; there is a total of 4.5 V from terminal A to terminal B with A more positive than B.

$$V_{AB} = 1.5\,\text{V} + 1.5\,\text{V} + 1.5\,\text{V} = +4.5\,\text{V}$$

The voltage has a double subscript, AB, to indicate that it is the voltage at point A with respect to point B.

In Figure 5–22(b), the middle voltage source is opposite to the other two; so its voltage has an opposite sign when added to the others. For this case the total voltage from A to B is

$$V_{AB} = +1.5\,\text{V} - 1.5\,\text{V} + 1.5\,\text{V} = +1.5\,\text{V}$$

Terminal A is 1.5 V more positive than terminal B.

A familiar example of voltage sources in series is the flashlight. When you put two 1.5 V batteries in your flashlight, they are connected in series, giving a total of 3 V. When connecting batteries or other voltage sources in series to increase the total voltage, always connect from the positive (+) terminal of one to the negative (−) terminal of another. Such a connection is illustrated in Figure 5–23.

TECH NOTE

When replacing batteries in a portable electronic device, it is best to use all of the same type of battery and not mix old batteries with new batteries. In particular, do not mix alkaline with nonalkaline batteries. Incorrect use of batteries can cause hydrogen gas to build inside the battery and cause the casing to rupture. Worse, the mixing of hydrogen gas with oxygen can be an explosion hazard.

5–6   KIRCHHOFF'S VOLTAGE LAW

Kirchhoff's voltage law is a fundamental circuit law that states that the algebraic sum of all the voltages around a single closed path is zero or, in other words, the sum of the voltage drops equals the total source voltage.

After completing this section, you should be able to

◆ **Apply Kirchhoff's voltage law**

  ◆ State Kirchhoff's voltage law

  ◆ Determine the source voltage by adding the voltage drops

  ◆ Determine an unknown voltage drop

In an electric circuit, the voltages across the resistors (voltage drops) *always* have polarities opposite to the source voltage polarity. For example, in Figure 5–30, follow a counterclockwise loop around the circuit. Note that the source polarity is plus-to-minus and each voltage drop is minus-to-plus. The voltage drops across resistors are designated as V_1, V_2, and so on.

▶ **FIGURE 5–30**

Illustration of voltage polarities in a closed-loop circuit.
In Figure 5–30, the current is out of the negative side of the source and through the resistors as the arrows indicate. The current is into the negative side of each resistor and out the positive side. The drop in energy level across a resistor creates a potential difference, or voltage drop, with a minus-to-plus polarity in the direction of the current.

The voltage from point A to point B in the circuit of Figure 5–30 is the source voltage, V_S. Also, the voltage from A to B is the sum of the series resistor voltage drops. Therefore, the source voltage is equal to the sum of the three voltage drops, as stated by **Kirchhoff's voltage law**.

The sum of all the voltage drops around a single closed path in a circuit is equal to the total source voltage in that loop.

Kirchhoff's voltage law applied to a series circuit is illustrated in Figure 5–31. For this case, Kirchhoff's voltage law can be expressed by Equation 5–3.

Equation 5–3

$$V_S = V_1 + V_2 + V_3 + \cdots + V_n$$

where the subscript n represents the number of voltage drops.

If all the voltage drops around a closed path are added and then this total is subtracted from the source voltage, the result is zero. This result occurs because the sum of the voltage drops always equals the source voltage.
◀ **FIGURE 5–31**

Sum of n voltage drops equals the source voltage.

The algebraic sum of all the voltages (both source and drops) around a single closed path is zero.

Therefore, another way of expressing Kirchhoff's voltage law in equation form is

$$V_S - V_1 - V_2 - V_3 - \cdots - V_n = 0$$

You can verify Kirchhoff's voltage law by connecting a circuit and measuring each resistor voltage and the source voltage as illustrated in Figure 5–32. When the resistor voltages are added together, their sum will equal the source voltage. Any number of resistors can be added.
◀ **FIGURE 5–32**

Illustration of an experimental verification of Kirchhoff's voltage law.

EXAMPLE 5–13

Determine the source voltage V_S in Figure 5–33 where the two voltage drops are given. There is no voltage drop across the fuse.

▶ **FIGURE 5–33**
Solution   By Kirchhoff's voltage law, (Eq. 5–3), the source voltage (applied voltage) must equal the sum of the voltage drops. Adding the voltage drops gives the value of the source voltage.

$$V_S = 5\,\text{V} + 10\,\text{V} = \textbf{15 V}$$

Related Problem   If V_S is increased to 30 V, determine the two voltage drops. What is the voltage across each component (including the fuse) if the fuse is blown?

EXAMPLE 5–14

Find the value of R_4 in Figure 5–34.

▶ **FIGURE 5–34**
Solution   In this problem you will use both Ohm's law and Kirchhoff's voltage law.
First, use Ohm's law to find the voltage drop across each of the known resistors.

$$V_1 = IR_1 = (10\,\text{mA})(100\,\Omega) = 1.0\,\text{V}$$
$$V_2 = IR_2 = (10\,\text{mA})(470\,\Omega) = 4.7\,\text{V}$$
$$V_3 = IR_3 = (10\,\text{mA})(1.0\,\text{k}\Omega) = 10\,\text{V}$$

Next, use Kirchhoff's voltage law to find V_4, the voltage drop across the unknown resistor.

$$V_S - V_1 - V_2 - V_3 - V_4 = 0\,\text{V}$$
$$50\,\text{V} - 1.0\,\text{V} - 4.7\,\text{V} - 10\,\text{V} - V_4 = 0\,\text{V}$$
$$34.3\,\text{V} - V_4 = 0\,\text{V}$$
$$V_4 = 34.3\,\text{V}$$

Now that you know V_4, use Ohm's law to calculate R_4.

$$R_4 = \frac{V_4}{I} = \frac{34.3\,\text{V}}{10\,\text{mA}} = \textbf{3.43 k}\boldsymbol{\Omega}$$

R_4 is most likely a 3.3 kΩ resistor because 3.43 kΩ is within a standard tolerance range ($\pm 5\%$) of 3.3 kΩ.

Related Problem   Determine R_4 in Figure 5–34 for $V_S = 25$ V and $I = 10$ mA.

Use Multisim file E05-14 to verify the calculated results in the example and to confirm your calculation for the related problem.

So far, you have seen how Kirchhoff's voltage law can be applied to a series circuit with a voltage source, but it can also be applied to other types of circuits. For example, there are cases where there is no source voltage in a given closed loop. Even so, Kirchhoff's voltage law still applies. This leads to a more-general form of Equation 5–3.

$$V_1 + V_2 + V_3 + \cdots + V_n = 0$$

Equation 5–4

If a voltage source is present, it is simply treated as one of the terms in Equation 5–4.

In applying Equation 5–4, an algebraic sign is given to each voltage in the path depending on whether it is voltage rise $(+)$ or a voltage drop $(-)$. A voltage across a resistor can appear as either a rise or a drop depending on the path direction chosen, so you will need to assign algebraic signs to voltage rises and voltage drops in a consistent manner. A practical example of writing Kirchhoff's voltage law around a loop with no source is given in the Application Activity in Chapter 6.

Sometimes you will see an equation such as Equation 5–4 expressed in shorthand notation using the Greek letter sigma (Σ) to denote summation, as follows:

$$\sum_{i=1}^{n} V_i = 0$$

This mathematical expression is equivalent to Equation 5–4 and means that you add the voltages from the first $(i = 1)$ to the last $(i = n)$.

EXAMPLE 5–15   Determine the unknown voltage drop, V_3, in Figure 5–35.

▶ **FIGURE 5–35**
Solution   By Kirchhoff's voltage law (Eq. 5–4), the algebraic sum of all the voltages around the circuit is zero. The value of each voltage drop except V_3 is known. Substitute these values into the equation.

$$V_{S1} + V_{S2} + V_3 + V_2 + V_1 = 0$$
$$50\text{ V} - 15\text{ V} - V_3 - 6\text{ V} - 12\text{ V} = 0$$

Next, combine the known values, transpose 17 V to the right side of the equation, and cancel the minus signs.

$$17\,V - V_3 = 0\,V$$
$$-V_3 = -17\,V$$
$$V_3 = \mathbf{17\,V}$$

The voltage drop across R_3 is 17 V, and its polarity is as shown in Figure 5–35.

Related Problem Determine V_3 if the polarity of V_{S2} is reversed in Figure 5–35.

5–7 VOLTAGE DIVIDERS

A series circuit acts as a voltage divider. The voltage divider is an important application of series circuits.

After completing this section, you should be able to

◆ **Use a series circuit as a voltage divider**

  ◆ Apply the voltage-divider formula

  ◆ Use a potentiometer as an adjustable voltage divider

  ◆ Describe some voltage-divider applications

A circuit consisting of a series string of resistors connected to a voltage source acts as a **voltage divider**. Figure 5–36 shows a circuit with two resistors in series, although there can be any number. There are two voltage drops across the resistors: one across R_1 and one

▶ **FIGURE 5–36**

Two-resistor voltage divider.
across R_2. These voltage drops are V_1 and V_2, respectively, as indicated in the schematic. Since each resistor has the same current, the voltage drops are proportional to the resistance values. For example, if the value of R_2 is twice that of R_1, then the value of V_2 is twice that of V_1.

The total voltage drop around a single closed path divides among the series resistors in amounts directly proportional to the resistance values. For example, in Figure 5–36, if V_S is 10 V, R_1 is 50 Ω, and R_2 is 100 Ω, then V_1 is one-third the total voltage, or 3.33 V, because R_1 is one-third the total resistance of 150 Ω. Likewise, V_2 is two-thirds V_S, or 6.67 V.

Voltage-Divider Formula

With a few calculations, you can develop a formula for determining how the voltages divide among series resistors. Assume a circuit with n resistors in series as shown in Figure 5–37, where n can be any number.
◀ **FIGURE 5–37**

Generalized voltage divider with n resistors.

Let V_x represent the voltage drop across any one of the resistors and R_x represent the number of a particular resistor or combination of resistors. By Ohm's law, you can express the voltage drop across R_x as follows:

$$V_x = IR_x$$

The current through the circuit is equal to the source voltage divided by the total resistance $(I = V_S/R_T)$. In the circuit of Figure 5–37, the total resistance is $R_1 + R_2 + R_3 + \cdots + R_n$. By substitution of V_S/R_T for I in the expression for V_x,

$$V_x = \left(\frac{V_S}{R_T}\right)R_x$$

Rearranging the terms you get

$$V_x = \left(\frac{R_x}{R_T}\right)V_S$$

Equation 5–5

Equation 5–5 is the general voltage-divider formula, which can be stated as follows:

The voltage drop across any resistor or combination of resistors in a series circuit is equal to the ratio of that resistance value to the total resistance, multiplied by the source voltage.

EXAMPLE 5–16

Determine V_1 (the voltage across R_1) and V_2 (the voltage across R_2) in the voltage divider in Figure 5–38.

▶ **FIGURE 5–38**
Solution   To determine V_1, use the voltage-divider formula, $V_x = (R_x/R_T)V_S$, where $x = 1$. The total resistance is

$$R_T = R_1 + R_2 = 100\ \Omega + 56\ \Omega = 156\ \Omega$$

R_1 is 100 Ω and V_S is 10 V. Substitute these values into the voltage-divider formula.

$$V_1 = \left(\frac{R_1}{R_T}\right)V_S = \left(\frac{100\ \Omega}{156\ \Omega}\right)10\ \text{V} = \textbf{6.41 V}$$

There are two ways to find the value of V_2: Kirchhoff's voltage law or the voltage-divider formula. If you use Kirchhoff's voltage law ($V_S = V_1 + V_2$), substitute the values for V_S and V_1 as follows:

$$V_2 = V_S - V_1 = 10\ \text{V} - 6.41\ \text{V} = \textbf{3.59 V}$$

To determine V_2, use the voltage-divider formula where $x = 2$.

$$V_2 = \left(\frac{R_2}{R_T}\right)V_S = \left(\frac{56\ \Omega}{156\ \Omega}\right)10\ \text{V} = \textbf{3.59 V}$$

Related Problem   Find the voltages across R_1 and R_2 in Figure 5–38 if R_2 is changed to 180 Ω.

Use Multisim file E05-16 to verify the calculated results in this example and to confirm your calculations for the related problem.

EXAMPLE 5–17

Calculate the voltage drop across each resistor in the voltage divider of Figure 5–39.

▶ **FIGURE 5–39**
Solution   Look at the circuit for a moment and consider the following: The total resistance is 1000 Ω. Ten percent of the total voltage is across R_1 because it is 10% of the total resistance (100 Ω is 10% of 1000 Ω). Likewise, 22% of the total voltage is dropped across R_2 because it is 22% of the total resistance (220 Ω is 22% of 1000 Ω). Finally, R_3 drops 68% of the total voltage because 680 Ω is 68% of 1000 Ω.

Because of the convenient values in this problem, it is easy to figure the voltages mentally. ($V_1 = 0.10 \times 10$ V $= 1$ V, $V_2 = 0.22 \times 10$ V $= 2.2$ V, and $V_3 = 0.68 \times 10$ V $= 6.8$ V). Such is usually not the case, but sometimes a little thinking will produce a result more efficiently and eliminate some calculating. This is also a good way to estimate what your results should be so that you will recognize an unreasonable answer as a result of a calculation error.

Although you have already reasoned through this problem, the calculations will verify your results.

$$V_1 = \left(\frac{R_1}{R_T}\right)V_S = \left(\frac{100\ \Omega}{1000\ \Omega}\right)10\ V = \mathbf{1\ V}$$

$$V_2 = \left(\frac{R_2}{R_T}\right)V_S = \left(\frac{220\ \Omega}{1000\ \Omega}\right)10\ V = \mathbf{2.2\ V}$$

$$V_3 = \left(\frac{R_3}{R_T}\right)V_S = \left(\frac{680\ \Omega}{1000\ \Omega}\right)10\ V = \mathbf{6.8\ V}$$

Notice that the sum of the voltage drops is equal to the source voltage, in accordance with Kirchhoff's voltage law. This check is a good way to verify your results.

Related Problem   If R_1 and R_2 in Figure 5–39 are changed to 680 Ω, what are the voltage drops?

EXAMPLE 5–18

Determine the voltages between the following points in the voltage divider of Figure 5–40:

(a) A to B **(b)** A to C **(c)** B to C **(d)** B to D **(e)** C to D

▶ **FIGURE 5–40**
Solution   First, determine R_T.

$$R_T = R_1 + R_2 + R_3 = 1.0\,k\Omega + 8.2\,k\Omega + 3.3\,k\Omega = 12.5\,k\Omega$$

Next, apply the voltage-divider formula to obtain each required voltage.

(a) The voltage A to B is the voltage drop across R_1.

$$V_{AB} = \left(\frac{R_1}{R_T}\right)V_S = \left(\frac{1.0\,\text{k}\Omega}{12.5\,\text{k}\Omega}\right)25\,\text{V} = \mathbf{2\,V}$$

(b) The voltage from A to C is the combined voltage drop across both R_1 and R_2. In this case, R_x in the general formula given in Equation 5–5 is $R_1 + R_2$.

$$V_{AC} = \left(\frac{R_1 + R_2}{R_T}\right)V_S = \left(\frac{9.2\,\text{k}\Omega}{12.5\,\text{k}\Omega}\right)25\,\text{V} = \mathbf{18.4\,V}$$

(c) The voltage from B to C is the voltage drop across R_2.

$$V_{BC} = \left(\frac{R_2}{R_T}\right)V_S = \left(\frac{8.2\,\text{k}\Omega}{12.5\,\text{k}\Omega}\right)25\,\text{V} = \mathbf{16.4\,V}$$

(d) The voltage from B to D is the combined voltage drop across both R_2 and R_3. In this case, R_x in the general formula is $R_2 + R_3$.

$$V_{BD} = \left(\frac{R_2 + R_3}{R_T}\right)V_S = \left(\frac{11.5\,\text{k}\Omega}{12.5\,\text{k}\Omega}\right)25\,\text{V} = \mathbf{23\,V}$$

(e) Finally, the voltage from C to D is the voltage drop across R_3.

$$V_{CD} = \left(\frac{R_3}{R_T}\right)V_S = \left(\frac{3.3\,\text{k}\Omega}{12.5\,\text{k}\Omega}\right)25\,\text{V} = \mathbf{6.6\,V}$$

If you connect this voltage divider, you can verify each of the calculated voltages by connecting a voltmeter between the appropriate points in each case.

A Potentiometer as an Adjustable Voltage Divider

Recall from Chapter 2 that a potentiometer is a variable resistor with three terminals. A linear potentiometer connected to a voltage source is shown in Figure 5–41(a) with the schematic shown in part (b). Notice that the two end terminals are labeled 1 and 2. The adjustable terminal or wiper is labeled 3. The potentiometer functions as a voltage divider,

(a) Pictorial   (b) Schematic   (c) Equivalent schematic
▲ **FIGURE 5–41**

The potentiometer used as a voltage divider.

which can be illustrated by separating the total resistance into two parts, as shown in Figure 5–41(c). The resistance between terminal 1 and terminal 3 (R_{13}) is one part, and the resistance between terminal 3 and terminal 2 (R_{32}) is the other part. So this potentiometer is equivalent to a two-resistor voltage divider that can be manually adjusted.

Figure 5–42 shows what happens when the wiper contact (3) is moved. In part (a), the wiper is exactly centered, making the two resistances equal. If you measure the voltage across terminals 3 to 2 as indicated by the voltmeter symbol, you have one-half of the total source voltage. When the wiper is moved up, as in part (b), the resistance between terminals 3 and 2 increases, and the voltage across it increases proportionally. When the wiper is moved down, as in part (c), the resistance between terminals 3 and 2 decreases, and the voltage decreases proportionally.
▲ FIGURE 5–42

Adjusting the voltage divider.

Applications

The volume control of some radio receivers is a common application of a potentiometer used as a voltage divider. Since the loudness of the sound is dependent on the amount of voltage associated with the audio signal, you can increase or decrease the volume by adjusting the potentiometer, that is, by turning the knob of the volume control on the set. The block diagram in Figure 5–43 shows how a potentiometer can be used for volume control in a typical receiver.
▲ FIGURE 5–43

A variable voltage divider used for volume control in a radio receiver.

Figure 5–44 illustrates another application in which a potentiometer voltage divider can be used as a level sensor in a liquid storage tank. As shown in part (a), the float moves up as the tank is filled and moves down as the tank empties. The float is mechanically linked to the wiper arm of a potentiometer, as shown in part (b). The output voltage varies proportionally with the position of the wiper arm. As the liquid in the tank decreases, the sensor output voltage also decreases. The output voltage goes to the indicator circuitry, which controls a digital readout to show the amount of liquid in the tank. The schematic of this system is shown in part (c).

▲ FIGURE 5–44

A potentiometer voltage divider used in a level sensor.

Still another application for voltage dividers is in setting the dc operating voltage (bias) in transistor amplifiers. Figure 5–45 shows a voltage divider used for this purpose. You will study transistor amplifiers and biasing in a later course, so it is important that you understand the basics of voltage dividers at this point.

▶ FIGURE 5–45

The voltage divider used as a bias circuit for a transistor amplifier, where the voltage at the base terminal of the transistor is determined by the voltage divider as $V_{base} = (R_2/(R_1 + R_2))V_S$.
A voltage divider is useful for converting a resistance sensor output to a voltage. Resistance sensors were described in Chapter 2 and include thermistors, CdS cells, and strain gauges. To convert a change in resistance to an output voltage, the resistance sensor can replace one of the resistors in a voltage divider.

EXAMPLE 5–19

Assume you have a CdS cell configured as shown in Figure 5–46 that uses three AA batteries for a voltage source (4.5 V). At dusk, the resistance of the cell rises from a low resistance to above $90\,k\Omega$. The cell is used to trigger a logic circuit that will turn on lights if V_{OUT} is greater than approximately 1.5 V. What value of R will produce an output voltage of 1.5 V when the cell resistance is $90\,k\Omega$?

V_S
+4.5 V

R

V_{OUT}

CdS cell
Solution   Notice that the threshold voltage (1.5 V) is one-third of the supply voltage. You know that $90\,k\Omega$ represents one-third of the total resistance at this point. Therefore, the total resistance is

$$R_T = 3(90\,k\Omega) = 270\,k\Omega$$

The resistance value needed to produce $V_{OUT} = 1.5$ V is

$$R = R_T - 90\,k\Omega = 270\,k\Omega - 90\,k\Omega = \mathbf{180\,k\Omega}$$

Related Problem   Starting with Equation 5–5, prove that the required resistance needed to produce an output voltage of 1.5 V is $180\,k\Omega$ when the cell resistance is $90\,k\Omega$.

5–8   POWER IN SERIES CIRCUITS

The power dissipated by each individual resistor in a series circuit contributes to the total power in the circuit. The individual powers are additive.

After completing this section, you should be able to

◆ **Determine power in a series circuit**

  ◆ Apply one of the power formulas

The total amount of power in a series resistive circuit is equal to the sum of the powers in each resistor in series.

Equation 5–6

$$P_T = P_1 + P_2 + P_3 + \cdots + P_n$$

where P_T is the total power and P_n is the power in the last resistor in series.

The power formulas that you learned in Chapter 4 are applicable to series circuits. Since there is the same current through each resistor in series, the following formulas are used to calculate the total power:

$$P_T = V_S I$$
$$P_T = I^2 R_T$$
$$P_T = \frac{V_S^2}{R_T}$$

where I is the current through the circuit, V_S is the total source voltage across the series connection, and R_T is the total resistance.

EXAMPLE 5–20

Determine the total amount of power in the series circuit in Figure 5–48.

▶ **FIGURE 5–48**
Solution   The source voltage is 15 V. The total resistance is

$$R_T = R_1 + R_2 + R_3 + R_4 = 10\,\Omega + 18\,\Omega + 56\,\Omega + 22\,\Omega = 106\,\Omega$$

The easiest formula to use is $P_T = V_S^2/R_T$ since you know both V_S and R_T.

$$P_T = \frac{V_S^2}{R_T} = \frac{(15\text{ V})^2}{106\,\Omega} = \frac{225\text{ V}^2}{106\,\Omega} = 2.12\text{ W}$$

If you determine the power in each resistor separately and all of these powers are added, you obtain the same result. First, find the current.

$$I = \frac{V_S}{R_T} = \frac{15\,\text{V}}{106\,\Omega} = 142\,\text{mA}$$

Next, calculate the power for each resistor using $P = I^2R$.

$$P_1 = I^2R_1 = (142\,\text{mA})^2(10\,\Omega) = 200\,\text{mW}$$
$$P_2 = I^2R_2 = (142\,\text{mA})^2(18\,\Omega) = 360\,\text{mW}$$
$$P_3 = I^2R_3 = (142\,\text{mA})^2(56\,\Omega) = 1.12\,\text{W}$$
$$P_4 = I^2R_4 = (142\,\text{mA})^2(22\,\Omega) = 441\,\text{mW}$$

Then, add these powers to get the total power.

$$P_T = P_1 + P_2 + P_3 + P_4 = 200\,\text{mW} + 360\,\text{mW} + 1.12\,\text{W} + 441\,\text{mW} = \textbf{2.12 W}$$

This result compares to the total power as determined previously by the formula $P_T = V_S^2/R_T$.

Related Problem   What is the power in the circuit of Figure 5–48 if V_S is increased to 30 V?

The amount of power in a resistor is important because the power rating of the resistors must be high enough to handle the expected power in the circuit. The following example illustrates practical considerations relating to power in a series circuit.

EXAMPLE 5–21

Determine if the indicated power rating ($\frac{1}{2}$ W) of each resistor in Figure 5–49 is sufficient to handle the actual power when the switch is closed. If a rating is not adequate, specify the required minimum rating.

▶ **FIGURE 5–49**
Solution   First, determine the total resistance.

$$R_T = R_1 + R_2 + R_3 + R_4 = 1.0\,\text{k}\Omega + 2.7\,\text{k}\Omega + 910\,\Omega + 3.3\,\text{k}\Omega = 7.91\,\text{k}\Omega$$

Next, calculate the current.

$$I = \frac{V_S}{R_T} = \frac{120\,\text{V}}{7.91\,\text{k}\Omega} = 15\,\text{mA}$$

Then calculate the power in each resistor.

$$P_1 = I^2R_1 = (15\,\text{mA})^2(1.0\,\text{k}\Omega) = \textbf{225 mW}$$
$$P_2 = I^2R_2 = (15\,\text{mA})^2(2.7\,\text{k}\Omega) = \textbf{608 mW}$$
$$P_3 = I^2R_3 = (15\,\text{mA})^2(910\,\Omega) = \textbf{205 mW}$$
$$P_4 = I^2R_4 = (15\,\text{mA})^2(3.3\,\text{k}\Omega) = \textbf{743 mW}$$

R_2 and R_4 do not have a rating sufficient to handle the actual power, which exceeds $\frac{1}{2}$ W in each of these two resistors, and they may burn out if the switch is closed. These resistors should be replaced by 1 W resistors.

Related Problem   Determine the minimum power rating required for each resistor in Figure 5–49 if the source voltage is increased to 240 V.

5–9   VOLTAGE MEASUREMENTS

The concept of *reference ground* was introduced in Chapter 2 and designated as the 0 V reference point for a circuit. Voltage is always measured with respect to another point in the circuit. In this section, ground is discussed in more detail.

After completing this section, you should be able to

◆ **Measure voltage with respect to ground**

    ◆ Define the term *reference ground*

    ◆ Explain the use of single and double subscripts for indicating voltages

    ◆ Identify ground in a circuit

The term *ground* has its origin in telephone systems in which one of the conductors was the earth itself. The term was also used in early radio receiving antennas (called *aerials*) where one part of the system was connected to a metal pipe driven into the earth. Today, *ground* can mean different things and is not necessarily at the same potential as the earth. In electronic systems, **reference ground** (or *common*) refers to a conductor that is the comparison point for voltage measurements in a circuit. Frequently, it is the conductor that carries the power supply return current. Most electronic circuit boards have a larger conducting surface area for ground. For many multilayer circuit boards the ground surface area is a separate internal layer, which is referred to as a *ground plane*.

In electrical wiring, the reference ground is usually the same as the earth potential because neutral and earth ground are connected at the entrance point to a building. In this case, reference ground and earth ground are at the same potential.

The concept of *reference ground* is also used in automotive electrical systems. In most automotive systems, the chassis of the automobile is the ground reference. In nearly all modern automobiles, the negative post of the battery is connected to the chassis with a solid low-resistance connection. This makes the chassis of the vehicle serve as the return path for all of the electrical circuits in the vehicle, as illustrated in the simplified drawing in Figure 5–50. In some vintage cars, the positive terminal was connected to the chassis in an arrangement called *positive ground*. In both cases, the chassis represents the reference ground point.

⚡ **SAFETY NOTE**

When removing a battery from an automobile, remove the ground wire first. If a tool should then accidentally come in contact with the chassis and the positive terminal, a spark will be avoided; there is no current because there is no return path. When installing a battery, always install the ground connection last.
The chassis serves as a return current path for the electrical circuits in a vehicle.

Measuring Voltages with Respect to Ground

When voltages are measured with respect to ground, they are indicated with a single letter subscript. For example, V_A is voltage at point A with respect to ground. The circuits in Figure 5–51 consist of three $1.0 \, k\Omega$ series resistors and four lettered reference points. Reference ground represents a potential of 0 V with respect to all other points in the circuit as illustrated. In part (a), the reference point is D and all voltages are positive with respect to D. In part (b), the reference point is A in the circuit, and all other points have a negative voltage.

(a) Positive voltages with respect to ground

(b) Negative voltages with respect to ground

(c) Positive and negative voltages with respect to ground
The ground point does not affect the current in the circuit or the voltage drops across the resistors.

Many circuits use both positive and negative voltages and as mentioned, the return path for these supplies is designated as reference ground. Figure 5–51(c) shows the same circuit but with two 6 V sources replacing the 12 V source. In this case, the reference point is arbitrarily designated between the two voltage sources. There is exactly the same current in all three circuits, but now voltages are referenced to the new ground point. As you can see from these examples, the reference ground point is arbitrary and does not change the current.

Not all voltages are measured with respect to ground. If you wish to specify the voltage drop across an ungrounded resistor, you can name the resistor in the subscript or use two subscripts. When two subscripts are used, the voltage represents the difference between the points. For example, V_{BC} means $V_B - V_C$. In Figure 5–51, V_{BC} is the same in all three circuits (+4.0 V) as you can confirm by performing the subtraction in each case. Another way of designating V_{BC} is to write simply V_{R2}.

There is one more convention commonly used to express voltages using subscripts. Power supply voltages are usually given with a double-letter subscript. The reference point is ground or common. For example, a voltage written as V_{CC} is a positive power supply voltage with respect to ground. Other common power supply voltages are V_{SS} (positive), V_{EE} (negative), and V_{SS} (negative).

To measure voltages with a digital meter, the meter leads can be connected across any two points and the meter will indicate the voltage, either positive or negative. The meter reference jack is labeled "COM" (normally black). This is common only to the meter, not to the

▶ **FIGURE 5–52**

A DMM has a "floating" common, so it can be connected to any point in the circuit and read the correct voltage between the two leads.
circuit. Figure 5–52 shows measuring a floating voltage using a DMM to measure the voltage across the ungrounded resistor R_2. The circuit is the same one given in Figure 5–51(b), which has a negative power supply. It is shown as it might be constructed in a lab. Notice that the meter indicates a negative voltage, which means that the meter's COM lead is the more positive lead. If you wanted to measure voltages with respect to the circuit's reference ground, you would connect the COM on the meter to the circuit's reference ground. The voltage with respect to the reference ground will be indicated.

If you are using an analog meter to make circuit measurements, you must connect the meter so that its common lead is connected to the most negative point in the circuit; otherwise, the meter movement will try to move backward. Figure 5–53 shows an analog meter connected to the same circuit as before; notice that the meter leads are reversed. To measure

▶ **FIGURE 5–53**

An analog meter needs to be connected so that the positive lead goes to the more positive point in the circuit.

5–10 TROUBLESHOOTING

Open resistors or contacts and one point shorted to another are common problems in all circuits including series circuits.

After completing this section, you should be able to

◆ **Troubleshoot series circuits**

  ◆ Check for an open circuit

  ◆ Check for a short circuit

  ◆ Identify primary causes of opens and shorts

Open Circuit

The most common failure in a series circuit is an **open**. For example, when a resistor or a lamp burns out, it causes a break in the current path and creates an open circuit, as illustrated in Figure 5–55.

An open in a series circuit prevents current.

(a) A complete series circuit has current.

(b) An open series circuit has no current.
▲ **FIGURE 5–55**

Current ceases when an open occurs.

Troubleshooting an Open   In Chapter 3, you were introduced to the analysis, planning, and measurement (APM) approach to troubleshooting. You also learned about the half-splitting method and saw an example using an ohmmeter. Now, the same principles will be applied using voltage measurements instead of resistance measurements. As you know, voltage measurements are generally the easiest to make because you do not have to disconnect anything.

As a beginning step, prior to analysis, it is a good idea to make a visual check of the faulty circuit. Occasionally, you can find a charred resistor, a broken lamp filament, a loose wire, or a loose connection this way. However, it is possible (and probably more common) for a resistor or other component to open without showing visible signs of damage. When a visual check reveals nothing, then proceed with the APM approach.

When an open occurs in a series circuit, all of the source voltage appears across the open. The reason for this is that the open condition prevents current through the series circuit. With no current, there can be no voltage drop across any of the other resistors (or other component). Since $IR = (0 \text{ A})R = 0 \text{ V}$, the voltage on each end of a good resistor is the same. Therefore, the voltage applied across a series string also appears across the open component because there are no other voltage drops in the circuit, as illustrated in

Figure 5–56. The source voltage will appear across the open resistor in accordance with Kirchhoff's voltage law as follows:

$$V_S = V_1 + V_2 + V_3 + V_4 + V_5 + V_6$$
$$V_4 = V_S - V_1 - V_2 - V_3 - V_5 - V_6$$
$$= 10\,V - 0\,V - 0\,V - 0\,V - 0\,V - 0\,V$$
$$V_4 = V_S = 10\,V$$
◀ FIGURE 5–56

The source voltage appears across the open series resistor.

Example of Half-Splitting Using Voltage Measurements Suppose a circuit has four resistors in series. You have determined by *analyzing* the symptoms (there is voltage but no current) that one of the resistors is open, and you are *planning* to find the open resistor using a voltmeter for *measuring* by the half-splitting method. A sequence of measurements for this particular case is illustrated in Figure 5–57.

Step 1: Measure across R_1 and R_2 (the left half of the circuit). A 0 V reading indicates that neither of these resistors is open.

Step 2: Move the meter to measure across R_3 and R_4; the reading is 10 V. This indicates there is an open in the right half of the circuit, so either R_3 or R_4 is the faulty resistor (assume no bad connections).

Step 3: Move the meter to measure across R_3. A measurement of 10 V across R_3 identifies it as the open resistor. If you had measured across R_4, it would have indicated 0 V. This would have also identified R_3 as the faulty component because it would have been the only one left that could have 10 V across it.

Short Circuit

Sometimes an unwanted short circuit occurs when two conductors touch or a foreign object such as solder or a wire clipping accidentally connects two sections of a circuit together. This situation is particularly common in circuits with a high component density. Several potential causes of short circuits are illustrated on the PC board in Figure 5–58.

Examples of shorts on a PC board.
When there is a **short**, a portion of the series resistance is bypassed (all of the current goes through the short), thus reducing the total resistance as illustrated in Figure 5–59. Notice that the current increases as a result of the short.

A short in a series circuit causes more current than normal.

Example of the effect of a short in a series circuit.

$$I = \frac{100\ \text{V}}{100\ \Omega} = 1\ \text{A}$$

(a) Before short

$$I = \frac{100\ \text{V}}{28\ \Omega} = 3.57\ \text{A}$$

(b) After short
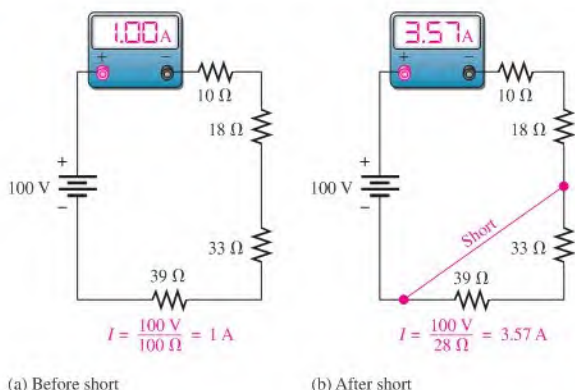

Troubleshooting a Short A short is very difficult to troubleshoot. As in any troubleshooting situation, it is a good idea to make a visual check of the faulty circuit. In the case of a short in the circuit, a wire clipping, solder splash, or touching leads is often found to be the culprit. In terms of component failure, shorts are less common than opens in many types of components. Furthermore, a short in one part of a circuit can cause overheating in another part due to the higher current caused by the short. As a result two failures, an open and a short, may occur together.

When a short occurs in a series circuit, there is essentially no voltage across the shorted part. A short has zero or near zero resistance, although shorts with significant resistance values can occur from time to time. These are called *resistive shorts*. For purposes of illustration, zero resistance is assumed for all shorts.

In order to troubleshoot a short, measure the voltage across each resistor until you get a reading of 0 V. This is the straightforward approach and does not use half-splitting. In order

to apply the half-splitting method, you must know the correct voltage at each point in the circuit and compare it to measured voltages. Example 5–23 illustrates using half-splitting to find a short.

EXAMPLE 5–23

Assume you have determined that there is a short in a circuit with four series resistors because the current is higher than it should be. You know that the voltage at each point in the circuit should be as shown in Figure 5–60 if the circuit is working properly. The voltages are shown relative to the negative terminal of the source. Find the location of the short.

► **FIGURE 5–60**

Series circuit (without a short) with correct voltages indicated.
Solution Use the half-splitting method to troubleshoot the short.

Step 1: Measure across R_1 and R_2. The meter shows a reading of 6.67 V, which is higher than the normal voltage (it should be 5 V). Look for a voltage that is lower than normal because a short will make the voltage less across that part of the circuit.

Step 2: Move the meter and measure across R_3 and R_4; the reading of 3.33 V is incorrect and lower than normal (it should be 5 V). This shows that the short is in the right half of the circuit and that either R_3 or R_4 is shorted.

Step 3: Again move the meter and measure across R_3. A reading of 3.3 V across R_3 tells you that R_4 is shorted because it must have 0 V across it. Figure 5–61 illustrates this troubleshooting technique.

5. When a resistor fails, it will normally fail open.   (T or F)

Application Activity

For this application activity, you have a voltage-divider circuit board to evaluate and modify if necessary. You will use it to obtain five different voltage levels from a 12 V battery that has a 6.5 Ah rating. The voltage divider provides positive reference voltages to an electronic circuit in an analog-to-digital converter. Your job is to check the circuit to see if it provides the following voltages within a tolerance of ±5% with respect to the negative side of the battery: 10.4 V, 8.0 V, 7.3 V, 6.0 V, and 2.7 V. If the existing circuit does not provide the specified voltages, you will modify it so that it does. Also, you must make sure that the power ratings of the resistors are adequate for the application and determine how long the battery will last with the voltage divider connected to it.

The Schematic of the Circuit

1. Use Figure 5–62 to determine the resistor values and draw the schematic of the voltage-divider circuit. All the resistors on the board are $\frac{1}{4}$ W.
▲ FIGURE 5–62

The Voltages

2. Determine the voltage at each pin on the circuit board with respect to the negative side of the battery when the positive side of the 12 V battery is connected to pin 3 and the negative side is connected to pin 1. Compare the existing voltages to the following specifications:

   Pin 1: negative terminal of 12 V battery

   Pin 2: 2.7 V ± 5%

   Pin 3: positive terminal of 12 V battery

   Pin 4: 10.4 V ± 5%

   Pin 5: 8.0 V ± 5%

   Pin 6: 7.3 V ± 5%

   Pin 7: 6.0 V ± 5%

3. If the output voltages of the existing circuit are not the same as those stated in the specifications, make the necessary changes in the circuit to meet the specifications. Draw a schematic of the modified circuit showing resistor values and adequate power ratings.

The Battery

4. Find the total current drawn from the 12 V battery when the voltage-divider circuit is connected and determine how many days the 6.5 Ah battery will last.

A Test Procedure

5. Determine how you would test the voltage-divider circuit board and what instruments you would use. Then detail your test procedure in a step-by-step format.

Troubleshooting

6. Determine the most likely fault for each of the following cases. Voltages are with respect to the negative battery terminal (pin 1 on the circuit board).

   ◆ No voltage at any of the pins on the circuit board

   ◆ 12 V at pins 3 and 4. All other pins have 0 V.

   ◆ 12 V at all pins except 0 V at pin 1

   ◆ 12 V at pin 6 and 0 V at pin 7

   ◆ 3.3 V at pin 2

Review

7. What is the total power dissipated by the voltage-divider circuit in Figure 5-62 with a 12 V battery?

8. What are the output voltages from the voltage divider if the positive terminal of a 6 V battery is connected to pin 3 and the negative terminal to pin 1?

APPLICATION ACTIVITY PREVIEW

In this application activity, a panel-mounted power supply will be modified by adding a milliammeter to indicate current to a load. Expansion of the meter for multiple current ranges using parallel (shunt) resistors will be demonstrated. The problem with very low-value resistors when a switch is used to select the current ranges will be introduced and the effect of switch contact resistance will be demonstrated. A way of eliminating the contact resistance problem will be presented. Finally, the ammeter circuit will be installed in the power supply. The knowledge of parallel circuits and of basic ammeters that you will acquire in this chapter plus your understanding of Ohm's law and current dividers will be put to good use.

INTRODUCTION

In Chapter 5, you learned about series circuits and how to apply Ohm's law and Kirchhoff's voltage law. You also saw how a series circuit can be used as a voltage divider to obtain several specified voltages from a single source voltage. The effects of opens and shorts in series circuits were also examined.

   In this chapter, you will see how Ohm's law is used in parallel circuits; and you will learn Kirchhoff's current law. Also, several applications of parallel circuits, including automotive lighting, residential wiring, control circuit, and the internal wiring of analog ammeters are presented. You will learn how to determine total parallel resistance and how to troubleshoot for open resistors.

   When resistors are connected in parallel and a voltage is applied across the parallel circuit, each resistor provides a separate path for current. The total resistance of a parallel circuit is reduced as more resistors are connected in parallel. The voltage across each of the parallel resistors is equal to the voltage applied across the entire parallel circuit.

6–1 RESISTORS IN PARALLEL

When two or more resistors are individually connected between two separate points (nodes) in a circuit, they are in parallel with each other. A parallel circuit provides more than one path for current.

After completing this section, you should be able to

◆ **Identify a parallel resistive circuit**

   ◆ Translate a physical arrangement of parallel resistors into a schematic

Each current path is called a **branch**, and a **parallel** circuit is one that has more than one branch. Two resistors connected in parallel are shown in Figure 6–1(a). As shown in part (b), the current out of the source (I_T) divides when it gets to point A. I_1 goes through R_1 and I_2 goes through R_2. If additional resistors are connected in parallel with the first two, more current paths are provided between point A and point B, as shown in Figure 6–1(c). All points along the top shown in blue are electrically the same as point A, and all points along the bottom shown in green are electrically the same as point B.
▲ **FIGURE 6–1**

Resistors in parallel.

In Figure 6–1, it is obvious that the resistors are connected in parallel. Often, in actual circuit diagrams, the parallel relationship is not as clear. It is important that you learn to recognize parallel circuits regardless of how they may be drawn.

A rule for identifying parallel circuits is as follows:

If there is more than one current path (branch) between two separate points and if the voltage between those two points also appears across each of the branches, then there is a parallel circuit between those two points.

Figure 6–2 shows parallel resistors drawn in different ways between two separate points labeled A and B. Notice that in each case, the current has two paths going from A to B, and
▲ **FIGURE 6–2**

Examples of circuits with two parallel paths.

⊕ *This icon indicates selected websites for further information on topics in this section. See the Companion Website provided with this text.*

the voltage across each branch is the same. Although these examples show only two paral-
lel paths, there can be any number of resistors in parallel.

EXAMPLE 6–1

Five resistors are positioned on a protoboard as shown in Figure 6–3. Show the wiring

schematic is shown in Figure 6–4(b). Again, note that the schematic does not necessar-
ily have to show the actual physical arrangement of the resistors. The schematic shows
how components are connected electrically.

6–2 VOLTAGE IN A PARALLEL CIRCUIT

The voltage across any given branch of a parallel circuit is equal to the voltage across each of the other branches in parallel. As you know, each current path in a parallel circuit is called a *branch*.

After completing this section, you should be able to

◆ **Determine the voltage across each branch in a parallel circuit**

  ◆ Explain why the voltage is the same across all parallel resistors

To illustrate voltage in a parallel circuit, let's examine Figure 6–7(a). Points A, B, C, and D along the left side of the parallel circuit are electrically the same point because the voltage is the same along this line. You can think of all of these points as being connected by a single wire to the negative terminal of the battery. The points E, F, G, and H along the right side of the circuit are all at a voltage equal to that of the positive terminal of the source. Thus, voltage across each parallel resistor is the same, and each is equal to the source voltage. Note that the parallel circuit in Figure 6–7 resembles a ladder.

Figure 6–7(b) is the same circuit as in part (a), drawn in a slightly different way. Here the left side of each resistor is connected to a single point, which is the negative battery terminal. The right side of each resistor is connected to a single point, which is the positive battery terminal. The resistors are still all in parallel across the source.

6–3   KIRCHHOFF'S CURRENT LAW

Kirchhoff's voltage law deals with voltages in a single closed path. Kirchhoff's current law applies to currents in multiple paths.

After completing this section, you should be able to

◆ **Apply Kirchhoff's current law**

  ◆ State Kirchhoff's current law

  ◆ Define *node*

  ◆ Determine the total current by adding the branch currents

  ◆ Determine an unknown branch current

Kirchhoff's current law, often abbreviated KCL, can be stated as follows:

The sum of the currents into a node (total current in) is equal to the sum of the currents out of that node (total current out).

A **node** is any point or junction in a circuit where two or more components are connected. In a parallel circuit, a node or junction is a point where the parallel branches come together. For example, in the circuit of Figure 6–12, point A is one node and point B is another. Let's start at the negative terminal of the source and follow the current. The total current I_T from the source is *into* node A. At this point, the current splits up among the three branches as indicated. Each of the three branch currents (I_1, I_2, and I_3) is *out of* node A. Kirchhoff's current law says that the total current into node A is equal to the total current out of node A; that is,

$$I_T = I_1 + I_2 + I_3$$

Now, following the currents in Figure 6–12 through the three branches, you see that they come back together at node B. Currents I_1, I_2, and I_3 are into node B, and I_T is
Kirchhoff's current law: The current into a node equals the current out of that node.

out of node B. Kirchhoff's current law formula at node B is therefore the same as at node A.

$$I_T = I_1 + I_2 + I_3$$

Figure 6–13 illustrates the general case of Kirchhoff's current law and can be written as a mathematical relationship:

$$I_{IN(1)} + I_{IN(2)} + I_{IN(3)} + \cdots + I_{IN(n)} = I_{OUT(1)} + I_{OUT(2)} + I_{OUT(3)} + \cdots + I_{OUT(m)}$$

Equation 6–1

Moving the terms on the right side to the left side and changing the sign results in the following equivalent equation:

$$I_{IN(1)} + I_{IN(2)} + I_{IN(3)} + \cdots + I_{IN(n)} - I_{OUT(1)} - I_{OUT(2)} - I_{OUT(3)} - \cdots - I_{OUT(m)} = 0$$

This equation shows that all current into and out of the junction sums to zero and can be stated as

The algebraic sum of all of the currents entering and leaving a node is equal to zero.

An equivalent way of writing Kirchhoff's current law can be expressed using the mathematical summation shorthand as was done for Kirchhoff's voltage law in Chapter 5.

$$\sum_{i=1}^{n} I_i = 0$$
Generalized circuit node illustrating Kirchhoff's current law.

$$I_{IN(1)} + I_{IN(2)} + I_{IN(3)} + \cdots + I_{IN(n)} = I_{OUT(1)} + I_{OUT(2)} + I_{OUT(3)} + \cdots I_{OUT(m)}$$

To express Kirchhoff's current law with this method, all currents are assigned a sequential subscript (1, 2, 3, and so on) no matter if the current is into or out of the node. Currents into the node are positive and currents leaving the node are negative.

You can verify Kirchhoff's current law by connecting a circuit and measuring each branch current and the total current from the source, as illustrated in Figure 6–14. When the branch currents are added together, their sum will equal the total current. This rule applies for any number of branches.

The following four examples illustrate use of Kirchhoff's current law.

▶ FIGURE 6–14

An illustration of Kirchhoff's current law.
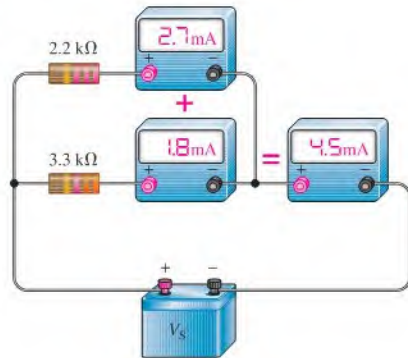

EXAMPLE 6–4

The branch currents are shown in the circuit of Figure 6–15. Determine the total current entering node A and the total current leaving node B.

▶ FIGURE 6–15
Solution The total current out of node A is the sum of the two branch currents. So the total current into node A is

$$I_T = I_1 + I_2 = 5\,\text{mA} + 12\,\text{mA} = \textbf{17\,mA}$$

The total current entering node B is the sum of the two branch currents. So the total current out of node B is

$$I_T = I_1 + I_2 = 5\,\text{mA} + 12\,\text{mA} = \textbf{17\,mA}$$

Related Problem If a third branch is added to the circuit in Figure 6–15 and its current is 3 mA, what is the total current into node A and out of node B?

EXAMPLE 6–5

Determine the current I_2 through R_2 in Figure 6–16.

▶ **FIGURE 6–16**
Solution The total current into the junction of the three branches is $I_T = I_1 + I_2 + I_3$. From Figure 6–16, you know the total current and the branch currents through R_1 and R_3. Solve for I_2 as follows:

$$I_2 = I_T - I_1 - I_3 = 100 \, \text{mA} - 30 \, \text{mA} - 20 \, \text{mA} = \textbf{50 mA}$$

Related Problem Determine I_T and I_2 if a fourth branch is added to the circuit in Figure 6–16 and it has 12 mA through it.

EXAMPLE 6–6

Use Kirchhoff's current law to find the current measured by ammeters A3 and A5 in Figure 6–17.

▶ **FIGURE 6–17**
Solution The total current into node X is 5 mA. Two currents are out of node X: 1.5 mA through resistor R_1 and the current through A3. Kirchhoff's current law applied at node X gives

$$5 \, \text{mA} - 1.5 \, \text{mA} - I_{A3} = 0$$

Solving for I_{A3} yields

$$I_{A3} = 5 \, \text{mA} - 1.5 \, \text{mA} = \textbf{3.5 mA}$$

The total current into node Y is $I_{A3} = 3.5$ mA. Two currents are out of node Y: 1 mA through resistor R_2 and the current through A5 and R_3. Kirchhoff's current law applied at node Y gives

$$3.5 \, \text{mA} - 1 \, \text{mA} - I_{A5} = 0$$

Solving for I_{A5} yields

$$I_{A5} = 3.5 \, \text{mA} - 1 \, \text{mA} = \textbf{2.5 mA}$$

Related Problem How much current will an ammeter measure when it is placed in the circuit right below R_3 in Figure 6–17? Below the negative battery terminal?

EXAMPLE 6–7

Using Kirchhoff's current law, find the current in each of two taillights given that the total current from the battery is 8.0 A and together the headlights draw 5.6 A.

Solution

$$I_{BAT} - I_{T(HEAD)} - I_{T(TAIL)} = 0$$

Rearranging and changing the signs,

$$I_{T(TAIL)} = I_{BAT} - I_{T(HEAD)} = 8.0\,A - 5.6\,A = 2.4\,A$$

Because the taillights are identical, each draws 2.4 A/2 = **1.2 A**

6–4 TOTAL PARALLEL RESISTANCE

When resistors are connected in parallel, the total resistance of the circuit decreases. The total resistance of a parallel circuit is always less than the value of the smallest resistor. For example, if a 10 Ω resistor and a 100 Ω resistor are connected in parallel, the total resistance is less than 10 Ω.

After completing this section, you should be able to

◆ **Determine total parallel resistance**

    ◆ Explain why resistance decreases as resistors are connected in parallel

    ◆ Apply the parallel-resistance formula

As you know, when resistors are connected in parallel, the current has more than one path. The number of current paths is equal to the number of parallel branches.

In Figure 6–18(a), there is only one current path because it is a series circuit. There is a certain amount of current, I_1, through R_1. If resistor R_2 is connected in parallel with R_1, as shown in Figure 6–18(b), there is an additional amount of current, I_2, through R_2. The total current from the source has increased with the addition of the parallel resistor. Assuming that the source voltage is constant, an increase in the total current from the source means that the total resistance has decreased, in accordance with Ohm's law. Additional resistors connected in parallel will further reduce the resistance and increase the total current.
▲ FIGURE 6–18

Addition of resistors in parallel reduces total resistance and increases total current.

Formula for Total Parallel Resistance

The circuit in Figure 6–19 shows a general case of n resistors in parallel (n can be any integer greater than 1). From Kirchhoff's current law, the equation for current is

$$I_T = I_1 + I_2 + I_3 + \cdots + I_n$$
▲ FIGURE 6–19

Circuit with n resistors in parallel.

Since V_S is the voltage across each of the parallel resistors, by Ohm's law, $I_1 = V_S/R_1$, $I_2 = V_S/R_2$, and so on. By substitution into the equation for current,

$$\frac{V_S}{R_T} = \frac{V_S}{R_1} + \frac{V_S}{R_2} + \frac{V_S}{R_3} + \cdots + \frac{V_S}{R_n}$$

The term V_S can be factored out of the right side of the equation and canceled with V_S on the left side, leaving only the resistance terms.

$$\frac{1}{R_T} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \cdots + \frac{1}{R_n}$$

Recall that the reciprocal of resistance ($1/R$) is called *conductance,* which is symbolized by G. The unit of conductance is the siemens (S). The equation for $1/R_T$ can be expressed in terms of conductance as

$$G_T = G_1 + G_2 + G_3 + \cdots + G_n$$

Solve for R_T by taking the reciprocal of (that is, by inverting) both sides of the equation for $1/R_T$.

$$R_T = \frac{1}{\left(\dfrac{1}{R_1}\right) + \left(\dfrac{1}{R_2}\right) + \left(\dfrac{1}{R_3}\right) + \cdots + \left(\dfrac{1}{R_n}\right)}$$

Equation 6–2

Equation 6–2 shows that to find the total parallel resistance, add all the $1/R$ (or conductance, G) terms and then take the reciprocal of the sum.

$$R_T = \frac{1}{G_T}$$

EXAMPLE 6–8

Calculate the total parallel resistance between points A and B of the circuit in Figure 6–20.

▶ **FIGURE 6–20**
Solution

To calculate the total parallel resistance when you know the individual resistances, first find the conductance, which is the reciprocal of the resistance, of each of the three resistors.

$$G_1 = \frac{1}{R_1} = \frac{1}{100 \ \Omega} = 10 \ \text{mS}$$

$$G_2 = \frac{1}{R_2} = \frac{1}{47 \ \Omega} = 21.3 \ \text{mS}$$

$$G_3 = \frac{1}{R_3} = \frac{1}{22 \ \Omega} = 45.5 \ \text{mS}$$

Next, calculate R_T by adding G_1, G_2, and G_3 and taking the reciprocal of the sum.

$$R_T = \frac{1}{G_T} = \frac{1}{10 \ \text{mS} + 21.3 \ \text{mS} + 45.5 \ \text{mS}} = \frac{1}{76.8 \ \text{mS}} = \textbf{13.0 } \boldsymbol{\Omega}$$

For a quick accuracy check, notice that the value of R_T (13.0 Ω) is smaller than the smallest value in parallel, which is R_3 (22 Ω), as it should be.

Related Problem

Calculator Tip

The parallel-resistance formula is easily solved on a calculator using Equation 6–2. The general procedure is to enter the value of R_1 and then take its reciprocal by pressing the x^{-1} key. (The reciprocal is a secondary function on some calculators.) Next press the + key; then enter the value of R_2 and take its reciprocal using the x^{-1} key and press the + key. Repeat this procedure until all of the resistor values have been entered; then press ENTER. The final step is to press the x^{-1} key and the ENTER key to get R_T. The total parallel resistance is now on the display. The display format may vary, depending on the particular calculator. For example, the steps required for a typical calculator solution of Example 6–7 are as follows:

1. Enter 100. Display shows 100.

2. Press x^{-1} (or 2nd then x^{-1}). Display shows 100^{-1}.

3. Press +. Display shows $100^{-1} +$.

4. Enter 47. Display shows $100^{-1} + 47$.

5. Press x^{-1} (or 2nd then x^{-1}). Display shows $100^{-1} + 47^{-1}$.

6. Press +. Display shows $100^{-1} + 47^{-1} +$.

7. Enter 22. Display shows $100^{-1} + 47^{-1} + 22$.

8. Press x^{-1} (or 2nd then x^{-1}). Display shows $100^{-1} + 47^{-1} + 22^{-1}$.

9. Press ENTER. Display shows a result of $76.7311411992\text{E}^{-3}$.

10. Press x^{-1} (or 2nd then x^{-1}) and then ENTER. Display shows a result of $13.0325182758\text{E}0$.

The number displayed in Step 10 is the total resistance in ohms. Round it to 13.0 Ω.

The Case of Two Resistors in Parallel

Equation 6–2 is a general formula for finding the total resistance for any number of resistors in parallel. The combination of two resistors in parallel occurs commonly in practice. Also, any number of resistors in parallel can be broken down into pairs as an alternate way to find the R_T. Based on Equation 6–2, the formula for the total resistance of two resistors in parallel is

$$R_T = \frac{1}{\left(\frac{1}{R_1}\right) + \left(\frac{1}{R_2}\right)}$$

Combining the terms in the denominator yields

$$R_T = \frac{1}{\left(\frac{R_1 + R_2}{R_1 R_2}\right)}$$

which can be rewritten as follows:

$$R_T = \frac{R_1 R_2}{R_1 + R_2}$$

Equation 6–3

Equation 6–3 states

The total resistance for two resistors in parallel is equal to the product of the two resistors divided by the sum of the two resistors.

This equation is sometimes referred to as the "product over the sum" formula.

EXAMPLE 6–9

Calculate the total resistance connected to the voltage source of the circuit in Figure 6–21.
▲ FIGURE 6–21

Solution　　Use Equation 6–3.

$$R_T = \frac{R_1 R_2}{R_1 + R_2} = \frac{(680\ \Omega)(330\ \Omega)}{680\ \Omega + 330\ \Omega} = \frac{224{,}400\ \Omega^2}{1010\ \Omega} = \mathbf{222\ \Omega}$$

Related Problem　　Determine R_T if a 220 Ω replaces R_1 in Figure 6–21.

The Case of Equal-Value Resistors in Parallel

Another special case of parallel circuits is the parallel connection of several resistors each having the same resistance value. There is a shortcut method of calculating R_T when this case occurs.

If several resistors in parallel have the same resistance, they can be assigned the same symbol R. For example, $R_1 = R_2 = R_3 = \cdots = R_n = R$. Starting with Equation 6–2, you can develop a special formula for finding R_T.

$$R_T = \cfrac{1}{\left(\dfrac{1}{R}\right) + \left(\dfrac{1}{R}\right) + \left(\dfrac{1}{R}\right) + \cdots + \left(\dfrac{1}{R}\right)}$$

Notice that in the denominator, the same term, $1/R$, is added n times (n is the number of equal-value resistors in parallel). Therefore, the formula can be written as

$$R_T = \frac{1}{n/R}$$

or

Equation 6–4

$$R_T = \frac{R}{n}$$

Equation 6–4 says that when any number of resistors (n), all having the same resistance (R), are connected in parallel, R_T is equal to the resistance divided by the number of resistors in parallel.

EXAMPLE 6–10

Four 8 Ω speakers are connected in parallel to the output of an amplifier. What is the total resistance across the output of the amplifier?

Solution There are four 8 Ω resistors in parallel. Use Equation 6–4 as follows:

$$R_T = \frac{R}{n} = \frac{8\,\Omega}{4} = \mathbf{2\,\Omega}$$

Related Problem If two of the speakers are removed, what is the resistance across the output?

Determining an Unknown Parallel Resistor

Sometimes you need to determine the values of resistors that are to be combined to produce a desired total resistance. For example, you use two parallel resistors to obtain a known total resistance. If you know or arbitrarily choose one resistor value, then you can calculate the second resistor value using Equation 6–3 for two parallel resistors. The formula for determining the value of an unknown resistor R_x is developed as follows:

$$\frac{1}{R_T} = \frac{1}{R_A} + \frac{1}{R_x}$$

$$\frac{1}{R_x} = \frac{1}{R_T} - \frac{1}{R_A}$$

$$\frac{1}{R_x} = \frac{R_A - R_T}{R_A R_T}$$

Equation 6–5

$$R_x = \frac{R_A R_T}{R_A - R_T}$$

where R_x is the unknown resistor and R_A is the known or selected value.

EXAMPLE 6–11

Suppose that you wish to obtain a resistance as close to 150 Ω as possible by combining two resistors in parallel. There is a 330 Ω resistor available. What other value do you need?

Solution $R_T = 150 \ \Omega$ and $R_A = 330 \ \Omega$. Therefore,

$$R_x = \frac{R_A R_T}{R_A - R_T} = \frac{(330 \ \Omega)(150 \ \Omega)}{330 \ \Omega - 150 \ \Omega} = 275 \ \Omega$$

The closest standard value is **270 Ω**.

Related Problem   If you need to obtain a total resistance of 130 Ω, what value can you add in parallel to the parallel combination of 330 Ω and 270 Ω? First find the value of 330 Ω and 270 Ω in parallel and treat that value as a single resistor.

Notation for Parallel Resistors

Sometimes, for convenience, parallel resistors are designated by two parallel vertical marks. For example, R_1 in parallel with R_2 can be written as $R_1 \| R_2$. Also, when several resistors are in parallel with each other, this notation can be used. For example,

$$R_1 \| R_2 \| R_3 \| R_4 \| R_5$$

indicates that R_1 through R_5 are all in parallel.

This notation is also used with resistance values. For example,

$$10 \ \text{k}\Omega \| 5 \ \text{k}\Omega$$

means that a 10 kΩ resistor is in parallel with a 5 kΩ resistor.

6–5   APPLICATION OF OHM'S LAW

Ohm's law can be applied to parallel circuit analysis.

After completing this section, you should be able to

◆ **Apply Ohm's law in a parallel circuit**

   ◆ Find the total current in a parallel circuit

   ◆ Find each branch current in a parallel circuit

   ◆ Find the voltage across a parallel circuit

   ◆ Find the resistance of a parallel circuit

The following examples illustrate how to apply Ohm's law to determine the total current, branch currents, voltage, and resistance in parallel circuits.

EXAMPLE 6–12

Find the total current produced by the battery in Figure 6–25.

▶ **FIGURE 6–25**
Solution   The battery "sees" a total parallel resistance that determines the amount of current that it generates. First, calculate R_T.

$$R_T = \frac{R_1 R_2}{R_1 + R_2} = \frac{(100\,\text{k}\Omega)(56\,\text{k}\Omega)}{100\,\text{k}\Omega + 56\,\text{k}\Omega} = \frac{5600\,\text{k}\Omega^2}{156\,\text{k}\Omega} = 35.9\,\text{k}\Omega$$

The battery voltage is 100 V. Use Ohm's law to find I_T.

$$I_T = \frac{V_S}{R_T} = \frac{100\,\text{V}}{35.9\,\text{k}\Omega} = \textbf{2.79 mA}$$

Related Problem   What is I_T in Figure 6–25 if R_2 is changed to 120 kΩ? What is the current through R_1?

Use Multisim file E06-12 to verify the calculated results in this example and to confirm your calculation for the related problem.

EXAMPLE 6–13

Determine the current through each resistor in the parallel circuit of Figure 6–26.

▶ **FIGURE 6–26**
Solution   The voltage across each resistor (branch) is equal to the source voltage. That is, the voltage across R_1 is 20 V, the voltage across R_2 is 20 V, and the voltage across R_3 is 20 V. Determine the current through each resistor as follows:

$$I_1 = \frac{V_S}{R_1} = \frac{20\,V}{1.0\,k\Omega} = \mathbf{20\,mA}$$

$$I_2 = \frac{V_S}{R_2} = \frac{20\,V}{2.2\,k\Omega} = \mathbf{9.09\,mA}$$

$$I_3 = \frac{V_S}{R_3} = \frac{20\,V}{560\,\Omega} = \mathbf{35.7\,mA}$$

Related Problem   If an additional resistor of 910 Ω is connected in parallel to the circuit in Figure 6–26, determine all of the branch currents.

Use Multisim file E06-13 to verify the calculated results in this example and to confirm your calculations for the related problem.

EXAMPLE 6–14   Find the voltage V_S across the parallel circuit in Figure 6–27.

▶ **FIGURE 6–27**
Solution   The total current in the parallel circuit is 10 mA. If you know the total resistance, then you can apply Ohm's law to get the voltage. The total resistance is

$$R_T = \frac{1}{G_1 + G_2 + G_3}$$

$$= \frac{1}{\left(\dfrac{1}{R_1}\right) + \left(\dfrac{1}{R_2}\right) + \left(\dfrac{1}{R_3}\right)}$$

$$= \frac{1}{\left(\dfrac{1}{220\,\Omega}\right) + \left(\dfrac{1}{560\,\Omega}\right) + \left(\dfrac{1}{1.0\,k\Omega}\right)}$$

$$= \frac{1}{4.55\,mS + 1.79\,mS + 1\,mS} = \frac{1}{7.34\,mS} = 136\,\Omega$$

Therefore, the source voltage is

$$V_S = I_T R_T = (10\,mA)(136\,\Omega) = \mathbf{1.36\,V}$$

Related Problem   Find the voltage if R_3 is decreased to 680 Ω in Figure 6–27 and I_T is 10 mA.

EXAMPLE 6–15

Sometimes a direct measurement of resistance is not practical. For example, tungsten filament bulbs get hot after turning them on, causing the resistance to increase. An ohmmeter can only measure the cold resistance. Assume you want to know the equivalent hot resistance of the two headlight bulbs and the two taillight bulbs in a car. The two headlights normally operate on 12.6 V and draw 2.8 A each when they are on.

(a) What is the total equivalent hot resistance when two headlights are on?

(b) Assume the total current for headlights and taillights is 8.0 A when all four bulbs are on. What is the equivalent resistance of each taillight?

Solution   **(a)** Use Ohm's law to calculate the equivalent resistance of one headlight.

$$R_{HEAD} = \frac{V}{I} = \frac{12.6 \text{ V}}{2.8 \text{ A}} = 4.5 \text{ }\Omega$$

Because the two bulbs are in parallel and have equal resistances,

$$R_{T(HEAD)} = \frac{R_{HEAD}}{n} = \frac{4.5 \text{ }\Omega}{2} = \textbf{2.25 }\boldsymbol{\Omega}$$

(b) Use Ohm's law to find the total resistance with two taillights and two headlights on.

$$R_{T(HEAD+TAIL)} = \frac{12.6 \text{ V}}{8.0 \text{ A}} = 1.58 \text{ }\Omega$$

Apply the formula for parallel resistors to find the resistance of the two taillights together.

$$\frac{1}{R_{T(HEAD + TAIL)}} = \frac{1}{R_{T(HEAD)}} + \frac{1}{R_{T(TAIL)}}$$

$$\frac{1}{R_{T(TAIL)}} = \frac{1}{R_{T(HEAD + TAIL)}} - \frac{1}{R_{T(HEAD)}} = \frac{1}{1.58 \text{ }\Omega} - \frac{1}{2.25 \text{ }\Omega}$$

$$R_{T(TAIL)} = 5.25 \text{ }\Omega$$

The two taillights are in parallel, so each light has a resistance of

$$R_{(TAIL)} = nR_{T(TAIL)} = 2(5.25 \text{ }\Omega) = \textbf{10.5 }\boldsymbol{\Omega}$$

6–6   CURRENT SOURCES IN PARALLEL

As you learned in Chapter 2, a **current source** is a type of energy source that provides a constant current to a load even if the resistance of that load changes. A transistor can be used as a current source; therefore, current sources are important in electronic circuits. Although the study of transistors is beyond the scope of this book, you should understand how current sources act in parallel.

After completing this section, you should be able to

◆ **Determine the total effect of current sources in parallel**

   ◆ Determine the total current from parallel sources having the same direction

   ◆ Determine the total current from parallel sources having opposite directions

In general, the total current produced by current sources in parallel is equal to the algebraic sum of the individual current sources. The algebraic sum means that you must consider the direction of current when you combine the sources in parallel. For example, in Figure 6–29(a), the three current sources in parallel provide current in the same direction (into node A). So the total current into node A is

$$I_T = 1\,A + 2\,A + 2\,A = 5\,A$$

In Figure 6–29(b), the 1 A source provides current in a direction opposite to the other two. The total current into node A in this case is

$$I_T = 2\,A + 2\,A - 1\,A = 3\,A$$

▶ **FIGURE 6–31**
🌐 6–7   **CURRENT DIVIDERS**

A parallel circuit acts as a current divider because the current entering the junction of parallel branches "divides" up into several individual branch currents.

After completing this section, you should be able to

◆ **Use a parallel circuit as a current divider**

   ◆ Apply the current-divider formula

   ◆ Determine an unknown branch current

In a parallel circuit, the total current into the junction of the parallel branches divides among the branches. Thus, a parallel circuit acts as a **current divider**. This current-divider principle is illustrated in Figure 6–32 for a two-branch parallel circuit in which part of the total current I_T goes through R_1 and part through R_2.

Since the same voltage is across each of the resistors in parallel, the branch currents are inversely proportional to the values of the resistors. For example, if the value of R_2 is twice that of R_1, then the value of I_2 is one-half that of I_1. In other words,

The total current divides among parallel resistors into currents with values inversely proportional to the resistance values.
Total current divides between the two branches.

The branches with higher resistance have less current, and the branches with lower resistance have more current, in accordance with Ohm's law. If all the branches have the same resistance, the branch currents are all equal.

Figure 6–33 shows specific values to demonstrate how the currents divide according to the branch resistances. Notice that in this case the resistance of the upper branch is one-tenth the resistance of the lower branch, but the upper branch current is ten times the lower branch current.
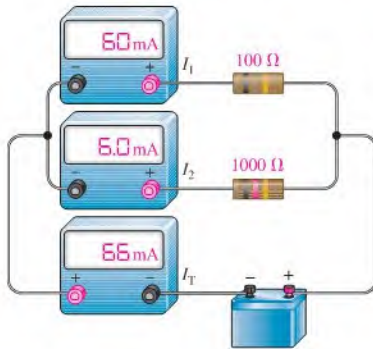

◄ FIGURE 6–33

The branch with the lower resistance has more current, and the branch with the higher resistance has less current.

Current-Divider Formula

You can develop a formula for determining how currents divide among any number of parallel resistors as shown in Figure 6–34, where n is the total number of resistors.
▲ FIGURE 6–34

A parallel circuit with n branches.

The current through any one of the parallel resistors is I_x, where x represents the number of a particular resistor (1, 2, 3, and so on). By Ohm's law, you can express the current through any one of the resistors in Figure 6–34 as follows:

$$I_x = \frac{V_S}{R_x}$$

The source voltage, V_S, appears across each of the parallel resistors, and R_x represents any one of the parallel resistors. The total source voltage, V_S, is equal to the total current times the total parallel resistance.

$$V_S = I_T R_T$$

Substituting $I_T R_T$ for V_S in the expression for I_x results in

$$I_x = \frac{I_T R_T}{R_x}$$

Rearranging terms yields

Equation 6–6
$$I_x = \left(\frac{R_T}{R_x}\right) I_T$$

where $x = 1, 2, 3$, etc. Equation 6–6 is the general current-divider formula and applies to a parallel circuit with any number of branches.

The current (I_x) through any branch equals the total parallel resistance (R_T) divided by the resistance (R_x) of that branch, and then multiplied by the total current (I_T) into the junction of parallel branches.

EXAMPLE 6–17

Determine the current through each resistor in the circuit of Figure 6–35.

▶ **FIGURE 6–35**
Solution First calculate the total parallel resistance.

$$R_T = \frac{1}{\left(\dfrac{1}{R_1}\right) + \left(\dfrac{1}{R_2}\right) + \left(\dfrac{1}{R_3}\right)} = \frac{1}{\left(\dfrac{1}{680\ \Omega}\right) + \left(\dfrac{1}{330\ \Omega}\right) + \left(\dfrac{1}{220\ \Omega}\right)} = 111\ \Omega$$

The total current is 10 mA. Use Equation 6–6 to calculate each branch current.

$$I_1 = \left(\frac{R_T}{R_1}\right) I_T = \left(\frac{111\ \Omega}{680\ \Omega}\right) 10\ \text{mA} = \mathbf{1.63\ mA}$$

$$I_2 = \left(\frac{R_T}{R_2}\right) I_T = \left(\frac{111\ \Omega}{330\ \Omega}\right) 10\ \text{mA} = \mathbf{3.36\ mA}$$

$$I_3 = \left(\frac{R_T}{R_3}\right) I_T = \left(\frac{111\ \Omega}{220\ \Omega}\right) 10\ \text{mA} = \mathbf{5.05\ mA}$$

Related Problem Determine the current through each resistor in Figure 6–35 if R_3 is removed.

Current-Divider Formulas for Two Branches Two parallel resistors are common in practical circuits, as shown in Figure 6–36. As you know from Equation 6–3,

$$R_T = \frac{R_1 R_2}{R_1 + R_2}$$

Using the general current-divider formula in Equation 6–6, the formulas for I_1 and I_2 can be written as follows:

$$I_1 = \left(\frac{R_T}{R_1}\right) I_T \quad \text{and} \quad I_2 = \left(\frac{R_T}{R_2}\right) I_T$$

Substituting $R_1 R_2/(R_1 + R_2)$ for R_T and canceling terms result in

$$I_1 = \frac{\left(\dfrac{\cancel{R_1} R_2}{R_1 + R_2}\right)}{\cancel{R_1}} I_T \quad \text{and} \quad I_2 = \frac{\left(\dfrac{R_1 \cancel{R_2}}{R_1 + R_2}\right)}{\cancel{R_2}} I_T$$

Therefore, the current-divider formulas for the special case of two branches are

$$I_1 = \left(\frac{R_2}{R_1 + R_2}\right) I_T$$

Equation 6–7

$$I_2 = \left(\frac{R_1}{R_1 + R_2}\right) I_T$$

Equation 6–8

Note that in Equations 6–7 and 6–8, the current in one of the branches is equal to the opposite branch resistance divided by the sum of the two resistors, all multiplied by the total current. In all applications of the current-divider equations, you must know the total current into the parallel branches.

Use Equation 6–8 to determine I_2.

$$I_2 = \left(\frac{R_1}{R_1 + R_2}\right) I_T = \left(\frac{100\,\Omega}{147\,\Omega}\right) 100\,\text{mA} = \mathbf{68.0\,mA}$$

6–8   POWER IN PARALLEL CIRCUITS

Total power in a parallel circuit is found by adding up the powers of all the individual resistors, the same as for series circuits.

After completing this section, you should be able to

◆ **Determine power in a parallel circuit**

Equation 6–9 states the formula for finding total power in a concise way for any number of resistors in parallel.

Equation 6–9

$$P_T = P_1 + P_2 + P_3 + \cdots + P_n$$

where P_T is the total power and P_n is the power in the last resistor in parallel. As you can see, the powers are additive, just as in a series circuit.

The power formulas in Chapter 4 are directly applicable to parallel circuits. The following formulas are used to calculate the total power P_T:

$$P_T = VI_T$$
$$P_T = I_T^2 R_T$$
$$P_T = \frac{V^2}{R_T}$$

where V is the voltage across the parallel circuit, I_T is the total current into the parallel circuit, and R_T is the total resistance of the parallel circuit. Examples 6–19 and 6–20 show how total power can be calculated in a parallel circuit.

EXAMPLE 6–19

Determine the total amount of power in the parallel circuit in Figure 6–40.
Solution The total current is 200 mA. The total resistance is

$$R_T = \cfrac{1}{\left(\cfrac{1}{68\ \Omega}\right) + \left(\cfrac{1}{33\ \Omega}\right) + \left(\cfrac{1}{22\ \Omega}\right)} = 11.1\ \Omega$$

The easiest power formula to use is $P_T = I_T^2 R_T$ because you know both I_T and R_T.

$$P_T = I_T^2 R_T = (200\ \text{mA})^2 (11.1\ \Omega) = \mathbf{444\ mW}$$

Let's demonstrate that if you determine the power in each resistor and if you add all of these values together, you will get the same result. First, find the voltage across each branch of the circuit.

$$V = I_T R_T = (200\ \text{mA})(11.1\ \Omega) = 2.22\ \text{V}$$

Remember that the voltage across all branches is the same.

Next, use $P = V^2/R$ to calculate the power for each resistor.

$$P_1 = \frac{(2.22\ \text{V})^2}{68\ \Omega} = 72.5\ \text{mW}$$

$$P_2 = \frac{(2.22\ \text{V})^2}{33\ \Omega} = 149\ \text{mW}$$

$$P_3 = \frac{(2.22\ \text{V})^2}{22\ \Omega} = 224\ \text{mW}$$

Add these powers to get the total power.

$$P_T = 72.5\ \text{mW} + 149\ \text{mW} + 224\ \text{mW} = 446\ \text{mW}$$

This calculation shows that the sum of the individual powers is equal (approximately) to the total power as determined by one of the power formulas. Rounding to three significant figures accounts for the difference.

EXAMPLE 6–20

The amplifier in one channel of a stereo system as shown in Figure 6–41 drives two speakers. If the maximum voltage* to the speakers is 15 V, how much power must the amplifier be able to deliver to the speakers?

▶ FIGURE 6–41
Solution The speakers are connected in parallel to the amplifier output, so the voltage across each is the same. The maximum power to each speaker is

$$P_{max} = \frac{V_{max}^2}{R} = \frac{(15\ V)^2}{8\ \Omega} = 28.1\ W$$

The total power that the amplifier must be capable of delivering to the speaker system is twice the power in an individual speaker because the total power is the sum of the individual powers.

$$P_{T(max)} = P_{(max)} + P_{(max)} = 2P_{(max)} = 2(28.1\ W) = \mathbf{56.2\ W}$$

6–9 PARALLEL CIRCUIT APPLICATIONS

Parallel circuits are found in some form in virtually every electronic system. In many of these applications, the parallel relationship of components may not be obvious until you have covered some advanced topics that you will study later. For now, let's look at some examples of common and familiar applications of parallel circuits.

After completing this section, you should be able to

◆ **Describe some basic applications of parallel circuits**

  ◆ Discuss the lighting system in automobiles

  ◆ Discuss residential wiring

  ◆ Explain basically how a multiple-range ammeter works

Automotive

One advantage of a parallel circuit over a series circuit is that when one branch opens, the other branches are not affected. For example, Figure 6–42 shows a simplified diagram of an automobile lighting system. When one headlight on a car goes out, it does not cause the other lights to go out because they are all in parallel.
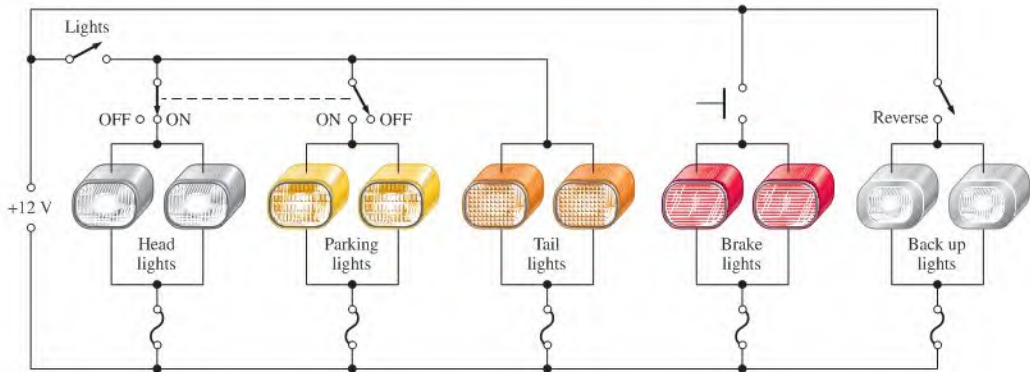

▲ FIGURE 6–42

Simplified diagram of the exterior light system of an automobile.

Notice that the brake lights are switched on independently of the headlights and taillights. They come on only when the driver closes the brake light switch by depressing the brake pedal. When the lights switch is closed, both headlights and both taillights are on. When the headlights are on, the parking lights are off and vice versa, as indicated by the dashed line connecting the switches. If any one of the lights burns out (opens), there is still current in each of the other lights. The back-up lights are switched on when the reverse gear is engaged.

Another automotive application of parallel resistances is the rear window defroster. As you know, power is dissipated in resistance in the form of heat. The defroster consists of a group of parallel resistance wires that warm the glass when power is applied. A typical defroster can dissipate over 100 W across the window. Although resistance heating is not as efficient as other forms of heat, in applications like this it is simple and cost effective.

Residential

Another common use of parallel circuits is in residential electrical systems. All the lights and appliances in a home are wired in parallel. Figure 6–43 shows a typical room wiring arrangement with two switch-controlled lights and three wall outlets in parallel.
▲ FIGURE 6–43

Example of a parallel circuit in residential wiring.

Control Circuits

Many control systems use parallel circuits or equivalent circuits for control and monitoring an industrial process such as a production line. Most complex control applications are implemented on a dedicated computer called a *programmable logic controller* (PLC). A PLC shows an equivalent parallel circuit, which is displayed on a computer screen. Internally, the circuit may exist only as a computer code, written in a computer programming language. However, the displayed circuit is one that could in principle be constructed with hardware. These circuits can be drawn to resemble a ladder—with rungs representing the load (and a source) and the rails representing the two principal nodes. (For example, notice that Figure 6–43 resembles a ladder on its side, with the lights and wall outlets as loads.) Parallel control circuits use ladder diagrams but add additional control elements (switches, relays, timers, and more). The result of adding the control elements creates a logical diagram, which is referred to as *ladder logic*. Ladder logic is easy to understand, so it is popular for showing control logic in industrial environments, such as factories or food processors. Entire books are written about ladder logic, but a ladder diagram (parallel circuit) is at the core of all ladder logic. The most important aspect is that ladder logic shows the basic functionality of the circuit in an easy-to-read format.

Analog Ammeters

Parallel circuits are used in the analog (needle-type) ammeter or milliammeter. Although analog meters are not as common as they once were, they are still used as panel meters in certain applications and analog multimeters are still available. Parallel circuits are an important part of analog ammeter operation because they allow the selection of various ranges in order to measure many different current values.

The mechanism in an ammeter that causes the pointer to move in proportion to the current is called the *meter movement,* which is based on a magnetic principle that you will learn later. Right now, it is sufficient to know that a given meter movement has a certain resistance and a maximum current. This maximum current, called the *full-scale deflection current,* causes the pointer to go all the way to the end of the scale. For example, a certain meter movement has a 50 Ω resistance and a full-scale deflection current of 1 mA. A meter with this particular movement can measure currents of 1 mA or less as indicated in Figure 6–44(a) and (b). Currents greater than 1 mA will cause the pointer to "peg" (or stop) slightly past the full scale mark as indicated in part (c), which can damage the meter.

(a) Half-scale deflection   (b) Full-scale deflection   (c) "Pegged"
▲ FIGURE 6–44

A 1 mA analog ammeter.

Figure 6–45 shows a simple ammeter with a resistor in parallel with the 1 mA meter movement; this resistor is called a *shunt resistor.* Its purpose is to bypass a portion of current around the meter movement to extend the range of current that can be measured. The figure specifically shows 9 mA through the shunt resistor and 1 mA through the meter
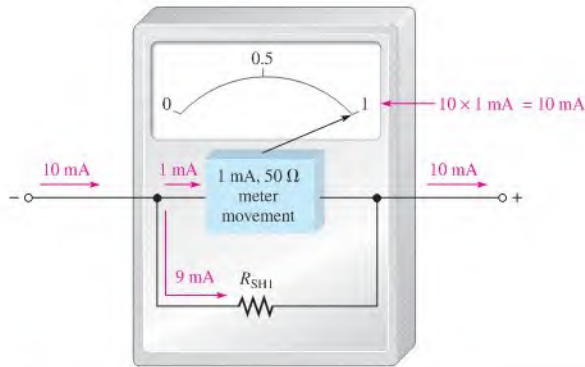

▲ FIGURE 6–45

A 10 mA analog ammeter.

movement. Thus, up to 10 mA can be measured. To find the actual current value, simply multiply the reading on the scale by 10.

A multiple-range ammeter has a range switch that permits the selection of several full-scale current settings. In each switch position, a certain amount of current is bypassed through a parallel resistor as determined by the resistance value. In our example, the current though the movement is never greater than 1 mA.

Figure 6–46 illustrates a meter with three ranges: 1 mA, 10 mA, and 100 mA. When the range switch is in the 1 mA position, all of the current into the meter goes through the meter movement. In the 10 mA setting, up to 9 mA goes through R_{SH1} and up to 1 mA through the movement. In the 100 mA setting, up to 99 mA goes through R_{SH2}, and the movement can still have only 1 mA for full-scale.

▲ FIGURE 6–46

An analog ammeter with three ranges.

The scale reading is interpreted based on the range setting. For example, in Figure 6–46, if 50 mA of current are being measured, the needle points at the 0.5 mark on the scale; you must multiply 0.5 by 100 to find the current value. In this situation, 0.5 mA is through the movement (half-scale deflection) and 49.5 mA are through R_{SH2}.

6–10   TROUBLESHOOTING

Recall that an open circuit is one in which the current path is interrupted and there is no current. In this section we examine what happens when a branch of a parallel circuit opens.

After completing this section, you should be able to

◆ **Troubleshoot parallel circuits**

   ◆ Check for an open in a circuit

Open Branches

If a switch is connected in a branch of a parallel circuit, as shown in Figure 6–47, an open or a closed path can be made by the switch. When the switch is closed, as in Figure 6–47(a), R_1 and R_2 are in parallel. The total resistance is 50 Ω (two 100 Ω resistors in parallel). Current is through both resistors. If the switch is opened, as in Figure 6–47(b), R_1 is effectively removed from the circuit, and the total resistance is 100 Ω. Current is now only through R_2. In general,

> **When an open occurs in a parallel branch, the total resistance increases, the total current decreases, and the same current continues through each of the remaining parallel paths.**

The decrease in total current equals the amount of current that was previously in the open branch. The other branch currents remain the same.

(a)   (b)
▲ **FIGURE 6–47**

When switch opens, total current decreases and current through R_2 remains unchanged.

Consider the lamp circuit in Figure 6–48. There are four bulbs in parallel with a 12 V source. In part (a), there is current through each bulb. Now suppose that one of the bulbs burns out, creating an open path as shown in Figure 6–48(b). This light will go out because there is no current through the open path. Notice, however, that current continues through all the other parallel bulbs, and they continue to glow. The open branch does not change the voltage across the parallel branches; it remains at 12 V, and the current through each branch remains the same.
▲ FIGURE 6–48

When one lamp opens, total current decreases and other branch currents remain unchanged.

You can see that a parallel circuit has an advantage over a series circuit in lighting systems because if one or more of the parallel bulbs burn out, the others will stay on. In a series circuit, when one bulb goes out, all of the others go out also because the current path is completely interrupted.

When a resistor in a parallel circuit opens, the open resistor cannot be located by measurement of the voltage across the branches because the same voltage exists across all the branches. Thus, there is no way to tell which resistor is open by simply measuring voltage. The good resistors will always have the same voltage as the open one, as illustrated in Figure 6–49 (note that the middle resistor is open).

If a visual inspection does not reveal the open resistor, it must be located by current measurements. In practice, measuring current is more difficult than measuring voltage because you must insert the ammeter in series to measure the current. Thus, a wire or a PC board connection must be cut or disconnected, or one end of a component must be lifted off the circuit board, in order to connect the ammeter in series. This procedure, of course, is not required when voltage measurements are made because the meter leads are simply connected across a component.
▲ FIGURE 6–49

Parallel branches (open or not) have the same voltage.

Finding an Open Branch by Current Measurement

In a parallel circuit with a suspected open branch, the total current can be measured to find the open. *When a parallel resistor opens, the total current, I_T, is always less than its normal value.* Once you know I_T and the voltage across the branches, a few calculations will determine the open resistor when all the resistors are of different resistance values.

Consider the two-branch circuit in Figure 6–50(a). If one of the resistors opens, the total current will equal the current in the good resistor. Ohm's law quickly tells you what the current in each resistor should be.

$$I_1 = \frac{50 \text{ V}}{560 \text{ }\Omega} = 89.3 \text{ mA}$$

$$I_2 = \frac{50 \text{ V}}{100 \text{ }\Omega} = 500 \text{ mA}$$

$$I_T = I_1 + I_2 = 589.3 \text{ mA}$$

If R_2 is open, the total current is 89.3 mA, as indicated in Figure 6–50(b). If R_1 is open, the total current is 500 mA, as indicated in Figure 6–50(c).

(a) Current with no open branch

(b) Current with R_2 open

(c) Current with R_1 open
▲ FIGURE 6–50

Finding an open path by current measurement.

This procedure can be extended to any number of branches having unequal resistances. If the parallel resistances are all equal, the current in each branch must be checked until a branch is found with no current. This is the open resistor.

EXAMPLE 6–21

In Figure 6–51, there is a total current of 31.09 mA, and the voltage across the parallel branches is 20 V. Is there an open resistor, and, if so, which one is it?

◆ FIGURE 6–51
Solution   Calculate the current in each branch.

$$I_1 = \frac{V}{R_1} = \frac{20\,V}{10\,k\Omega} = 2\,mA$$

$$I_2 = \frac{V}{R_2} = \frac{20\,V}{4.7\,k\Omega} = 4.26\,mA$$

$$I_3 = \frac{V}{R_3} = \frac{20\,V}{2.2\,k\Omega} = 9.09\,mA$$

$$I_4 = \frac{V}{R_4} = \frac{20\,V}{1.0\,k\Omega} = 20\,mA$$

The total current should be

$$I_T = I_1 + I_2 + I_3 + I_4 = 2\,mA + 4.26\,mA + 9.09\,mA + 20\,mA = 35.35\,mA$$

The actual measured current is 31.09 mA, as stated, which is 4.26 mA less than normal, indicating that the branch carrying 4.26 mA is open. Thus, R_2 **must be open.**

Related Problem   What is the total current measured in Figure 6–51 if R_4 and not R_2 is open?

Finding an Open Branch by Resistance Measurement

If the parallel circuit to be checked can be disconnected from its voltage source and from any other circuit to which it may be connected, a measurement of the total resistance can be used to locate an open branch.

Recall that conductance, G, is the reciprocal of resistance ($1/R$) and its unit is the siemens (S). The total conductance of a parallel circuit is the sum of the conductances of all the resistors.

$$G_T = G_1 + G_2 + G_3 + \cdots + G_n$$

To locate an open branch, do the following steps:

1. Calculate what the total conductance should be using the individual resistor values.

$$G_{T(calc)} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \cdots + \frac{1}{R_n}$$

2. Measure the total resistance with an ohmmeter and calculate the total measured conductance.

$$G_{T(meas)} = \frac{1}{R_{T(meas)}}$$

3. Subtract the measured total conductance (Step 2) from the calculated total conductance (Step 1). The result is the conductance of the open branch and the resistance is obtained by taking its reciprocal ($R = 1/G$).

$$R_{open} = \frac{1}{G_{T(calc)} - G_{T(meas)}}$$

Solution   There are two separate parallel circuits on the board. The circuit between pin 1 and pin 4 is checked as follows (we will assume one of the resistors is open):

1. Calculate what the total conductance should be using the individual resistor values.

$$G_{T(calc)} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \frac{1}{R_4} + \frac{1}{R_{11}} + \frac{1}{R_{12}}$$

$$= \frac{1}{1.0\,k\Omega} + \frac{1}{1.8\,k\Omega} + \frac{1}{2.2\,k\Omega} + \frac{1}{2.7\,k\Omega} + \frac{1}{3.3\,k\Omega} + \frac{1}{3.9\,k\Omega} = 2.94\,mS$$

2. Measure the total resistance with an ohmmeter and calculate the total measured conductance.

$$G_{T(meas)} = \frac{1}{402\,\Omega} = 2.49\,mS$$

3. Subtract the measured total conductance (Step 2) from the calculated total conductance (Step 1). The result is the conductance of the open branch and the resistance is obtained by taking its reciprocal.

$$G_{open} = G_{T(calc)} - G_{T(meas)} = 2.94\,mS - 2.49\,mS = 0.45\,mS$$

$$R_{open} = \frac{1}{G_{open}} = \frac{1}{0.45\,mS} = 2.2\,k\Omega$$

Resistor R_3 is open and must be replaced.

Related Problem   Your ohmmeter indicates 9.6 kΩ between pin 2 and pin 3 on the PC board in Figure 6–52. Determine if this is correct and, if not, which resistor is open.

Shorted Branches

When a branch in a parallel circuit shorts, the current increases to an excessive value, causing a fuse or circuit breaker to blow. This results in a difficult troubleshooting problem because it is hard to isolate the shorted branch.

A pulser and a current tracer are tools often used to find shorts in a circuit. They are not restricted to use in digital circuits but can be effective in any type of circuit. The pulser is a pen-shaped tool that applies pulses to a selected point in a circuit, causing pulses of current to flow through the shorted path. The current tracer is also a pen-shaped tool that senses pulses of current. By following the current with the tracer, the current path can be identified.

SECTION 6–10 CHECKUP

5. A three-branch circuit normally has the following branch currents: 100 mA, 250 mA, and 120 mA. If the total current measures 350 mA, which branch is open?

Application Activity

In this application activity, a dc power supply is modified by adding a 3-range ammeter to indicate current to the load. As you have learned, parallel resistances can be used to extend the range of an ammeter. These parallel resistors, called *shunts*, bypass current around the meter movement, allowing for the meter to effectively measure higher currents than the maximum current for which the meter movement is designed.

The Power Supply

A rack-mounted power supply is shown in Figure 6–53. The voltmeter indicates the output voltage, which can be adjusted

▶ **FIGURE 6–53**

▲ FIGURE 6–54

Basic block diagram of the dc power supply.

from 0 V to 10 V using the voltage control. The power supply is capable of providing up to 2 A to a load. A basic block diagram of the power supply is shown in Figure 6–54. It consists of a rectifier circuit that converts ac voltage from the wall outlet to dc voltage and a regulator circuit that keeps the output voltage at a constant value.

It is required that the power supply be modified by adding an ammeter with three switch-selected current ranges of 25 mA, 250 mA, and 2.5 A. To accomplish this, two shunt resistances are used that can each be switched into a parallel connection with the meter movement. This approach works fine as long as the required values of the shunt resistors are not too small. However, there are problems at very low values of shunt resistance and you will see why next.

The Shunt Circuit

An ammeter is selected that has a full-scale deflection of 25 mA and a resistance of 6 Ω. Two shunt resistors must be added—one for 250 mA and one for 2.5 A full-scale deflections. The internal meter movement provides the 25 mA range. This is shown in Figure 6–55. The range selection is provided by a 1-pole, 3-position rotary switch with a contact resistance of 50 mΩ. Contact resistance of switches can be from less than 20 mΩ to about 100 mΩ. The contact resistance of a given switch can vary with temperature, current, and usage and, therefore, cannot be relied upon to remain within a reasonable tolerance of the specified value. Also, the switch is a make-before-break type, which means that contact with the previous position is not broken until contact with the new position is made.

The shunt resistance value for the 2.5 A range is determined as follows where the voltage across the meter movement is

$$V_M = I_M R_M = (25 \text{ mA})(6 \text{ }\Omega) = 150 \text{ mV}$$

The current through the shunt resistor for full-scale deflection is

$$I_{SH2} = I_{FULL SCALE} - I_M = 2.5 \text{ A} - 25 \text{ mA} = 2.475 \text{ A}$$
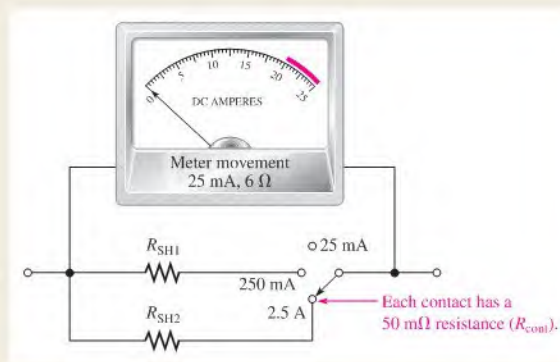

▲ FIGURE 6–55

Ammeter modified to provide three current ranges.

The total shunt resistance is

$$R_{SH2(tot)} = \frac{V_M}{I_{SH2}} = \frac{150\,\text{mV}}{2.475\,\text{A}} = 60.6\,\text{m}\Omega$$

Low-ohm precision resistors are generally available in values from 1 mΩ to 10 Ω or greater from various manufacturers.

Notice in Figure 6–55 that the contact resistance, R_{CONT}, of the switch appears in series with R_{SH2}. Since the total shunt resistance must be 60.6 mΩ, the value of the shunt resistor R_{SH2} is

$$R_{SH2} = R_{SH2(tot)} - R_{CONT} = 60.6\,\text{m}\Omega - 50\,\text{m}\Omega = 10.6\,\text{m}\Omega$$

Although this value, or one close to it, may be available, the problem in this case is that the switch contact resistance is nearly five times that of R_{SH2} and any variation in it would create a significant inaccuracy in the meter. As you can see, this approach is not acceptable for these particular requirements.

Another Approach

A variation of the standard shunt resistance circuit is shown in Figure 6–56. The shunt resistor, R_{SH}, is connected in parallel for the two higher current range settings and disconnected for the 25 mA setting using a 2-pole, 3-position switch. This circuit avoids dependency on the switch contact resistance by using resistor values that are large enough to make it insignificant. The disadvantages of this meter circuit are that it requires a more complex switch and the voltage drops from input to output are greater than in the previous shunt circuit.

For the 250 mA range, the current through the meter movement for full-scale deflection is 25 mA. The voltage across the meter movement is 150 mV.

$$I_{SH} = 250\,\text{mA} - 25\,\text{mA} = 225\,\text{mA}$$

$$R_{SH} = \frac{150\,\text{mV}}{225\,\text{mA}} = 0.67\,\Omega = 670\,\text{m}\Omega$$

This value of R_{SH} is more than thirteen times the expected switch contact resistance of 50 mΩ, thus minimizing the effect of the contact resistance.

For the 2.5 A range, the current through the meter movement for full-scale deflection is still 25 mA. This is also the current through R_1.

$$I_{SH} = 2.5\,\text{A} - 25\,\text{mA} = 2.475\,\text{A}$$

The voltage across the meter circuit from A to B is

$$V_{AB} = I_{SH}R_{SH} = (2.475\,\text{A})(670\,\text{m}\Omega) = 1.66\,\text{V}$$

Applying Kirchhoff's voltage law and Ohm's law to find R_1,

$$V_{R1} + V_M = V_{AB}$$

$$V_{R1} = V_{AB} - V_M = 1.66\,\text{V} - 150\,\text{mV} = 1.51\,\text{V}$$

$$R_1 = \frac{V_{R1}}{I_M} = \frac{1.51\,\text{V}}{25\,\text{mA}} = 60.4\,\Omega$$

This value is much greater than the contact resistance of the switch.

1. Determine the maximum power dissipated by R_{SH} in Figure 6–56 for each range setting.

2. How much voltage is there from A to B in Figure 6–56 when the switch is set to the 2.5 A range and the current is 1 A?

3. The meter indicates 250 mA. How much does the voltage across the meter circuit from A to B change when the switch is moved from the 250 mA position to the 2.5 A position?

4. Assume the meter movement has a resistance of 4 Ω instead of 6 Ω. Specify any changes necessary in the circuit of Figure 6–56.

Implementing the Power Supply Modification

Once the proper values are obtained, the resistors are placed on a board which is then mounted in the power supply. The resistors and the range switch are connected to the power supply as shown in Figure 6–57. The ammeter circuit is connected between the rectifier circuit in the power supply and the regulator circuit in order to reduce the impact of the voltage drop across the meter circuit on the output voltage. The regulator maintains, within certain limits, a constant dc output voltage even though its input voltage coming through the meter circuit may change.

INTRODUCTION

In Chapters 5 and 6, series circuits and parallel circuits were studied individually. In this chapter, both series and parallel resistors are combined into series-parallel circuits. In many practical situations, you will have both series and parallel combinations within the same circuit, and the analysis methods you learned for series circuits and for parallel circuits will apply.

Important types of series-parallel circuits are introduced in this chapter. These circuits include the voltage divider with a resistive load, the ladder network, and the Wheatstone bridge.

The analysis of series-parallel circuits requires the use of Ohm's law, Kirchhoff's voltage and current laws, and the methods for finding total resistance and power that you learned in the last two chapters. The topic of loaded voltage dividers is important because this type of circuit is found in many practical situations, such as the voltage-divider bias circuit for a transistor amplifier. Ladder networks are important in several areas, including a major type of digital-to-analog conversion, which you will study in a digital fundamentals course. The Wheatstone bridge is used in many types of systems for the measurement of unknown parameters, including most electronic scales.

7–1 IDENTIFYING SERIES-PARALLEL RELATIONSHIPS

A series-parallel circuit consists of combinations of both series and parallel current paths. It is important to be able to identify how the components in a circuit are arranged in terms of their series and parallel relationships.

After completing this section, you should be able to

◆ **Identify series-parallel relationships**

   ◆ Recognize how each resistor in a given circuit is related to the other resistors

   ◆ Determine series and parallel relationships on a PC board

Figure 7–1(a) shows an example of a simple series-parallel combination of resistors. Notice that the resistance from point A to point B is R_1. The resistance from point B to point C is R_2 and R_3 in parallel ($R_2 \parallel R_3$). The total resistance from point A to point C is R_1 in series with the parallel combination of R_2 and R_3, as indicated in Figure 7–1(b). The term *point* can refer to either a node or a terminal. For example, in Figure 7–1(a), A is a terminal because it is an end point, B is a node because it is the junction of two or more components, and C is both a terminal and a node. So, the term *point* will sometimes be used to represent either or both.

A simple series-parallel resistive circuit.

(a)   (b)   (c)
When the circuit of Figure 7–1(a) is connected to a voltage source as shown in Figure 7–1(c), the total current is through R_1 and divides at point B into the two parallel paths. These two branch currents then recombine, and the total current is into the positive source terminal as shown.

Now, to illustrate series-parallel relationships, let's increase the complexity of the circuit in Figure 7–1(a) step-by-step. In Figure 7–2(a), another resistor (R_4) is connected in

R_4 is added to the circuit in series with R_1.

(a)   (b)
series with R_1. The resistance between points A and B is now $R_1 + R_4$, and this combination is in series with the parallel combination of R_2 and R_3, as illustrated in Figure 7–2(b).

In Figure 7–3(a), R_5 is connected in series with R_2. The series combination of R_2 and R_5 is in parallel with R_3. This entire series-parallel combination is in series with the series combination of R_1 and R_4, as illustrated in Figure 7–3(b).
▲ **FIGURE 7–3**

R_5 is added to the circuit in series with R_2.

In Figure 7–4(a), R_6 is connected in parallel with the series combination of R_1 and R_4. The series-parallel combination of R_1, R_4, and R_6 is in series with the series-parallel combination of R_2, R_3, and R_5, as indicated in Figure 7–4(b).
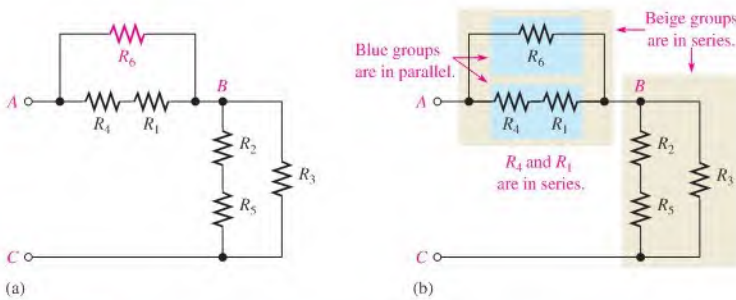

▲ **FIGURE 7–4**

R_6 is added to the circuit in parallel with the series combination of R_1 and R_4.

EXAMPLE 7–1

Identify the series-parallel relationships in Figure 7–5.

▶ **FIGURE 7–5**
Solution Starting at the negative terminal of the source, follow the current paths. All of the current produced by the source must go through R_1, which is in series with the rest of the circuit.

The total current takes two paths when it gets to node A. Part of it is through R_2, and part of it is through R_3. Resistors R_2 and R_3 are in parallel with each other, and this parallel combination is in series with R_1.

At node B, the currents through R_2 and R_3 come together again. Thus, the total current is through R_4. Resistor R_4 is in series with R_1 and the parallel combination of R_2 and R_3. The currents are shown in Figure 7–6, where I_T is the total current.

▶ FIGURE 7–6
In summary, R_1 and R_4 are in series with the parallel combination of R_2 and R_3 as stated by the following expression:

$$R_1 + R_2 \parallel R_3 + R_4$$

Related Problem* If another resistor, R_5, is connected from node A to the positive side of the source in Figure 7–6, what is its relationship to the other resistors?

*Answers are at the end of the chapter.

EXAMPLE 7–2 Identify the series-parallel relationships in Figure 7–7.
▲ FIGURE 7–7   ▲ FIGURE 7–8

Solution Sometimes it is easier to see a particular circuit arrangement if it is drawn in a different way. In this case, the circuit schematic is redrawn in Figure 7–8, which better illustrates the series-parallel relationships. Now you can see that R_2 and R_3 are in parallel with

each other and also that R_4 and R_5 are in parallel with each other. Both parallel combinations are in series with each other and with R_1 as stated by the following expression:

$$R_1 + R_2 \parallel R_3 + R_4 \parallel R_5$$

Related Problem   If a resistor is connected from the bottom end of R_3 to the top end of R_5 in Figure 7–8, what effect does it have on the circuit?

EXAMPLE 7–3   Describe the series-parallel combination between terminals A and D in Figure 7–9.

▶ **FIGURE 7–9**
Solution   Between nodes B and C, there are two parallel paths. The lower path consists of R_4, and the upper path consists of a series combination of R_2 and R_3. This parallel combination is in series with R_5. The R_2, R_3, R_4, R_5 combination is in parallel with R_6. Resistor R_1 is in series with this entire combination as stated by the following expression:

$$R_1 + R_6 \parallel (R_5 + R_4 \parallel (R_2 + R_3))$$

Related Problem   If a resistor is connected from C to D in Figure 7–9, describe its parallel relationship.

EXAMPLE 7–4   Describe the total resistance between each pair of terminals in Figure 7–10.

$$R_1 \parallel (R_2 + R_3)$$

2. From A to C: R_3 is in parallel with the series combination of R_1 and R_2.

$$R_3 \parallel (R_1 + R_2)$$

3. From B to C: R_2 is in parallel with the series combination of R_1 and R_3.

$$R_2 \parallel (R_1 + R_3)$$

Related Problem In Figure 7–10, describe the total resistance between each terminal and an added ground if a new resistor, R_4, is connected from C to ground. None of the existing resistors connect directly to the ground.

Usually, the physical arrangement of components on a PC or protoboard bears no resemblance to the actual circuit relationships. By tracing out the circuit and rearranging the components on paper into a recognizable form, you can determine the series-parallel relationships.

EXAMPLE 7–5 Determine the relationships of the resistors on the PC board in Figure 7–11.

▶ **FIGURE 7–11**
Solution In Figure 7–12(a), the schematic is drawn in the same arrangement as that of the resistors on the board. In part (b), the resistors are rearranged so that the series-parallel relationships are more obvious.

Resistors R_1 and R_4 are in series; $R_1 + R_4$ is in parallel with R_2; R_5 and R_6 are in parallel and this combination is in series with R_3.

The R_3, R_5, and R_6 series-parallel combination is in parallel with both R_2 and the $R_1 + R_4$ combination. This entire series-parallel combination is in series with R_7.

Figure 7–12(c) illustrates these relationships. Summarizing in equation form,

$$R_{AB} = (R_5 \| R_6 + R_3) \| R_2 \| (R_1 + R_4) + R_7$$

7–2   ANALYSIS OF SERIES-PARALLEL RESISTIVE CIRCUITS

The analysis of series-parallel circuits can be approached in many ways, depending on what information you need and what circuit values you know. The examples in this section do not represent an exhaustive coverage, but they give you an idea of how to approach series-parallel circuit analysis.

After completing this section, you should be able to

◆ **Analyze series-parallel circuits**

  ◆ Determine total resistance

  ◆ Determine all the currents

  ◆ Determine all the voltage drops

If you know Ohm's law, Kirchhoff's laws, the voltage-divider formula, and the current-divider formula, and if you know how to apply these laws, you can solve most resistive circuit analysis problems. The ability to recognize series and parallel combinations is, of course,

⊕ *This icon indicates selected websites for further information on topics in this section. See the Companion Website provided with this text.*

essential. A few circuits, such as the unbalanced Wheatstone bridge, do not have basic series and parallel combinations. Other methods are needed for these cases, as we will discuss later.
Total Resistance

In Chapter 5, you learned how to determine total series resistance. In Chapter 6, you learned how to determine total parallel resistance. To find the total resistance (R_T) of a series-parallel combination, simply define the series and parallel relationships; then perform the calculations that you have previously learned. The following two examples illustrate this general approach.

EXAMPLE 7–6

Determine R_T of the circuit in Figure 7–16 between terminals A and B.

► **FIGURE 7–16**

Solution First, calculate the equivalent parallel resistance of R_2 and R_3. Since R_2 and R_3 are equal in value, you can use Equation 6–4.

$$R_{2\|3} = \frac{R}{n} = \frac{100\ \Omega}{2} = 50\ \Omega$$

Notice that the term $R_{2\|3}$ is used here to designate the total resistance of a portion of a circuit in order to distinguish it from the total resistance, R_T, of the complete circuit.

Now, since R_1 is in series with $R_{2\|3}$, add their values as follows:

$$R_T = R_1 + R_{2\|3} = 10\ \Omega + 50\ \Omega = \mathbf{60\ \Omega}$$

Related Problem Determine R_T in Figure 7–16 if R_3 is changed to 82 Ω.

EXAMPLE 7–7

Find the total resistance between the positive and negative terminals of the battery in Figure 7–17.
▲ **FIGURE 7–17**

Solution   In the upper branch, R_2 is in series with R_3. This series combination is designated R_{2+3} and is equal to $R_2 + R_3$.

$$R_{2+3} = R_2 + R_3 = 47\ \Omega + 47\ \Omega = 94\ \Omega$$

In the lower branch, R_4 and R_5 are in parallel with each other. This parallel combination is designated $R_{4\|5}$.

$$R_{4\|5} = \frac{R_4 R_5}{R_4 + R_5} = \frac{(68\ \Omega)(39\ \Omega)}{68\ \Omega + 39\ \Omega} = 24.8\ \Omega$$

Also in the lower branch, the parallel combination of R_4 and R_5 is in series with R_6. This series-parallel combination is designated $R_{4\|5+6}$.

$$R_{4\|5+6} = R_6 + R_{4\|5} = 75\ \Omega + 24.8\ \Omega = 99.8\ \Omega$$

Figure 7–18 shows the original circuit in a simplified equivalent form.
▲ **FIGURE 7–18**

Now you can find the equivalent resistance between *A* and *B*. It is R_{2+3} in parallel with $R_{4\|5+6}$. Calculate the equivalent resistance as follows:

$$R_{AB} = \frac{1}{\dfrac{1}{R_{2+3}} + \dfrac{1}{R_{4\|5+6}}} = \frac{1}{\dfrac{1}{94\ \Omega} + \dfrac{1}{99.8\ \Omega}} = 48.4\ \Omega$$

Finally, the total resistance is R_1 in series with R_{AB}.

$$R_T = R_1 + R_{AB} = 100\ \Omega + 48.4\ \Omega = \mathbf{148.4\ \Omega}$$

Related Problem   Determine R_T if a 68 Ω resistor is added in parallel from *A* to *B* in Figure 7–17.

Total Current

Once you know the total resistance and the source voltage, you can apply Ohm's law to find the total current in a circuit. Total current is the source voltage divided by the total resistance.

$$I_T = \frac{V_S}{R_T}$$

For example, assuming that the source voltage is 10 V, the total current in the circuit of Example 7–7 (Figure 7–17) is

$$I_T = \frac{V_S}{R_T} = \frac{10\ \text{V}}{148.4\ \Omega} = 67.4\ \text{mA}$$

Branch Currents

Using the current-divider formula, Kirchhoff's current law, Ohm's law, or combinations of these, you can find the current in any branch of a series-parallel circuit. In some cases, it may take repeated application of the formula to find a given current. The following two examples will help you understand the procedure. (Notice that the subscripts for the current variables (I) match the R subscripts; for example, current through R_1 is referred to as I_1.)

EXAMPLE 7–8

Find the current through R_2 and the current through R_3 in Figure 7–19.
▲ **FIGURE 7–19**

Solution   First, identify the series and parallel relationship. Next, determine how much current is out of node A. This is the total circuit current. To find I_T, you must know R_T.

$$R_T = R_1 + \frac{R_2 R_3}{R_2 + R_3} = 1.0\,\text{k}\Omega + \frac{(2.2\,\text{k}\Omega)(3.3\,\text{k}\Omega)}{2.2\,\text{k}\Omega + 3.3\,\text{k}\Omega} = 1.0\,\text{k}\Omega + 1.32\,\text{k}\Omega = 2.32\,\text{k}\Omega$$

$$I_T = \frac{V_S}{R_T} = \frac{22\,\text{V}}{2.32\,\text{k}\Omega} = 9.48\,\text{mA}$$

Use the current-divider rule for two branches as given in Chapter 6 to find the current through R_2.

$$I_2 = \left(\frac{R_3}{R_2 + R_3}\right)I_T = \left(\frac{3.3\,\text{k}\Omega}{5.5\,\text{k}\Omega}\right)9.48\,\text{mA} = \mathbf{5.69\,mA}$$

Now you can use Kirchhoff's current law to find the current through R_3.

$$I_T = I_2 + I_3$$
$$I_3 = I_T - I_2 = 9.48\,\text{mA} - 5.69\,\text{mA} = \mathbf{3.79\,mA}$$

Related Problem   A 4.7 kΩ resistor is connected in parallel with R_3 in Figure 7–19. Determine the current through the new resistor.
Use Multisim file E07-08 to verify the calculated results in this example and to confirm your calculation for the related problem.

EXAMPLE 7–9

Determine the current through R_4 in Figure 7–20 if $V_S = 5$ V.

Solution First, find the current (I_2) into node B. Once you know this current, use the current-divider formula to find I_4, the current through R_4.

Notice that there are two main branches in the circuit. The left-most branch consists of only R_1. The right-most branch has R_2 in series with the parallel combination of R_3 and R_4. The voltage across both of these main branches is the same and equal to 5 V. Calculate the equivalent resistance ($R_{2+3\|4}$) of the right-most main branch and then apply Ohm's law; I_2 is the total current through this main branch. Thus,

$$R_{2+3\|4} = R_2 + \frac{R_3 R_4}{R_3 + R_4} = 330 \ \Omega + \frac{(330 \ \Omega)(560 \ \Omega)}{890 \ \Omega} = 538 \ \Omega$$

$$I_2 = \frac{V_S}{R_{2+3\|4}} = \frac{5 \ \text{V}}{538 \ \Omega} = 9.3 \ \text{mA}$$

Use the two-resistor current-divider formula to calculate I_4.

$$I_4 = \left(\frac{R_3}{R_3 + R_4} \right) I_2 = \left(\frac{330 \ \Omega}{890 \ \Omega} \right) 9.3 \ \text{mA} = \textbf{3.45 mA}$$

Related Problem Determine the current through R_1 and R_3 in Figure 7–20 if $V_S = 2$ V.

Voltage Drops

To find the voltages across certain parts of a series-parallel circuit, you can use the voltage-divider formula given in Chapter 5, Kirchhoff's voltage law, Ohm's law, or combinations of each. The following three examples illustrate use of the formulas. (The subscripts for V match the subscripts for the corresponding R: V_1 is the voltage across R_1; V_2 is the voltage across R_2, etc.)

EXAMPLE 7–10

Determine the voltage drop from node A to ground in Figure 7–21. Then find the voltage (V_1) across R_1.
Solution   Note that R_2 and R_3 are in parallel in this circuit. Since they are equal in value, their equivalent resistance from node A to ground is

$$R_A = \frac{560 \ \Omega}{2} = 280 \ \Omega$$

In the equivalent circuit shown in Figure 7–22, R_1 is in series with R_A. The total circuit resistance as seen from the source is

$$R_T = R_1 + R_A = 150 \ \Omega + 280 \ \Omega = 430 \ \Omega$$

▶ **FIGURE 7–22**
Use the voltage-divider formula to find the voltage across the parallel combination of Figure 7–21 (between node A and ground).

$$V_A = \left(\frac{R_A}{R_T}\right)V_S = \left(\frac{280 \ \Omega}{430 \ \Omega}\right)80 \ V = \mathbf{52.1 \ V}$$

Now use Kirchhoff's voltage law to find V_1.

$$V_S = V_1 + V_A$$
$$V_1 = V_S - V_A = 80 \ V - 52.1 \ V = \mathbf{27.9 \ V}$$

Related Problem   Determine V_A and V_1 if R_1 is changed to 220 Ω in Figure 7–21.

Use Multisim file E07-10 to verify the calculated results in this example and to confirm your calculation for the related problem.

EXAMPLE 7–11   Determine the voltage drop across each resistor in the circuit of Figure 7–23.
▲ **FIGURE 7–23**

Solution   The source voltage is not given, but you know the total current from the figure. Since R_1 and R_2 are in parallel, they each have the same voltage. The current through R_1 is

$$I_1 = \left(\frac{R_2}{R_1 + R_2}\right)I_T = \left(\frac{2.2\,\text{k}\Omega}{3.2\,\text{k}\Omega}\right)1\,\text{mA} = 688\,\mu\text{A}$$

The voltages across R_1 and R_2 are

$$V_1 = I_1R_1 = (688\,\mu\text{A})(1.0\,\text{k}\Omega) = \mathbf{688\,mV}$$
$$V_2 = V_1 = \mathbf{688\,mV}$$

The series combination of R_4 and R_5 form the branch resistance, R_{4+5}. Apply the current-divider formula to determine the current through R_3.

$$I_3 = \left(\frac{R_{4+5}}{R_3 + R_{4+5}}\right)I_T = \left(\frac{2.06\,\text{k}\Omega}{5.96\,\text{k}\Omega}\right)1\,\text{mA} = 346\,\mu\text{A}$$

The voltage across R_3 is

$$V_3 = I_3R_3 = (346\,\mu\text{A})(3.9\,\text{k}\Omega) = \mathbf{1.35\,V}$$

The currents through R_4 and R_5 are the same because these resistors are in series.

$$I_4 = I_5 = I_T - I_3 = 1\,\text{mA} - 346\,\mu\text{A} = 654\,\mu\text{A}$$

Calculate the voltages across R_4 and R_5 as follows:

$$V_4 = I_4R_4 = (654\,\mu\text{A})(1.5\,\text{k}\Omega) = \mathbf{981\,mV}$$
$$V_5 = I_5R_5 = (654\,\mu\text{A})(560\,\Omega) = \mathbf{366\,mV}$$

Use Multisim file E07-11 to verify the calculated results in this example and to confirm your calculation for the related problem.

EXAMPLE 7–12

Determine the voltage drop across each resistor in Figure 7–24.
▲ FIGURE 7–24

Solution   Because the total voltage is given in the figure, you can solve this problem using the voltage-divider formula. First, you need to reduce each parallel combination to an equivalent resistance. Since R_1 and R_2 are in parallel between A and B, combine their values.

$$R_{AB} = \frac{R_1 R_2}{R_1 + R_2} = \frac{(3.3\,\text{k}\Omega)(6.2\,\text{k}\Omega)}{9.5\,\text{k}\Omega} = 2.15\,\text{k}\Omega$$
Since R_4 is in parallel with the R_5 and R_6 series combination (R_{5+6}) between C and D, combine these values.

$$R_{CD} = \frac{R_4 R_{5+6}}{R_4 + R_{5+6}} = \frac{(1.0\,\text{k}\Omega)(1.07\,\text{k}\Omega)}{2.07\,\text{k}\Omega} = 517\,\Omega$$

The equivalent circuit is drawn in Figure 7–25. The total circuit resistance is

$$R_{\text{T}} = R_{AB} + R_3 + R_{CD} = 2.15\,\text{k}\Omega + 1.0\,\text{k}\Omega + 517\,\Omega = 3.67\,\text{k}\Omega$$

▶ **FIGURE 7–25**

Next, use the voltage-divider formula to determine the voltages in the equivalent circuit.

$$V_{AB} = \left(\frac{R_{AB}}{R_{\text{T}}}\right)V_{\text{S}} = \left(\frac{2.15\,\text{k}\Omega}{3.67\,\text{k}\Omega}\right)8\,\text{V} = 4.69\,\text{V}$$

$$V_{CD} = \left(\frac{R_{CD}}{R_{\text{T}}}\right)V_{\text{S}} = \left(\frac{517\,\Omega}{3.67\,\text{k}\Omega}\right)8\,\text{V} = 1.13\,\text{V}$$

$$V_3 = \left(\frac{R_3}{R_{\text{T}}}\right)V_{\text{S}} = \left(\frac{1.0\,\text{k}\Omega}{3.67\,\text{k}\Omega}\right)8\,\text{V} = \textbf{2.18 V}$$

Refer to Figure 7–24. V_{AB} equals the voltage across both R_1 and R_2, so

$$V_1 = V_2 = V_{AB} = \textbf{4.69 V}$$

V_{CD} is the voltage across R_4 and across the series combination of R_5 and R_6. Therefore,

$$V_4 = V_{CD} = \textbf{1.13 V}$$

Now apply the voltage-divider formula to the series combination of R_5 and R_6 to get V_5 and V_6.

$$V_5 = \left(\frac{R_5}{R_5 + R_6}\right)V_{CD} = \left(\frac{680\,\Omega}{1070\,\Omega}\right)1.13\,\text{V} = \textbf{718 mV}$$

$$V_6 = \left(\frac{R_6}{R_5 + R_6}\right)V_{CD} = \left(\frac{390\,\Omega}{1070\,\Omega}\right)1.13\,\text{V} = \textbf{412 mV}$$

7–3 VOLTAGE DIVIDERS WITH RESISTIVE LOADS

Voltage dividers were introduced in Chapter 5. In this section, you will learn how resistive loads affect the operation of voltage-divider circuits.

After completing this section, you should be able to

- ◆ **Analyze loaded voltage dividers**
  - ◆ Determine the effect of a resistive load on a voltage-divider circuit
  - ◆ Define *bleeder current*

The voltage divider in Figure 7–28(a) produces an output voltage (V_{OUT}) of 5 V because the two resistors are of equal value. This voltage is the *unloaded output voltage.* When a load resistor, R_L, is connected from the output to ground as shown in Figure 7–28(b), the output voltage is reduced by an amount that depends on the value of R_L. The load resistor is in parallel with R_2, reducing the resistance from node A to ground and, as a result, also

(a) Unloaded (b) Loaded

reducing the voltage across the parallel combination. This is one effect of loading a voltage divider. Another effect of a load is that more current is drawn from the source because the total resistance of the circuit is reduced.

The larger R_L is, compared to R_2, the less the output voltage is reduced from its unloaded value, as illustrated in Figure 7–29. When R_L is large compared to R_2 (at least ten times), the loading effect is small, and the output voltage will change only a small amount from its unloaded value, as shown in Figure 7–29(c). In this case, the divider is said to be a **stiff voltage divider.**

(b) Find the loaded output voltages of the voltage divider in Figure 7–30 for the following two values of load resistance: $R_L = 10\,\text{k}\Omega$ and $R_L = 100\,\text{k}\Omega$.

▶ **FIGURE 7–30**
Solution (a) The unloaded output voltage is

$$V_{\text{OUT(unloaded)}} = \left(\frac{R_2}{R_1 + R_2}\right)V_S = \left(\frac{10\,\text{k}\Omega}{14.7\,\text{k}\Omega}\right)5\,\text{V} = \textbf{3.40 V}$$

(b) With the 10 kΩ load resistor connected, R_L is in parallel with R_2, which gives

$$R_2 \,\|\, R_L = \frac{R_2 R_L}{R_2 + R_L} = \frac{100\,\text{M}\Omega}{20\,\text{k}\Omega} = 5\,\text{k}\Omega$$

The equivalent circuit is shown in Figure 7–31(a). The loaded output voltage is

$$V_{\text{OUT(loaded)}} = \left(\frac{R_2 \,\|\, R_L}{R_1 + R_2 \,\|\, R_L}\right)V_S = \left(\frac{5\,\text{k}\Omega}{9.7\,\text{k}\Omega}\right)5\,\text{V} = \textbf{2.58 V}$$

With the 100 kΩ load, the resistance from output to ground is

$$R_2 \,\|\, R_L = \frac{R_2 R_L}{R_2 + R_L} = \frac{(10\,\text{k}\Omega)(100\,\text{k}\Omega)}{110\,\text{k}\Omega} = 9.1\,\text{k}\Omega$$

The equivalent circuit is shown in Figure 7–31(b). The loaded output voltage is

$$V_{OUT(loaded)} = \left(\frac{R_2 \| R_L}{R_1 + R_2 \| R_L}\right)V_S = \left(\frac{9.1\text{ k}\Omega}{13.8\text{ k}\Omega}\right)5\text{ V} = \mathbf{3.30\ V}$$

(a) $R_L = 10\text{ k}\Omega$ (b) $R_L = 100\text{ k}\Omega$

▲ **FIGURE 7–31**

For the smaller value of R_L, the reduction in V_{OUT} is

$$3.40\text{ V} - 2.58\text{ V} = 0.82\text{ V} \qquad \text{(a 24\% drop in output voltage)}$$

For the larger value of R_L, the reduction in V_{OUT} is

$$3.40\text{ V} - 3.30\text{ V} = 0.10\text{ V} \qquad \text{(a 3\% drop in output voltage)}$$

This illustrates the loading effect of R_L on the voltage divider.

Load Current and Bleeder Current

In a multiple-tap loaded voltage-divider circuit, the total current drawn from the source consists of currents through the load resistors, called *load currents*, and the divider resistors. Figure 7–32 shows a voltage divider with two voltage outputs or two taps. Notice that the total current, I_T, is through R_1. The total current is composed of the two branch currents, I_{RL1} and I_2. The current I_2 is composed of two additional branch currents, I_{RL2}
◄ **FIGURE 7–32**

and I_3. Current I_3 is called the **bleeder current**, which is the current left after the total load current is subtracted from the total current in the circuit.

$$I_{\text{BLEEDER}} = I_{\text{T}} - I_{RL1} - I_{RL2}$$

EXAMPLE 7–14

Determine the load currents I_{RL1} and I_{RL2} and the bleeder current I_3 in the two-tap loaded voltage divider in Figure 7–32.

Solution The equivalent resistance from node A to ground is the 100 kΩ load resistor R_{L1} in parallel with the combination of R_2 in series with the parallel combination of R_3 and R_{L2}. Determine the resistance values first. R_3 in parallel with R_{L2} is designated R_B. The resulting equivalent circuit is shown in Figure 7–33(a).

$$R_B = \frac{R_3 R_{L2}}{R_3 + R_{L2}} = \frac{(6.2\,\text{k}\Omega)(100\,\text{k}\Omega)}{106.2\,\text{k}\Omega} = 5.84\,\text{k}\Omega$$

R_2 in series with R_B is designated R_{2+B}. The resulting equivalent circuit is shown in Figure 7–33(b).

$$R_{2+B} = R_2 + R_B = 6.2\,\text{k}\Omega + 5.84\,\text{k}\Omega = 12.0\,\text{k}\Omega$$

R_{L1} in parallel with R_{2+B} is designated R_A. The resulting equivalent circuit is shown in Figure 7–33(c).

$$R_A = \frac{R_{L1} R_{2+B}}{R_{L1} + R_{2+B}} = \frac{(100\,\text{k}\Omega)(12.0\,\text{k}\Omega)}{112\,\text{k}\Omega} = 10.7\,\text{k}\Omega$$

R_A is the total resistance from node A to ground. The total resistance for the circuit is

$$R_{\text{T}} = R_A + R_1 = 10.7\,\text{k}\Omega + 12\,\text{k}\Omega = 22.7\,\text{k}\Omega$$
▲ **FIGURE 7–33**

Determine the voltage across R_{L1} as follows, using the equivalent circuit in Figure 7–33(c):

$$V_{RL1} = V_A = \left(\frac{R_A}{R_{\text{T}}}\right) V_{\text{S}} = \left(\frac{10.7\,\text{k}\Omega}{22.7\,\text{k}\Omega}\right) 24\,\text{V} = 11.3\,\text{V}$$

The load current through R_{L1} is

$$I_{RL1} = \frac{V_{RL1}}{R_{L1}} = \left(\frac{11.3\,\text{V}}{100\,\text{k}\Omega}\right) = \mathbf{113\,\mu A}$$

Determine the voltage at node B by using the equivalent circuit in Figure 7–33(a) and the voltage at node A.

$$V_B = \left(\frac{R_B}{R_{2+B}}\right)V_A = \left(\frac{5.84\,\text{k}\Omega}{12.0\,\text{k}\Omega}\right)11.3\,\text{V} = 5.50\,\text{V}$$

The load current through R_{L2} is

$$I_{RL2} = \frac{V_{RL2}}{R_{L2}} = \frac{V_B}{R_{L2}} = \frac{5.50\,\text{V}}{100\,\text{k}\Omega} = 55\,\mu\text{A}$$

The bleeder current is

$$I_3 = \frac{V_B}{R_3} = \frac{5.50\,\text{V}}{6.2\,\text{k}\Omega} = 887\,\mu\text{A}$$

7–4   LOADING EFFECT OF A VOLTMETER

As you have learned, voltmeters must be connected in parallel with a resistor in order to measure the voltage across the resistor. Because of its internal resistance, a voltmeter puts a load on the circuit and will affect, to a certain extent, the voltage that is being measured. Until now, we have ignored the loading effect because the internal resistance of a voltmeter is very high, and normally it has negligible effect on the circuit that is being measured. However, if the internal resistance of the voltmeter is not

sufficiently greater than the circuit resistance across which it is connected, the loading effect will cause the measured voltage to be less than its actual value. You should always be aware of this effect.

After completing this section, you should be able to

◆ **Determine the loading effect of a voltmeter on a circuit**

   ◆ Explain why a voltmeter can load a circuit

   ◆ Discuss the internal resistance of a voltmeter

When a voltmeter is connected to a circuit as shown, for example, in Figure 7–35(a), its internal resistance appears in parallel with R_3, as shown in part (b). The resistance from A to B is altered by the loading effect of the voltmeter's internal resistance, R_M, and is equal to $R_3 \parallel R_M$, as indicated in part (c).

▲ **FIGURE 7–35**

The loading effect of a voltmeter.

If R_M is much greater than R_3, the resistance from A to B changes very little, and the meter indicates the actual voltage. If R_M is not sufficiently greater than R_3, the resistance from A to B is reduced significantly, and the voltage across R_3 is altered by the loading effect of the meter. A good rule of thumb for troubleshooting work is that *if the loading effect is less than 10%, it can usually be neglected, depending on the accuracy required*.

Most voltmeters are part of a multifunction instrument such as the DMM or the analog multimeter discussed in Chapter 2. The voltmeter in a DMM will typically have an internal resistance of 10 MΩ or more, so the loading effect is important only in very high-resistance circuits. DMMs have a constant resistance on all ranges because the input is connected to an internal fixed voltage divider. For analog multimeters, the internal resistance depends on the range selected for making a measurement. To determine the loading effect, you need to know the sensitivity of the meter, a value given by the manufacturer on the meter or in the manual. Sensitivity is expressed in ohms/volt and is typically about 20,000 Ω/V. To determine the internal series resistance, multiply the sensitivity by the maximum voltage on the range selected. For example, a 20,000 Ω/V meter will have an internal resistance of 20,000 Ω on the 1 V range and 200,000 Ω on the 10 V range. As you can see, there is a smaller loading effect for higher voltage ranges than for lower ones on the analog multimeter.

EXAMPLE 7–15

How much does the digital voltmeter affect the voltage being measured for each circuit indicated in Figure 7–36? Assume the meter has an input resistance (R_M) of 10 MΩ.
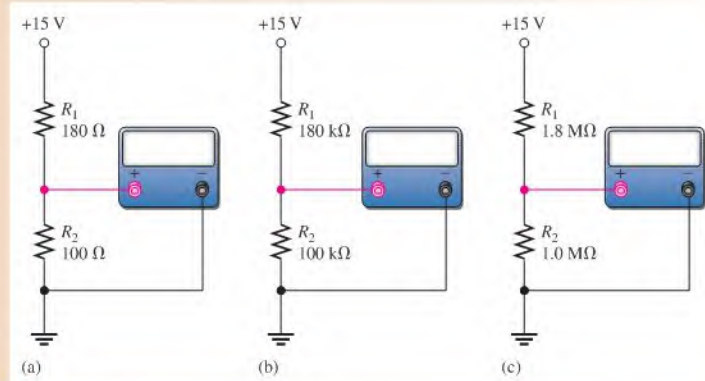

▲ **FIGURE 7–36**

Solution   To show the small differences more clearly, the results are expressed in more than three significant figures in this example.

(a) Refer to Figure 7–36(a). The unloaded voltage across R_2 in the voltage-divider circuit is

$$V_2 = \left(\frac{R_2}{R_1 + R_2}\right)V_S = \left(\frac{100\ \Omega}{280\ \Omega}\right)15\ \text{V} = 5.357\ \text{V}$$

The meter's resistance in parallel with R_2 is

$$R_2 \parallel R_M = \left(\frac{R_2 R_M}{R_2 + R_M}\right) = \frac{(100\ \Omega)(10\ \text{M}\Omega)}{10.0001\ \text{M}\Omega} = 99.999\ \Omega$$

The voltage actually measured by the meter is

$$V_2 = \left(\frac{R_2 \parallel R_M}{R_1 + R_2 \parallel R_M}\right)V_S = \left(\frac{99.999\ \Omega}{279.999\ \Omega}\right)15\ \text{V} = 5.357\ \text{V}$$

The voltmeter has no measurable loading effect.

(b) Refer to Figure 7–36(b).

$$V_2 = \left(\frac{R_2}{R_1 + R_2}\right)V_S = \left(\frac{100\ \text{k}\Omega}{280\ \text{k}\Omega}\right)15\ \text{V} = 5.357\ \text{V}$$

$$R_2 \parallel R_M = \frac{R_2 R_M}{R_2 + R_M} = \frac{(100\ \text{k}\Omega)(10\ \text{M}\Omega)}{10.1\ \text{M}\Omega} = 99.01\ \text{k}\Omega$$

The voltage actually measured by the meter is

$$V_2 = \left(\frac{R_2 \parallel R_M}{R_1 + R_2 \parallel R_M}\right)V_S = \left(\frac{99.01\ \text{k}\Omega}{279.01\ \text{k}\Omega}\right)15\ \text{V} = 5.323\ \text{V}$$

The loading effect of the voltmeter reduces the voltage by a very small amount.

(c) Refer to Figure 7–36(c).

$$V_2 = \left(\frac{R_2}{R_1 + R_2}\right)V_S = \left(\frac{1.0\,\text{M}\Omega}{2.8\,\text{M}\Omega}\right)15\,\text{V} = 5.357\,\text{V}$$

$$R_2 \parallel R_M = \frac{R_2 R_M}{R_2 + R_M} = \frac{(1.0\,\text{M}\Omega)(10\,\text{M}\Omega)}{11\,\text{M}\Omega} = 909.09\,\text{k}\Omega$$

The voltage actually measured is

$$V_2 = \left(\frac{R_2 \parallel R_M}{R_1 + R_2 \parallel R_M}\right)V_S = \left(\frac{909.09\,\text{k}\Omega}{2.709\,\text{M}\Omega}\right)15\,\text{V} = 5.034\,\text{V}$$

The loading effect of the voltmeter reduces the voltage by a noticeable amount. As you can see, the higher the resistance across which a voltage is measured, the more the loading effect.

Related Problem   Calculate the voltage across R_2 in Figure 7–36(c) if the meter resistance is 20 MΩ.

7–5   LADDER NETWORKS

A resistive ladder network is a special type of series-parallel circuit. The $R/2R$ ladder network is commonly used to scale down voltages to certain weighted values for digital-to-analog conversion, which is a process that you will study in another course.

After completing this section, you should be able to

◆ **Analyze ladder networks**

   ◆ Determine the voltages in a three-step ladder network

   ◆ Analyze an $R/2R$ ladder

One approach to the analysis of a ladder network such as the one shown in Figure 7–37 is to simplify it one step at a time, starting at the side farthest from the source. In this way, you can determine the current in any branch or the voltage at any node, as illustrated in Example 7–16.
▲ FIGURE 7–37

Basic three-step ladder network.

EXAMPLE 7–16

Determine the current through each resistor and the voltage at each labeled node with respect to ground in the ladder network of Figure 7–38.

▲ FIGURE 7–38

Solution   To find the current through each resistor, you must know the total source current (I_T). To obtain I_T, you must find the total resistance "seen" by the source.

Determine R_T in a step-by-step process, starting at the right of the circuit diagram. First, notice that R_5 and R_6 are in series across R_4. Neglecting the circuit to the left of node B, the resistance from node B to ground is

$$R_B = \frac{R_4(R_5 + R_6)}{R_4 + (R_5 + R_6)} = \frac{(10\,\text{k}\Omega)(9.4\,\text{k}\Omega)}{19.4\,\text{k}\Omega} = 4.85\,\text{k}\Omega$$

Using R_B, you can draw the equivalent circuit as shown in Figure 7–39.

▲ FIGURE 7–39

Next, neglecting the circuit to the left of node A, the resistance from node A to ground (R_A) is R_2 in parallel with the series combination of R_3 and R_B. Calculate resistance R_A.

$$R_A = \frac{R_2(R_3 + R_B)}{R_2 + (R_3 + R_B)} = \frac{(8.2\,\text{k}\Omega)(8.15\,\text{k}\Omega)}{16.35\,\text{k}\Omega} = 4.09\,\text{k}\Omega$$

Using R_A, you can further simplify the equivalent circuit of Figure 7–39 as shown in Figure 7–40.
Finally, the total resistance "seen" by the source is R_1 in series with R_A.

$$R_T = R_1 + R_A = 1.0 \, k\Omega + 4.09 \, k\Omega = 5.09 \, k\Omega$$

The total circuit current is

$$I_T = \frac{V_S}{R_T} = \frac{45 \, V}{5.09 \, k\Omega} = \textbf{8.84 mA}$$

As indicated in Figure 7–39, I_T is out of node A and consists of the currents through R_2 and the branch containing $R_3 + R_B$. Since the branch resistances are approximately equal in this particular example, half the total current is through R_2 and half out of node B. So the currents through R_2 and R_3 are

$$I_2 = \textbf{4.42 mA}$$
$$I_3 = \textbf{4.42 mA}$$

If the branch resistances are not equal, use the current-divider formula. As indicated in Figure 7–38. I_3 is out of node B and consists of the currents through R_4 and the branch containing $R_5 + R_6$. Therefore, the currents through $R_4, R_5,$ and R_6 can be calculated.

$$I_4 = \left(\frac{R_5 + R_6}{R_4 + (R_5 + R_6)} \right) I_3 = \left(\frac{9.4 \, k\Omega}{19.4 \, k\Omega} \right) 4.42 \, mA = \textbf{2.14 mA}$$
$$I_5 = I_6 = I_3 - I_4 = 4.42 \, mA - 2.14 \, mA = \textbf{2.28 mA}$$

To determine V_A, V_B, and V_C, apply Ohm's law.

$$V_A = I_2 R_2 = (4.42 \, mA)(8.2 \, k\Omega) = \textbf{36.2 V}$$
$$V_B = I_4 R_4 = (2.14 \, mA)(10 \, k\Omega) = \textbf{21.4 V}$$
$$V_C = I_6 R_6 = (2.28 \, mA)(4.7 \, k\Omega) = \textbf{10.7 V}$$

The R/2R Ladder Network

A basic $R/2R$ ladder network is shown in Figure 7–41. As you can see, the name comes from the relationship of the resistor values. R represents a common value, and one set of resistors has twice the value of the others. This type of ladder network is used in applications

where digital codes are converted to speech, music, or other types of analog signals as found, for example, in the area of digital recording and reproduction. This application is called *digital-to-analog (D/A) conversion.*

Let's examine the general operation of a basic $R/2R$ ladder using the four-step circuit in Figure 7–42. In a later course in digital fundamentals, you will learn specifically how this type of circuit is used in D/A conversion.

► **FIGURE 7–42**

$R/2R$ ladder with switch inputs to simulate a two-level (digital) code.

The switches used in this illustration simulate the digital (two-level) inputs. One switch position is connected to ground (0 V), and the other position is connected to a positive voltage (V). The analysis is as follows: Start by assuming that switch SW4 in Figure 7–42 is at the V position and the others are at ground so that the inputs are as shown in Figure 7–43(a).

The total resistance from node A to ground is found by first combining R_1 and R_2 in parallel from node D to ground. The simplified circuit is shown in Figure 7–43(b).

$$R_1 \parallel R_2 = \frac{2R}{2} = R$$

$R_1 \parallel R_2$ is in series with R_3 from node C to ground as illustrated in part (c).

$$R_1 \parallel R_2 + R_3 = R + R = 2R$$

Next, this combination is in parallel with R_4 from node C to ground as shown in part (d).

$$(R_1 \parallel R_2 + R_3) \parallel R_4 = 2R \parallel 2R = \frac{2R}{2} = R$$
▲ FIGURE 7–43

Simplification of R/2R ladder for analysis.

Continuing this simplification process results in the circuit in part (e) in which the output voltage can be expressed using the voltage-divider formula as

$$V_{OUT} = \left(\frac{2R}{4R}\right)V = \frac{V}{2}$$

A similar analysis, except with switch SW3 in Figure 7–42 connected to V and the other switches connected to ground, results in the simplified circuit shown in Figure 7–44.
▲ FIGURE 7–44

Simplified ladder with only V input at SW3 in Figure 7–42.

The analysis for this case is as follows: The resistance from node B to ground is

$$R_B = (R_7 + R_8) \parallel 2R = 3R \parallel 2R = \frac{6R}{5}$$

Using the voltage-divider formula, we can express the voltage at node B with respect to ground as

$$V_B = \left(\frac{R_B}{R_6 + R_B}\right)V = \left(\frac{6R/5}{2R + 6R/5}\right)V = \left(\frac{6R/5}{10R/5 + 6R/5}\right)V = \left(\frac{6R/5}{16R/5}\right)V$$

$$= \left(\frac{6R}{16R}\right)V = \frac{3V}{8}$$

The output voltage is, therefore,

$$V_{OUT} = \left(\frac{R_8}{R_7 + R_8}\right)V_B = \left(\frac{2R}{3R}\right)\left(\frac{3V}{8}\right) = \frac{V}{4}$$

Notice that the output voltage in this case ($V/4$) is one half the output voltage ($V/2$) for the case where V is connected at switch SW4.

A similar analysis for each of the remaining switch inputs in Figure 7–42 results in output voltages as follows: For SW2 connected to V and the other switches connected to ground,

$$V_{OUT} = \frac{V}{8}$$

For SW1 connected to V and the other switches connected to ground,

$$V_{OUT} = \frac{V}{16}$$

When more than one input at a time are connected to V, the total output is the sum of the individual outputs, according to the superposition theorem that is covered in Section 8–4. These particular relationships among the output voltages for the various levels of inputs are important in the application of $R/2R$ ladder networks to digital-to-analog conversion.

7–6 THE WHEATSTONE BRIDGE

The Wheatstone bridge circuit can be used to precisely measure resistance. However, the bridge is most commonly used in conjunction with transducers to measure physical quantities such as strain, temperature, and pressure. **Transducers** are devices that sense a change in a physical parameter and convert that change into an electrical quantity such as a change in resistance. For example, a strain gauge exhibits a change in resistance when it is exposed to mechanical factors such as force, pressure, or displacement. A thermistor exhibits a change in its resistance when it is exposed to a change in temperature. The Wheatstone bridge can be operated in a balanced or an unbalanced condition. The condition of operation depends on the type of application.

After completing this section, you should be able to

◆ **Analyze and apply a Wheatstone bridge**

  ◆ Determine when a bridge is balanced

  ◆ Determine an unknown resistance with a balanced bridge

  ◆ Determine when a bridge is unbalanced

  ◆ Discuss measurements using an unbalanced bridge

A **Wheatstone bridge** circuit is shown in its most common "diamond" configuration in Figure 7–46(a). It consists of four resistors and a dc voltage source connected across the top and bottom points of the "diamond." The output voltage is taken across the left and right points of the "diamond" between A and B. In part (b), the circuit is drawn in a slightly different way to more clearly show its series-parallel configuration.

(a)   (b)
▲ **FIGURE 7–46**

Wheatstone bridge. Notice that the bridge forms two back-to-back voltage dividers.

The Balanced Wheatstone Bridge

The Wheatstone bridge in Figure 7–46 is in the **balanced bridge** condition when the output voltage (V_{OUT}) between terminals A and B is equal to zero.

$$V_{OUT} = 0 \text{ V}$$

When the bridge is balanced, the voltages across R_1 and R_2 are equal ($V_1 = V_2$) and the voltages across R_3 and R_4 are equal ($V_3 = V_4$). Therefore, the voltage ratios can be written as

$$\frac{V_1}{V_3} = \frac{V_2}{V_4}$$

Substituting IR for V by Ohm's law gives

$$\frac{I_1R_1}{I_3R_3} = \frac{I_2R_2}{I_4R_4}$$

Since $I_1 = I_3$ and $I_2 = I_4$, all the current terms cancel, leaving the resistor ratios.

$$\frac{R_1}{R_3} = \frac{R_2}{R_4}$$

Solving for R_1 results in the following formula:

$$R_1 = R_3\left(\frac{R_2}{R_4}\right)$$

This formula allows you to find the value of resistor R_1 in terms of the other resistor values when the bridge is balanced. You can also find the value of any other resistor in a similar way.

Using the Balanced Wheatstone Bridge to Find an Unknown Resistance   Assume that R_1 in Figure 7–46 has an unknown value, which we call R_X. Resistors R_2 and R_4 have fixed values so that their ratio, R_2/R_4, also has a fixed value. Since R_X can be any value, R_3 must be adjusted to make $R_1/R_3 = R_2/R_4$ in order to create a balanced condition. Therefore, R_3 is a variable resistor, which we will call R_V. When R_X is placed in the bridge, R_V is adjusted until the bridge is balanced as indicated by a zero output voltage. Then, the unknown resistance is found as

$$R_X = R_V\left(\frac{R_2}{R_4}\right)$$

The ratio R_2/R_4 is the scale factor.

An older type of measuring instrument called a *galvanometer* can be connected between the output terminals A and B to detect a balanced condition. The galvanometer is essentially a very sensitive ammeter that senses current in either direction. It differs from a regular ammeter in that the midscale point is zero. In modern instruments, an amplifier connected across the bridge output indicates a balanced condition when its output is 0 V. Also, high precision micro-adjustable resistors can be used in demanding applications. The micro-adjustable resistors enable fine adjustment of the bridge resistors during manufacture for applications such as medical sensors, scales, and precision measurements.

From Equation 7–2, the value of R_V at balance multiplied by the scale factor R_2/R_4 is the actual resistance value of R_X. If $R_2/R_4 = 1$, then $R_X = R_V$, if $R_2/R_4 = 0.5$, then $R_X = 0.5R_V$, and so on. In a practical bridge circuit, the position of the R_V adjustment can be calibrated to indicate the actual value of R_X on a scale or with some other method of display.

EXAMPLE 7–17   Determine the value of R_X in the balanced bridge shown in Figure 7–47.

▶ **FIGURE 7–47**
Solution   The scale factor is

$$\frac{R_2}{R_4} = \frac{150 \ \Omega}{100 \ \Omega} = 1.5$$

The bridge is balanced ($V_{OUT} = 0 \ V$) when R_V is set at $1200 \ \Omega$, so the unknown resistance is

$$R_X = R_V\left(\frac{R_2}{R_4}\right) = (1200 \ \Omega)(1.5) = \mathbf{1800 \ \Omega}$$

*Related Problem*   If R_V must be adjusted to $2.2 \ k\Omega$ to balance the bridge in Figure 7–47, what is R_X?

Use Multisim file E07-17 to verify the calculated results in this example and to confirm your calculation for the related problem.

The Unbalanced Wheatstone Bridge

An **unbalanced bridge** condition occurs when V_{OUT} is not equal to zero. The unbalanced bridge is used to measure several types of physical quantities such as mechanical strain, temperature, or pressure. This can be done by connecting a transducer in one leg of the bridge, as shown in Figure 7–48. The resistance of the transducer changes proportionally to the changes in the parameter that it is measuring. If the bridge is balanced at a known point, then the amount of deviation from the balanced condition, as indicated by the output voltage, indicates the amount of change in the parameter being measured. Therefore, the value of the parameter being measured can be determined by the amount that the bridge is unbalanced.

▶ **FIGURE 7–48**

A bridge Circuit for measuring a physical parameter using a transducer.
A Bridge Circuit for Measuring Temperature   If temperature is to be measured, the transducer can be a thermistor, which is a temperature-sensitive resistor. The thermistor resistance changes in a predictable way as the temperature changes. A change in temperature causes a change in thermistor resistance, which causes a corresponding change in the output voltage of the bridge as it becomes unbalanced. The output voltage is proportional to the temperature; therefore, either a voltmeter connected across the output can be calibrated to show the temperature or the output voltage can be amplified and converted to digital form to drive a readout display of the temperature.

A bridge circuit used to measure temperature is designed so that it is balanced at a reference temperature and becomes unbalanced at a measured temperature. For example, let's say the bridge is to be balanced at 25°C. A thermistor will have a known value of resistance at 25°C. For simplicity, let's assume the other three bridge resistors are equal to the thermistor resistance at 25°C, so $R_{therm} = R_2 = R_3 = R_4$. For this particular case, the change

in output voltage (ΔV_{OUT}) can be shown to be related to the change in R_{therm} by the following formula:

$$\Delta V_{OUT} \cong \Delta R_{therm}\left(\frac{V_S}{4R}\right)$$

The Δ (Greek letter delta) in front of a variable means a change in the variable. This formula applies only to the case where all resistances in the bridge are equal when the bridge is balanced. A derivation is provided in Appendix B. Keep in mind that the bridge can be initially balanced without having all the resistors equal as long as $R_1 = R_2$ and $R_3 = R_4$ (see Figure 7–46), but the formula for ΔV_{OUT} would be more complicated.

EXAMPLE 7–18

Determine the output voltage of the temperature-measuring bridge circuit in Figure 7–49 if the thermistor is exposed to a temperature of 50°C and its resistance at 25°C is 1.0 kΩ. Assume the resistance of the thermistor decreases to 900 Ω at 50°C.

▶ **FIGURE 7–49**

Solution

$$\Delta R_{therm} = 1.0\,k\Omega - 900\,\Omega = 100\,\Omega$$

$$\Delta V_{OUT} \cong \Delta R_{therm}\left(\frac{V_S}{4R}\right) = 100\,\Omega\left(\frac{12\,V}{4\,k\Omega}\right) = 0.3\,V$$

Since $V_{OUT} = 0$ V when the bridge is balanced at 25°C and it changes 0.3 V, then

$$V_{OUT} = \mathbf{0.3\,V}$$

when the temperature is 50°C.

*Related Problem*

If the temperature is increased to 60°C, causing the thermistor resistance in Figure 7–49 to decrease to 850 Ω, what is V_{OUT}?

Other Unbalanced Wheatstone Bridge Applications A Wheatstone bridge with a strain gauge can be used to measure forces. A strain gauge is a device that exhibits a change in resistance when it is compressed or stretched by the application of an external force. As the resistance of the strain gauge changes, the previously balanced bridge becomes unbalanced. This unbalance causes the output voltage to change from zero, and this change can be measured to determine the amount of strain. In strain gauges, the resistance change is extremely small. This tiny change unbalances a Wheatstone bridge and can be detected because of its high sensitivity. For example, Wheatstone bridges with strain gauges are commonly used in weight scales.

Some resistive transducers have extremely small resistance changes, and these changes are difficult to measure accurately with a direct measurement. In particular, strain gauges are one

of the most useful resistive transducers that convert the stretching or compression of a fine wire into a change in resistance. When strain causes the wire in the gauge to stretch, the resistance increases a small amount; and when it compresses, the resistance of the wire decreases.

Strain gauges are used in many types of scales, from those that are used for weighing small parts to those for weighing huge trucks. Typically, the gauges are mounted on a special block of aluminum that deforms when a weight is on the scale. The strain gauges are extremely delicate and must be mounted properly, so the entire assembly is generally prepared as a single unit called a *load cell*. A **load cell** is a transducer that uses strain gauges to convert mechanical force into an electrical signal. A wide variety of load cells with different shapes and sizes are available from manufacturers depending on the application. A typical S-type load cell for a weighing application is shown in Figure 7–50(a). The load cell has four strain gauges as illustrated in Figure 7–50(b). The gauges are mounted so that two of the gauges stretch (tension) when a load is placed on the scale and two of the gauges compress.
(a) A typical S-type load cell
(b) A load cell with four active strain gauges (two compression, two tension)
(c) Wheatstone bridge

▲ **FIGURE 7–50**

Wheatstone bridge in a scale application.

Load cells are usually connected to a Wheatstone bridge as shown in Figure 7–50(c) with strain gauges (SG) in tension (T) and compression (C) in opposite diagonal legs as shown. The output of the bridge is normally digitized and converted to a reading for a display or sent to a computer for processing. The major advantage of the Wheatstone bridge circuit is that it is capable of accurately measuring very small differences in resistance. The use of four active transducers increases the sensitivity of the measurement and makes the bridge the ideal circuit for instrumentation. The Wheatstone bridge circuit has the added benefit of compensating for temperature variations and wire resistance of connecting wires that would otherwise contribute to inaccuracies.

In addition to scales, strain gauges are used with Wheatstone bridges in other types of measurements including pressure measurements, displacement and acceleration measurements to name a few. In pressure measurements, the strain gauges are bonded to a flexible diaphragm that stretches when pressure is applied to the transducer. The amount of flexing is related to the pressure, which again converts to a very small resistance change.

7–7   TROUBLESHOOTING

As you know, troubleshooting is the process of identifying and locating a failure or problem in a circuit. Some troubleshooting techniques and the application of logical thought have already been discussed in relation to both series circuits and parallel circuits. A basic premise of troubleshooting is that you must know what to look for before you can successfully troubleshoot a circuit.

After completing this section, you should be able to

◆ **Troubleshoot series-parallel circuits**

   ◆ Determine the effects of an open in a circuit

   ◆ Determine the effects of a short in a circuit

   ◆ Locate opens and shorts

Opens and shorts are typical problems that occur in electric circuits. As mentioned in Chapter 5, if a resistor burns out, it will normally produce an open. Bad solder connections, broken wires, and poor contacts can also be causes of open paths. Pieces of foreign material, such as solder splashes, broken insulation on wires, and so on, can lead to shorts in a circuit. A short is considered to be a zero resistance path between two points.

In addition to complete opens or shorts, partial opens or partial shorts can develop in a circuit. A partial open would be a much higher than normal resistance, but not infinitely large. A partial short would be a much lower than normal resistance, but not zero.

The following three examples illustrate troubleshooting series-parallel circuits.

EXAMPLE 7–19

From the indicated voltmeter reading in Figure 7–51, determine if there is a fault by applying the APM approach. If there is a fault, identify it as either a short or an open.

◆ **FIGURE 7–51**
Solution   **Step 1:** Analysis

Determine what the voltmeter should be indicating as follows. Since R_2 and R_3 are in parallel, their combined resistance is

$$R_{2\|3} = \frac{R_2 R_3}{R_2 + R_3} = \frac{(4.7\,k\Omega)(10\,k\Omega)}{14.7\,k\Omega} = 3.20\,k\Omega$$

Determine the voltage across the parallel combination by the voltage-divider formula.

$$V_{2\|3} = \left(\frac{R_{2\|3}}{R_1 + R_{2\|3}}\right)V_S = \left(\frac{3.2\,k\Omega}{18.2\,k\Omega}\right)24\,V = 4.22\,V$$

This calculation shows that 4.22 V is the voltage reading that you should get on the meter. However, the meter reads 9.6 V across $R_{2\|3}$. This value is incorrect, and, because it is higher than it should be, either R_2 or R_3 is probably open. Why? Because if either of these two resistors is open, the resistance across which the meter is connected is larger than expected. A higher resistance will drop a higher voltage in this circuit.

Step 2: Planning

Start trying to find the open resistor by assuming that R_2 is open. If it is, the voltage across R_3 is

$$V_3 = \left(\frac{R_3}{R_1 + R_3} \right)V_S = \left(\frac{10 \text{ k}\Omega}{25 \text{ k}\Omega} \right)24 \text{ V} = 9.6 \text{ V}$$

Since the measured voltage is also 9.6 V, this calculation shows that R_2 is probably open.

Step 3: Measurement

Disconnect power and remove R_2. Measure its resistance to verify it is open. If it is not, inspect the wiring, solder, or connections around R_2, looking for the open.

*Related Problem*   What would be the voltmeter reading if R_3 were open in Figure 7–51? If R_1 were open?

Open Multisim file E07-19 and verify the result in this example by removing R_2 to simulate an open and observe the meter reading.

EXAMPLE 7–20

Suppose that you measure 24 V with the voltmeter in Figure 7–52. Determine if there is a fault, and, if there is, identify it.

▶ **FIGURE 7–52**

Solution   **Step 1:** Analysis

There is no voltage drop across R_1 because both sides of the resistor are at +24 V. Either there is no current through R_1 from the source, which tells you that R_2 is open in the circuit, or R_1 is shorted.

Step 2: Planning

The most probable failure is an open R_2. If it is open, then there will be no current from the source. To verify this, measure across R_2 with the voltmeter. If R_2 is open, the meter will indicate 24 V. The right side of R_2 will be at zero volts because there is no current through any of the other resistors to cause a voltage drop across them.

Step 3: Measurement

The measurement to verify that R_2 is open is shown in Figure 7–53.

◆ FIGURE 7–53
Related Problem   What would be the voltage across an open R_5 in Figure 7–52 assuming no other faults?

Open Multisim file E07-20 and confirm the fault by measurement.

EXAMPLE 7–21

The two voltmeters in Figure 7–54 indicate the voltages shown. Apply logical thought and your knowledge of circuit operation to determine if there are any opens or shorts in the circuit and, if so, where they are located.

◆ FIGURE 7–54
Solution   **Step 1:**   Determine if the voltmeter readings are correct. $R_1, R_2,$ and R_3 act as a voltage divider. Calculate the voltage (V_A) across R_3 as follows:

$$V_A = \left(\frac{R_3}{R_1 + R_2 + R_3} \right) V_S = \left(\frac{3.3\,\text{k}\Omega}{21.6\,\text{k}\Omega} \right) 24\,\text{V} = 3.67\,\text{V}$$

The voltmeter A reading is correct. This indicates that $R_1, R_2,$ and R_3 are connected and are not faulty.

Step 2:   See if the voltmeter B reading is correct. $R_6 + R_7$ is in parallel with R_5. The series-parallel combination of $R_5, R_6,$ and R_7 is in series with R_4. Calculate the resistance of the $R_5, R_6,$ and R_7 combination as follows:

$$R_{5\|(6+7)} = \frac{R_5(R_6 + R_7)}{R_5 + R_6 + R_7} = \frac{(10\,\text{k}\Omega)(17.2\,\text{k}\Omega)}{27.2\,\text{k}\Omega} = 6.32\,\text{k}\Omega$$

$R_{5\|(6+7)}$ and R_4 form a voltage divider, and voltmeter B measures the voltage across $R_{5\|(6+7)}$. Is it correct? Check as follows:

$$V_B = \left(\frac{R_{5\|(6+7)}}{R_4 + R_{5\|(6+7)}} \right) V_S = \left(\frac{6.32\,\text{k}\Omega}{11\,\text{k}\Omega} \right) 24\,\text{V} = 13.8\,\text{V}$$

Thus, the actual measured voltage (6.65 V) at this point is incorrect. Some logical thinking will help to isolate the problem.

Step 3: R_4 is not open, because if it were, the meter would read 0 V. If there were a short across it, the meter would read 24 V. Since the actual voltage is much less than it should be, $R_{5\|(6+7)}$ must be less than the calculated value of 6.32 kΩ. The most likely problem is a short across R_7. If there is a short from the top of R_7 to ground, R_6 is effectively in parallel with R_5. In this case,

$$R_5 \| R_6 = \frac{R_5 R_6}{R_5 + R_6} = \frac{(10\,\text{k}\Omega)(2.2\,\text{k}\Omega)}{12.2\,\text{k}\Omega} = 1.80\,\text{k}\Omega$$

Then V_B is

$$V_B = \left(\frac{1.80\,\text{k}\Omega}{6.5\,\text{k}\Omega}\right)24\,\text{V} = 6.65\,\text{V}$$

This value for V_B agrees with the voltmeter B reading. So there is a short across R_7. If this were an actual circuit, you would try to find the physical cause of the short.

Related Problem   If the only fault in Figure 7–54 is that R_2 is shorted, what will voltmeter A read? What will voltmeter B read?

Open Multisim file E07-21 and verify the fault by measurement.

Application Activity

The Wheatstone bridge is widely used in measurement applications that use sensors to convert a physical parameter to a change in resistance. Modern Wheatstone bridges are automated; with intelligent interface modules, the output can be conditioned and converted to any desired unit for display or processing (for example, the output might be displayed in pounds for a scale application).

The Wheatstone bridge provides a null measurement, which enables it to have great sensitivity. It can also be designed to compensate for changes in temperature, a great advantage for many resistive measurements, particularly when the resistance change of the sensor is very small. Usually, the output voltage of the bridge is increased by an amplifier that has a minimum loading effect on the bridge.

Temperature Controller

In this application activity, a Wheatstone bridge circuit is used in a temperature controller. The sensor is a thermistor ("thermal resistor"), which is a resistive sensor that changes resistance as temperature changes. Thermistors are available with positive or negative resistance characteristics as a function of temperature. The thermistor in this circuit is one of the resistors in a Wheatstone bridge but is located a short distance from the circuit board for sensing the temperature at a point off the board. The threshold voltage for the output to change is controlled by the $10\,k\Omega$ potentiometer, R_3.

The amplifier and LEDs are shown only to provide a context for this wheatstone bridge application and are not intended to be the focus. You will study operational amplifiers in a later course. The amplifier is an operational amplifier ("op-amp"), which is an integrated circuit. The term *amplifier* is used in electronics to describe a device that produces a larger replica of the input

voltage or current at its output. The term *gain* refers to the amount of amplification. The op-amp in this circuit is configured as a *comparator,* which is be used to compare the voltage on one side of the bridge with the voltage on the other.

The advantage of a comparator is that it is extremely sensitive to an unbalanced bridge and produces a large output when the bridge is unbalanced. In fact, it is so sensitive, it is virtually impossible to adjust the bridge for perfect balance. Even the tiniest imbalance will cause the output to go to a voltage near either the maximum or minimum possible (the power supply voltages). This is handy for turning on a heater or other device based on the temperature.

The Control Circuit

This application has a tank containing a liquid that needs to be held at a warm temperature, as illustrated in Figure 7–57(a). The circuit board for the temperature controller is shown in Figure 7–57(b). The circuit board controls a heating unit (through an interface, which is not shown) when the temperature is too cold. The thermistor, which is located in the tank, is connected between one of the amplifier inputs and ground as illustrated.

The op-amp has two inputs, an output, and connections for positive and negative supply voltages. The schematic symbol for the op-amp with light-emitting diodes (LEDs) connected to the output is shown in Figure 7–58. The red LED is on when the op-amp output is a positive voltage, indicating the heater is on. The green LED is on when the output is a negative voltage, indicating the heater is off.
1. Using the circuit board as a guide, complete the schematic in Figure 7–58. The op-amp inputs are connected to a Wheatstone bridge. Show the values for all resistors.

The op-amp and output LED indicators.

The Thermistor

The thermistor is a mixture of two metal-oxides, which exhibit a large resistance change as a function of temperature. The thermistor in the temperature controller circuit is located off the board near the point where temperature is to be sensed in the tank and is connected between the thermistor input and ground.

Thermistors have a nonlinear resistance-temperature characteristic described by the exponential equation:

$$R_T = R_0 e^{\beta\left(\frac{T_0-T}{T_0 T}\right)}$$

Where:

R_T = the resistance at a given temperature

R_0 = the resistance at a reference temperature

T_0 = the reference temperature in Kelvin (K), typically 298 K, which is 25°C

T = temperature in K

β = a constant (K) provided by the manufacturer

This exponential equation where e is the base of natural logarithms can be solved easily on a scientific calculator. Exponential equations are studied in Chapters 12 and 13.

The thermistor in this application is a Thermometrics RL2006-13.3K-140-D1 thermistor with a specified resistance of 25 kΩ at 25°C and a β of 4615 K. For convenience, the resistance of this thermistor is plotted as a function of temperature in Figure 7–59. Notice that the negative slope indicates this thermistor has a negative temperature coefficient (NTC); that is, its resistance decreases as the temperature increases.

As an example, the calculation for finding the resistance at $T = 50°C$ is shown. First, convert 50°C to K.

$$T = °C + 273 = 50°C + 273 = 323 \text{ K}$$

Also,

$$T_0 = °C + 273 = 25°C + 273 = 298 \text{ K}$$
$$R_0 = 25 \text{ k}\Omega$$
$$R_T = R_0 e^{\beta\left(\frac{T_0-T}{T_0 T}\right)}$$
$$= (25 \text{ k}\Omega)e^{4615\left(\frac{298-323}{298\times323}\right)}$$
$$= (25 \text{ k}\Omega)e^{-1.198}$$
$$= (25 \text{ k}\Omega)(0.302)$$
$$= 7.54 \text{ k}\Omega$$

SUMMARY

◆ A series-parallel circuit is a combination of both series and parallel current paths.

◆ To determine total resistance in a series-parallel circuit, identify the series and parallel relationships, and then apply the formulas for series resistance and parallel resistance from Chapters 5 and 6.

◆ To find the total current, apply Ohm's law and divide the total voltage by the total resistance.

◆ To determine branch currents, apply the current-divider formula, Kirchhoff's current law, or Ohm's law. Consider each circuit problem individually to determine the most appropriate method.

◆ To determine voltage drops across any portion of a series-parallel circuit, use the voltage-divider formula, Kirchhoff's voltage law, or Ohm's law. Consider each circuit problem individually to determine the most appropriate method.

◆ When a load resistor is connected across a voltage-divider output, the output voltage decreases.

◆ The load resistor should be large compared to the resistance across which it is connected, in order that the loading effect may be minimized.

◆ To find total resistance of a ladder network, start at the point farthest from the source and reduce the resistance in steps.

◆ A balanced Wheatstone bridge can be used to measure an unknown resistance.

◆ A bridge is balanced when the output voltage is zero. The balanced condition produces zero current through a load connected across the output terminals of the bridge.

◆ An unbalanced Wheatstone bridge can be used to measure physical quantities using transducers.

◆ Opens and shorts are typical circuit faults.

◆ Resistors normally open when they burn out.

INTRODUCTION

In previous chapters, you analyzed various types of circuits using Ohm's law and Kirchhoff's laws. Some types of circuits are difficult to analyze using only those basic laws and require additional methods in order to simplify the analysis.

The theorems and conversions in this chapter make analysis easier for certain types of circuits. These methods do not replace Ohm's law and Kirchhoff's laws, but they are normally used in conjunction with the laws in certain situations.

Because all electric circuits are driven by either voltage sources or current sources, it is important to understand how to work with these elements. The superposition theorem will help you to deal with circuits that have multiple sources. Thevenin's and Norton's theorems provide methods for reducing a circuit to a simple equivalent form for ease of analysis. The maximum power transfer theorem is used in applications where it is important for a given circuit to provide maximum power to a load. An example of this is an audio amplifier that provides maximum power to a speaker. Delta-to-wye and wye-to-delta conversions are sometimes useful when you analyze bridge circuits that are commonly found in systems that measure physical parameters such as temperature, pressure, and strain.

8–1   THE DC VOLTAGE SOURCE

As you learned in Chapter 2, the dc voltage source is one of the principal types of energy source in electronic applications, so it is important to understand its characteristics. The dc voltage source ideally provides constant voltage to a load even when the load resistance varies.

After completing this section, you should be able to

◆ **Describe the characteristics of a dc voltage source**

　　◆ Compare a practical voltage source to an ideal source

　　◆ Discuss the effect of loading on a practical voltage source

Figure 8–1(a) is the familiar symbol for an ideal dc voltage source. The voltage across its terminals, A and B, remains fixed regardless of the value of load resistance that may be connected across its output. Figure 8–1(b) shows a load resistor, R_L, connected. All of the source voltage, V_S, is dropped across R_L. Ideally, R_L can be changed to any value except zero, and the voltage will remain fixed. The ideal voltage source has an internal resistance of zero.

▶ **FIGURE 8–1**

Ideal dc voltage source.

(a) Unloaded　　　　　(b) Loaded
In reality, no voltage source is ideal; however, regulated power supplies can approach ideal when operated within the specified output current. All voltage sources have some inherent internal resistance as a result of their physical and/or chemical makeup, which can be represented by a resistor in series with an ideal source, as shown in Figure 8–2(a). R_S is the internal source resistance and V_S is the source voltage. With no load, the output voltage (voltage from A to B) is V_S. This voltage is sometimes called the *open circuit voltage.*

Loading of the Voltage Source

When a load resistor is connected across the output terminals, as shown in Figure 8–2(b), all of the source voltage does not appear across R_L. Some of the voltage is dropped across R_S because R_S and R_L are in series.

If R_S is very small compared to R_L, the source approaches ideal because almost all of the source voltage, V_S, appears across the larger resistance, R_L. Very little voltage is dropped across the internal resistance, R_S. If R_L changes, most of the source voltage remains across the output as long as R_L is much larger than R_S. As a result, very little change occurs in the output voltage. The larger R_L is, compared to R_S, the less change there is in the output voltage. Example 8–1 illustrates the effect of changes in R_L on the output voltage when R_L is much greater than R_S.

EXAMPLE 8–1

Calculate the voltage output of the source in Figure 8–3 for the following values of R_L: 100 Ω, 560 Ω, and 1.0 kΩ.

▶ **FIGURE 8–3**
Solution For $R_L = 100\ \Omega$, the voltage output is

$$V_{OUT} = \left(\frac{R_L}{R_S + R_L}\right)V_S = \left(\frac{100\ \Omega}{110\ \Omega}\right)100\ \text{V} = \textbf{90.9 V}$$

For $R_L = 560\ \Omega$,

$$V_{OUT} = \left(\frac{560\ \Omega}{570\ \Omega}\right)100\ \text{V} = \textbf{98.2 V}$$

For $R_L = 1.0\ \text{k}\Omega$,

$$V_{OUT} = \left(\frac{1000\ \Omega}{1010\ \Omega}\right)100\ \text{V} = \textbf{99.0 V}$$

Notice that the output voltage is within 10% of the source voltage, V_S, for all three values of R_L because R_L is at least ten times R_S.

Related Problem* Determine V_{OUT} in Figure 8–3 if $R_S = 50\ \Omega$ and $R_L = 10\ \text{k}\Omega$.

Use Multisim file E08-01 to verify the calculated results in this example and to confirm your calculation for the related problem.

---

*Answers are at the end of the chapter.

The output voltage decreases significantly as the load resistance is made smaller compared to the internal source resistance. Example 8–2 illustrates the effect of a smaller R_L and confirms the requirement that R_L must be much larger than R_S (at least 10 times) in order to maintain the output voltage near its open circuit value.

EXAMPLE 8–2

Determine V_{OUT} for $R_L = 10 \, \Omega$ and for $R_L = 1.0 \, \Omega$ in Figure 8–3.

Solution   For $R_L = 10 \, \Omega$, the voltage output is

$$V_{OUT} = \left(\frac{R_L}{R_S + R_L} \right) V_S = \left(\frac{10 \, \Omega}{20 \, \Omega} \right) 100 \text{ V} = \mathbf{50 \text{ V}}$$

For $R_L = 1.0 \, \Omega$,

$$V_{OUT} = \left(\frac{1.0 \, \Omega}{11 \, \Omega} \right) 100 \text{ V} = \mathbf{9.09 \text{ V}}$$

4. What effect does the load have on the output voltage of the practical voltage source?

8–2 THE CURRENT SOURCE

As you learned in Chapter 2, the current source is another type of energy source that ideally provides a constant current to a variable load. The concept of the current source is important in certain types of transistor circuits.

After completing this section, you should be able to

◆ **Describe the characteristics of a current source**

  ◆ Compare a practical current source to an ideal source

  ◆ Discuss the effect of loading on a practical current source

Figure 8–4(a) shows a symbol for the ideal current source. The arrow indicates the direction of source current, I_S. An ideal current source produces a constant value of current through a load, regardless of the value of the load. This concept is illustrated in Figure 8–4(b), where a load resistor is connected to the current source between terminals A and B. The ideal current source has an infinitely large internal parallel resistance.

▶ **FIGURE 8–4**

Ideal current source.

(a) Unloaded   (b) Loaded
Transistors act basically as current sources, and for this reason, knowledge of the current source concept is important. You will find that the equivalent model of a transistor does contain a current source.

Although the ideal current source can be used in most analysis work, no actual device is ideal. A practical current source representation is shown in Figure 8–5. Here the internal resistance appears in parallel with the ideal current source.

Current source

◀ FIGURE 8–5

Practical current source with load.

If the internal source resistance, R_S, is much larger than a load resistor, the practical source approaches ideal. The reason is illustrated in the practical current source shown in Figure 8–5. Part of the current, I_S, is through R_S, and part is through R_L. The internal source resistance, R_S, and the load resistor, R_L, act as a current divider. If R_S is much larger than R_L, most of the current is through R_L and very little through R_S. As long as R_L remains much smaller than R_S, the current through R_L will stay almost constant, no matter how much R_L changes.

If there is a constant-current source, you can normally assume that R_S is so much larger than the load resistance that R_S can be neglected. This simplifies the source to ideal, making the analysis easier.

Example 8–3 illustrates the effect of changes in R_L on the load current when R_L is much smaller than R_S. Generally, R_L should be at least ten times smaller than R_S ($10R_L \leq R_S$) for a source to act as a reasonable current source.

EXAMPLE 8–3

Calculate the load current (I_L) in Figure 8–6 for the following values of R_L: 1 kΩ, 5.6 kΩ, and 10 kΩ.

▶ FIGURE 8–6
Solution For $R_L = 1$ kΩ, the load current is

$$I_L = \left(\frac{R_S}{R_S + R_L}\right)I_S = \left(\frac{100\ \text{k}\Omega}{101\ \text{k}\Omega}\right)1\ \text{A} = \textbf{990 mA}$$

For $R_L = 5.6$ kΩ,

$$I_L = \left(\frac{100\ \text{k}\Omega}{105.6\ \text{k}\Omega}\right)1\ \text{A} = \textbf{947 mA}$$

For $R_L = 10\ \text{k}\Omega$,

$$I_L = \left(\frac{100\ \text{k}\Omega}{110\ \text{k}\Omega}\right)1\ \text{A} = \mathbf{909\ mA}$$

Notice that the load current, I_L, is within 10% of the source current for each value of R_L because R_L is at least ten times smaller than R_S in each case.

Related Problem   At what value of R_L in Figure 8–6 will the load current equal 750 mA?

8–3 SOURCE CONVERSIONS

In circuit analysis, it is sometimes useful to convert a voltage source to an equivalent current source, or vice versa.

After completing this section, you should be able to

◆ **Perform source conversions**

   ◆ Convert a voltage source to a current source

   ◆ Convert a current source to a voltage source

   ◆ Define *terminal equivalency*

Converting a Voltage Source to a Current Source

The source voltage, V_S, divided by the internal source resistance, R_S, gives the value of the equivalent source current.

$$I_S = \frac{V_S}{R_S}$$

The value of R_S is the same for both the voltage and current sources. As illustrated in Figure 8–7, the directional arrow for the current points from plus to minus. The equivalent current source is in parallel with R_S.

▶ **FIGURE 8–7**

Conversion of voltage source to equivalent current source.

(a) Voltage source   (b) Current source
Equivalency of two sources means that for any given load resistance connected to the two sources, the same load voltage and load current are produced by both sources. This concept is called **terminal equivalency**.

You can show that the voltage source and the current source in Figure 8–7 are equivalent by connecting a load resistor to each, as shown in Figure 8–8, and then calculating the load current. For the voltage source, the load current is

$$I_L = \frac{V_S}{R_S + R_L}$$

(a) Loaded voltage source   (b) Loaded current source
▲ **FIGURE 8–8**

Equivalent sources with loads.
For the current source,

$$I_L = \left(\frac{R_S}{R_S + R_L} \right) \frac{V_S}{R_S} = \frac{V_S}{R_S + R_L}$$

As you see, both expressions for I_L are the same. These equations show that the sources are equivalent as far as the load or terminals A and B are concerned.

EXAMPLE 8–4

Convert the voltage source in Figure 8–9 to an equivalent current source and show the equivalent circuit.

▸ **FIGURE 8–9**

Solution   The value of the internal resistance, R_S, of the equivalent current is the same as the internal resistance of the voltage source. Therefore, the equivalent current source is

$$I_S = \frac{V_S}{R_S} = \frac{100 \text{ V}}{47 \text{ } \Omega} = 2.13 \text{ A}$$

Figure 8–10 shows the equivalent circuit.

▶ FIGURE 8–10

Related Problem   Determine I_S and R_S of a current source equivalent to a voltage source with $V_S = 12$ V and $R_S = 10$ Ω.

Converting a Current Source to a Voltage Source

The source current, I_S, multiplied by the internal source resistance, R_S, gives the value of the equivalent source voltage.

$$V_S = I_S R_S$$

Again, R_S remains the same. The polarity of the voltage source is plus to minus in the direction of the current. The equivalent voltage source is the voltage in series with R_S, as illustrated in Figure 8–11.

8–4   THE SUPERPOSITION THEOREM

Some circuits use more than one voltage or current source. For example, most amplifiers operate with two voltage sources: an ac and a dc source. Additionally, some amplifiers require both a positive and a negative dc voltage source for proper operation. When multiple sources are used in a circuit, the superposition theorem provides a method for analysis.

After completing this section, you should be able to

◆ **Apply the superposition theorem to circuit analysis**

  ◆ State the superposition theorem

  ◆ List the steps in applying the theorem

The superposition method is a way to determine currents in a circuit with multiple sources by leaving one source at a time and replacing the other sources by their internal resistances. Recall that an ideal voltage source has a zero internal resistance and an ideal current source has infinite internal resistance. All sources will be treated as ideal in order to simplify the coverage.

A general statement of the **superposition theorem** is as follows:

The current in any given branch of a multiple-source circuit can be found by determining the currents in that particular branch produced by each source acting alone, with all other sources replaced by their internal resistances. The total current in the branch is the algebraic sum of the individual currents in that branch.

The steps in applying the superposition method are as follows:

Step 1: Leave one voltage (or current) source at a time in the circuit and replace each of the other voltage (or current) sources with its internal resistance. For ideal sources a short represents zero internal resistance and an open represents infinite internal resistance.

Step 2: Determine the particular current (or voltage) that you want just as if there were only one source in the circuit.

Step 3: Take the next source in the circuit and repeat Steps 1 and 2. Do this for each source.

Step 4: To find the actual current in a given branch, algebraically sum the currents due to each individual source. Once you find the current, you can determine the voltage using Ohm's law.

The approach to superposition is demonstrated in Figure 8–16 for a series-parallel circuit with two ideal voltage sources. Study the steps in this figure.

▲ **FIGURE 8–16**

Demonstration of the superposition method.

EXAMPLE 8–6   Use the superposition theorem to find the current through R_2 of Figure 8–17.
Solution   **Step 1:** Replace V_{S2} with a short and find the current through R_2 due to voltage source V_{S1}, as shown in Figure 8–18. To find I_2, use the current-divider formula (Equation 6–6). Looking from V_{S1},

$$R_{T(S1)} = R_1 + \frac{R_3}{2} = 100\ \Omega + 50\ \Omega = 150\ \Omega$$

$$I_{T(S1)} = \frac{V_{S1}}{R_{T(S1)}} = \frac{10\ V}{150\ \Omega} = 66.7\ mA$$

The current through R_2 due to V_{S1} is

$$I_{2(S1)} = \left(\frac{R_3}{R_2 + R_3}\right)I_{T(S1)} = \left(\frac{100\ \Omega}{200\ \Omega}\right)66.7\ mA = 33.3\ mA$$

Note that this current is upward through R_2.
Step 2: Find the current through R_2 due to voltage source V_{S2} by replacing V_{S1} with a short, as shown in Figure 8–19. Looking from V_{S2},

$$R_{T(S2)} = R_3 + \frac{R_1}{2} = 100\ \Omega + 50\ \Omega = 150\ \Omega$$

$$I_{T(S2)} = \frac{V_{S2}}{R_{T(S2)}} = \frac{5\ V}{150\ \Omega} = 33.3\ mA$$

The current through R_2 due to V_{S2} is

$$I_{2(S2)} = \left(\frac{R_1}{R_1 + R_2}\right)I_{T(S2)} = \left(\frac{100\ \Omega}{200\ \Omega}\right)33.3\ mA = 16.7\ mA$$

Note that this current is upward through R_2.
Step 3: Both component currents are upward through R_2, so they have the same algebraic sign. Therefore, add the values to get the total current through R_2.

$$I_{2(tot)} = I_{2(S1)} + I_{2(S2)} = 33.3 \text{ mA} + 16.7 \text{ mA} = \mathbf{50 \text{ mA}}$$

Related Problem   Determine the total current through R_2 if the polarity of V_{S2} in Figure 8–17 is reversed.

Use Multisim file E08-06 to verify the calculated results in this example and to confirm your calculation for the related problem.

EXAMPLE 8–7   Find the current through R_2 in the circuit of Figure 8–20.
Solution   **Step 1:** Find the current through R_2 due to V_S by replacing I_S with an open, as shown in Figure 8–21.
Notice that all of the current produced by V_S is through R_2. Looking from V_S,

$$R_T = R_1 + R_2 = 320 \ \Omega$$

The current through R_2 due to V_S is

$$I_{2(V_S)} = \frac{V_S}{R_T} = \frac{10 \text{ V}}{320 \ \Omega} = 31.2 \text{ mA}$$

Note that this current is upward through R_2.

Step 2: Find the current through R_2 due to I_S by replacing V_S with a short, as shown in Figure 8–22.

▲ FIGURE 8–22

Use the current-divider formula to determine the current through R_2 due to I_S.

$$I_{2(I_S)} = \left(\frac{R_1}{R_1 + R_2}\right)I_S = \left(\frac{220\,\Omega}{320\,\Omega}\right)100\,\text{mA} = 68.8\,\text{mA}$$

Note that this current also is upward through R_2.

Step 3: Both currents are in the same direction through R_2, so add them to get the total.

$$I_{2(\text{tot})} = I_{2(V_S)} + I_{2(I_S)} = 31.2\,\text{mA} + 68.8\,\text{mA} = \textbf{100 mA}$$

EXAMPLE 8–8

Find the current through the 100 Ω resistor in Figure 8–23.

▶ FIGURE 8–23
Solution **Step 1:** Find the current through the 100 Ω resistor due to current source I_{S1} by replacing source I_{S2} with an open, as shown in Figure 8–24. As you can see, the entire 10 mA from the current source I_{S1} is downward through the 100 Ω resistor.

▶ FIGURE 8–24
Step 2: Find the current through the 100 Ω resistor due to source I_{S2} by replacing source I_{S1} with an open, as indicated in Figure 8–25. Notice that all of the 3 mA from source I_{S2} is upward through the 100 Ω resistor.
▲ FIGURE 8–25

Step 3: To get the total current through the 100 Ω resistor, subtract the smaller current from the larger because they are in opposite directions. The resulting total current is in the direction of the larger current from source I_{S1}.

$$I_{100\Omega(tot)} = I_{100\Omega(I_{S1})} - I_{100\Omega(I_{S2})}$$
$$= 10\,\text{mA} - 3\,\text{mA} = \textbf{7 mA}$$

The resulting current is downward through the resistor.

Solution **Step 1:** Find the current through R_3 due to source V_{S1} by replacing source V_{S2} with a short, as shown in Figure 8–27.

▶ FIGURE 8–27
Looking from V_{S1},

$$R_{T(S1)} = R_1 + \frac{R_2 R_3}{R_2 + R_3} = 1.0\,k\Omega + \frac{(1.0\,k\Omega)(2.2\,k\Omega)}{3.2\,k\Omega} = 1.69\,k\Omega$$

$$I_{T(S1)} = \frac{V_{S1}}{R_{T(S1)}} = \frac{20\,V}{1.69\,k\Omega} = 11.8\,mA$$

Now apply the current-divider formula to get the current through R_3 due to source V_{S1}.

$$I_{3(S1)} = \left(\frac{R_2}{R_2 + R_3}\right)I_{T(S1)} = \left(\frac{1.0\,k\Omega}{3.2\,k\Omega}\right)11.8\,mA = 3.69\,mA$$

Notice that this current is upward through R_3.

Step 2: Find I_3 due to source V_{S2} by replacing source V_{S1} with a short, as shown in Figure 8–28.

▶ FIGURE 8–28
Looking from V_{S2},

$$R_{T(S2)} = R_2 + \frac{R_1 R_3}{R_1 + R_3} = 1.0\,k\Omega + \frac{(1.0\,k\Omega)(2.2\,k\Omega)}{3.2\,k\Omega} = 1.69\,k\Omega$$

$$I_{T(S2)} = \frac{V_{S2}}{R_{T(S2)}} = \frac{15\,V}{1.69\,k\Omega} = 8.88\,mA$$

Now apply the current-divider formula to find the current through R_3 due to source V_{S2}.

$$I_{3(S2)} = \left(\frac{R_1}{R_1 + R_3}\right)I_{T(S2)} = \left(\frac{1.0\,k\Omega}{3.2\,k\Omega}\right)8.88\,mA = 2.78\,mA$$

Notice that this current is downward through R_3.

Step 3: Calculate the total current through R_3.

$$I_{3(tot)} = I_{3(S1)} - I_{3(S2)} = 3.69 \text{ mA} - 2.78 \text{ mA} = 0.91 \text{ mA} = \textbf{910 } \boldsymbol{\mu}\textbf{A}$$

This current is upward through R_3.

Although regulated dc power supplies are close to ideal voltage sources, many ac sources are not. For example, function generators generally have 50 Ω or 600 Ω of internal resistance, which appears as a resistance in series with an ideal source. Also, batteries can look ideal when they are fresh; but as they age, the internal resistance increases. When applying the superposition theorem, it is important to recognize when a source is not ideal and replace it with its equivalent internal resistance.

Current sources are not as common as voltage sources and are also not always ideal. If a current source is not ideal, as in the case of many transistors, it should be replaced by its equivalent internal resistance when the superposition theorem is applied.

- ◆ Thevenize a bridge circuit

The Thevenin equivalent form of any two-terminal resistive circuit consists of an equivalent voltage source (V_{TH}) and an equivalent resistance (R_{TH}), arranged as shown in Figure 8–30. The values of the equivalent voltage and resistance depend on the values in the original circuit. Any resistive circuit can be simplified regardless of its complexity with respect to two output terminals.
◄ **FIGURE 8–30**

The general form of a thevenin equivalent circuit is a voltage source in series with a resistance.

The equivalent voltage, V_{TH}, is one part of the complete Thevenin equivalent circuit. The other part is R_{TH}.

The Thevenin equivalent voltage (V_{TH}) is the open circuit (no-load) voltage between two output terminals in a circuit.

Any component connected between these two terminals effectively "sees" V_{TH} in series with R_{TH}. As defined by **Thevenin's theorem**,

The Thevenin equivalent resistance (R_{TH}) is the total resistance appearing between two terminals in a given circuit with all sources replaced by their internal resistances.

Although a Thevenin equivalent circuit is not the same as its original circuit, it acts the same in terms of the output voltage and current. Try the following demonstration as illustrated in Figure 8–31. Place a resistive circuit of any complexity in a box with only the

(a)

(b)
◄ **FIGURE 8–31**

Which box contains the original circuit and which contains the Thevenin equivalent circuit? You cannot tell by observing the meters.

output terminals exposed. Then place the Thevenin equivalent of that circuit in an identical box with, again, only the output terminals exposed. Connect identical load resistors across the output terminals of each box. Next connect a voltmeter and an ammeter to measure the voltage and current for each load as shown in the figure. The measured values will be identical (neglecting tolerance variations), and you will not be able to determine which box contains the original circuit and which contains the Thevenin equivalent. That is, in terms of your observations based on any electrical measurements, both circuits appear to be the same. This condition is sometimes known as *terminal equivalency* because both circuits look the same from the "viewpoint" of the two output terminals.

To find the Thevenin equivalent of any circuit, determine the equivalent voltage, V_{TH}, and the equivalent resistance, R_{TH}, looking from the output terminals. As an example, the Thevenin equivalent for the circuit between terminals A and B is developed in Figure 8–32.

(a) Finding V_{TH}

(b) Finding R_{TH}

(c) Thevenin equivalent circuit
▲ FIGURE 8–32

Example of the simplification of a circuit by Thevenin's theorem.

In Figure 8–32(a), the voltage across the designated terminals A and B is the Thevenin equivalent voltage. In this particular circuit, the voltage from A to B is the same as the voltage across R_2 because there is no current through R_3 and, therefore, no voltage drop across it. The Thevenin voltage is expressed as follows for this particular example:

$$V_{TH} = \left(\frac{R_2}{R_1 + R_2}\right)V_S$$

In Figure 8–32(b), the resistance between terminals A and B with the source replaced by a short (zero internal resistance) is the Thevenin equivalent resistance. In this particular circuit, the resistance from A to B is R_3 in series with the parallel combination of R_1 and R_2. Therefore, R_{TH} is expressed as follows:

$$R_{TH} = R_3 + \frac{R_1R_2}{R_1 + R_2}$$

The Thevenin equivalent circuit is shown in Figure 8–32(c).

EXAMPLE 8–10

Find the Thevenin equivalent circuit between *A* and *B* of the circuit in Figure 8–33.

▶ **FIGURE 8–33**
Solution

First, remove R_L. Then V_{TH} equals the voltage across $R_2 + R_3$, as shown in Figure 8–34(a), because $V_4 = 0$ V since there is no current through it.

$$V_{TH} = \left(\frac{R_2 + R_3}{R_1 + R_2 + R_3}\right)V_S = \left(\frac{690\ \Omega}{1690\ \Omega}\right)10\ \text{V} = \textbf{4.08 V}$$

To find R_{TH}, first replace the source with a short to simulate a zero internal resistance. Then R_1 appears in parallel with $R_2 + R_3$, and R_4 is in series with the series-parallel combination of R_1, R_2, and R_3, as indicated in Figure 8–34(b).

$$R_{TH} = R_4 + \frac{R_1(R_2 + R_3)}{R_1 + R_2 + R_3} = 1000\ \Omega + \frac{(1000\ \Omega)(690\ \Omega)}{1690\ \Omega} = \textbf{1410 }\Omega$$

The resulting Thevenin equivalent circuit is shown in Figure 8–34(c).

(a) The voltage from *A* to *B* is V_{TH} and equals V_{2+3}.

(b) Looking from terminals *A* and *B*, R_4 appears in series with the combination of R_1 in parallel with $(R_2 + R_3)$.

Thevenin Equivalency Depends on the Viewpoint

The Thevenin equivalent for any circuit depends on the location of the two output terminals from which the circuit is "viewed." In Figure 8–33, you viewed the circuit from between the two terminals labeled A and B. Any given circuit can have more than one Thevenin equivalent, depending on how the output terminals are designated. For example, if you view the circuit in Figure 8–35 from between terminals A and C, you obtain a completely different result than if you viewed it from between terminals A and B or from between terminals B and C.

In Figure 8–36(a), when viewed from between terminals A and C, V_{TH} is the voltage across $R_2 + R_3$ and can be expressed using the voltage-divider formula as

$$V_{TH(AC)} = \left(\frac{R_2 + R_3}{R_1 + R_2 + R_3} \right) V_S$$

Also, as shown in Figure 8–36(b), the resistance between terminals A and C is $R_2 + R_3$ in parallel with R_1 (the source is replaced by a short) and can be expressed as

$$R_{TH(AC)} = \frac{R_1(R_2 + R_3)}{R_1 + R_2 + R_3}$$

The resulting Thevenin equivalent circuit is shown in Figure 8–36(c).

When viewed from between terminals B and C as indicated in Figure 8–36(d), V_{TH} is the voltage across R_3 and can be expressed as

$$V_{TH(BC)} = \left(\frac{R_3}{R_1 + R_2 + R_3} \right) V_S$$

As shown in Figure 8–36(e), the resistance between terminals B and C is R_3 in parallel with the series combination of R_1 and R_2.

$$R_{TH(BC)} = \frac{R_3(R_1 + R_2)}{R_1 + R_2 + R_3}$$

The resulting Thevenin equivalent is shown in Figure 8–36 (f).

Thevenizing a Portion of a Circuit

In many cases, it helps to thevenize only a portion of a circuit. For example, when you need to know the equivalent circuit as viewed by one particular resistor in the circuit, you can remove the resistor and apply Thevenin's theorem to the remaining part of the circuit as viewed from the points between which that resistor was connected. Figure 8–39 illustrates the thevenizing of part of a circuit.

$$V_{TH} = \left(\frac{R_2}{R_1 + R_2} \right) V_S$$

(c) Thevenin equivalent of original circuit with R_3 connected

Using this type of approach, you can easily find the voltage and current for a specified resistor for any number of resistor values using only Ohm's law. This method eliminates the necessity of reanalyzing the original circuit for each different resistance value.

Thevenizing a Bridge Circuit

The usefulness of Thevenin's theorem is perhaps best illustrated when it is applied to a Wheatstone bridge circuit. For example, when a load resistor is connected to the output terminals of a Wheatstone bridge, as shown in Figure 8–40, the circuit is difficult to analyze because it is not a straightforward series-parallel arrangement. There are no resistors that are in series or in parallel with another resistor.

Using Thevenin's theorem, you can simplify the bridge circuit to an equivalent circuit viewed from the load resistor as shown step-by-step in Figure 8–41. Study carefully the steps in this figure. Once the equivalent circuit for the bridge is found, the voltage and current for any value of load resistor can easily be determined.

EXAMPLE 8–12

Determine the voltage and current for the load resistor, R_L, in the bridge circuit of Figure 8–42.

▶ **FIGURE 8–42**
Solution **Step 1:** Remove R_L.

Step 2: To thevenize the bridge as viewed from between terminals A and B, as was shown in Figure 8–41, first determine V_{TH}.

$$V_{TH} = V_A - V_B = \left(\dfrac{R_2}{R_1 + R_2}\right)V_S - \left(\dfrac{R_4}{R_3 + R_4}\right)V_S$$

$$= \left(\dfrac{680\ \Omega}{1010\ \Omega}\right)24\ \text{V} - \left(\dfrac{560\ \Omega}{1240\ \Omega}\right)24\ \text{V} = 16.16\ \text{V} - 10.84\ \text{V} = 5.32\ \text{V}$$

Step 3: Determine R_{TH}.

$$R_{TH} = \frac{R_1 R_2}{R_1 + R_2} + \frac{R_3 R_4}{R_3 + R_4}$$

$$= \frac{(330\ \Omega)(680\ \Omega)}{1010\ \Omega} + \frac{(680\ \Omega)(560\ \Omega)}{1240\ \Omega} = 222\ \Omega + 307\ \Omega = 529\ \Omega$$

Step 4: Place V_{TH} and R_{TH} in series to form the Thevenin equivalent circuit.

Step 5: Connect the load resistor between terminals A and B of the equivalent circuit, and determine the load voltage and current as illustrated in Figure 8–43.

$$V_L = \left(\frac{R_L}{R_L + R_{TH}}\right) V_{TH} = \left(\frac{1.0\ \text{k}\Omega}{1.529\ \text{k}\Omega}\right) 5.32\ \text{V} = \mathbf{3.48\ V}$$

$$I_L = \frac{V_L}{R_L} = \frac{3.48\ \text{V}}{1.0\ \text{k}\Omega} = \mathbf{3.48\ mA}$$

Use Multisim files E08-12A and E08-12B to verify the calculated results in this example and to confirm your calculation for the related problem.

An Alternate Approach An alternate way to thevenize the Wheatstone bridge is to consider a different viewpoint. Instead of viewing it from between the A and B terminals, you can view it from terminal A to ground and from terminal B to ground, as illustrated in Figure 8–44(a) and (b). The resulting equivalent circuit is simplified into two facing Thevenin circuits that still include ground, as illustrated in Figure 8–44(c). When calculating the Thevenin resistance, replace the voltage source by a short; thus, two of the bridge resistors are shorted out. In Figure 8–44(a), R_3 and R_4 are shorted and in part (b) R_1 and R_2 are shorted. In each case, the remaining two resistors appear in parallel to form the Thevenin resistance. The load resistor can be replaced as in Figure 8–44(d), which is seen to be a simple series circuit with two opposing sources. The advantage of this method is that ground is still shown in this equivalent circuit, so it is easy to find the voltage at terminal A or B with respect to ground by applying the superposition theorem to the equivalent circuit.

Summary of Thevenin's Theorem

Remember, the Thevenin equivalent circuit is *always* in the form of an equivalent voltage source in series with an equivalent resistance regardless of the original circuit that it replaces.

(a) Viewed between A and ground   (b) Viewed between B and ground

(c) Equivalent facing Thevenin circuits   (d) Load resistor connected
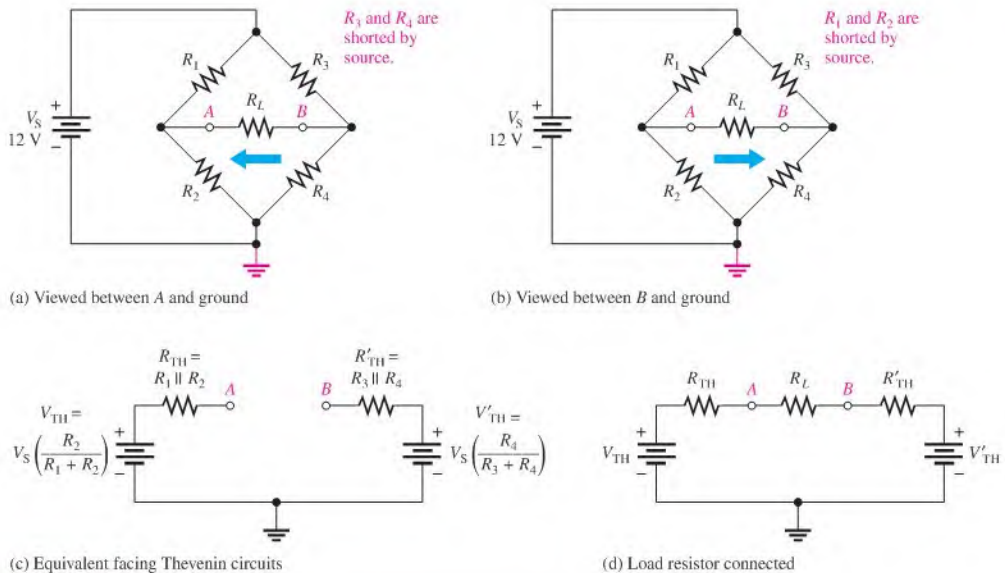

▲ **FIGURE 8–44**

The significance of Thevenin's theorem is that the equivalent circuit can replace the original circuit as far as any external load is concerned. Any load resistor connected between the terminals of a Thevenin equivalent circuit will have the same current through it and the same voltage across it as if it were connected to the terminals of the original circuit.

A summary of steps for applying Thevenin's theorem is as follows:

Step 1: Open the two terminals (remove any load) between which you want to find the Thevenin equivalent circuit.

Step 2: Determine the voltage (V_{TH}) across the two open terminals.

Step 3: Determine the resistance (R_{TH}) between the two open terminals with all sources replaced with their internal resistances (ideal voltage sources shorted and ideal current sources opened).

Step 4: Connect V_{TH} and R_{TH} in series to produce the complete Thevenin equivalent for the original circuit.

Step 5: Replace the load removed in Step 1 across the terminals of the Thevenin equivalent circuit. You can now calculate the load current and load voltage using only Ohm's law. They have the same value as the load current and load voltage in the original circuit.

Determining V_{TH} and R_{TH} by Measurement

Thevenin's theorem is largely an analytical tool that is applied theoretically in order to simplify circuit analysis. However, you can find Thevenin's equivalent for an actual circuit by the following general measurement methods. These steps are illustrated in Figure 8–45.

Step 1: Remove any load from the output terminals of the circuit.

Step 2: Measure the open terminal voltage. The voltmeter used must have an internal resistance much greater (at least 10 times greater) than the R_{TH} of the circuit so that it has negligible loading effect. (V_{TH} is the open terminal voltage.)

Step 1: Open the output terminals (remove load).

Step 2: Measure V_{TH}.

Step 3: Connect variable load resistance set to its maximum value across the terminals.

Step 4: Adjust R_L until $V_L = 0.5V_{TH}$. When $V_L = 0.5V_{TH}$, $R_L = R_{TH}$.

Step 5: Remove R_L from the circuit under test and measure its resistance to get R_{TH}.
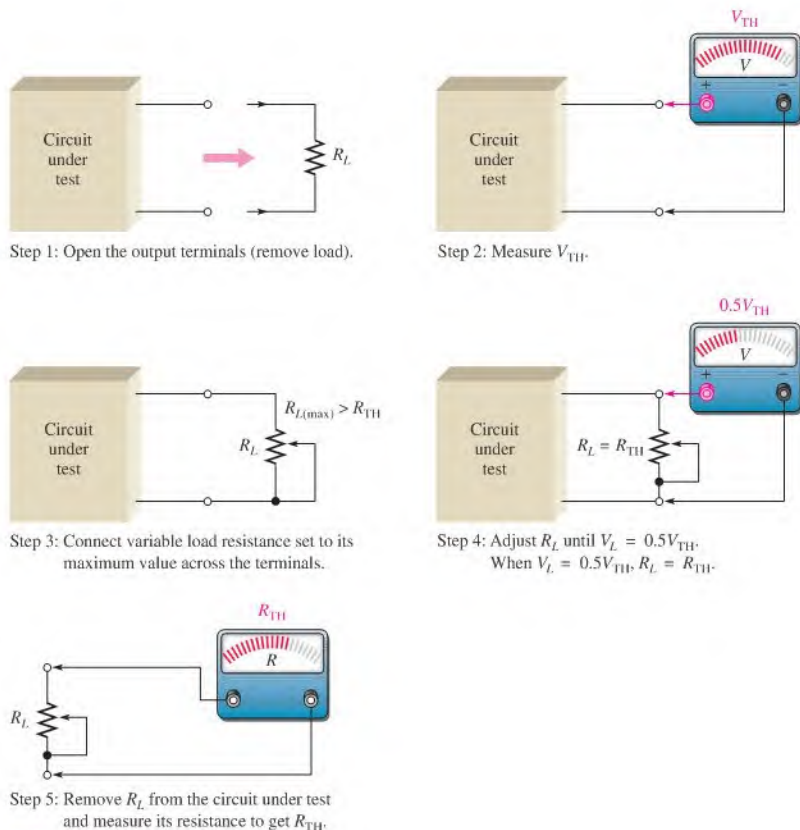

▲ FIGURE 8–45

Determination of Thevenin's equivalent by measurement.

Step 3: Connect a variable resistor (rheostat) across the output terminals. Set it at its maximum value, which must be greater than R_{TH}.

Step 4: Adjust the rheostat until the terminal voltage equals $0.5V_{TH}$. At this point, the resistance of the rheostat is equal to R_{TH}.

Step 5: Disconnect the rheostat from the terminals and measure its resistance with an ohmmeter. This measured resistance is equal to R_{TH}.

This procedure for determining R_{TH} differs from the theoretical procedure because it is impractical to short voltage sources or open current sources in an actual circuit. Also, when measuring R_{TH}, be certain that the circuit is capable of providing the required current to the variable resistor load and that the variable resistor can handle the required power. These considerations may make the procedure impractical in some cases.

An Example of a Practical Application

Although you have not studied transistor circuits, a basic amplifier can be used to illustrate the usefulness of Thevenin's equivalent circuit. A transistor circuit can be modeled with basic components including a dependent current source and a Thevenin equivalent

circuit. Modeling is generally a mathematical simplification of a complex circuit, retaining only the most important parts of the circuit and eliminating those that have only a minimum effect.

A typical dc model of a transistor is shown in Figure 8–46. This type of transistor (bipolar junction transistor) has three terminals, labeled base (B), collector (C), and emitter (E). In this case, the emitter terminal is both an input and an output, so it is common. The dependent current source (diamond-shaped symbol) is controlled by the base current, I_B. For this example, the current from the dependent source is 200 times larger than the base current as expressed by the term βI_B, where β is a transistor gain parameter and, in this case, $\beta = 200$.

The transistor is part of a dc amplifier circuit, and you can use the basic model to predict the output current. The output current is larger than the input circuit can provide by itself. For example, the source can represent a small transducer, such as a solar cell with an internal resistance of 6.8 kΩ. It is shown as an equivalent Thevenin voltage and Thevenin resistance. The load could be any device that requires higher current than the source can provide directly.

(c) Calculate the output voltage and the power in the load resistor R_L.

(d) Compare the power determined in (c) with the power delivered to the load if the load resistor were connected directly to the Thevenin circuit.

Solution

(a) $V_{TH} - R_{TH}I_B - 0.7\,V = 0$

$$I_B = \frac{V_{TH} - 0.7\,V}{R_{TH}} = \frac{1.6\,V - 0.7\,V}{6.8\,k\Omega} = \mathbf{132\,\mu A}$$

(b) $I_C = \beta I_B = 200(132\,\mu A) = \mathbf{26.5\,mA}$

(c) $V_{OUT} = I_C R_L = (26.5\,mA)(470\,\Omega) = \mathbf{12.4\,V}$

$$P_L = \frac{V_{OUT}^2}{R_L} = \frac{(12.4\,V)^2}{470\,\Omega} = \mathbf{327\,mW}$$

(d) $P_L = I_B^2 R_L = (132\,\mu A)^2(470\,\Omega) = 8.19\,\mu W$

The power in the load resistor is 327 mW/8.19 μW = 39,927 times greater than the power that the Thevenin input circuit could deliver to the same load. This illustrates that the transistor can operate as a power amplifier.

8–6   NORTON'S THEOREM

Like Thevenin's theorem, Norton's theorem provides a method of reducing a more complex circuit to a simpler equivalent form. The basic difference is that Norton's theorem results in an equivalent current source in parallel with an equivalent resistance.

After completing this section, you should be able to

◆ **Apply Norton's theorem to simplify a circuit**

  ◆ Describe the form of a Norton equivalent circuit

  ◆ Obtain the Norton equivalent current source

  ◆ Obtain the Norton equivalent resistance
▲ **FIGURE 8–48**

Form of Norton's equivalent circuit.

Norton's theorem is a method for simplifying a two-terminal linear circuit to an equivalent circuit with only a current source in parallel with a resistor. The form of Norton's equivalent circuit is shown in Figure 8–48. Regardless of how complex the original two-terminal circuit is, it can always be reduced to this equivalent form. The equivalent current source is designated I_N, and the equivalent resistance is designated R_N. To apply Norton's theorem, you must know how to find the two quantities I_N and R_N. Once you know them for a given circuit, simply connect them in parallel to get the complete Norton circuit.

Norton's Equivalent Current (I_N)

Norton's equivalent current (I_N) is the short-circuit current between two output terminals in a circuit.

Any component connected between these two terminals effectively "sees" a current source I_N in parallel with R_N. To illustrate, suppose that a resistive circuit of some kind has a resistor (R_L) connected between two output terminals in the circuit, as shown in Figure 8–49(a). You want to find the Norton circuit that is equivalent to the one shown as "seen" by R_L. To find I_N, calculate the current between terminals A and B with these two terminals shorted, as shown in Figure 8–49(b). Example 8–14 demonstrates how to find I_N.

▶ **FIGURE 8–50**

(a)

(b)
Solution   Short terminals A and B as shown in Figure 8–50(b). I_N is the current through the short. First, the total resistance seen by the voltage source is

$$R_T = R_1 + \frac{R_2 R_3}{R_2 + R_3} = 47\ \Omega + \frac{(47\ \Omega)(100\ \Omega)}{147\ \Omega} = 79\ \Omega$$

The total current from the source is

$$I_T = \frac{V_S}{R_T} = \frac{5\ \text{V}}{79\ \Omega} = 63.3\ \text{mA}$$

Now apply the current-divider formula to find I_N (the current through the short).

$$I_N = \left(\frac{R_2}{R_2 + R_3}\right)I_T = \left(\frac{47\ \Omega}{147\ \Omega}\right)63.3\ \text{mA} = \mathbf{20.2\ mA}$$

This is the value for the equivalent Norton current source.

Related Problem   Determine I_N in Figure 8–50(a) if the value of R_2 is doubled.

Use Multisim file E08-14 to verify the calculated results in this example and to confirm your calculation for the related problem.

Norton's Equivalent Resistance (R_N)

Norton's equivalent resistance (R_N) is defined in the same way as R_{TH}.

The Norton equivalent resistance, R_N, is the total resistance appearing between two output terminals in a given circuit with all sources replaced by their internal resistances.

Example 8–15 demonstrates how to find R_N.

EXAMPLE 8–15

Find R_N for the circuit within the beige area of Figure 8–50(a) (see Example 8–14).

Solution   First reduce V_S to zero by shorting it, as shown in Figure 8–51. Looking in at terminals A and B, you can see that the parallel combination of R_1 and R_2 is in series with R_3. Thus,

$$R_N = R_3 + \frac{R_1}{2} = 100\ \Omega + \frac{47\ \Omega}{2} = \textbf{124}\ \boldsymbol{\Omega}$$

▶ **FIGURE 8–51**
Related Problem   Determine R_N in Figure 8–50(a) if the value of R_2 is doubled.

Examples 8–14 and 8–15 have shown how to find the two equivalent components of a Norton equivalent circuit, I_N and R_N. Keep in mind that these values can be found for any linear circuit. Once these are known, they must be connected in parallel to form the Norton equivalent circuit, as illustrated in Example 8–16.

EXAMPLE 8–16

Solution   In Examples 8–14 and 8–15 it was found that $I_N = 20.2$ mA and $R_N = 124\ \Omega$. The Norton equivalent circuit is shown in Figure 8–52.

Summary of Norton's Theorem

Any load resistor connected between the output terminals of a Norton equivalent circuit will have the same current through it and the same voltage across it as if it were connected to the output terminals of the original circuit. A summary of steps for theoretically applying Norton's theorem is as follows:

Step 1: Short the two terminals between which you want to find the Norton equivalent circuit.

Step 2: Determine the current (I_N) through the shorted terminals.

Step 3: Determine the resistance (R_N) between the two open terminals with all sources replaced with their internal resistances (ideal voltage sources shorted and ideal current sources opened). $R_N = R_{TH}$.

Step 4: Connect I_N and R_N in parallel to produce the complete Norton equivalent for the original circuit.

Norton's equivalent circuit can also be derived from Thevenin's equivalent circuit by use of the source conversion method discussed in Section 8–3.

An Example of a Practical Application

A voltage amplifier in a digital light meter is modeled using a Norton equivalent circuit and a dependent voltage source. A block diagram of the light meter is shown in Figure 8–53. The light meter uses a photocell as a sensor. The photocell is a current source that produces a very small current proportional to the incident light. Because it is a current source, a Norton circuit can be used to model the photocell. The very small amount of current from the photocell is converted to a small input voltage across R_N. A dc amplifier is used to increase the voltage to a level sufficient for driving the analog-to-digital converter.

◀ **FIGURE 8–53**

Light meter block diagram.

In this application, only with the first two blocks in the light meter diagram are of interest. These have been modeled as shown in Figure 8–54. The photocell has been modeled as a Norton circuit on the input. The output of the Norton circuit is fed to the amplifier's input resistance, which converts the current I_N to a small voltage V_{IN}. The amplifier increases this voltage by 33 to drive the analog-to-digital converter which, for simplicity, is modeled simply as a load resistor, R_L. The value of 33 is the gain of this particular amplifier.

8–7 MAXIMUM POWER TRANSFER THEOREM

The maximum power transfer theorem is important when you need to know the value of the load at which the most power is delivered from the source.

After completing this section, you should be able to

◆ **Apply the maximum power transfer theorem**

  ◆ State the theorem

  ◆ Determine the value of load resistance for which maximum power is transferred from a given circuit

The **maximum power transfer** theorem is stated as follows:

For a given source voltage, maximum power is transferred from a source to a load when the load resistance is equal to the internal source resistance.

The source resistance, R_S, of a circuit is the equivalent resistance as viewed from the output terminals using Thevenin's theorem. A Thevenin equivalent circuit with its output resistance and load is shown in Figure 8–56. When $R_L = R_S$, the maximum power possible is transferred from the voltage source to R_L for a given value of V_S.
▸ **FIGURE 8–56**

Maximum power is transferred to the load when $R_L = R_S$.

Practical applications of the maximum power transfer theorem include audio systems such as stereo, radio, and public address. In these systems the resistance of the speaker is the load. The circuit that drives the speaker is a power amplifier. The systems are typically optimized for maximum power to the speakers. Thus, the resistance of the speaker must equal the internal source resistance of the amplifier.

Example 8–18 shows that maximum power occurs when $R_L = R_S$.

EXAMPLE 8–18

The source in Figure 8–57 has an internal source resistance of 75 Ω. Determine the load power for each of the following values of load resistance:

Draw a graph showing the load power versus the load resistance.

▸ **FIGURE 8–57**
Solution Use Ohm's law ($I = V/R$) and the power formula ($P = I^2R$) to find the load power, P_L, for each value of load resistance.

(a) For $R_L = 0\ \Omega$,

$$I = \frac{V_S}{R_S + R_L} = \frac{10\ \text{V}}{75\ \Omega + 0\ \Omega} = 133\ \text{mA}$$

$$P_L = I^2R_L = (133\ \text{mA})^2(0\ \Omega) = \mathbf{0\ mW}$$

(b) For $R_L = 25\ \Omega$,

$$I = \frac{V_S}{R_S + R_L} = \frac{10\ \text{V}}{75\ \Omega + 25\ \Omega} = 100\ \text{mA}$$

$$P_L = I^2R_L = (100\ \text{mA})^2(25\ \Omega) = \mathbf{250\ mW}$$

(c) For $R_L = 50 \, \Omega$,

$$I = \frac{V_S}{R_S + R_L} = \frac{10 \, V}{125 \, \Omega} = 80 \, mA$$

$$P_L = I^2 R_L = (80 \, mA)^2 (50 \, \Omega) = \mathbf{320 \, mW}$$

(d) For $R_L = 75 \, \Omega$,

$$I = \frac{V_S}{R_S + R_L} = \frac{10 \, V}{150 \, \Omega} = 66.7 \, mA$$

$$P_L = I^2 R_L = (66.7 \, mA)^2 (75 \, \Omega) = \mathbf{334 \, mW}$$

(e) For $R_L = 100 \, \Omega$,

$$I = \frac{V_S}{R_S + R_L} = \frac{10 \, V}{175 \, \Omega} = 57.1 \, mA$$

$$P_L = I^2 R_L = (57.1 \, mA)^2 (100 \, \Omega) = \mathbf{326 \, mW}$$

(f) For $R_L = 125 \, \Omega$,

$$I = \frac{V_S}{R_S + R_L} = \frac{10 \, V}{200 \, \Omega} = 50 \, mA$$

$$P_L = I^2 R_L = (50 \, mA)^2 (125 \, \Omega) = \mathbf{313 \, mW}$$

Notice that the load power is greatest when $R_L = 75 \, \Omega$, which is the same as the internal source resistance. When the load resistance is less than or greater than this value, the power drops off, as the curve in Figure 8–58 graphically illustrates.

8–8   DELTA-TO-WYE (Δ-TO-Y) AND WYE-TO-DELTA (Y-TO-Δ) CONVERSIONS

Conversions between delta-type and wye-type circuit arrangements are useful in certain specialized three-terminal applications. One example is in the analysis of a loaded Wheatstone bridge circuit.

After completing this section, you should be able to

◆ **Perform Δ-to-Y and Y-to-Δ conversions**

  ◆ Apply Δ-to-Y conversion to a bridge circuit

A resistive delta (Δ) circuit is a three-terminal arrangement as shown in Figure 8–59(a). A wye (Y) circuit is shown in Figure 8–59(b). Notice that letter subscripts are used to designate resistors in the delta circuit and that numerical subscripts are used to designate resistors in the wye circuit.

(a) Delta   (b) Wye
◀ **FIGURE 8–59**

Delta and wye circuits.

Δ-to-Y Conversion

It is convenient to think of the wye positioned within the delta, as shown in Figure 8–60. To convert from delta to wye, you need R_1, R_2, and R_3 in terms of R_A, R_B, and R_C. The conversion rule is as follows:

Each resistor in the wye is equal to the product of the resistors in two adjacent delta branches, divided by the sum of all three delta resistors.
◀ **FIGURE 8–60**

"Y within Δ" aid for conversion formulas.

In Figure 8–60, R_A and R_C are adjacent to R_1; therefore,

Equation 8–1
$$R_1 = \frac{R_A R_C}{R_A + R_B + R_C}$$

Also, R_B and R_C are adjacent to R_2, so

Equation 8–2
$$R_2 = \frac{R_B R_C}{R_A + R_B + R_C}$$

and R_A and R_B are adjacent to R_3, so

Equation 8–3
$$R_3 = \frac{R_A R_B}{R_A + R_B + R_C}$$

Y-to-Δ Conversion

To convert from wye to delta, you need R_A, R_B, and R_C in terms of R_1, R_2, and R_3. The conversion rule is as follows:

Each resistor in the delta is equal to the sum of all possible products of wye resistors taken two at a time, divided by the opposite wye resistor.

In Figure 8–60, R_2 is opposite to R_A; therefore,

Equation 8–4
$$R_A = \frac{R_1 R_2 + R_1 R_3 + R_2 R_3}{R_2}$$

Also, R_1 is opposite to R_B, so

Equation 8–5
$$R_B = \frac{R_1 R_2 + R_1 R_3 + R_2 R_3}{R_1}$$

and R_3 is opposite to R_C, so

Equation 8–6
$$R_C = \frac{R_1 R_2 + R_1 R_3 + R_2 R_3}{R_3}$$

Application of Δ-to-Y Conversion to a Bridge Circuit

In Section 8–5 you learned how Thevenin's theorem can be used to simplify a bridge circuit. Now you will see how Δ-to-Y conversion can be used for converting a bridge circuit to a series-parallel form for easier analysis.

Figure 8–65 illustrates how the delta (Δ) formed by R_A, R_B, and R_C can be converted to a wye (Y), thus creating an equivalent series-parallel circuit. Equations 8–1, 8–2, and 8–3 are used in this conversion.

(a) R_A, R_B, and R_C form a delta.

(b) R_1, R_2, and R_3 form an equivalent wye.

(c) Part (b) redrawn as a series-parallel circuit.
▲ **FIGURE 8–65**

Conversion of a bridge circuit to a series-parallel configuration.

In a bridge circuit, the load is connected between terminals C and D. In Figure 8–65(a), R_C represents the load resistor. When voltage is applied across terminals A and B, the voltage from C to D (V_{CD}) can be determined using the equivalent series-parallel circuit in Figure 8–65(c) as follows. The total resistance from terminal A to terminal B is

$$R_T = \frac{(R_1 + R_D)(R_2 + R_E)}{(R_1 + R_D) + (R_2 + R_E)} + R_3$$

Then,

$$I_T = \frac{V_{AB}}{R_T}$$

The resistance of the parallel portion of the circuit in Figure 8–65(c) is

$$R_{T(p)} = \frac{(R_1 + R_D)(R_2 + R_E)}{(R_1 + R_D) + (R_2 + R_E)}$$

The current through the left branch is

$$I_{AC} = \left(\frac{R_{T(p)}}{R_1 + R_D}\right)I_T$$

The current through the right branch is

$$I_{AD} = \left(\frac{R_{T(p)}}{R_2 + R_E}\right)I_T$$

The voltage at terminal C with respect to terminal A is

$$V_{CA} = V_A - I_{AC}R_D$$

The voltage at terminal D with respect to terminal A is

$$V_{DA} = V_A - I_{AD}R_E$$

The voltage from terminal C to terminal D is

$$V_{CD} = V_{CA} - V_{DA}$$
$$= (V_A - I_{AC}R_D) - (V_A - I_{AD}R_E) = I_{AD}R_E - I_{AC}R_D$$

V_{CD} is the voltage across the load (R_C) in the bridge circuit of Figure 8–65(a).

The load current through R_C can be found by Ohm's law.

$$I_{R_C} = \frac{V_{CD}}{R_C}$$

EXAMPLE 8–21

Determine the voltage across the load resistor and the current through the load resistor in the bridge circuit in Figure 8–66. Notice that the resistors are labeled for convenient conversion using Equations 8–1, 8–2, and 8–3. R_C is the load resistor.

▶ **FIGURE 8–66**
Solution First, convert the delta formed by R_A, R_B, and R_C to a wye.

$$R_1 = \frac{R_A R_C}{R_A + R_B + R_C} = \frac{(2.2\,\text{k}\Omega)(18\,\text{k}\Omega)}{2.2\,\text{k}\Omega + 2.7\,\text{k}\Omega + 18\,\text{k}\Omega} = 1.73\,\text{k}\Omega$$

$$R_2 = \frac{R_B R_C}{R_A + R_B + R_C} = \frac{(2.7\,\text{k}\Omega)(18\,\text{k}\Omega)}{22.9\,\text{k}\Omega} = 2.12\,\text{k}\Omega$$

$$R_3 = \frac{R_A R_B}{R_A + R_B + R_C} = \frac{(2.2\,\text{k}\Omega)(2.7\,\text{k}\Omega)}{22.9\,\text{k}\Omega} = 259\,\Omega$$

The resulting equivalent series-parallel circuit is shown in Figure 8–67.

Next, determine R_T and the branch currents in Figure 8–67.

$$R_T = \frac{(R_1 + R_D)(R_2 + R_E)}{(R_1 + R_D) + (R_2 + R_E)} + R_3$$

$$= \frac{(6.43\,\text{k}\Omega)(6.02\,\text{k}\Omega)}{6.43\,\text{k}\Omega + 6.02\,\text{k}\Omega} + 259\,\Omega = 3.11\,\text{k}\Omega + 259\,\Omega = 3.37\,\text{k}\Omega$$

$$I_T = \frac{V_{AB}}{R_T} = \frac{12\,\text{V}}{3.37\,\text{k}\Omega} = 3.56\,\text{mA}$$
▲ FIGURE 8–67

The total resistance of the parallel part of the circuit, $R_{T(p)}$, is 3.11 kΩ.

$$I_{AC} = \left(\frac{R_{T(p)}}{R_1 + R_D}\right)I_T = \left(\frac{3.11\,\text{k}\Omega}{1.73\,\text{k}\Omega + 4.7\,\text{k}\Omega}\right)3.56\,\text{mA} = 1.72\,\text{mA}$$

$$I_{AD} = \left(\frac{R_{T(p)}}{R_2 + R_E}\right)I_T = \left(\frac{3.11\,\text{k}\Omega}{2.12\,\text{k}\Omega + 3.9\,\text{k}\Omega}\right)3.56\,\text{mA} = 1.84\,\text{mA}$$

The voltage from terminal C to terminal D is

$$V_{CD} = I_{AD}R_E - I_{AC}R_D = (1.84\,\text{mA})(3.9\,\text{k}\Omega) - (1.72\,\text{mA})(4.7\,\text{k}\Omega)$$
$$= 7.18\,\text{V} - 8.08\,\text{V} = -0.9\,\text{V}$$

V_{CD} is the voltage across the load (R_C) in the bridge circuit shown in Figure 8–66. The load current through R_C is

$$I_{R_C} = \frac{V_{CD}}{R_C} = \frac{-0.9\,\text{V}}{18\,\text{k}\Omega} = -50\,\mu\text{A}$$

Related Problem   Determine the load current, I_{R_C}, in Figure 8–66 for the following resistor values:

Application Activity

The Wheatstone bridge circuit was introduced in Chapter 7 and expanded in this chapter to include the use of Thevenin's theorem. In Chapter 7, the circuit application used a thermistor in one arm of the bridge to sense temperature. The bridge was used to compare the resistance of the thermistor with the resistance of a rheostat, which set the temperature at which the output would switch from one polarity to the opposite for turning on a heater in a tank filled with a liquid. In this application activity, you will work with a similar circuit, but this time it will be used to monitor the temperature in the tank to provide a visual indication that the temperature is within a specified range.

The Temperature Monitor

The basic measuring circuit in the temperature monitor is a Wheatstone bridge with an ammeter and a series resistor acting as the load. The meter is an analog panel meter with a sensitivity of 50 μA full scale. The Wheatstone bridge temperature-measuring circuit is shown in Figure 8–68(a), and the meter panel is shown in Figure 8–68(b).

The Thermistor

The thermistor is the same one used in the circuit application of Chapter 7, specifically a Thermometrics RL2006-13.3K-140-D1 thermistor with a specified resistance of 25 kΩ at 25°C and a β of 4615K. Recall that β is a constant supplied by the manufacturer that indicates the shape of the temperature-resistance characteristic. As given in Chapter 7, the exponential equation for the resistance of a thermistor is approximated by

$$R_T = R_0 e^{\beta\left(\frac{T_0 - T}{T_0 T}\right)}$$

where:

R_T = the resistance at a given temperature

R_0 = the resistance at a reference temperature

T_0 = the reference temperature in K (typically 298 K, which is 25°C)

T = temperature (K)

β = a constant (K) provided by the manufacturer

A plot of this equation was given previously in Figure 7–59. You can confirm that your thermistor resistance calculations in this circuit application are in reasonable agreement with this plot.

Temperature Measuring Circuit

The Wheatstone bridge is designed to be balanced at 20°C. The resistance of the thermistor is approximately 33 kΩ at this temperature. You can confirm this value by substituting the temperature (in Kelvin) into the equation for R_T. Remember that the temperature in K is °C + 273.

1. Substituting into the equation for R_T, calculate the resistance of the thermistor at a temperature of 50°C (full-scale deflection of the meter).

2. Thevenize the bridge between terminals A and B by keeping the ground reference and forming two facing Thevenin circuits as was illustrated in Figure 8–44. Assume the thermistor temperature is 50°C and its resistance is the value calculated previously. Draw the Thevenin circuit for this temperature but do not show a load.

3. Show the load resistor for the Thevenin circuit you drew. The load is a resistor in series with the ammeter, which will have a current of 50 μA at full scale (50°C). You can find the value of the required load resistor by applying the
(a) Temperature-measuring circuit with thermistor

(b) Meter panel

superposition theorem to the two sources and calculating the total resistance from Ohm's law (using the full-scale deflection as the current). Subtract the Thevenin resistance of each arm from the total resistance to obtain the required load resistance. Neglect the meter resistance. Show the value calculated on the Thevenin circuit.

4. Calculate the thermistor resistance for the lower and upper limits of temperature (30°C and 40°C). Draw Thevenin circuits for each temperature and calculate the current through the load resistor.

The Meter Scale

A requirement for the temperature monitor is to mark three color bands on the meter to indicate that the temperature is within the desired range. The desired range is between a low of 30°C and 40°C. The meter should indicate a too-cold range from 20°C to 30°C, a proper operating range from 30°C to 40°C, and a too hot range from 40°C and 50°C. Full-scale deflection of the meter should be set for 50°C

5. Indicate how you would mark the meter to have a quick visual indication of the temperature in the tank.

Review

6. At 35°C, what is the current in the meter?

7. What change is needed if a 100 μA meter is used instead of a 50 μA meter?

INTRODUCTION

In the last chapter, you learned about the superposition theorem, Thevenin's theorem, Norton's theorem, maximum power transfer theorem, and several types of conversion methods. These theorems and conversion methods are useful in solving some types of circuit problems for both dc and ac.

In this chapter, three more circuit analysis methods are introduced. These methods, based on Ohm's law and Kirchhoff's laws, are particularly useful in the analysis of multiple-loop circuits having two or more voltage or current sources. The methods presented here can be used alone or in conjunction with the techniques covered in the previous chapters. With experience, you will learn which method is best for a particular problem or you may develop a preference for one of them.

In the branch current method, you will apply Kirchhoff's laws to solve for current in various branches of a multiple-loop circuit. A loop is a complete current path within a circuit. In the loop current method, you will solve for loop currents rather than branch currents. In the node voltage method, you will find the voltages at the independent nodes in a circuit. As you know, a node is the junction of two or more components.

9–1 SIMULTANEOUS EQUATIONS IN CIRCUIT ANALYSIS

The circuit analysis methods covered in this chapter allow you to find two or more unknown currents or voltages by solving simultaneous equations. These analysis methods, which include branch current, loop current, and node voltage methods, result in a number of equations equal to the number of unknowns. Coverage is limited to equations with two unknowns (2nd order) and equations with three unknowns (3rd order). These equations can then be solved simultaneously for the unknown quantities using one of the methods covered in this section.

After completing this section, you should be able to

◆ **Discuss three methods to solve simultaneous equations**

  ◆ Write a set of simultaneous equations in standard form

  ◆ Solve simultaneous equations using algebraic substitution

  ◆ Solve simultaneous equations using determinants

  ◆ Solve simultaneous equations using a calculator

Simultaneous equations consist of a set of n equations containing n unknowns, where n is a number with a value of 2 or more. The number of equations in the set must equal the number of unknowns. For example, to solve for two unknown variables, you must have two equations; to solve for three unknowns you must have three equations, and so on.

Standard Form Equations

An equation with two variables is called a *second-order equation*. In circuit analysis, the variables can represent unknowns such as current or voltage. In order to solve for variables x_1 and x_2, there must be a set of two equations containing those variables expressed in standard form.

In standard form, the x_1 variables are in the first position in each equation, and the x_2 variables are in the second position in each equation. The variables with their coefficients are on the left side of the equation, and the constants are on the right side.

The set of two simultaneous second-order equations written in standard form is

$$a_{1,1}x_1 + a_{1,2}x_2 = b_1$$
$$a_{2,1}x_1 + a_{2,2}x_2 = b_2$$

In these simultaneous equations, the "a" is the coefficient of the variables x_1 and x_2 and can represent values of circuit components, such as resistors. Notice that the subscripts of the coefficients contain two numbers. For example, $a_{1,1}$ appears in the *first* equation as the coefficient of x_1 and $a_{2,1}$ appears in the *second* equation as the coefficient of x_1. The "b" is the constant and can represent a voltage source. This notation will be useful when you use a calculator to solve the equations.

EXAMPLE 9–1

Assume the following two equations describe a particular circuit with two unknown currents I_1 and I_2. The coefficients are resistance values and the constants are voltages in the circuit. Write the equations in standard form.

$$2I_1 = 8 - 5I_2$$
$$4I_2 - 5I_1 + 6 = 0$$

● *This icon indicates selected websites for further information on topics in this section. See the Companion Website provided with this text.*

Solution Rearrange the equations in standard form as follows:

$$2I_1 + 5I_2 = 8$$
$$5I_1 + 4I_2 = -6$$

*Related Problem** Convert these two equations to standard form:

$$20x_1 + 15 = 11x_2$$
$$10 = 25x_2 + 18x_1$$

*Answers are at the end of the chapter.

A third-order equation contains three variables and a constant term. Just as in second-order equations, each variable has a coefficient. In order to solve for the variables x_1, x_2, and x_3, there must be a set of three simultaneous equations containing those variables. The general form for three simultaneous third-order equations written in standard form is

$$a_{1,1}x_1 + a_{1,2}x_2 + a_{1,3}x_3 = b_1$$
$$a_{2,1}x_1 + a_{2,2}x_2 + a_{2,3}x_3 = b_2$$
$$a_{3,1}x_1 + a_{3,2}x_2 + a_{3,3}x_3 = b_3$$

EXAMPLE 9–2

Assume the following three equations describe a particular circuit with three unknown currents I_1, I_2, and I_3. The coefficients are resistance values and the constants are known voltages in the circuit. Write the equations in standard form.

$$4I_3 + 2I_2 + 7I_1 = 0$$
$$5I_1 + 6I_2 + 9I_3 - 7 = 0$$
$$8 = 1I_1 + 2I_2 + 5I_3$$

Solution The equations are rearranged to put them in standard form as follows:

$$7I_1 + 2I_2 + 4I_3 = 0$$
$$5I_1 + 6I_2 + 9I_3 = 7$$
$$1I_1 + 2I_2 + 5I_3 = 8$$

Related Problem Convert these three equations to standard form:

$$10V_1 + 15 = 21V_2 + 50V_3$$
$$10 + 12V_3 = 25V_2 + 18V_1$$
$$12V_3 - 25V_2 + 18V_1 = 9$$

Solutions of Simultaneous Equations

Three ways for solving simultaneous equations are algebraic substitution, the determinant method, and using a calculator.

Solving by Substitution   You can solve two or three simultaneous equations in standard form using algebraic substitution by first solving one of the variables in terms of the others.

However, because the process can become quite lengthy, we will restrict this method to second-order equations. Consider the following set of simultaneous equations:

$$2x_1 + 6x_2 = 8 \quad \text{(Eq. 1)}$$
$$3x_1 + 6x_2 = 2 \quad \text{(Eq. 2)}$$

Step 1: Solve for x_1 in terms of x_2 in Eq. 1.

$$2x_1 = 8 - 6x_2$$
$$x_1 = 4 - 3x_2$$

Step 2: Substitute the result for x_1 into Eq. 2 and solve for x_2.

$$3x_1 + 6x_2 = 2$$
$$3(4 - 3x_2) + 6x_2 = 2$$
$$12 - 9x_2 + 6x_2 = 2$$
$$-3x_2 = -10$$
$$x_2 = \frac{-10}{-3} = 3.33$$

Step 3: Substitute the value for x_2 into the equation for x_1 in Step 1.

$$x_1 = 4 - 3x_2 = 4 - 3(3.33) = 4 - 9.99 = -5.99$$

Solving by Determinants The determinant method is a part of matrix algebra and provides a "cookbook" approach for solving simultaneous equations with two or three variables. A **matrix** is an array of numbers, and a **determinant** is effectively the solution to a matrix, resulting in a specific value. Second-order determinants are used for two variables and third-order determinants are used for three variables. The equations must be in standard form for a solution.

To illustrate the determinant method for second-order equations, let's find the values of I_1 and I_2 in the following two equations expressed in standard form. The coefficients are resistance values in ohms, and the constants are voltage values in volts.

$$10I_1 + 5I_2 = 15$$
$$2I_1 + 4I_2 = 8$$

First, form the characteristic determinant from the matrix of the coefficients of the unknown currents. The first column in the determinant consists of the coefficients of I_1, and the second column consists of the coefficients of I_2. The resulting determinant is

1st column ⟶ ↓ ↓ 2nd column

$$\begin{vmatrix} 10 & 5 \\ 2 & 4 \end{vmatrix}$$

An evaluation of this characteristic determinant requires three steps.

Step 1: Multiply the first number in the left column by the second number in the right column.

$$\begin{vmatrix} 10 & 5 \\ 2 & 4 \end{vmatrix} = 10 \times 4 = 40$$

Step 2: Multiply the second number in the left column by the first number in the right column.

$$\begin{vmatrix} 10 & 5 \\ 2 & 4 \end{vmatrix} = 2 \times 5 = 10$$

Step 3: Subtract the product in Step 2 from the product in Step 1.

$$40 - 10 = 30$$

This difference is the value of the characteristic determinant (30 in this case).

Next, replace the coefficients of I_1 in the first column of the characteristic determinant with the constants (fixed numbers) on the right side of the equations to form another determinant:

$$\begin{vmatrix} 15 & 5 \\ 8 & 4 \end{vmatrix}$$

Replace coefficients of I_1 with constants from right sides of equations.

Evaluate this I_1 determinant as follows:

$$\begin{vmatrix} 15 & 5 \\ 8 & 4 \end{vmatrix} = 15 \times 4 = 60$$

$$\begin{vmatrix} 15 & 5 \\ 8 & 4 \end{vmatrix} = 60 - (8 \times 5) = 60 - 40 = 20$$

The value of this determinant is 20.

Now solve for I_1 by dividing the I_1 determinant by the characteristic determinant as follows:

$$I_1 = \frac{\begin{vmatrix} 15 & 5 \\ 8 & 4 \end{vmatrix}}{\begin{vmatrix} 10 & 5 \\ 2 & 4 \end{vmatrix}} = \frac{20}{30} = 0.667 \text{ A}$$

To find I_2, form another determinant by substituting the constants on the right side of the given equations for the coefficients of I_2 in the second column of the characteristic determinant.

$$\begin{vmatrix} 10 & 15 \\ 2 & 8 \end{vmatrix}$$

Replace coefficients of I_2 with constants from right sides of equations.

Solve for I_2 by dividing this determinant by the characteristic determinant previously found.

$$I_2 = \frac{\begin{vmatrix} 10 & 15 \\ 2 & 8 \end{vmatrix}}{30} = \frac{(10 \times 8) - (2 \times 15)}{30} = \frac{80 - 30}{30} = \frac{50}{30} = 1.67 \text{ A}$$

EXAMPLE 9–3

Solve the following set of equations for the unknown currents:

$$2I_1 - 5I_2 = 10$$
$$6I_1 + 10I_2 = 20$$

Solution Given that the coefficients are in ohms and the constants are in volts, evaluate the characteristic determinant as follows:

$$\begin{vmatrix} 2 & -5 \\ 6 & 10 \end{vmatrix} = (2)(10) - (-5)(6) = 20 - (-30) = 20 + 30 = 50$$

Solving for I_1 yields

$$I_1 = \frac{\begin{vmatrix} 10 & -5 \\ 20 & 10 \end{vmatrix}}{50} = \frac{(10)(10) - (-5)(20)}{50} = \frac{100 - (-100)}{50} = \frac{200}{50} = \textbf{4 A}$$

Solving for I_2 yields

$$I_2 = \frac{\begin{vmatrix} 2 & 10 \\ 6 & 20 \end{vmatrix}}{50} = \frac{(2)(20) - (6)(10)}{50} = \frac{40 - 60}{50} = -0.4\,\text{A}$$

In a circuit problem, a result with a negative sign indicates that the direction of actual current is opposite to the assigned direction.

Note that multiplication can be expressed either by the multiplication sign such as 2×10 or by parentheses such as $(2)(10)$.

Related Problem   Solve the following set of equations for I_1:

$$5I_1 + 3I_2 = 4$$
$$I_1 + 2I_2 = -6$$

Third-order determinants can be evaluated by the expansion method. We will illustrate this method by finding the unknown current values in the following three equations expressed in standard form:

$$1I_1 + 3I_2 - 2I_3 = 7$$
$$0I_1 + 4I_2 + 1I_3 = 8$$
$$-5I_1 + 1I_2 + 6I_3 = 9$$

The characteristic determinant for the matrix of coefficients for this set of equations is formed in a similar way to that used earlier for the second-order determinant. The first column consists of the coefficients of I_1, the second column consists of the coefficients of I_2, and the third column consists of the coefficients of I_3, as shown below.

This third-order determinant is evaluated by the expansion method as follows:

Step 1: Rewrite the first two columns immediately to the right of the determinant.

Step 2: Identify the three downward diagonal groups of three coefficients each.

Step 3: Multiply the numbers in each diagonal and add the products.

$$(1)(4)(6) + (3)(1)(-5) + (-2)(0)(1) = 24 + (-15) + 0 = 9$$

Step 4: Repeat Steps 2 and 3 for the three upward diagonal groups of three coefficients.

$$
\begin{vmatrix}
1 & 3 & -2 \\
0 & 4 & 1 \\
-5 & 1 & 6
\end{vmatrix}
\begin{matrix}
1 & 3 \\
0 & 4 \\
-5 & 1
\end{matrix}
$$

$$(-5)(4)(-2) + (1)(1)(1) + (6)(0)(3) = 40 + 1 + 0 = 41$$

Step 5: Subtract the result in Step 4 from the result in Step 3 to get the value of the characteristic determinant.

$$9 - 41 = -32$$

Next, form another determinant by substituting the constants on the right of the equations for the coefficients of I_1 in the characteristic determinant.

$$
\begin{vmatrix}
7 & 3 & -2 \\
8 & 4 & 1 \\
9 & 1 & 6
\end{vmatrix}
$$

Evaluate this determinant using the method described in the previous steps.

$$
\begin{vmatrix}
7 & 3 & -2 \\
8 & 4 & 1 \\
9 & 1 & 6
\end{vmatrix}
\begin{matrix}
7 & 3 \\
8 & 4 \\
9 & 1
\end{matrix}
$$

$$= [(7)(4)(6) + (3)(1)(9) + (-2)(8)(1)] - [(9)(4)(-2) + (1)(1)(7) + (6)(8)(3)]$$
$$= (168 + 27 - 16) - (-72 + 7 + 144) = 179 - 79 = 100$$

Solve for I_1 by dividing this determinant by the characteristic determinant. The negative result indicates that the actual current is in a direction opposite to the original assumption.

$$
I_1 = \frac{\begin{vmatrix} 7 & 3 & -2 \\ 8 & 4 & 1 \\ 9 & 1 & 6 \end{vmatrix}}{\begin{vmatrix} 1 & 3 & -2 \\ 0 & 4 & 1 \\ -5 & 1 & 6 \end{vmatrix}} = \frac{100}{-32} = -3.125 \text{ A}
$$

You can find I_2 and I_3 in a similar way.

EXAMPLE 9–4

Given that the coefficients are in ohms and the constants are in volts, determine the value of I_2 from the following set of equations:

$$2I_1 + 0.5I_2 + 1I_3 = 0$$
$$0.75I_1 + 0I_2 + 2I_3 = 1.5$$
$$3I_1 + 0.2I_2 + 0I_3 = -1$$

Solution Evaluate the characteristic determinant as follows:

$$
\begin{vmatrix}
2 & 0.5 & 1 \\
0.75 & 0 & 2 \\
3 & 0.2 & 0
\end{vmatrix}
\begin{matrix}
2 & 0.5 \\
0.75 & 0 \\
3 & 0.2
\end{matrix}
$$

$$= [(2)(0)(0) + (0.5)(2)(3) + (1)(0.75)(0.2)] - [(3)(0)(1) + (0.2)(2)(2) + (0)(0.75)(0.5)]$$
$$= (0 + 3 + 0.15) - (0 + 0.8 + 0) = 3.15 - 0.8 = 2.35$$

Evaluate the determinant for I_2 is as follows:

$$\begin{vmatrix} 2 & 0 & 1 \\ 0.75 & 1.5 & 2 \\ 3 & -1 & 0 \end{vmatrix}\begin{matrix} 2 & 0 \\ 0.75 & 1.5 \\ 3 & -1 \end{matrix}$$

$$= [(2)(1.5)(0) + (0)(2)(3) + (1)(0.75)(-1)] - [(3)(1.5)(1) + (-1)(2)(2) + (0)(0.75)(0)]$$

$$= [0 + 0 + (-0.75)] - [4.5 + (-4) + 0] = -0.75 - 0.5 = -1.25$$

Finally, divide the two determinants.

$$I_2 = \frac{-1.25}{2.35} = -0.532\,\text{A} = -532\,\text{mA}$$

Related Problem   Determine the value of I_1 in the set of equations used in this example.

Solving by Calculator   Calculators generally employ matrix algorithms for simultaneous equation solution and make the results much easier to obtain. As with the two "manual" methods, it is important to first get the equations into the standard form before entering data on a calculator. Calculators that offer simultaneous equation solutions generally employ the notation discussed earlier in relation to the general form of equations. Variables are labeled as x_1, x_2, etc, coefficients are designated as $a_{1,1}, a_{1,2}, a_{2,1}, a_{2,2}$, etc., and constants are designated as b_1, b_2, etc.

9–2   BRANCH CURRENT METHOD

The branch current method is a circuit analysis method using Kirchhoff's voltage and current laws to find the current in each branch of a circuit by generating simultaneous equations. Once you know the branch currents, you can determine voltages.

After completing this section, you should be able to

◆ **Use the branch current method to find unknown quantities in a circuit**

  ◆ Identify loops and nodes in a circuit

  ◆ Develop a set of branch current equations

  ◆ Solve the branch current equations

Figure 9–6 shows a circuit that will be used as the basic model throughout the chapter to illustrate each of the three circuit analysis methods. In this circuit, there are only two nonredundant closed loops. A **loop** is a complete current path within a circuit, and you can view a set of nonredundant closed loops as a set of "windowpanes," where each windowpane represents one nonredundant loop. Also, there are four nodes as indicated by the letters A, B, C, and D. A **node** is a point where two or more components are connected. A **branch** is a path that connects two nodes, and there are three branches in this circuit: one containing R_1, one containing R_2, and one containing R_3.

▶ FIGURE 9–6

Circuit showing loops, nodes, and branches.
The following are the general steps used in applying the branch current method.

Step 1: Assign a current in each circuit branch in an arbitrary direction.

Step 2: Show the polarities of the resistor voltages according to the assigned branch current directions.

Step 3: Apply Kirchhoff's voltage law around each closed loop (algebraic sum of voltages is equal to zero).

Step 4: Apply Kirchhoff's current law at the minimum number of nodes so that all branch currents are included (algebraic sum of currents at a node equals zero).

Step 5: Solve the equations resulting from Steps 3 and 4 for the branch current values.
Circuit for demonstrating branch current analysis.

These steps are demonstrated with the aid of Figure 9–7. First, the **branch currents** I_1, I_2, and I_3 are assigned in the direction shown. Don't worry about the actual current directions at this point. Second, the polarities of the voltage drops across R_1, R_2, and R_3 are indicated in the figure according to the assigned current directions. Third, Kirchhoff's voltage law applied to the two loops gives the following equations where the resistance values are the coefficients for the unknown currents:

Equation 1: $R_1I_1 + R_2I_2 - V_{S1} = 0$ for loop 1
Equation 2: $R_2I_2 + R_3I_3 - V_{S2} = 0$ for loop 2

Fourth, Kirchhoff's current law is applied to node A, including all branch currents as follows:

Equation 3: $I_1 - I_2 + I_3 = 0$

The negative sign indicates that I_2 is into the node. Fifth and last, the three equations must be solved for the three unknown currents, I_1, I_2, and I_3. Example 9–7 shows how to solve equations by the *substitution* method.

EXAMPLE 9–7

Use the branch current method to find each branch current in Figure 9–8.
Solution   **Step 1:** Assign branch currents as shown in Figure 9–8. Keep in mind that you can assume any current direction at this point and that the final solution will have a negative sign if the actual current is opposite to the assigned current.

Step 2: Mark the polarities of the resistor voltage drops in accordance with the assigned current directions as shown in the figure.

Step 3: Applying Kirchhoff's voltage law around the left loop gives

$$470I_1 + 220I_2 - 10 = 0$$

Around the right loop gives

$$220I_2 + 820I_3 - 5 = 0$$

where all resistance values are in ohms and voltage values are in volts. For simplicity, the units are not shown.

Step 4: At node A, the current equation is

$$I_1 - I_2 + I_3 = 0$$

Step 5: The equations are solved by substitution as follows. First, find I_1 in terms of I_2 and I_3.

$$I_1 = I_2 - I_3$$

Now, substitute $I_2 - I_3$ for I_1 in the left loop equation.

$$470(I_2 - I_3) + 220I_2 = 10$$
$$470I_2 - 470I_3 + 220I_2 = 10$$
$$690I_2 - 470I_3 = 10$$

Next, take the right loop equation and solve for I_2 in terms of I_3.

$$220I_2 = 5 - 820I_3$$
$$I_2 = \frac{5 - 820I_3}{220}$$

Substituting this expression for I_2 into $820I_2 - 470I_3 = 10$ yields

$$690\left(\frac{5 - 820I_3}{220}\right) - 470I_3 = 10$$

$$\frac{3450 - 565800I_3}{220} - 470I_3 = 10$$

$$15.68 - 2571.8I_3 - 470I_3 = 10$$

$$-3041.8I_3 = -5.68$$

$$I_3 = \frac{5.68}{3041.8} = 0.00187\,\text{A} = \mathbf{1.87\,mA}$$

Now, substitute the value of I_3 in amps into the right loop equation.

$$220I_2 + 820(0.00187) = 5$$

Solve for I_2.

$$I_2 = \frac{5 - 820(0.00187)}{220} = \frac{3.47}{220} = 0.0158 = \mathbf{15.8\,mA}$$

Substituting I_2 and I_3 values into the current equation at node A yields

$$I_1 - 0.0158 + 0.00187 = 0$$
$$I_1 = 0.0158 - 0.00187 = 0.0139\,\text{A} = \mathbf{13.9\,mA}$$

**SECTION 9–2
CHECKUP**

1. What basic circuit laws are used in the branch current method?
2. When assigning branch currents, you should be careful that the assigned directions match the actual directions.   (T or F)
3. What is a loop?
4. What is a node?

9–3   LOOP CURRENT METHOD

In the loop current method (also known as the mesh current method), you will work with loop currents instead of branch currents. An ammeter placed in a given branch will measure the branch current. Unlike branch currents, loop currents are mathematical quantities, rather than actual physical currents, that are used to make circuit analysis somewhat easier than with the branch current method.

After completing this section, you should be able to

◆ **Use loop analysis to find unknown quantities in a circuit**

   ◆ Assign loop currents

   ◆ Apply Kirchhoff's voltage law around each loop

   ◆ Develop the loop equations

   ◆ Solve the loop equations

A systematic method of loop analysis is given in the following steps and is illustrated in Figure 9–9, which is the same circuit configuration used in the branch current analysis. It demonstrates the basic principles well.

Step 1: Although direction of an assigned loop current is arbitrary, we will assign a current in the counterclockwise (CCW) direction around each nonredundant closed loop, for consistency. This may not be the actual current direction, but it does not matter. The number of loop-current assignments must be sufficient to include current through all components in the circuit.

Step 2: Indicate the voltage drop polarities in each loop based on the assigned current directions.

Step 3: Apply Kirchhoff's voltage law around each closed loop. When more than one loop current passes through a component, include its voltage drop. This results in one equation for each loop.

Step 4: Using substitution or determinants, solve the resulting equations for the loop currents.
▲ FIGURE 9–9

First, the **loop currents** I_A and I_B are assigned in the CCW direction as shown in Figure 9–9. A loop current could be assigned around the outer perimeter of the circuit, but this would be redundant since I_A and I_B already pass through all of the components.

Second, the polarities of the voltage drops across R_1, R_2, and R_3 are shown based on the loop-current directions. Notice that I_A and I_B are in opposite directions through R_2 because R_2 is common to both loops. Therefore, two voltage polarities are indicated. In

reality, the R_2 current cannot be separated into two parts, but remember that the loop currents are basically mathematical quantities used for analysis purposes. The polarities of the voltage sources are fixed and are not affected by the current assignments.

Third, Kirchhoff's voltage law applied to the two loops results in the following two equations:

$$R_1I_A + R_2(I_A - I_B) = V_{S1} \qquad \text{for loop A}$$
$$R_3I_B + R_2(I_B - I_A) = -V_{S2} \qquad \text{for loop B}$$

Notice that I_A is positive in loop A and I_B is positive in loop B.

Fourth, the like terms in the equations are combined and rearranged into standard form for convenient solution so that they have the same position in each equation, that is, the I_A term is first and the I_B term is second. The equations are rearranged into the following form. Once the loop currents are evaluated, all of the branch currents can be determined.

$$(R_1 + R_2)I_A - R_2I_B = V_{S1} \qquad \text{for loop A}$$
$$-R_2I_A + (R_2 + R_3)I_B = -V_{S2} \qquad \text{for loop B}$$

Notice that in the loop current method only two equations are required for the same circuit that required three equations in the branch current method. The last two equations (developed in the fourth step) follow a form to make loop analysis easier. Referring to these last two equations, notice that for loop A, the total resistance in the loop, $R_1 + R_2$, is multiplied by I_A (its loop current). Also in the loop A equation, the resistance common to both loops, R_2, is multiplied by the other loop current, I_B, and subtracted from the first term. The same form is seen in the loop B equation except that the terms have been rearranged. From these observations, a concise rule for applying steps 1 to 4 is as follows:

(Sum of resistors in loop) times (loop current) minus (each resistor common to both loops) times (associated adjacent loop current) equals (source voltage in the loop).

Example 9–8 illustrates the application of this rule to the loop current analysis of a circuit.

EXAMPLE 9–8

Using the loop current method, find the branch currents in Figure 9–10.
▲ FIGURE 9–10

Solution   Assign the loop currents (I_A and I_B) as shown in Figure 9–10; resistance values are in ohms and voltage values are in volts. Use the rule described to set up the two loop equations.

$$(470 + 220)I_A - 220I_B = 10$$
$$690I_A - 220I_B = 10 \qquad \text{for loop A}$$
$$-220I_A + (220 + 820)I_B = -5$$
$$-220I_A + 1040I_B = -5 \qquad \text{for loop B}$$

Use determinants to find I_A.

$$I_A = \frac{\begin{vmatrix} 10 & -220 \\ -5 & 1040 \end{vmatrix}}{\begin{vmatrix} 690 & -220 \\ -220 & 1040 \end{vmatrix}} = \frac{(10)(1040) - (-5)(-220)}{(690)(1040) - (-220)(-220)} = \frac{104000 - 1100}{717600 - 48400} = \frac{102900}{669200} = 13.9 \, \text{mA}$$

Solving for I_B yields

$$I_B = \frac{\begin{vmatrix} 690 & 10 \\ -220 & -5 \end{vmatrix}}{669200} = \frac{(690)(-5) - (-220)(10)}{669200} = \frac{-3450 - (-2200)}{669200} = -1.87 \, \text{mA}$$

The negative sign on I_B means that its assigned direction is opposite to the actual current.

Now find the actual branch currents. Since I_A is the only current through R_1, it is also the branch current I_1.

$$I_1 = I_A = \mathbf{13.9 \, mA}$$

Since I_B is the only current through R_3, it is also the branch current I_3.

$$I_3 = I_B = \mathbf{-1.87 \, mA}$$

The negative sign indicates opposite direction of that originally assigned to I_B.

As originally assigned, both loop currents I_A and I_B are through R_2 in opposite directions. The branch current I_2 is the difference between I_A and I_B.

$$I_2 = I_A - I_B = 13.9 \, \text{mA} - (-1.87 \, \text{mA}) = \mathbf{15.8 \, mA}$$

Keep in mind that once you know the branch currents, you can find the voltages by using Ohm's law. Notice that these results are the same as in Example 9–7 where the branch current method was used.

Related Problem Solve for the two loop currents using your calculator.

Use Multisim file E09-08 to verify the calculated results in this example and to verify your calculations for the related problem.

Circuits with More Than Two Loops

The loop current method can be systematically applied to circuits with any number of loops. Of course, the more loops there are, the more difficult is the solution, but calculators have greatly simplified solving simultaneous equations. Most circuits that you will encounter will not have more than three loops. Keep in mind that the loop currents are not the actual physical currents but are mathematical quantities assigned for analysis purposes.

A widely used circuit that you have already encountered is the Wheatstone bridge. The Wheatstone bridge was originally designed as a stand-alone measuring instrument but has largely been replaced with other instruments. However, the Wheatstone bridge circuit is incorporated in automated measuring instruments, and as explained previously, is widely used in the scale industry and in other measurement applications.

One method for solving the bridge parameters, which directly leads to finding the current in each arm of the bridge and the load current, is to write loop equations for the bridge. Figure 9–11 shows a Wheatstone bridge with three loops. Example 9–9 illustrates how to solve for all of the currents in the bridge.

Wheatstone bridge with three loops.
EXAMPLE 9–9

For the Wheatstone bridge circuit in Figure 9–12, find the loop currents. Use the loop currents to solve for the current in each resistor (branch current).

► FIGURE 9–12
Solution   Assign three counterclockwise loop currents (I_A, I_B, and I_C) as shown in Figure 9-12. Then write the loop equations. The equations for the loops are

Loop A: $-12 + 330(I_A - I_B) + 300(I_A - I_C) = 0$

Loop B: $330(I_B - I_A) + 360I_B + 1000(I_B - I_C) = 0$

Loop C: $300(I_C - I_A) + 1000(I_C - I_B) + 390I_C = 0$

Rearrange the equations into standard form:

Loop A: $630I_A - 330I_B - 300I_C = 12$ V

Loop B: $-330I_A + 1690I_B - 1000I_C = 0$

Loop C: $-300I_A - 1000I_B + 1690I_C = 0$

You can solve these equations with substitution, but this is tedious with three unknowns. The determinant method or directly solving with your calculator are simpler ways. Units are not shown until the end of the problem.

Evaluating the characteristic determinant using the expansion method,

$$\begin{vmatrix} 630 & -330 & -300 \\ -330 & 1690 & -1000 \\ -300 & -1000 & 1690 \end{vmatrix} \begin{matrix} 630 & -330 \\ -330 & 1690 \\ -300 & -1000 \end{matrix}$$

$= [(630)(1690)(1690) + (-330)(-1000)(-300) + (-300)(-330)(-1000)]$

$\quad -[(-300)(1690)(-300) + (-1000)(-1000)(630) + (1690)(-330)(-330)]$

$= 635202000$

Solving for I_A:

$$\frac{\begin{vmatrix} 12 & -330 & -300 \\ 0 & 1690 & -1000 \\ 0 & -1000 & 1690 \end{vmatrix}}{635202000} = \frac{(12)(1690)(1690) - (12)(-1000)(-1000)}{635202000} = 0.0351 \text{ A} = 35.1 \text{ mA}$$

Solving for I_B:

$$\frac{\begin{vmatrix} 630 & 12 & -300 \\ -330 & 0 & -1000 \\ -300 & 0 & 1690 \end{vmatrix}}{635202000} = \frac{(12)(-1000)(-300) - (-330)(12)(1690)}{635202000} = 0.0162 \text{ A} = 16.2 \text{ mA}$$

Solving for I_C:

$$\frac{\begin{vmatrix} 630 & -330 & 12 \\ -330 & 1690 & 0 \\ -300 & -1000 & 0 \end{vmatrix}}{635202000} = \frac{(12)(-330)(-1000) - (-300)(1690)(12)}{635202000} = 0.0158 \text{ A} = 15.8 \text{ mA}$$

The current in R_1 is the difference between I_A and I_B:

$$I_1 = (I_A - I_B) = 35.1 \text{ mA} - 16.2 \text{ mA} = \textbf{18.9 mA}$$

The current in R_2 is the difference between I_A and I_C:

$$I_2 = (I_A - I_C) = 35.1 \text{ mA} - 15.8 \text{ mA} = \textbf{19.3 mA}$$

The current in R_3 is I_B:

$$I_3 = I_B = \textbf{16.2 mA}$$

The current in R_4 is I_C:

$$I_4 = I_C = \textbf{15.8 mA}$$

The current in R_L is the difference between I_B and I_C:

$$I_L = (I_B - I_C) = 16.2 \text{ mA} - 15.8 \text{ mA} = \textbf{0.4 mA}$$

Another useful three-loop circuit is the bridged-T circuit. While the circuit is primarily applied in ac filter circuits using reactive components, it is introduced here to illustrate the three-loop circuit solution. A loaded resistive bridged-T is shown in Figure 9–13.

Resistors will often be in kΩ (or even MΩ) so the coefficients for simultaneous equations will become quite large if they are shown explicitly in solving equations. To simplify entering and solving equations with kΩ, it is common practice to drop the kΩ in the equations and recognize that the unit for current is the mA if the voltage is volts. The following example of a bridged-T circuit illustrates this idea.
EXAMPLE 9–10

Figure 9–14 shows a bridged-T circuit with three loops. Set up the standard form equations for the loop currents. Solve the equations with a calculator and find the current in each resistor.

▶ FIGURE 9–14
Solution   Assign three counterclockwise loop currents(I_A, I_B, and I_C) as shown in Figure 9–14. Write the loop equations, but drop the k prefix from the resistances. Current will be in mA.

Loop A: $22(I_A - I_B) + 15I_A + 7.5(I_A - I_C) = 0$
Loop B: $-12 + 22(I_B - I_A) + 8.2(I_B - I_C) = 0$
Loop C: $8.2(I_C - I_B) + 7.5(I_C - I_A) + 10I_C = 0$

Rearrange the equations into standard form:

Loop A: $44.5I_A - 22I_B \quad - 7.5I_C \quad = 0$
Loop B: $-22I_A + 30.2I_B - 8.2I_C \quad = 12$
Loop C: $-7.5I_A - 8.2I_B \quad + 25.7I_C = 0$

Calculator Solution: A calculator solution requires entry of the number of equations (3), the coefficients, and the constants. The calculator SOLVE function produces the results as shown in Figure 9–15. Because the resistors were in kΩ, the unit for the loop currents is mA. Solve for the current in each resistor. The current in $R_1 = I_A$.

$$I_1 = \textbf{0.512 mA}$$

▶ FIGURE 9–15
The current in R_2 is the difference between I_A and I_B.

$$I_2 = (I_A - I_B) = 0.512\,\text{mA} - 0.887\,\text{mA} = -0.375\,\text{mA}$$

The negative sign indicates that current is the opposite direction to I_A; the positive side of the resistor is the right side.

The current in R_3 is $I_A - I_C$.

$$I_3 = 0.512\,\text{mA} - 0.432\,\text{mA} = 0.08\,\text{mA}$$

The current in R_4 is $I_B - I_C$.

$$I_4 = I_B - I_C = 0.887\,\text{mA} - 0.432\,\text{mA} = 0.455\,\text{mA}$$

The current in R_L is I_C.

$$I_L = 0.432\,\text{mA}$$

SECTION 9–3 CHECKUP

2. When you solve for a current using the loop method and get a negative value, what does it mean?
3. What circuit law is used in the loop current method?

9–4   NODE VOLTAGE METHOD

Another method of analysis of multiple-loop circuits is called the node voltage method. It is based on finding the voltages at each node in the circuit using Kirchhoff's current law. Recall that a node is the junction of two or more components.

After completing this section, you should be able to

◆ **Use node analysis to find unknown quantities in a circuit**

   ◆ Select the nodes at which the voltage is unknown and assign currents

   ◆ Apply Kirchhoff's current law at each node

   ◆ Develop and solve the node equations

The general steps for the node voltage method of circuit analysis are as follows:

Step 1: Determine the number of nodes.

Step 2: Select one node as a reference. All voltages will be relative to the reference node. Assign voltage designations to each node where the voltage is unknown.

Step 3: Assign currents at each node where the voltage is unknown, except at the reference node. The directions are arbitrary.

Step 4: Apply Kirchhoff's current law to each node where currents are assigned.

Step 5: Express the current equations in terms of voltages, and solve the equations for the unknown node voltages using Ohm's law.

Circuit for node voltage analysis.
We will use Figure 9–16 to illustrate the general approach to node voltage analysis. First, establish the nodes. In this case, there are four nodes, as indicated in the figure. Second, let's use node B as the reference. Think of it as the circuit's reference ground. Node voltages C and D are already known to be the source voltages. The voltage at node A is the only unknown; it is designated as V_A. Third, arbitrarily assign the branch currents at node A as indicated in the figure. Fourth, the Kirchhoff current equation at node A is

$$I_1 - I_2 + I_3 = 0$$

Fifth, express the currents in terms of circuit voltages using Ohm's law.

$$I_1 = \frac{V_1}{R_1} = \frac{V_{S1} - V_A}{R_1}$$

$$I_2 = \frac{V_2}{R_2} = \frac{V_A}{R_2}$$

$$I_3 = \frac{V_3}{R_3} = \frac{V_{S3} - V_A}{R_3}$$

Substituting these terms into the current equation yields

$$\frac{V_{S1} - V_A}{R_1} - \frac{V_A}{R_2} + \frac{V_{S2} - V_A}{R_3} = 0$$

The only unknown is V_A; so solve the single equation by combining and rearranging terms. Once you know the voltage, you can calculate all branch currents. Example 9–11 illustrates this method further.

EXAMPLE 9–11

Find the node voltage V_A in Figure 9–17 and determine the branch currents.
▲ FIGURE 9–17

Solution   The reference node is chosen at *B*. The unknown node voltage is V_A, as indicated in Figure 9–17. This is the only unknown voltage. Branch currents are assigned at node *A* as shown. The current equation is

$$I_1 - I_2 + I_3 = 0$$

Substitution for currents using Ohm's law gives the equation in terms of voltages.

$$\frac{10 - V_A}{470} - \frac{V_A}{220} + \frac{5 - V_A}{820} = 0$$

Rearranging the terms yields

$$\frac{10}{470} - \frac{V_A}{470} - \frac{V_A}{220} + \frac{5}{820} - \frac{V_A}{820} = 0$$

$$-\frac{V_A}{470} - \frac{V_A}{220} - \frac{V_A}{820} = -\frac{10}{470} - \frac{5}{820}$$

To solve for V_A, combine the terms on each side of the equation and find the common denominator.

$$\frac{1804V_A + 3854V_A + 1034V_A}{847880} = \frac{820 + 235}{38540}$$

$$\frac{6692V_A}{847880} = \frac{1055}{38540}$$

$$V_A = \frac{(1055)(847880)}{(6692)(38540)} = \textbf{3.47 V}$$

You can now determine the branch currents.

$$I_1 = \frac{10\,\text{V} - 3.47\,\text{V}}{470\,\Omega} = \textbf{13.9 mA}$$

$$I_2 = \frac{3.47\,\text{V}}{220\,\Omega} = \textbf{15.8 mA}$$

$$I_3 = \frac{5\,\text{V} - 3.47\,\text{V}}{820\,\Omega} = \textbf{1.87 mA}$$

These results agree with those for the same circuit in Example 9–7 and in Example 9–8 using the branch and loop current methods.

Related Problem   Find V_A in Figure 9–17 if the 5 V source is reversed.

Use Multisim file E09-11 to verify the calculated results in this example and to confirm your calculation for the related problem.

Example 9–11 illustrated an obvious advantage to the node method. The branch current method required three equations for the three unknown currents. The loop current method reduced the number of simultaneous equations but required the extra step of converting the fictitious loop currents to the actual currents in the resistors. The node method for the circuit in Figure 9–17 reduced the equations to one, in which all of the currents were written in terms of one unknown node voltage. The node voltage method also has the advantage of finding unknown voltages, which are easier to directly measure than current.

Node Voltage Method for a Wheatstone Bridge

The node voltage method can be applied to a Wheatstone bridge. The Wheatstone bridge is shown with nodes identified in Figure 9–18 with currents shown. Node *D* is usually

Wheatstone bridge with node assignments.
selected as the reference node, and node A has the same potential as the source voltage. When setting up the equations for the two unknown node voltages (B and C), it is necessary to specify a current direction as described in the general steps. The direction of current in R_L is dependent on the bridge resistances; if the assigned direction is incorrect, it will show up as a negative current in the solution.

Kirchhoff's current law is then written for each of the unknown nodes. Each current is then expressed in terms of node voltages using Ohm's law as follows:

Node B:

$$I_1 + I_L = I_2$$

$$\frac{V_A - V_B}{R_1} + \frac{V_C - V_B}{R_L} = \frac{V_B}{R_2}$$

Node C:

$$I_3 = I_L + I_4$$

$$\frac{V_A - V_C}{R_3} = \frac{V_C - V_B}{R_L} + \frac{V_C}{R_4}$$

The equations are put in standard form and can be solved with any of the methods you have learned. The following example illustrates this for the Wheatstone bridge that was solved by loop equations in Example 9–9.

EXAMPLE 9–12

For the Wheatstone bridge circuit in Figure 9–19, find the node voltages at node B and node C. Node D is the reference, and node A has the same voltage as the source.
Solution Apply Kirchhoff's current law at node *B* and node *C* in terms of node voltages. To keep coefficients more manageable, all resistances are shown in $k\Omega$; current will be in mA.

Node *B*:

$$I_1 + I_L = I_2$$

$$\frac{V_A - V_B}{R_1} + \frac{V_C - V_B}{R_L} = \frac{V_B}{R_2}$$

$$\frac{12 - V_B}{0.33\,k\Omega} + \frac{V_C - V_B}{1.0\,k\Omega} = \frac{V_B}{0.30\,k\Omega}$$

Node *C*:

$$I_3 = I_L + I_4$$

$$\frac{V_A - V_C}{R_3} = \frac{V_C - V_B}{R_L} + \frac{V_C}{R_4}$$

$$\frac{12\,V - V_C}{0.36\,k\Omega} = \frac{V_C - V_B}{1.0\,k\Omega} + \frac{V_C}{0.39\,k\Omega}$$

Rearrange the equations for each node into standard form. Resistance units of $k\Omega$ will be omitted for simplicity.

Node *B*: Multiply each term in the expression for node *B* by $R_1R_2R_L$ and combine like terms to get the standard form.

$$R_2R_L(V_A - V_B) + R_1R_2(V_C - V_B) = R_1R_LV_B$$

$$(0.30)(1.0)(12 - V_B) + (0.33)(0.30)(V_C - V_B) = (0.33)(1.0)V_B$$

$$0.729V_B - 0.099V_C = 3.6$$

Node *C*: Multiply each term in the expression for node *C* by $R_3R_4R_L$ and combine like terms to get the standard form.

$$R_4R_L(V_A - V_C) = R_3R_4(V_C - V_B) + R_3R_LV_C$$

$$(0.39)(1.0)(12 - V_C) = (0.36)(0.39)(V_C - V_B) + (0.36)(1.0)V_C$$

$$0.1404V_B - 0.8904V_C = -4.68$$

You can solve the two simultaneous equations using substitution, determinants, or the calculator. Solving by determinants,

$$0.729V_B - 0.099V_C = 3.6$$

$$0.1404V_B - 0.8904V_C = -4.68$$

$$V_B = \frac{\begin{vmatrix} 3.6 & -0.099 \\ -4.68 & -0.8904 \end{vmatrix}}{\begin{vmatrix} 0.729 & -0.099 \\ 0.1404 & -0.8904 \end{vmatrix}} = \frac{(3.6)(-0.8904) - (-0.099)(-4.68)}{(0.729)(-0.8904) - (0.1404)(-0.099)} = \mathbf{5.78\,V}$$

$$V_C = \frac{\begin{vmatrix} 0.729 & 3.6 \\ 0.1404 & -4.68 \end{vmatrix}}{\begin{vmatrix} 0.729 & -0.099 \\ 0.1404 & -0.8904 \end{vmatrix}} = \frac{(0.729)(-4.68) - (0.1404)(3.6)}{(0.729)(-0.8904) - (0.1404)(-0.099)} = \mathbf{6.17\,V}$$

## Node Voltage Method for the Bridged-T Circuit

Applying the node voltage method to the bridged-T circuit also results in two equations with two unknowns. As in the case of the Wheatstone bridge, there are four nodes as shown in Figure 9–20. Node D is the reference and node A is the source voltage, so the two unknown voltages are at nodes C and D. The effect of a load resistor on the circuit is usually the most important question, so the voltage at node C is the focus. A calculator solution of the simultaneous equations is simplified for analyzing the effect of various loads because only the equation for node C is affected when the load changes. Example 9–13 illustrates this idea.

▶ **FIGURE 9–20**

EXAMPLE 9–13

The circuit in Figure 9–21 is the same as in Example 9–10.

(a) Solve for the voltage across R_L using node analysis and a calculator.

(b) Find the effect on the load voltage when the load resistor is changed to 15 kΩ.

▶ **FIGURE 9–21**
Solution   **(a)** Apply Kirchhoff's current law at nodes B and C in terms of node voltages.

Node B:

$$I_2 = I_3 + I_4$$

$$\frac{V_A - V_B}{R_2} = \frac{V_B - V_C}{R_3} + \frac{V_B}{R_4}$$

$$\frac{12 - V_B}{22\,\text{k}\Omega} = \frac{V_B - V_C}{7.5\,\text{k}\Omega} + \frac{V_B}{8.2\,\text{k}\Omega}$$

Node C:

$$I_1 + I_3 = I_L$$

$$\frac{V_A - V_C}{R_1} + \frac{V_B - V_C}{R_3} = \frac{V_C}{R_L}$$

$$\frac{12\,V - V_C}{15\,k\Omega} + \frac{V_B - V_C}{7.5\,k\Omega} = \frac{V_C}{10\,k\Omega}$$

Rearrange the equations for each node into standard form. Resistance units of $k\Omega$ will be omitted for simplicity.

Node B: Multiply each term in the equation for node B by $R_2R_3R_4$ to cancel the denominator. Combine like terms to get the standard form.

$$R_3R_4(V_A - V_B) = R_2R_4(V_B - V_C) + R_2R_3V_B$$

$$(7.5)(8.2)(12 - V_B) = (22)(8.2)(V_B - V_C) + (22)(7.5)V_B$$

$$406.9V_B - 180.4V_C = 738$$

Node C: Multiply each term in the equation for node C by $R_1R_3R_L$ and combine like terms to get the standard form.

$$R_3R_L(V_A - V_C) + R_1R_L(V_B - V_C) = R_1R_3V_C$$

$$(7.5)(10)(12 - V_C) + (15)(10)(V_B - V_C) = (15)(7.5)V_C$$

$$150V_B - 337.5V_C = -900$$

Calculator Solution: The two equations in standard form are

$$406.9V_B - 180.4V_C = 738$$

$$150V_B - 337.5V_C = -900$$

Enter the number of equations (2), the coefficients, and the constants into a calculator to solve for V_B and V_C as shown in Figure 9–22. As a check, notice that this voltage implies that the load current is 0.432 mA, which is in agreement with the result found by the loop current method in Example 9–10.

◄ **FIGURE 9–22**

(b) To calculate the load voltage with a 15 kΩ load resistor, notice that the equation for node B is unaffected. The node C equation is modified as follows:

$$\frac{12\,V - V_C}{15\,k\Omega} + \frac{V_B - V_C}{7.5\,k\Omega} = \frac{V_C}{15\,k\Omega}$$

$$(7.5)(15)(12 - V_C) + (15)(15)(V_B - V_C) = (15)(7.5)V_C$$

$$225V_B - 450V_C = -1350$$

Change the parameters for the node C equation and press solve. The result is

$$V_C = V_L = \mathbf{5.02\ V}$$

Application Activity

Dependent sources were covered in Chapter 8 and applied to the modeling of transistors and amplifiers. In this circuit application, you will see how a particular type of amplifier can be modeled and analyzed using the methods introduced in this chapter. The point is not to learn how amplifiers work because that is beyond the scope of this text and will be covered in a later course. The focus is on the application of circuit analysis methods to circuit models and not the amplifier itself. The amplifier is simply used as an example to illustrate how you can apply analysis methods to a practical circuit.

Operational amplifiers are integrated circuit devices that are widely used in analog applications for signal processing. An operational amplifier symbol is shown in Figure 9–23(a). The equivalent dependent source model is shown in part (b). The gain (A) of the dependent source can be positive or negative, depending on how it is configured.
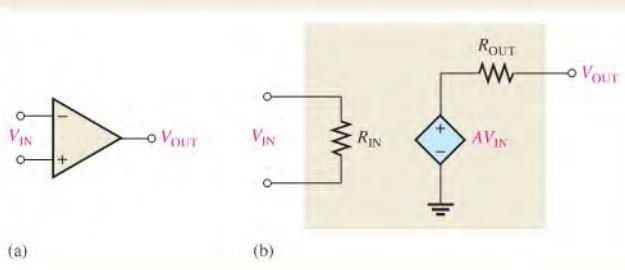

Assume you need to calculate in detail the effect of an operational amplifier circuit on a transducer that serves as an input. Some transducers, such as pH meters, appear as a small source voltage with a high series resistance. The transducer that is shown here is modeled as a small Thevenin dc voltage source in series with a Thevenin resistance of $10 \, k\Omega$.

Practical amplifiers are created using an operational amplifier with external components. Figure 9–24(a) shows one type of amplifier configuration that includes the Thevenin resistance of the source along with two other external resistors. R_S represents the Thevenin source resistance. R_L is connected from the operational amplifier output to ground as a load, and R_F is connected from the output to the input as a feedback resistor. Feedback is used in most operational amplifier circuits and is simply a path from the output back to the input. It has many advantages as you will learn in a later course.

▶ FIGURE 9–23

(a)   (b)

(a) Op-amp   (b) Model
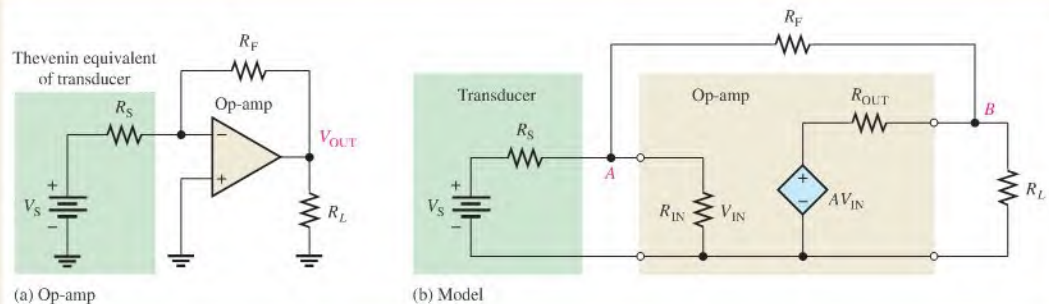

▲ FIGURE 9–24

▲ **FIGURE 9–25**

Figure 9–24(b) is the equivalent circuit model of the source, the op-amp, and the load that we will use for analysis purposes. The internal gain of the dependent source, shown with the letter A on the op-amp block, is negative because it is an inverting amplifier (the output has the opposite sign of the input). This internal gain is generally extremely high. Although it is a very large number, the actual gain of the circuit with the external components is much lower because it is controlled by the external components rather than the internal gain.

The specific values for the circuit in this application are given in Figure 9–25 along with assigned currents. All values are shown in $k\Omega$ to simplify entering the coefficients in the equations that you will use. Although op-amp circuits have excellent simple approximations for determining the output voltage, there are times you may want to know the exact output. You can apply your knowledge from this chapter to the circuit to find the exact output voltage.

The amplifier model in Figure 9–25 can be analyzed easiest with the node voltage method because there are only two nodes, A and B, that have unknown voltages. At node A, the voltage is designated and is the same as the input to the op-amp (V_{IN}). At node B, the voltage is designated and also represents the output (or load voltage), V_L. Current names and directions are assigned as shown.

Analysis

Apply Kirchhoff's current law at each of the unknown nodes to write the node equations.

Node A: $I_S = I_F + I_{IN}$

Node B: $I_{OUT} + I_F = I_L$

Next, apply Ohm's law and let $V_{IN} = V_A$. The internal source voltage for the op-amp is AV_{IN}, so this is written as AV_A to express the unknowns in terms of V_A and V_B.

Node A: $\dfrac{V_S - V_A}{R_S} = \dfrac{V_A}{R_{IN}} + \dfrac{V_A - V_B}{R_F}$

Node B: $\dfrac{AV_A - V_B}{R_{OUT}} + \dfrac{V_A - V_B}{R_F} = \dfrac{V_B}{R_L}$

Expressing the equations in standard form,

Node A: $-\left(\dfrac{1}{R_S} + \dfrac{1}{R_{IN}} + \dfrac{1}{R_F}\right)V_A + \left(\dfrac{1}{R_F}\right)V_B = -\left(\dfrac{1}{R_S}\right)V_S$

Node B: $-\left(\dfrac{A}{R_{OUT}} + \dfrac{1}{R_F}\right)V_A + \left(\dfrac{1}{R_L} + \dfrac{1}{R_{OUT}} + \dfrac{1}{R_F}\right)V_B = 0$

1. Substitute the values that were given in Figure 9–25 into the standard form equations. Solve the equations to find V_{IN} and V_L. (Resistance can be entered in $k\Omega$.)

2. Calculate the input current, I_{IN}, and the current in the feedback resistor, I_F.

INTRODUCTION

This chapter departs from the coverage of dc circuits and introduces the concepts of magnetism and electromagnetism. The operation of devices such as the relay, the solenoid, and the speaker is based partially on magnetic or electromagnetic principles. Electromagnetic induction is important in an electrical component called an inductor or coil, which is the topic in Chapter 13.

Two types of magnets are the permanent magnet and the electromagnet. The permanent magnet maintains a constant magnetic field between its two poles with no external excitation. The electromagnet produces a magnetic field only when there is current through it. The electromagnet is basically a coil of wire wound around a magnetic core material.

The chapter concludes with an introduction to dc generators and dc motors.

10–1 THE MAGNETIC FIELD

A permanent magnet has a magnetic field surrounding it. **A magnetic field** is visualized by **lines of force** that radiate from the north pole (N) to the south pole (S) and back to the north pole through the magnetic material.

After completing this section, you should be able to

◆ **Explain the principles of a magnetic field**

  ◆ Define *magnetic flux*

  ◆ Define *magnetic flux density*

  ◆ Discuss how materials are magnetized

  ◆ Explain how a magnetic switch works

A permanent magnet, such as the bar magnet shown in Figure 10–1, has a magnetic field surrounding it. All magnetic fields have their origin in moving charge, which in solid materials is caused by moving electrons. In certain materials such as iron, atoms can be aligned so that the electron motion is reinforced, creating a measurable field that extends in three dimensions. Even some electrical insulators can exhibit this behavior; ceramics make excellent magnets but are electrical insulators.

◀ **FIGURE 10–1**

Magnetic lines of force around a bar magnet.
Blue lines represent only a few of the many magnetic lines of force in the magnetic field.

To illustrate magnetic fields, "lines of force" or flux lines are used to represent an unseen field. Flux lines are widely used as a description of a field, showing the strength and direction of the field. The flux lines never cross. When lines are close together, the field is more intense; when they are farther apart, the field is weaker. The flux lines are always drawn from the north pole (N) to the south pole (S) of a magnet. Even in small magnets, the number of lines based on the mathematical definition is extremely large, so for clarity, only a few lines are generally shown in drawings of magnetic fields.

When unlike poles of two permanent magnets are placed close together, their magnetic fields produce an attractive force, as indicated in Figure 10–2(a). When two like poles are brought close together, they repel each other, as shown in part (b).

When a nonmagnetic material such as paper, glass, wood, or plastic is placed in a magnetic field, the lines of force are unaltered, as shown in Figure 10–3(a). However, when a magnetic material such as iron is placed in the magnetic field, the lines of force tend to change course and pass through the iron rather than through the surrounding air. They do so because the iron provides a magnetic path that is more easily established than that of air.

Magnetic attraction and repulsion.

(a)   (b)
▲ **FIGURE 10–3**

Effect of (a) nonmagnetic and (b) magnetic materials on a magnetic field.

Figure 10–3(b) illustrates this principle. The fact that magnetic lines of force follow a path through iron or other materials is a consideration in the design of shields that prevent stray magnetic fields from affecting sensitive circuits.

Magnetic Flux (ϕ)

The group of force lines going from the north pole to the south pole of a magnet is called the **magnetic flux**, symbolized by ϕ (the Greek letter phi). A stronger field is represented by more lines of force. Several factors determine the strength of a magnet, including the material and physical geometry as well as the distance from the magnet. Magnetic field lines tend to be more concentrated at the poles.

The unit of magnetic flux is the **weber (Wb)**. One weber equals 10^8 lines. The weber is a very large unit; thus, in most practical situations, the microweber (μWb) is used. One microweber equals 100 lines of magnetic flux.

Magnetic Flux Density (*B*)

The **magnetic flux density** is the amount of flux per unit area perpendicular to the magnetic field. Its symbol is *B*, and its SI unit is the **tesla (T)**. One tesla equals one weber per square meter (Wb/m²). The following formula expresses the flux density:

$$B = \frac{\phi}{A}$$

where ϕ is the flux (Wb) and *A* is the cross-sectional area in square meters (m²) of the magnetic field.

EXAMPLE 10–1

Compare the flux and the flux density in the two magnetic cores shown in Figure 10–4. The diagram represents the cross section of a magnetized material. Assume that each dot represents 100 lines or 1 μWb.

◆ **FIGURE 10–4**

(a)   (b)
Solution

The flux is simply the number of lines. In Figure 10–4(a) there are 49 dots. Each represents 1 μWb, so the flux is 49 μWb. In Figure 10–4(b) there are 72 dots, so the flux is 72 μWb. To calculate the flux density in Figure 10–4(a), first calculate the area in m².

$$A = l \times w = 0.025 \text{ m} \times 0.025 \text{ m} = 6.25 \times 10^{-4} \text{ m}^2$$

For Figure 10–4(b) the area is

$$A = l \times w = 0.025 \text{ m} \times 0.050 \text{ m} = 1.25 \times 10^{-3} \text{ m}^2$$

Use Equation 10–1 to calculate the flux density. For Figure 10–4(a) the flux density is

$$B = \frac{\phi}{A} = \frac{49 \, \mu\text{Wb}}{6.25 \times 10^{-4} \text{ m}^2} = 78.4 \times 10^{-3} \text{ Wb/m}^2 = 78.4 \times 10^{-3} \text{ T}$$

For Figure 10–4(b) the flux density is

$$B = \frac{\phi}{A} = \frac{72 \, \mu\text{Wb}}{1.25 \times 10^{-3} \text{ m}^2} = 57.6 \times 10^{-3} \text{ Wb/m}^2 = 57.6 \times 10^{-3} \text{ T}$$

The data in Table 10–1 compares the two cores. Note that the core with the largest flux does not necessarily have the highest flux density.

◆ **TABLE 10–1**

	FLUX (Wb)	AREA (m²)	FLUX DENSITY (T)
Figure 10–4(a)	49 μWb	6.25×10^{-4} m²	78.4×10^{-3} T
Figure 10–4(b)	72 μWb	1.25×10^{-3} m²	57.6×10^{-3} T

*Related Problem**

What happens to the flux density if the same flux shown in Figure 10–4(a) is in a core that is 5.0 cm × 5.0 cm?

---

*Answers are at the end of the chapter.

EXAMPLE 10–2

If the flux density in a certain magnetic material is 0.23 T and the area of the material is 0.38 in.^{2}, what is the flux through the material?

Solution

First, 0.38 in.^{2} must be converted to square meters. 39.37 in. = 1 m; therefore,

$$A = 0.38 \text{ in.}^2[1 \text{ m}^2/(39.37 \text{ in.})^2] = 245 \times 10^{-6} \text{ m}^2$$

The flux through the material is

$$\phi = BA = (0.23 \text{ T})(245 \times 10^{-6} \text{ m}^2) = \mathbf{56.4\ \mu Wb}$$

Related Problem

Calculate B if $A = 0.05$ in.^{2} and $\phi = 1000\ \mu$Wb.

HISTORY NOTE

Karl
Friedrich
Gauss
1777–1855

Gauss, a German mathematician, disproved many 18th century mathematical theories. Later, he worked closely with Weber on a worldwide system of stations for systematic observations of terrestrial magnetism. The most important result of their work in electromagnetism was the later development of telegraphy by others. The CGS unit of magnetic flux density is named in his honor. (Credit: Illustration by Steven S. Nau.)

The Gauss   Although the tesla (T) is the SI unit for flux density, another unit called the **gauss, G,** from the CGS (centimeter-gram-second) system, is used (10^4 G = 1 T). In fact, the instrument used to measure flux density is the gaussmeter. A typical gaussmeter is shown in Figure 10–5. This particular gaussmeter is a portable unit with four ranges that can measure magnetic fields as small as the earth's field (about 0.5 G, but changes depending on location) to strong fields such as in a MRI unit (about 10,000 G). The unit *gauss* is still in widespread use, so you should be familiar with it as well as the *tesla*.

How Materials Become Magnetized

Ferromagnetic materials such as iron, nickel, and cobalt become magnetized when placed in the magnetic field of a magnet. We have all seen a permanent magnet pick up things like paper clips, nails, and iron filings. In these cases, the object becomes magnetized (that is, it actually becomes a magnet itself) under the influence of the permanent magnetic field and becomes attracted to the magnet. When removed from the magnetic field, the object tends to lose its magnetism.

Ferromagnetic materials have minute magnetic domains created within their atomic structure. These domains can be viewed as very small bar magnets with north and south

(a) The magnetic domains (N ◀■ S) are randomly oriented in the unmagnetized material.

(b) The magnetic domains become aligned when the material is magnetized.
▲ FIGURE 10–6

poles. When the material is not exposed to an external magnetic field, the magnetic domains are randomly oriented, as shown in Figure 10–6(a). When the material is placed in a magnetic field, the domains align themselves as shown in part (b). Thus, the object itself effectively becomes a magnet.

Effects of the Magnetic Material The magnetic material affects not only the magnetic flux density at the poles but also how the magnetic flux density falls off as distance from the poles increases. The physical size also affects the flux density. For example, two disk magnets (both made from sintered Alnico) have very similar densities near the pole, but the larger magnet has much higher flux density, as you move away from the pole, as shown in Figure 10–7. Notice that the flux density falls off rapidly as you move away from the pole. This type of plot can illustrate if a given magnet is effective for a specific application that depends on the distance in which the magnet must work.
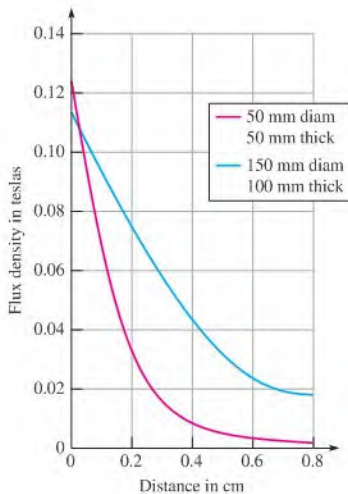

◀ FIGURE 10–7

Example of magnetic flux density for two disk magnets as a function of distance. The blue curve represents the larger magnet.

The type of material is an important parameter for the actual flux density of magnets. Table 10–2 lists the flux densities of typical magnetic fields in teslas. For permanent magnets, the numbers given are based on the flux density of the field that is typical if measured close to the pole. As previously discussed, these values can drop significantly as distance from the poles is increased. The strongest field most people will ever experience is about 1 T (10,000 G) if they have an MRI exam. The strongest commercially available permanent magnets are neodymium-iron-boron composites (NdFeB). To find the flux density in gauss, multiply the values in teslas by 10^4 (10,000).

Applications

Permanent magnets are widely used in brushless motors (discussed in Section 10–7), magnetic separators, speakers, microphones, automobiles, and magnetic resonance-imaging devices. They are also commonly used in switches, such as the normally closed switch illustrated in Figure 10–8. When the magnet is near the switch mechanism, as in Figure 10–8(a), the switch is closed. When the magnet is moved away, as in part (b), the spring pulls the arm open. Magnetic switches are widely used in security systems.

(a) Contact is closed when magnet is near.

(b) Contact opens when magnet is moved away.
▲ FIGURE 10–8

Operation of a magnetic switch.

Another important application of permanent magnets is in sensors that take advantage of an effect known as the Hall effect. The **Hall effect** is the occurrence of a small voltage (a few μV) that is generated on opposite sides of a thin current-carrying conductor or semiconductor (the Hall element) in a magnetic field. A voltage called the Hall voltage appears across the Hall element, as illustrated in Figure 10–9. The Hall voltage is due to the forces exerted on the electrons as they traverse the magnetic field, causing an excess of charge on one side of the Hall element. Although the effect was first noticed in a conductor, it is more pronounced in semiconductors, which are normally used in Hall-effect sensors. Notice that the magnetic field, the electric current, and the Hall voltage are all at right angles to each other. This voltage is amplified and can be used to detect the presence of the magnetic field. The detection of a magnetic field is useful in sensor applications.

Hall-effect sensors are widely used because they are small, inexpensive, and have no moving parts. In addition, they are noncontacting sensors, so they can last for billions of repeated operations, a clear advantage over contacting sensors that can wear out. Hall-effect sensors can detect the nearby presence of a magnet by sensing its magnetic

field. For this reason, they can be used for position measurements or for sensing motion. They are used in conjunction with other sensor elements to measure current, temperature, or pressure.

There are many applications for Hall-effect sensors. In automobiles, Hall-effect sensors are used to measure various parameters such as throttle angle, crankshaft and camshaft positions, distributor position, tachometer, power seat and rear-view mirror positions. A few other applications for Hall-effect sensors include measuring parameters for rotating devices such as drills, fans, vanes in flow meters, and disk speed detection. They are also used in dc motors as will be seen in Section 10–7.

10–2 ELECTROMAGNETISM

Electromagnetism is the production of a magnetic field by current in a conductor.

After completing this section, you should be able to

◆ **Explain the principles of electromagnetism**

   ◆ Determine the direction of the magnetic lines of force

   ◆ Define *permeability*

   ◆ Define *reluctance*

   ◆ Define *magnetomotive force*

   ◆ Describe a basic electromagnet

Current produces a magnetic field, called an **electromagnetic field**, around a conductor, as illustrated in Figure 10–10. The invisible lines of force of the magnetic field form a concentric circular pattern around the conductor and are continuous along its length. Unlike the bar magnet, the magnetic field surrounding a wire does not have a north or south pole. The direction of the lines of force surrounding the conductor shown in the figure is for electron flow. The lines are in a clockwise direction. When current is reversed, the magnetic field lines are in a counterclockwise direction.

Although the magnetic field cannot be seen, it is capable of producing visible effects. For example, if a current-carrying wire is inserted through a sheet of paper in a perpendicular
▲ **FIGURE 10–10**

▲ **FIGURE 10–11**

direction, iron filings placed on the surface of the paper arrange themselves along the magnetic lines of force in concentric rings, as illustrated in Figure 10–11(a). Part (b) of the figure illustrates that the north pole of a compass placed in the electromagnetic field will point in the direction of the lines of force. The field is stronger closer to the conductor and becomes weaker with increasing distance from the conductor.

Left-Hand Rule An aid to remembering the direction of the lines of force is illustrated in Figure 10–12. Imagine that you are grasping the conductor with your left hand, with your thumb pointing in the direction of current. Your fingers point in the direction of the magnetic lines of force.

▶ **FIGURE 10–12**

Illustration of left-hand rule. The left-hand rule is used for electron flow current ($-$ to $+$).
Electromagnetic Properties

Several important properties are related to electromagnetic fields.

Permeability *(μ)*   The ease with which a magnetic field can be established in a given material is measured by the **permeability** of that material. The higher the permeability, the more easily a magnetic field can be established.

The symbol of permeability is μ (the Greek letter mu), and its value varies depending on the type of material. The permeability of a vacuum (μ_0) is $4\pi \times 10^{-7}$ Wb/At · m (webers/ampere-turn · meter) and is used as a reference. Ferromagnetic materials typically have permeabilities hundreds of times larger than that of a vacuum, indicating that a magnetic field can be set up with relative ease in these materials. Ferromagnetic materials include iron, steel, nickel, cobalt, and their alloys.

The *relative permeability* (μ_r) of a material is the ratio of its absolute permeability to the permeability of a vacuum (μ_0).

$$\mu_r = \frac{\mu}{\mu_0}$$

Because it is a ratio of permeabilities, μ_r is dimensionless. Typical magnetic materials, such as iron, have a relative permeability of a few hundred. Highly permeable materials can have a relative permeability as high as 100,000.

Reluctance *($\Re$)*   The opposition to the establishment of a magnetic field in a material is called **reluctance**. The value of reluctance is directly proportional to the length (l) of the magnetic path and inversely proportional to the permeability (μ) and to the cross-sectional area (A) of the material, as expressed by the following equation:

$$\Re = \frac{l}{\mu A}$$

Reluctance in magnetic circuits is analogous to resistance in electric circuits. The unit of reluctance can be derived using l in meters, A (area) in square meters, and μ in Wb/At · m as follows:

$$\Re = \frac{l}{\mu A} = \frac{\cancel{m}}{(\text{Wb/At} \cdot \cancel{m})(\cancel{m^2})} = \frac{\text{At}}{\text{Wb}}$$

At/Wb is ampere-turns/weber.

Equation 10–3 is similar to Equation 2–6 for determining wire resistance. Recall that Equation 2–6 is

$$R = \frac{\rho l}{A}$$

The reciprocal of resistivity (ρ) is conductivity (σ). By substituting $1/\sigma$ for ρ, Equation 2–6 can be written as

$$R = \frac{l}{\sigma A}$$

Compare this last equation for wire resistance with Equation 10–3. The length (l) and the area (A) have the same meaning in both equations. The conductivity (σ) in electrical circuits is analogous to permeability (μ) in magnetic circuits. Also, resistance (R) in electric circuits is analogous to reluctance ($\Re$) in magnetic circuits; both are oppositions. Typically, the reluctance of a magnetic circuit is 50,000 At/Wb or more, depending on the size and type of material.

EXAMPLE 10–3

Calculate the reluctance of a torus (a doughnut-shaped core) made of low-carbon steel. The inner radius of the torus is 1.75 cm and the outer radius of the torus is 2.25 cm. Assume the permeability of low-carbon steel is 2×10^{-4} Wb/At·m.

Solution

You must convert centimeters to meters before you calculate the area and length. From the dimensions given, the thickness (diameter) is 0.5 cm = 0.005 m. Thus, the cross-sectional area is

$$A = \pi r^2 = \pi(0.0025)^2 = 1.96 \times 10^{-5} \, \text{m}^2$$

The length is equal to the circumference of the torus measured at the average radius of 2.0 cm or 0.020 m.

$$l = C = 2\pi r = 2\pi(0.020 \, \text{m}) = 0.125 \, \text{m}$$

Substituting values into Equation 10–3,

$$\mathcal{R} = \frac{l}{\mu A} = \frac{0.125 \, \text{m}}{(2 \times 10^{-4} \, \text{Wb/At·m})(1.96 \times 10^{-5} \, \text{m}^2)} = \mathbf{31.9 \times 10^6 \, At/Wb}$$

Related Problem

What happens to the reluctance if cast steel with a permeability of 5×10^{-4} Wb/At·m is substituted for the cast iron core?

EXAMPLE 10–4

Mild steel has a relative permeability of 800. Calculate the reluctance of a mild steel core that has a length of 10 cm and has a cross section of 1.0 cm × 1.2 cm.

Solution

First, determine the permeability of mild steel.

$$\mu = \mu_0\mu_r = (4\pi \times 10^{-7} \, \text{Wb/At·m})(800) = 1.00 \times 10^{-3} \, \text{Wb/At·m}$$

Next, convert the length to meters and the area to square meters.

$$l = 10 \, \text{cm} = 0.10 \, \text{m}$$
$$A = 0.010 \, \text{m} \times 0.012 \, \text{m} = 1.2 \times 10^{-4} \, \text{m}^2$$

Substituting values into Equation 10–3,

$$\mathcal{R} = \frac{l}{\mu A} = \frac{0.10 \, \text{m}}{(1.00 \times 10^{-3} \, \text{Wb/At·m})(1.2 \times 10^{-4} \, \text{m}^2)} = \mathbf{8.33 \times 10^5 \, At/Wb}$$

Related Problem

Magnetomotive Force (mmf)   As you have learned, current in a conductor produces a magnetic field. The cause of a magnetic field is called the **magnetomotive force (mmf)**. Magnetomotive force is something of a misnomer because in a physics sense mmf is not really a force, but rather it is a direct result of the movement of charge (current). The unit of mmf, the **ampere-turn (At)**, is established on the basis of the current in a single loop (turn) of wire. The formula for mmf is

Equation 10–4

$$F_m = NI$$

where F_m is the magnetomotive force, N is the number of turns of wire, and I is the current in amperes.

Figure 10–13 illustrates that a number of turns of wire carrying a current around a magnetic material creates a force that sets up flux lines through the magnetic path. The amount
A basic magnetic circuit.

of flux depends on the magnitude of the mmf and on the reluctance of the material, as expressed by the following equation:

$$\phi = \frac{F_m}{\mathcal{R}}$$

Equation 10–5

Equation 10–5 is known as the *Ohm's law for magnetic circuits* because the flux (ϕ) is analogous to current, the mmf (F_m) is analogous to voltage, and the reluctance ($\mathcal{R}$) is analogous to resistance. Like other phenomena in science, the flux is an effect, the mmf is a cause, and the reluctance is an opposition.

One important difference between an electric circuit and a magnetic circuit is that in magnetic circuits, Equation 10–5 is only valid up to a certain point before the magnetic material saturates (flux becomes a maximum). You will see this when you look at magnetization curves in Section 10–4. Another difference that was already noted is that flux does occur in permanent magnets with no source of mmf. In a permanent magnet, the flux is due to internal electron motion rather than an external current. No equivalent effect occurs in electric circuits.

In many magnetic circuits, the core is not continuous. For example, if an air gap is cut into the core, it will increase the reluctance of the magnetic circuit. This means that more current is required to establish the same flux as before because an air gap represents a significant opposition to establishing flux. The situation is analogous to a series electrical circuit; the total reluctance of the magnetic circuit is the sum of the reluctance of the core and the reluctance of the air gap.

The Electromagnet

An electromagnet is based on the properties that you have just learned. A basic electromagnet is simply a coil of wire wound around a core material that can be easily magnetized.

The shape of an electromagnet can be designed for various applications. For example, Figure 10–15 shows a U-shaped magnetic core. When the coil of wire is connected to a battery and there is current, as shown in part (a), a magnetic field is established as indicated. If the current is reversed, as shown in part (b), the direction of the magnetic field is also reversed. The closer the north and south poles are brought together, the smaller the air gap between them becomes, and the easier it becomes to establish a magnetic field because the reluctance is lessened.

10–3 ELECTROMAGNETIC DEVICES

Many types of useful devices such as tape recorders, electric motors, speakers, solenoids, and relays are based on electromagnetism.

After completing this section, you should be able to

◆ **Describe the principle of operation for several types of electromagnetic devices**

  ◆ Discuss how a solenoid and a solenoid valve work

  ◆ Discuss how a relay works

  ◆ Discuss how a speaker works

  ◆ Discuss the basic analog meter movement

  ◆ Explain a magnetic disk and tape Read/Write operation

  ◆ Explain the concept of the magneto-optical disk

The Solenoid

The **solenoid** is a type of electromagnetic device that has a movable iron core called a *plunger*. The movement of this iron core depends on both an electromagnetic field and a mechanical spring force. The basic structure of a solenoid is shown in Figure 10–16. It consists of a cylindrical coil of wire wound around a nonmagnetic hollow form. A stationary iron core is fixed in position at the end of the shaft and a sliding iron core (plunger) is attached to the stationary core with a spring.

▲ FIGURE 10–16

Basic solenoid structure.

The basic solenoid operation is illustrated in Figure 10–17 for the unenergized and the energized conditions. In the at-rest (or unenergized) state, the plunger is extended. The solenoid is energized by current through the coil, which sets up an electromagnetic field that magnetizes both iron cores. The south pole of the stationary core attracts the north pole of

the movable core causing it to slide inward, thus retracting the plunger and compressing the spring. As long as there is coil current, the plunger remains retracted by the attractive force of the magnetic fields. When the current is cut off, the magnetic fields collapse and the force of the compressed spring pushes the plunger back out. The solenoid is used for applications such as opening and closing valves and automobile door locks.

The Solenoid Valve   In industrial controls, **solenoid valves** are widely used to control the flow of air, water, steam, oils, refrigerants, and other fluids. Solenoid valves are used in both pneumatic (air) and hydraulic (oil) systems, common in machine controls. Solenoid valves are also common in the aerospace and medical fields. Solenoid valves can either move a plunger to open or close a port or can rotate a blocking flap a fixed amount.

A solenoid valve consists of two functional units: a solenoid coil that provides the magnetic field to provide the required movement to open or close the valve and a valve body, which is isolated from the coil assembly via a leakproof seal and includes a pipe and butterfly valve. Figure 10–18 shows a cutaway of one type of solenoid valve. When the solenoid is energized, the butterfly valve is turned to open a normally closed (NC) valve or to close a normally open (NO) valve.

▶ FIGURE 10–18

A basic solenoid valve structure.

Solenoid

Pipe

Butterfly valve

Solenoid valves are available with a wide variety of configurations including normally open or normally closed valves. They are rated for different types of fluids (for example, gas or water), pressures, number of pathways, sizes, and more. The same valve may control more than one line and may have more than one solenoid to move.

The Relay

The **relay** differs from the solenoid in that the electromagnetic action is used to open or close electrical contacts rather than to provide mechanical movement. Figure 10–19 shows the basic operation of an *armature-type relay* with one normally open (NO) contact and one normally closed (NC) contact (single pole–double throw). When there is no coil current, the armature is held against the upper contact by the spring, thus providing continuity from

terminal 1 to terminal 2, as shown in part (a) of the figure. When energized with coil current, the armature is pulled down by the attractive force of the electromagnetic field and makes connection with the lower contact to provide continuity from terminal 1 to terminal 3, as shown in Figure 10–19(b). A typical armature relay is shown in part (c), and the schematic symbol is shown in part (d).

Another widely used type of relay is the *reed relay,* which is shown in Figure 10–20. The reed relay, like the armature relay, uses an electromagnetic coil. The contacts are thin reeds of magnetic material and are usually located inside the coil. When there is no coil current, the reeds are in the open position as shown in part (b). When there is current through the coil, the reeds make contact because they are magnetized and attract each other as shown in part (c).

(b) Unenergized

(c) Energized
▲ FIGURE 10–20

Reed relays are superior to armature relays in that they are faster, more reliable, and produce less contact arcing. However, they have less current-handling capability than armature relays and are more susceptible to mechanical shock.

The Speaker

A **speaker** is an electromagnetic device that converts electrical signals into sound. Essentially, it is a linear motor that alternately attracts and repels an electromagnet to and from a permanent magnet called a donut magnet. Figure 10–21 shows the key parts of a speaker. The audio signal is connected using very flexible wires to a cylindrical coil called the voice coil. The voice coil and its movable core form an electromagnet, which is suspended in an accordion-like structure called the spider. The spider acts like an accordion spring, keeping the voice coil in the center and restoring it to the rest position when there is no input signal.

Current from the audio input alternates back and forth and powers the electromagnet; when there is more current, the attraction or repulsion is greater. When the input current reverses direction, the polarity of the electromagnet reverses direction also, faithfully following the input signal. The voice coil and its moving magnet are firmly attached to the cone. The cone is a flexible diaphragm that vibrates to produce sound.

▶ **FIGURE 10–21**

Meter Movement

The d'Arsonval meter movement is the most common type used in analog multimeters. In this type of meter movement, the pointer is deflected in proportion to the amount of current through a coil. Figure 10–22 shows a basic d'Arsonval meter movement. It consists of a

▶ **FIGURE 10–22**

coil of wire wound on a bearing-mounted assembly that is placed between the poles of a permanent magnet. A pointer is attached to the moving assembly. With no current through the coil, a spring mechanism keeps the pointer at its left-most (zero) position. When there is current through the coil, electromagnetic forces act on the coil, causing a rotation to the right. The amount of rotation depends on the amount of current.

Figure 10–23 illustrates how the interaction of magnetic fields produces rotation of the coil assembly. Current is inward at the "cross" and outward at the "dot" in the single winding shown. The outward current produces a clockwise electromagnetic field that reinforces the permanent magnetic field above it. The result is a downward force on the right side of the coil as shown. The inward current produces a counterclockwise electromagnetic field that reinforces the permanent magnetic field below it. The result is an upward force on the left side of the coil as shown. These forces produce a clockwise rotation of the coil assembly and are opposed by a spring mechanism. The indicated forces and the spring force are balanced at the value of the current. When current is removed, the spring force returns the pointer to its zero position.

◀ FIGURE 10–23

When the electromagnetic field interacts with the permanent magnetic field, forces are exerted on the rotating coil assembly, causing it to move clockwise and thus deflecting the pointer.

Magnetic Disk and Tape Read/Write Head

A simplified diagram of a magnetic disk or tape surface read/write operation is shown in Figure 10–24. A data bit (1 or 0) is written on the magnetic surface by the magnetization of a small segment of the surface as it moves by the write head. The direction of the magnetic flux lines is controlled by the direction of the current pulse in the winding, as shown in Figure 10–24(a). At the air gap in the write head, the magnetic flux takes a path through the surface of the storage device. This magnetizes a small spot on the surface in the direction of the field. A magnetized spot of one polarity represents a binary 1, and one of the opposite polarity represents a binary 0. Once a spot on the surface is magnetized, it remains until written over with an opposite magnetic field.

(a) The magnetic flux from the write head follows the low reluctance path through the moving magnetic surface.

(b) When read head passes over magnetized spot, an induced voltage appears at the output.
▲ FIGURE 10–24

Read/write function on a magnetic surface.

When the magnetic surface passes a read head, the magnetized spots produce magnetic fields in the read head, which induce voltage pulses in the winding. The polarity of these pulses depends on the direction of the magnetized spot and indicates whether the stored bit is a 1 or a 0. This process is illustrated in Figure 10–24(b). Often the read and write heads are combined into a single unit.

The Magneto-Optical Disk

The magneto-optical disk uses an electromagnet and laser beams to read and write (record) data on a magnetic surface. Magneto-optical disks are formatted in tracks and sectors similar to magnetic floppy disks and hard disks. However, because of the ability of a laser beam to be precisely directed to an extremely small spot, magneto-optical disks are capable of storing much more data than standard magnetic hard disks.

Figure 10–25(a) illustrates a small cross-sectional area of a disk before recording, with an electromagnet positioned below it. Tiny magnetic particles, represented by the arrows, are all magnetized in the same direction.

Writing (recording) on the disk is accomplished by applying an external magnetic field opposite to the direction of the magnetic particles, as indicated in Figure 10–25(b), and

(a) Small cross-section of unrecorded disk

(b) Writing: A high-power laser beam heats the spot, causing the magnetic particle to align with the electromagnetic field.

(c) Reading: A low-power laser beam reflects off of the reversed-polarity magnetic particle and its polarization shifts. If the particle is not reversed, the polarization of the reflected beam is unchanged.

(d) Erasing: The electromagnetic field is reversed as the high-power laser beam heats the spot, causing the magnetic particle to be restored to the original polarity.

▲ FIGURE 10–25

then directing a high-power laser beam to heat the disk at a precise point where a binary 1 is to be stored. The disk material, a magneto-optic alloy, is highly resistant to magnetization at room temperature; but at the spot where the laser beam heats the material, the inherent direction of magnetism is reversed by the external magnetic field produced by the electromagnet. At points where binary 0s are to be stored, the laser beam is not applied and the inherent upward direction of the magnetic particle remains.

As illustrated in Figure 10–25(c), reading data from the disk is accomplished by turning off the external magnetic field and directing a low-power laser beam at a spot where a bit is to be read. Basically, if a binary 1 is stored at the spot (reversed magnetization), the laser beam is reflected and its polarization is shifted; but if a binary 0 is stored, the polarization of the reflected laser beam is unchanged. A detector senses the difference in the polarity of the reflected laser beam to determine if the bit being read is a 1 or a 0.

Figure 10–25(d) shows that the disk is erased by restoring the original magnetic direction of each particle by reversing the external magnetic field and applying the high power laser beam.

10–4 MAGNETIC HYSTERESIS

When a magnetizing force is applied to a material, the flux density in the material changes in a certain way.

After completing this section, you should be able to

◆ **Explain magnetic hysteresis**

  ◆ State the formula for magnetic field intensity

  ◆ Discuss a hysteresis curve

  ◆ Define *retentivity*

Magnetic Field Intensity (H)

The **magnetic field intensity** (also called *magnetizing force*) in a material is defined to be the magnetomotive force (F_m) per unit length (l) of the material, as expressed by the following equation. The unit of magnetic field intensity (H) is ampere-turns per meter (At/m).

$$H = \frac{F_m}{l}$$

where $F_m = NI$. Note that the magnetic field intensity depends on the number of turns (N) of the coil of wire, the current (I) through the coil, and the length (l) of the material. It does not depend on the type of material.

Since $\phi = F_m/\mathcal{R}$, as F_m increases, the flux increases. Also, the magnetic field intensity (H) increases. Recall that the flux density (B) is the flux per unit cross-sectional area ($B = \phi/A$), so B is also proportional to H. The curve showing how these two quantities (B and H) are related is called the *B-H* curve or the hysteresis curve. The parameters that influence both B and H are illustrated in Figure 10–26.

Parameters that determine the magnetic field intensity (H) and the flux density (B).

$$B = \frac{\phi}{A}$$

$$H = \frac{F_m}{l}$$

$$F_m = NI$$
The Hysteresis Curve and Retentivity

Hysteresis is a characteristic of a magnetic material whereby a change in magnetization lags the application of the magnetic field intensity. The magnetic field intensity (H) can be readily increased or decreased by varying the current through the coil of wire, and it can be reversed by reversing the voltage polarity across the coil.

Figure 10–27 illustrates the development of the hysteresis curve. Let's start by assuming a magnetic core is unmagnetized so that $B = 0$. As the magnetic field intensity (H) is increased from zero, the flux density (B) increases proportionally, as indicated by the curve
▲ FIGURE 10–27

Development of a magnetic hysteresis curve.

in Figure 10–27(a). When H reaches a certain value, B begins to level off. As H continues to increase, B reaches a saturation value (B_{sat}) when H reaches a value (H_{sat}), as illustrated in Figure 10–27(b). Once saturation is reached, a further increase in H will not increase B.

Now, if H is decreased to zero, B will fall back along a different path to a residual value (B_R), as shown in Figure 10–27(c). This indicates that the material continues to be magnetized even when the magnetic field intensity is zero ($H = 0$). The ability of a material to maintain a magnetized state without magnetic field intensity is called **retentivity**. The retentivity of a material represents the maximum flux that can be retained after the material has been magnetized to saturation and is indicated by the ratio of B_R to B_{sat}.

Reversal of the magnetic field intensity is represented by negative values of H on the curve and is achieved by reversing the current in the coil of wire. An increase in H in the negative direction causes saturation to occur at a value ($-H_{sat}$) where the flux density is at its maximum negative value, as indicated in Figure 10–27(d).

When the magnetic field intensity is removed ($H = 0$), the flux density goes to its negative residual value ($-B_R$), as shown in Figure 10–27(e). From the $-B_R$ value, the flux density follows the curve indicated in part (f) back to its maximum positive value when the magnetic field intensity equals H_{sat} in the positive direction.

The complete B-H curve is shown in Figure 10–27(g) and is called the *hysteresis curve*. The magnetic field intensity required to make the flux density zero is called the *coercive force, H_C*.

Materials with a low retentivity do not retain a magnetic field very well, while those with high retentivities exhibit values of B_R very close to the saturation value of B. Depending on the application, retentivity in a magnetic material can be an advantage or a disadvantage. In permanent magnets and magnetic tape, for example, high retentivity is required; while in tape recorder read/write heads, low retentivity is necessary. In ac motors, retentivity is undesirable because the residual magnetic field must be overcome each time the current reverses, thus wasting energy.

SECTION 10–4 CHECKUP	1. For a given wirewound core, how does an increase in current through the coil affect the flux density?

10–5 ELECTROMAGNETIC INDUCTION

In this section, electromagnetic induction is introduced. The principle of electromagnetic induction is what makes transformers, electrical generators, and many other devices possible.

After completing this section, you should be able to

  ◆ Explain how voltage is induced in a conductor in a magnetic field

  ◆ State Faraday's law

  ◆ State Lenz's law

  ◆ Explain how a crankshaft position sensor works

Relative motion between a straight conductor and a magnetic field.

(a) Conductor moving downward

(b) Magnetic field moving upward
Relative Motion

When a straight conductor is moved perpendicular to a magnetic field, there is a relative motion between the conductor and the magnetic field. Likewise, when a magnetic field is moved past a stationary conductor, there is also relative motion. In either case, this relative motion results in an **induced voltage (v_{ind})** in the conductor, as Figure 10–28 indicates. This principle is known as **electromagnetic induction**. The lowercase v stands for instantaneous voltage. Voltage is only induced when the conductor "cuts" magnetic lines as shown. The amount of the induced voltage (v_{ind}) depends on the flux density (B), the length of the conductor (l) that is exposed to the magnetic field, and the rate at which the conductor and the magnetic field move with respect to each other. The faster the relative speed, the greater the induced voltage. The equation for induced voltage in a straight conductor is

Equation 10–7

$$v_{ind} = B_\perp l v$$

where v_{ind} is the induced voltage, $B_\perp$ is the flux density in teslas, l is the length of the conductor exposed to the magnetic field in meters, and v is the relative velocity in meters per second.

Polarity of the Induced Voltage

If the conductor in Figure 10–28 is moved first one way and then another in the magnetic field, a reversal of the polarity of the induced voltage will be observed. As the conductor is moved downward, a voltage is induced with the polarity indicated in Figure 10–29(a). As the conductor is moved upward, the polarity is as indicated in part (b) of the figure.

Polarity of induced voltage depends on direction of motion.

Induced Current

When a load resistor is connected to the conductor in Figure 10–29, the voltage induced by the relative motion in the magnetic field will cause a current in the load, as shown in Figure 10–30. This current is called the **induced current (i_{ind})**. The lowercase i stands for instantaneous current.
◄ **FIGURE 10–30**

Induced current in a load as the conductor moves through the magnetic field.

The action of producing a voltage and a resulting current in a load by moving a conductor across a magnetic field is the basis for electrical generators. A single conductor will have a small induced current, so practical generators use coils with many turns. The concept of a conductor in a moving magnetic field is the basis for inductance in an electric circuit.

Faraday's law

Michael Faraday discovered the principle of electromagnetic induction in 1831. The key idea behind Faraday's law is that a changing magnetic field can induce a voltage in a conductor. Sometimes Faraday's law is stated as Faraday's law of induction. Faraday experimented with coils, and his law is an extension of the principle of electromagnetic induction for straight conductors discussed previously.

When a conductor is coiled into multiple turns, more conductors can be exposed to the magnetic field, increasing the induced voltage. When the magnetic flux is caused to change by any means, an induced voltage will result. The change in the magnetic field can be caused by relative motion between the magnetic field and the coil. Faraday's observations can be stated as follows:

1. The amount of voltage induced in a coil is directly proportional to the rate of change of the magnetic field with respect to the coil ($d\phi/dt$).
2. The amount of voltage induced in a coil is directly proportional to the number of turns of wire in the coil (N).

Faraday's first observation is demonstrated in Figure 10–31, where a bar magnet is moved through a coil, thus creating a changing magnetic field. In part (a) of the figure, the magnet is moved at a certain rate, and a certain induced voltage is produced as indicated. In part (b), the magnet is moved at a faster rate through the coil, creating a greater induced voltage.

Faraday's second observation is demonstrated in Figure 10–32. In part (a), the magnet is moved through the coil and a voltage is induced as shown. In part (b), the magnet is moved at the same speed through a coil that has a greater number of turns. The greater number of turns creates a greater induced voltage.
(a) As the magnet moves slowly to the right, its magnetic field is changing with respect to the coil, and a voltage is induced.

(b) As the magnet moves more rapidly to the right, its magnetic field is changing more rapidly with respect to the coil, and a greater voltage is induced.

▲ FIGURE 10–31

A demonstration of Faraday's first observation: The amount of induced voltage is directly proportional to the rate of change of the magnetic field with respect to the coil.
(a) Magnet moves through a coil and induces a voltage.
(b) Magnet moves at same rate through a coil with more turns (loops) and induces a greater voltage.

▲ FIGURE 10–32

A demonstration of Faraday's second observation: The amount of induced voltage is directly proportional to the number of turns in the coil.

Faraday's law is stated as follows:

The voltage induced across a coil equals the number of turns in the coil times the rate of change of the magnetic flux.

Faraday's law is expressed in equation form as

Equation 10–8

$$v_{ind} = N\left(\frac{d\phi}{dt}\right)$$

where v_{ind} is the induced voltage, N is the number of turns in the coil, and $d\phi/dt$ is the rate of change of the magnetic flux.

EXAMPLE 10–8

Apply Faraday's law to find the induced voltage across a coil with 500 turns that is located in a magnetic field that is changing at a rate of 8000 μWb/s.

Solution

$$v_{ind} = N\left(\frac{d\phi}{dt}\right) = (500\ t)(8000\ \mu Wb/s) = \textbf{4.0 V}$$

Related Problem   Find the induced voltage across a 250 turn coil in a magnetic field that is changing at 50 μWb/s.

Any *relative* motion between the magnetic field and the coil will produce the changing magnetic field that will induce a voltage in the coil. The changing magnetic field can even be induced by ac applied to an electromagnet, just as if there were motion. This type of changing magnetic field is the basis for transformer action in ac circuits, as you will see in Chapter 14.

Lenz's Law

Faraday's law states that a changing magnetic field induces a voltage in a coil that is directly proportional to the rate of change of the magnetic field and the number of turns in the coil. **Lenz's law** defines the polarity or direction of the induced voltage.

> **When the current through a coil changes, an induced voltage is created as a result of the changing electromagnetic field and the polarity of the induced voltage is such that it always opposes the change in current.**

An Application of Electromagnetic Induction

In automobiles, it is necessary to know the position of the crankshaft to control ignition timing and sometimes to adjust the fuel mixture. As mentioned previously, a Hall-effect sensor is one method to determine the position of the crankshaft (or camshaft). Another widely used method is to detect a change in the magnetic field as a metallic tab moves though the air gap in a magnetic assembly. A basic concept is shown in Figure 10–33. A steel disk with protruding tabs is connected to the end of the crankshaft. As the crankshaft turns, the tabs move through the magnetic field. Steel has a much lower reluctance than does air, so the magnetic flux increases when a tab is in the air gap. This change in the magnetic flux causes an induced voltage to appear across the coil, indicating the position of the crankshaft.
◄ **FIGURE 10–33**

A crankshaft position sensor that produces a voltage when a tab passes through the air gap of the magnet.

Forces on a Current-Carrying Conductor in a Magnetic Field (Motor Action)

Figure 10–34(a) shows current inward through a wire in a magnetic field. The electromagnetic field set up by the current interacts with the permanent magnetic field; as a result, the permanent lines of force above the wire tend to be deflected down under the wire because they are opposite in direction to the electromagnetic lines of force. Therefore, the

(b) Downward force: strong field above, weak field below

⊙ Current out
⊕ Current in
flux density above is reduced, and the magnetic field is weakened. The flux density below the conductor is increased, and the magnetic field is strengthened. An upward force on the conductor results, and the conductor tends to move toward the weaker magnetic field.

Figure 10–34(b) shows the current outward, resulting in a force on the conductor in the downward direction. This force is the basis for electrical motors. The force on a current-carrying conductor is given by the equation

Equation 10–9

$$F = BIl$$

where F is the force in newtons, B is the magnetic flux density in teslas, I is the current in amperes, and l is the length of the conductor exposed to the magnetic field in meters.

EXAMPLE 10–9

Assume a magnetic pole face is a square that is 3.0 cm on a side. Find the force on a conductor that has a current of 2 A if the conductor is perpendicular to the field and the flux density is 0.35 T.

Solution   The length of conductor exposed to the magnetic flux is 3.0 cm (0.030 m). Therefore,

$$F = BIl = (0.35 \text{ T})(2.0 \text{ A})(0.03 \text{ m}) = \textbf{0.21 N}$$

10–6 THE DC GENERATOR

DC generators produce a voltage that is proportional to the magnetic flux and the rotational speed of the armature.

After completing this section, you should be able to

◆ **Explain how a dc generator works**

   ◆ Draw an equivalent circuit for a self-excited shunt-type dc generator

   ◆ Discuss the parts of a dc generator

◄ FIGURE 10–35

A simplified dc generator.

Figure 10–35 shows a simplified dc generator consisting of a single loop of wire in a permanent magnetic field. Notice that each end of the wire loop is connected to a split-ring arrangement. This conductive metal ring is called a *commutator.* As the wire loop rotates in the magnetic field, the split commutator ring also rotates. Each half of the split ring rubs against the fixed contacts, called *brushes,* and connects the wire loop to an external circuit.

As the wire loop rotates through the magnetic field, it cuts through the flux lines at varying angles, as illustrated in Figure 10–36. At position *A* in its rotation, the loop of wire is effectively moving parallel with the magnetic field. Therefore, at this instant, the rate at which it is cutting through the magnetic flux lines is zero. As the loop moves from position *A* to position *B*, it cuts through the flux lines at an increasing rate. At position *B*, it is moving effectively perpendicular to the magnetic field and thus is cutting through a maximum number of lines. As the loop rotates from position *B* to position *C*, the rate at which it cuts the flux lines decreases to minimum (zero) at *C*. From position *C* to position *D*, the rate at which the loop cuts the flux lines increases to a maximum at *D* and then back to a minimum again at *A*.
◄ FIGURE 10–36

End view of wire loop cutting through the magnetic field.

As you have learned, when a wire moves through a magnetic field, a voltage is induced, and by Faraday's law, the amount of induced voltage is proportional to the number of loops (turns) in the wire and the rate at which it is moving with respect to the magnetic field. The angle at which the wire moves with respect to the magnetic flux lines determines the amount of induced voltage because the rate at which the wire cuts through the flux lines depends on the angle of motion.

Figure 10–37 illustrates how a voltage is induced in the external circuit as the single loop rotates in the magnetic field. Assume that the loop is in its instantaneous horizontal position,
Position *B*: Loop is moving perpendicular to flux lines, and voltage is maximum.
Position *C*: Loop is moving parallel with flux lines, and voltage is zero.
Position *D*: Loop is moving perpendicular to flux lines, and voltage is maximum.
Position *A*: Loop is moving parallel with flux lines, and voltage is zero.

▲ **FIGURE 10–37**

Operation of a basic dc generator.

so the induced voltage is zero. As the loop continues in its rotation, the induced voltage builds up to a maximum at position *B*, as shown in part (a) of the figure. Then, as the loop continues from *B* to *C*, the voltage decreases to zero at position *C*, as shown in part (b).

During the second half of the revolution, shown in Figure 10–37(c) and (d), the brushes switch to opposite commutator sections, so the polarity of the voltage remains the same across the output. Thus, as the loop rotates from position *C* to position *D* and then back to position *A*, the voltage increases from zero at *C* to a maximum at *D* and back to zero at *A*.

Figure 10–38 shows how the induced voltage varies as the wire loop in the dc generator goes through several rotations (three in this case). This voltage is a dc voltage because its polarities do not change. However, the voltage is pulsating between zero and its maximum value.

In practical generators, multiple coils are pressed into slots in a ferromagnetic-core assembly. The entire assembly, called the **rotor**, is connected to bearings and rotates in the magnetic field. Figure 10–39 is a diagram of the rotor core with no wire loops (coils)
Induced voltage over three rotations of the wire loop in the dc generator.
◀ FIGURE 10–39

A simplified rotor core. The coils are pressed into the slots and connected to the commutator.

shown. The commutator is divided into segments, with each pair of segments connected to the end of a coil. With more coils, the voltages from several coils are combined because the brushes can contact more than one of the commutator segments at once. The loops do not reach maximum voltage at the same time, so the pulsating output voltage is much smoother than is the case with only one coil or loop shown previously. The variations can be further smoothed by filters to produce a nearly constant dc output. (Filters are discussed in Chapter 18.)

Instead of permanent magnets, most generators use electromagnets to provide the required magnetic field. One advantage to this is that flux density can be controlled, thus controlling the output voltage of the generator. The windings for the electromagnets, called field windings, require current to produce the magnetic field.

The current for the field windings can be provided from a separate voltage source, but this is a disadvantage. A better method is to use the generator itself to provide the current for the electromagnets; this is called a **self-excited generator**. The generator starts because there is normally enough residual magnetism in the field magnets due to hysteresis that causes a small initial field and allows the generator to start producing a voltage. In cases where a generator has not been used for a long time, it may be necessary to provide an external source to the field windings to start it.

The stationary part of a generator (or motor) includes all of the nonmoving parts and is called the **stator**. Figure 10–40 illustrates a simplified two-pole dc generator showing the magnetic paths (end caps, bearings, and commutator are not shown). Notice that the frame is part of the magnetic path for the field magnets. To make a generator have high efficiency, the air gap is kept as small as possible. The **armature** is the power-producing component and can be either on the rotor or the stator. In the dc generator described previously, the armature is the rotor because power is produced in the moving conductors and taken from the rotor via the commutator.
▲ FIGURE 10–40

The magnetic structure of a generator or motor. In this case, the rotor is also the armature because it produces the power.

Equivalent Circuit for a DC Generator

A self-excited generator can be represented by a basic dc circuit with a coil to produce the magnetic field and a mechanically driven generator, as shown in Figure 10–41. There are other configurations of dc generators, but this represents a common one. In the case shown, the field windings are in parallel with the source; this configuration is called a *shunt-wound generator*. The resistance of the field windings is shown as R_F. For the equivalent circuit, this resistance is shown in series with the field windings. The armature is driven by a mechanical input, causing it to spin; it looks like a voltage source of V_G. The armature resistance is shown as the series resistance, R_A. The rheostat, R_{REG}, is in series with the field winding resistance and regulates the output voltage by controlling the current to the field windings and thus the flux density.

▶ FIGURE 10–41

When a load is connected to the output, current in the armature is shared between the load and the field windings. The efficiency of the generator can be calculated as the ratio of the power delivered to the load (P_L) to the total power (P_T), which includes the losses in the armature and the resistance in the field circuit.

10–7   THE DC MOTOR

Motors convert electrical energy to mechanical motion by taking advantage of the force produced when a current-carrying conductor is in a magnetic field. A dc motor operates from a dc source and can use either an electromagnet or a permanent magnet to supply the field.

After completing this section, you should be able to

◆ **Explain how a dc motor works**

   ◆ Draw an equivalent circuit for a series and a shunt-type dc motor

   ◆ Discuss back emf and how it reduces armature current

   ◆ Discuss power rating of motors

Basic Operation

As in the case of generators, motor action is the result of the interaction of magnetic fields. In a dc motor, the rotor field interacts with the magnetic field set up by current in the stator windings. The rotor in all dc motors contains the armature winding, which sets up a magnetic field. The rotor moves because of the attractive force between opposite poles and the repulsive force between like poles, as illustrated in the simplified diagram of Figure 10–42. The rotor moves because of the attraction of its north pole with the south pole of the stator (and vice-versa). As the two poles near each other, the polarity of the rotor current is suddenly switched by the commutator, reversing the magnetic poles of the rotor. The commutator serves as a mechanical switch to reverse the current in the armature just as the unlike poles are near each other, continuing the rotation of the rotor.
▲ **FIGURE 10–42**

Simplified dc motor.

Brushless DC Motors

Many dc motors do not use a commutator to reverse the polarity of the current. Instead of supplying current to a moving armature, the magnetic field is rotated in the stator windings using an electronic controller. The direction of current in the field coils is periodically reversed by the controller by producing an ac waveform (or modified ac waveform) from the dc input. This causes the stator field to rotate, and the permanent magnet rotor moves in the same direction to keep up with the rotating field. A common way to sense the position of the rotating magnet is to use a Hall-effect sensor, which provides the controller with position information. Brushless motors have higher reliability than traditional brushed motors because they do not need to have periodic brush replacement, but have the added complexity of the electronic controller. Figure 10–43 shows a cutaway view of a brushless dc motor.

Back EMF

When a dc motor is first started, a magnetic field is present from the field windings. Armature current develops another magnetic field that interacts with the one from the field windings and starts the motor turning. The armature windings are now spinning in the presence of the magnetic field, so generator action occurs. In effect, the spinning armature has a voltage developed across it that opposes the original applied voltage in accordance with Lenz's law. This self-generated voltage is called **back emf** (electromotive force). The term *emf* was once common for voltage but is not favored because voltage is not a "force" in the physics sense, but back emf is still applied to the self-generated voltage in motors. Back emf, also called *counter emf*, serves to significantly reduce the armature current when the motor is turning at constant speed.

Motor Ratings

Some motors are rated by the torque they can provide, others are rated by the power they produce. Torque and power are important parameters for any motor. Although torque and power are different physical parameters, if one is known, the other can be obtained.

Torque tends to rotate an object. In a dc motor, the torque is proportional to the amount of flux and to the armature current. Torque, *T*, in a dc motor can be calculated from the equation

Equation 10–10

$$T = K\phi I_A$$

where T is torque in newton-meters (N-m), K is a constant that depends on physical parameters of the motor, ϕ is magnetic flux in webers (Wb), and I_A is armature current in amperes (A).

Recall that power is defined as the rate of doing work. To calculate power from torque, you must know the speed of the motor in rpm for the torque that you measured. The equation to determine the power, given the torque at a certain speed, is

$$P = 0.105Ts$$

where P is power in W, T is torque in N-m, and s is speed of motor in rpm.

EXAMPLE 10–10

What is the power developed by a motor that turns at 350 rpm when the torque is 3.6 N-m?

Solution   Substitute into Equation 10–11.

$$P = 0.105Ts = 0.105(3.6 \text{ N-m})(350 \text{ rpm}) = \textbf{132 W}$$

*Related Problem*   Determine the power produced by a motor if $T = 5$ N-m and $s = 1000$ rpm.

The Series DC Motor

The series dc motor has the field coil windings and the armature coil windings in series. A schematic of this arrangement is shown in Figure 10–44(a). The internal resistance is generally small and consists of field coil resistance, armature winding resistance, and brush resistance. As in the case of generators, dc motors may also contain an interpole winding, as shown, and current limiting for speed control. In a series dc motor, the armature current, field current, and line current are all the same.

> **TECH NOTE**
>
> One characteristic of dc motors is that if they are allowed to run without a load, the torque can cause the motor to "run away" to a speed beyond the manufacturer's rating. Therefore, dc motors should always be operated with a load to prevent self-destruction.

(a)   (b)
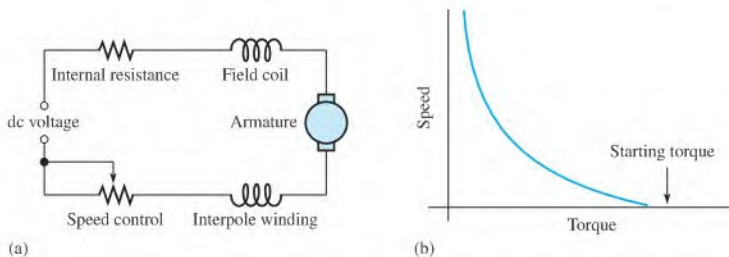

▲ **FIGURE 10–44**

Simplified schematic and torque-speed characteristic for a series dc motor.

As you know, magnetic flux is proportional to the current in a coil. The magnetic flux created by the field windings is proportional to armature current because of the series connection. Thus, when the motor is loaded, armature current rises, and the magnetic flux rises too. Recall that Equation 10–10 showed that the torque in a dc motor is proportional to both the armature current and the magnetic flux. Thus, the series-wound motor will have a very high starting torque when the current is high because flux and armature current are high. For this reason, series dc motors are used when high starting torques are required (such as a starter motor in a car).

The plot of the torque and motor speed for a series dc motor is shown in Figure 10–44(b). The starting torque is at its maximum value. At low speeds, the torque is still very high, but drops off dramatically as the speed increases. As you can see, the speed can be very high if the torque is low; for this reason, the series-wound dc motor always is operated with a load.

The Shunt DC Motor

A shunt dc motor has the field coil in parallel with the armature, as shown in the equivalent circuit in Figure 10–45(a). In the shunt motor, the field coil is supplied by a constant voltage source, so the magnetic field set up by the field coils is constant. The armature resistance and the back emf produced by generator action in the armature determine the armature current.

The torque-speed characteristic for a shunt dc motor is quite different than for a series dc motor. When a load is applied, the shunt motor will slow down, causing the back emf to be reduced and the armature current to increase. The increase in armature current tends to compensate for the added load by increasing the torque of the motor. Although the motor has slowed because of the additional load, the torque-speed characteristic is nearly a straight line for the shunt dc motor as shown in Figure 10–45(b). At full load, the shunt dc motor still has high torque.

Application Activity

The relay is a common type of electromagnetic device that is used in many types of control applications. With a relay, a lower voltage, such as from a battery, can be used to switch a much higher voltage, such as the 120 V from an ac outlet. You will see how a relay can be used in a basic security alarm system.

The schematic in Figure 10–46 shows a simplified intrusion alarm system that uses a relay to turn on an audible alarm (siren) and lights. The system operates from a 9 V battery so that even if power to the house is off, the audible alarm will still work.

The detection switches are normally open (NO) magnetic switches that are parallel connected and located in the windows and doors. The relay is a triple-pole–double-throw device that operates with a coil voltage of 9 V dc and draws approximately 50 mA. When an intrusion occurs, one of the switches closes and allows current from the battery to the relay coil, which energizes the relay and causes the three sets of normally open contacts to close. Closure of contact A turns on the alarm, which

draws 2 A from the battery. Closure of contact C turns on a light circuit in the house. Closure of contact B latches the relay and keeps it energized even if the intruder closes the door or window through which entry was made. If not for contact B in parallel with the detection switches, the alarm and lights would go off as soon as the window or door was shut behind the intruder.

The relay contacts are not physically remote in relation to the coil as the schematic indicates. The schematic is drawn this way for functional clarity. The entire relay is housed in the

INTRODUCTION

In the preceding chapters, you have studied resistive circuits with dc currents and voltages. This chapter provides an introduction to ac circuit analysis in which time-varying electrical signals, particularly the sine wave, are studied. An electrical signal is a voltage or current that changes in some consistent manner with time. In other words, the voltage or current fluctuates according to a certain pattern called a waveform.

An alternating voltage is one that changes polarity at a certain rate, and an alternating current is one that changes direction at a certain rate. The sinusoidal waveform (sine wave) is the most common and fundamental type because all other types of repetitive waveforms can be broken down into composite sine waves. The sine wave is a periodic type of waveform that repeats at fixed intervals. The use of phasors to represent sine waves is discussed.

Special emphasis is given to the sinusoidal waveform (sine wave) because of its fundamental importance in ac circuit analysis. Alternators, which generate sine waves, and ac motors are introduced. Other types of waveforms are also introduced, including pulse, triangular, and sawtooth. The use of the oscilloscope for displaying and measuring waveforms is introduced.

11–1 THE SINUSOIDAL WAVEFORM

The sinusoidal waveform or *sine wave* is the fundamental type of alternating current (ac) and alternating voltage. It is also referred to as a sinusoidal wave or, simply, sinusoid. The electrical service provided by the power company is in the form of sinusoidal voltage and current. In addition, other types of repetitive **waveforms** are composites of many individual sine waves called harmonics.
After completing this section, you should be able to

◆ **Identify a sinusoidal waveform and measure its characteristics**

   ◆ Determine the period

   ◆ Determine the frequency

   ◆ Relate the period and the frequency

   ◆ Describe two types of electronic signal generators.

Sinusoidal voltages are produced by two types of sources: rotating electrical machines (ac generators) or electronic oscillator circuits, which are used in instruments commonly known as electronic signal generators. Figure 11–1 shows the symbol used to represent either source of sinusoidal voltage. AC generators are covered in Section 11–7, and electronic signal generators are discussed at the end of this section.

▲ **FIGURE 11–1**

Symbol for a sinusoidal voltage source.

Figure 11–2 is a graph showing the general shape of a **sine wave**, which can be either an alternating current or an alternating voltage. Voltage (or current) is displayed on the vertical axis and time (t) is displayed on the horizontal axis. Notice how the voltage (or current) varies with time. Starting at zero, the voltage (or current) increases to a positive maximum (peak), returns to zero, and then increases to a negative maximum (peak) before returning again to zero, thus completing one full cycle.

◀ **FIGURE 11–2**

Graph of one cycle of a sine wave.

Polarity of a Sine Wave

As mentioned, a sine wave changes polarity at its zero value; that is, it alternates between positive and negative values. When a sinusoidal voltage source (V_s) is applied to a resistive circuit, as in Figure 11–3, an alternating sinusoidal current results. When the voltage changes polarity, the current correspondingly changes direction as indicated.

During the positive alternation of the applied voltage V_s, the current is in the direction shown in Figure 11–3(a). During a negative alternation of the applied voltage, the current

(a) During a positive alternation of voltage, current is in the direction shown.

(b) During a negative alternation of voltage, current reverses direction, as shown.

▲ FIGURE 11–3

Alternating current and voltage.

is in the opposite direction, as shown in Figure 11–3(b). The combined positive and negative alternations make up one **cycle** of a sine wave.
Period of a Sine Wave

A sine wave varies with time (t) in a definable manner.

> **The time required for a sine wave to complete one full cycle is called the period (T).**

Figure 11–4(a) illustrates the period of a sine wave. Typically, a sine wave continues to repeat itself in identical cycles, as shown in Figure 11–4(b). Since all cycles of a repetitive sine wave are the same, the period is always a fixed value for a given sine wave. The period of a sine wave can be measured from a zero crossing to the next corresponding zero crossing, as indicated in Figure 11–4(a). The period can also be measured from any peak in a given cycle to the corresponding peak in the next cycle.

▶ FIGURE 11–4

The period of a sine wave is the same for each cycle.

EXAMPLE 11–1

What is the period of the sine wave in Figure 11–5?

▶ FIGURE 11–5
Solution   As shown in Figure 11–5, it takes four seconds (4 s) to complete each cycle. There-fore, the period is 4 s.
$$T = 4\,\text{s}$$

Related Problem*   What is the period if the sine wave goes through five cycles in 12 s?

*Answers are at the end of the chapter.

EXAMPLE 11–2   Show three possible ways to measure the period of the sine wave in Figure 11–6. How many cycles are shown?

▶ **FIGURE 11–6**

Solution   **Method 1:** The period can be measured from one zero crossing to the corresponding zero crossing in the next cycle (the slope must be the same at the corresponding zero crossings).

Method 2: The period can be measured from the positive peak in one cycle to the positive peak in the next cycle.

Method 3: The period can be measured from the negative peak in one cycle to the negative peak in the next cycle.

These measurements are indicated in Figure 11–7, where **two cycles of the sine wave** are shown. Keep in mind that you obtain the same value for the period no matter which corresponding points on the waveform you use.

▶ **FIGURE 11–7**

Measurement of the period of a sine wave.
Related Problem   If a positive peak occurs at 1 ms and the next positive peak occurs at 2.5 ms, what is the period?

Frequency of a Sine Wave

Frequency (*f*) is the number of cycles that a sine wave completes in one second.

The more cycles completed in one second, the higher the frequency. Frequency (*f*) is measured in units of hertz. One **hertz (Hz)** is equivalent to one cycle per second; 60 Hz is 60 cycles per second, for example. Figure 11–8 shows two sine waves. The sine wave in part (a) completes two full cycles in one second. The one in part (b) completes four cycles in one second. Therefore, the sine wave in part (b) has twice the frequency of the one in part (a).

(a) Lower frequency: fewer cycles per second

(b) Higher frequency: more cycles per second
▲ FIGURE 11–8

Illustration of frequency.

Relationship of Frequency and Period

The formulas for the relationship between frequency (*f*) and period (*T*) are as follows:

Equation 11–1

$$f = \frac{1}{T}$$

Equation 11–2

$$T = \frac{1}{f}$$

There is a reciprocal relationship between *f* and *T*. Knowing one, you can calculate the other with the x^{-1} or $1/x$ key on your calculator. This inverse relationship makes sense because a sine wave with a longer period goes through fewer cycles in one second than one with a shorter period.

EXAMPLE 11–3

Which sine wave in Figure 11–9 has a higher frequency? Determine the frequency and the period of both waveforms.

◆ FIGURE 11–9

(a)

(b)
Solution   The sine wave in Figure 11–9(b) has the higher frequency because it completes more cycles in 1 s than does the sine wave in part (a).

In Figure 11–9(a), three cycles are completed in 1 s; therefore,

$$f = \textbf{3 Hz}$$

One cycle takes 0.333 s (one-third second), so the period is

$$T = 0.333 \text{ s} = \textbf{333 ms}$$

In Figure 11–9(b), five cycles are completed in 1 s; therefore,

$$f = \textbf{5 Hz}$$

One cycle takes 0.2 s (one-fifth second), so the period is

$$T = 0.2 \text{ s} = \textbf{200 ms}$$

Related Problem   If the time between negative peaks of a given sine wave is 50 μs, what is the frequency?

EXAMPLE 11–4   The period of a certain sine wave is 10 ms. What is the frequency?

Solution   Use Equation 11–1.

$$f = \frac{1}{T} = \frac{1}{10 \text{ ms}} = \frac{1}{10 \times 10^{-3} \text{ s}} = \textbf{100 Hz}$$

Related Problem   A certain sine wave goes through four cycles in 20 ms. What is the frequency?

EXAMPLE 11–5   The frequency of a sine wave is 60 Hz. What is the period?

Solution   Use Equation 11–2.

$$T = \frac{1}{f} = \frac{1}{60 \text{ Hz}} = \textbf{16.7 ms}$$

Related Problem   If $T = 15 \mu$s, what is f?

Electronic Signal Generators

The signal generator is an instrument that electronically produces sine waves for use in testing or controlling electronic circuits and systems. There are a variety of signal generators, ranging from special-purpose instruments that produce only one type of waveform in a limited frequency range, to programmable instruments that produce a wide range of frequencies and a variety of waveforms. All signal generators consist basically of an **oscillator**, which is an electronic circuit that produces repetitive waves. All generators have controls for adjusting the amplitude and frequency.

Function Generators and Arbitrary Waveform Generators   A **function generator** is an instrument that produces more than one type of waveform. It provides pulse waveforms as well as sine waves and triangular waves. Typical function generators are shown in Figure 11–10(a).

(a) Examples of function generators   (b) A typical arbitrary waveform generator

An arbitrary waveform generator can be used to generate standard signals like sine waves, triangular waves, and pulses as well as signals with various shapes and characteristics. Waveforms can be defined by mathematical or graphical input. A typical arbitrary waveform generator is shown in Figure 11–10(b).

SECTION 11–1 CHECKUP Answers are at the end of the chapter.	1. Describe one cycle of a sine wave. 2. At what point does a sine wave change polarity? 3. How many maximum points does a sine wave have during one cycle? 4. How is the period of a sine wave measured? 5. Define *frequency*, and state its unit. 6. Determine f when $T = 5\ \mu s$. 7. Determine T when $f = 120$ Hz.

11–2 SINUSOIDAL VOLTAGE AND CURRENT VALUES

Five ways to express the value of a sine wave in terms of its voltage or its current magnitude are instantaneous, peak, peak-to-peak, rms, and average values.

After completing this section, you should be able to

◆ **Determine the various voltage and current values of a sine wave**

  ◆ Find the instantaneous value at any point

  ◆ Find the peak value

  ◆ Find the peak-to-peak value

  ◆ Define *rms*

  ◆ Explain why the average value is always zero over a complete cycle

  ◆ Find the half-cycle average value

Instantaneous Value

Figure 11–11 illustrates that at any point in time on a sine wave, the voltage (or current) has an **instantaneous value**. This instantaneous value is different at different points along the
Instantaneous values.

curve. Instantaneous values are positive during the positive alternation and negative during the negative alternation. Instantaneous values of voltage and current are symbolized by lowercase v and i, respectively. The curve in part (a) shows voltage only, but it applies equally for current when the v's are replaced with i's. An example of instantaneous values is shown in part (b) where the instantaneous voltage is 3.1 V at 1 μs, 7.07 V at 2.5 μs, 10 V at 5 μs, 0 V at 10 μs, −3.1 V at 11 μs, and so on.

Peak Value

The **peak value** of a sine wave is the value of voltage (or current) at the positive or the negative maximum (peak) with respect to zero. Since the positive and negative peak values are equal in **magnitude**, a sine wave is characterized by a single peak value. This is illustrated in Figure 11–12. For a given sine wave, the peak value is constant and is represented by V_p or I_p. The peak value is also called the **amplitude**.
◄ FIGURE 11–12

Peak values.

Peak-to-Peak Value

The **peak-to-peak value** of a sine wave, as shown in Figure 11–13, is the voltage or current from the positive peak to the negative peak. It is always twice the peak value as
◄ FIGURE 11–13

Peak-to-peak value.

expressed in the following equations. Peak-to-peak voltage or current values are represented by V_{pp} or I_{pp}.

Equation 11–3

$$V_{pp} = 2V_p$$

Equation 11–4

$$I_{pp} = 2I_p$$

RMS Value

The term *rms* stands for *root mean square*. Most ac voltmeters display rms voltage. The 120 V at your wall outlet is an rms value. The **rms value**, also referred to as the **effective value**, of a sinusoidal voltage is actually a measure of the heating effect of the sine wave. For example, when a resistor is connected across an ac (sinusoidal) voltage source, as shown in Figure 11–14(a), a certain amount of heat is generated by the power in the resistor. Figure 11–14(b) shows the same resistor connected across a dc voltage source. The value of the dc voltage can be adjusted so that the resistor gives off the same amount of heat as it does when connected to the ac source.

The rms value of a sinusoidal voltage is equal to the dc voltage that produces the same amount of heat in a resistance as does the sinusoidal voltage.

(a)   (b)
▲ **FIGURE 11–14**

When the same amount of heat is produced in both setups, the sinusoidal voltage has an rms value equal to the dc voltage.

The peak value of a sine wave can be converted to the corresponding rms value using the following relationships, derived in Appendix B, for either voltage or current:

Equation 11–5

$$V_{rms} = 0.707V_p$$

Equation 11–6

$$I_{rms} = 0.707I_p$$

Using these formulas, you can also determine the peak value if you know the rms value.

$$V_p = \frac{V_{rms}}{0.707}$$

Equation 11–7

$$V_p = 1.414V_{rms}$$

Similarly,

Equation 11–8

$$I_p = 1.414I_{rms}$$

To get the peak-to-peak value, simply double the peak value.

Equation 11–9

$$V_{pp} = 2.828V_{rms}$$

and

Equation 11–10

$$I_{pp} = 2.828I_{rms}$$

Average Value

The average value of a sine wave taken over one complete cycle is always zero because the positive values (above the zero crossing) offset the negative values (below the zero crossing).

To be useful for certain purposes such as measuring types of voltages found in power supplies, the average value of a sine wave is defined over a half-cycle rather than over a full cycle. The **average value** is the total area under the half-cycle curve divided by the distance in radians of the curve along the horizontal axis. The result is derived in Appendix B and is expressed in terms of the peak value as follows for both voltage and current sine waves:

$$V_{avg} = \left(\frac{2}{\pi}\right)V_p$$

$$V_{avg} = 0.637V_p$$

Equation 11–11

$$I_{avg} = \left(\frac{2}{\pi}\right)I_p$$

$$I_{avg} = 0.637I_p$$

Equation 11–12

EXAMPLE 11–6

Determine V_p, V_{pp}, V_{rms}, and the half-cycle V_{avg} for the sine wave in Figure 11–15.

◆ **FIGURE 11–15**
Solution V_p = **4.5 V** is read directly from the graph. From this, calculate the other values.

$$V_{pp} = 2V_p = 2(4.5\,V) = \textbf{9 V}$$
$$V_{rms} = 0.707V_p = 0.707(4.5\,V) = \textbf{3.18 V}$$
$$V_{avg} = 0.637V_p = 0.637(4.5\,V) = \textbf{2.87 V}$$

Related Problem   If V_p = 25 V, determine V_{pp}, V_{rms}, and V_{avg} for a voltage sine wave.

   (a) $V_p = 10\,V$ (b) $V_{rms} = 2.3\,V$ (c) $V_{pp} = 60\,V$

11–3 ANGULAR MEASUREMENT OF A SINE WAVE

As you have seen, sine waves can be measured along the horizontal axis on a time basis; however, since the time for completion of one full cycle or any portion of a cycle is frequency-dependent, it is often useful to specify points on the sine wave in terms of an angular measurement expressed in degrees or radians.

After completing this section, you should be able to

◆ **Describe angular relationships of sine waves**

   ◆ Show how to measure a sine wave in terms of angles

   ◆ Define *radian*

   ◆ Convert radians to degrees

   ◆ Determine the phase angle of a sine wave
▲ **FIGURE 11–16**

Angular measurement showing relationship of radian (rad) to degrees (°).

A sinusoidal voltage can be produced by an alternator, which is an ac generator. There is a direct relationship between the rotation of the rotor in an alternator and the sine wave output. Thus, the angular measurement of the rotor's position is directly related to the angle assigned to the sine wave.

Angular Measurement

A **degree** is an angular measurement corresponding to 1/360 of a circle or a complete revolution. A **radian** is the angular measurement along the circumference of a circle that is equal to the radius of the circle. One radian (rad) is equivalent to 57.3°, as illustrated in Figure 11–16. In a 360° revolution, there are 2π radians.
The Greek letter π (pi) represents the ratio of the circumference of any circle to its diameter and has a constant value of approximately 3.1416.

Scientific calculators have a π function so that the actual numerical value does not have to be entered.

Table 11–1 lists several values of degrees and the corresponding radian values. These angular measurements are illustrated in Figure 11–17.

Radian/Degree Conversion

Degrees can be converted to radians.

$$\text{rad} = \left(\frac{\pi \text{ rad}}{180°} \right) \times \text{degrees}$$

Equation 11–13

Similarly, radians can be converted to degrees.

$$\text{degrees} = \left(\frac{180°}{\pi \text{ rad}} \right) \times \text{rad}$$

Sine Wave Angles

The angular measurement of a sine wave is based on 360° or 2π rad for a complete cycle. A half-cycle is 180° or π rad; a quarter-cycle is 90° or $\pi/2$ rad; and so on. Figure 11–18(a) shows angles in degrees for a full cycle of a sine wave; part (b) shows the same points in radians.

Phase of a Sine Wave

The **phase** of a sine wave is an angular measurement that specifies the position of that sine wave relative to a reference. Figure 11–19 shows one cycle of a sine wave to be used as the reference. Note that the first positive-going crossing of the horizontal axis (zero crossing) is at 0° (0 rad), and the positive peak is at 90° ($\pi/2$ rad). The negative-going zero crossing is at 180° (π rad), and the negative peak is at 270° ($3\pi/2$ rad). The cycle is completed at 360° (2π rad). When the sine wave is shifted left or right with respect to this reference, there is a phase shift.

▲ **FIGURE 11–19**

Phase reference.

Figure 11–20 illustrates phase shifts of a sine wave. In part (a), sine wave *B* is shifted to the right by 90° ($\pi/2$ rad) with respect to sine wave *A*. Thus, there is a phase angle of 90° between sine wave *A* and sine wave *B*. In terms of time, the positive peak of sine wave *B* occurs later than the positive peak of sine wave *A* because time increases to the right along the horizontal axis. In this case, sine wave *B* is said to **lag** sine wave *A* by 90° or $\pi/2$ radians. Stated another way, sine wave *A* leads sine wave *B* by 90°.

(a) *A* leads *B* by 90°, or *B* lags *A* by 90°.

(b) *B* leads *A* by 90°, or *A* lags *B* by 90°.

▲ **FIGURE 11–20**

Illustration of a phase shift.

In Figure 11–20(b), sine wave *B* is shown shifted left by 90° with respect to sine wave *A*. Thus, again there is a phase angle of 90° between sine wave *A* and sine wave *B*. In this case, the positive peak of sine wave *B* occurs earlier in time than that of sine wave *A*; therefore, sine wave *B* is said to **lead** sine wave *A* by 90°.

EXAMPLE 11–8

What are the phase angles between the two sine waves in parts (a) and (b) of Figure 11–21?

(a)   (b)
▲ **FIGURE 11–21**

Solution   In Figure 11–21(a) the zero crossing of sine wave A is at 0°, and the corresponding zero crossing of sine wave B is at 45°. There is a 45° phase angle between the two waveforms with sine wave B lagging sine wave A.

In Figure 11–21(b) the zero crossing of sine wave B is at −30°, and the corresponding zero crossing of sine wave A is at 0°. There is a 30° phase angle between the two waveforms with sine wave B leading sine wave A.

Related Problem   If the positive-going zero crossing of one sine wave is at 15° and that of the second sine wave is at 23°, what is the phase angle between them?

As a practical matter, when you measure the phase shift between two waveforms on an oscilloscope, you should make them appear to have the same amplitude. This is done by taking one of the oscilloscope channels out of vertical calibration and adjusting the corresponding waveform until its apparent amplitude equals that of the other waveform. This procedure eliminates the error caused if both waveforms are not measured at their exact center.

Polyphase Power

One important application of phase-shifted sine waves is in electrical power systems. Electrical utilities generate ac with three phases that are separated by 120°, as shown in Figure 11–22. The reference is called neutral. Normally, three-phase power is delivered to the user with four lines (three hot lines and neutral). There are important advantages to three-phase power for ac motors. Three-phase motors are more efficient and simpler than an equivalent single-phase motor. Motors are discussed further in Section 11–8.
◄ **FIGURE 11–22**

Three-phase power waveforms.

The three phases can be split up by the utility company to supply three separate single-phase systems. If only one of the three phases plus neutral is supplied, the result is standard

120 V, which is single-phase power. Single-phase power is distributed to residential and small commercial buildings; it consists of two 120 V hot lines that are 180° out of phase with each other and a neutral, which is grounded at the service entrance. The two hot lines allow for connecting to 240 V for high-power appliances (dryers, air conditioners).

11–4 THE SINE WAVE FORMULA

A sine wave can be graphically represented by voltage or current values on the vertical axis and by angular measurement (degrees or radians) along the horizontal axis. This graph can be expressed mathematically, as you will see.

After completing this section, you should be able to

◆ **Mathematically analyze a sinusoidal waveform**

   ◆ State the sine wave formula

   ◆ Find instantaneous values using the sine wave formula

A generalized graph of one cycle of a sine wave is shown in Figure 11–24. The sine wave amplitude (A) is the maximum value of the voltage or current on the vertical axis; angular values run along the horizontal axis. The variable y is an instantaneous value that

▶ **FIGURE 11–24**

One cycle of a generic sine wave showing amplitude and phase.
represents either voltage or current at a given angle, θ. The symbol θ is the Greek letter *theta*.

All electrical sine waves follow a specific mathematical formula. The general expression for the sine wave curve in Figure 11–24 is

$$y = A \sin\theta$$

This formula states that any point on the sine wave, represented by an instantaneous value (y), is equal to the maximum value A times the sine (sin) of the angle θ at that point. For example, a certain voltage sine wave has a peak value of 10 V. You can calculate the instantaneous voltage at a point 60° along the horizontal axis as follows, where $y = v$ and $A = V_p$:

$$v = V_p \sin\theta = (10\,\text{V})\sin 60° = (10\,\text{V})(0.866) = 8.66\,\text{V}$$

Figure 11–25 shows this particular instantaneous value of the curve. You can find the sine of any angle on most calculators by first entering the value of the angle and then pressing the SIN key. Verify that your calculator is in the degree mode.

Expressions for Phase-Shifted Sine Waves

When a sine wave is shifted to the right of the reference (lagging) by a certain angle, ϕ (Greek letter phi), as illustrated in Figure 11–26(a) where the reference is the vertical axis, the general expression is
$$y = A \sin(\theta - \phi)$$

where y represents instantaneous voltage or current, and A represents the peak value (amplitude). When a sine wave is shifted to the left of the reference (leading) by a certain angle, ϕ, as shown in Figure 11–26(b), the general expression is

$$y = A\sin(\theta + \phi)$$

(a) $y = A \sin(\theta - \phi)$

(b) $y = A \sin(\theta + \phi)$

$$v_B = V_p \sin(\theta + \phi_B)$$

$$v_C = V_p \sin(\theta - \phi_C)$$
$$= (8\ \text{V})\sin(90° - 45°) = (8\ \text{V})\sin(45°) = (8\ \text{V})(0.7071) = \mathbf{5.66\ V}$$

11–5 Introduction to Phasors

Phasors provide a graphic means for representing quantities that have both magnitude and direction (angular position). Phasors are especially useful for representing sine waves in terms of their magnitude and phase angle and also for the analysis of reactive circuits discussed in later chapters.

After completing this section, you should be able to

◆ **Use a phasor to represent a sine wave**

   ◆ Define *phasor*

   ◆ Explain how phasors are related to the sine wave formula

   ◆ Draw a phasor diagram

   ◆ Discuss angular velocity

You may already be familiar with vectors. In math and science, a vector is any quantity with both magnitude and direction. Examples of vectors are force, velocity, and acceleration. The simplest way to describe a vector is to assign a magnitude and an angle to a quantity.

In electronics, a **phasor** is a type of vector but the term generally refers to quantities that vary with time, such as sine waves. Examples of phasors are shown in Figure 11–28. The length of the phasor "arrow" represents the magnitude of a quantity. The angle, θ (relative to $0°$), represents the angular position, as shown in part (a) for a positive angle. The specific phasor example in part (b) has a magnitude of 2 and a phase angle of $45°$. The phasor in part (c) has a magnitude of 3 and a phase angle of $180°$. The phasor in part (d) has a magnitude of 1 and a phase angle of $-45°$ (or $+315°$). Notice that positive angles are measured counterclockwise (CCW) from the reference ($0°$) and negative angles are measured clockwise (CW) from the reference.

(a) (b) (c) (d)
▲ FIGURE 11–28

Examples of phasors.

Phasor Representation of a Sine Wave

A full cycle of a sine wave can be represented by rotation of a phasor through 360 degrees.

> **The instantaneous value of the sine wave at any point is equal to the vertical distance from the tip of the phasor to the horizontal axis.**

Figure 11–29 shows how the phasor traces out the sine wave as it goes from $0°$ to $360°$. You can relate this concept to the rotation in an ac generator. Notice that the length of the phasor is equal to the peak value of the sine wave (observe the $90°$ and the $270°$ points). The angle of the phasor measured from $0°$ is the corresponding angular point on the sine wave.
◀ FIGURE 11–29

Sine wave represented by rotational phasor motion.

Phasors and the Sine Wave Formula

Let's examine a phasor representation at one specific angle. Figure 11–30 shows a voltage phasor at an angular position of $45°$ and the corresponding point on the sine wave. The instantaneous value of the sine wave at this point is related to both the position and the length of the
▲ FIGURE 11–30

Right triangle derivation of sine wave formula.

phasor. As previously mentioned, the vertical distance from the phasor tip down to the horizontal axis represents the instantaneous value of the sine wave at that point.

Notice that when a vertical line is drawn from the phasor tip down to the horizontal axis, a right triangle is formed, as shown shaded in Figure 11–30. The length of the phasor is the hypotenuse of the triangle, and the vertical projection is the opposite side. From trigonometry,

The opposite side of a right triangle is equal to the hypotenuse times the sine of the angle θ.

The length of the phasor is the peak value of the sinusoidal voltage, V_p. Thus, the opposite side of the triangle, which is the instantaneous value, can be expressed as

$$v = V_p\sin \theta$$

Recall that this formula is the one stated earlier for calculating instantaneous sinusoidal voltage. A similar formula applies to a sinusoidal current.

$$i = I_p\sin \theta$$

Positive and Negative Phasor Angles

The position of a phasor at any instant can be expressed as a positive angle, as you have seen, or as an equivalent negative angle. Positive angles are measured counterclockwise from $0°$. Negative angles are measured clockwise from $0°$. For a given positive angle θ, the corresponding negative angle is $\theta - 360°$, as illustrated in Figure 11–31(a). In part (b), a specific example is shown. The angle of the phasor in this case can be expressed as $+225°$ or $-135°$.

Positive and negative phasor angles.

EXAMPLE 11–10

Related Problem If a phasor is at 45° and its length represents 15 V, what is the instantaneous sine wave value?

Phasor Diagrams

A phasor diagram can be used to show the relative relationship of two or more sine waves of the same frequency. A phasor in a *fixed position* is used to represent a complete sine wave because once the phase angle between two or more sine waves of the same frequency

or between the sine wave and a reference is established, the phase angle remains constant throughout the cycles. For example, the two sine waves in Figure 11–33(a) can be represented by a phasor diagram, as shown in part (b). As you can see, sine wave *B* leads sine wave *A* by 30° and has less amplitude than sine wave *A*, as indicated by the lengths of the phasors.

(a) (b)

▶ FIGURE 11–35

Related Problem Describe a phasor to represent a 5 V peak sine wave that lags sine wave *C* in Figure 11–34 by 25°.

Angular Velocity of a Phasor

As you have seen, one cycle of a sine wave is traced out when a phasor is rotated through 360 degrees or 2π radians. The faster it is rotated, the faster the sine wave cycle is traced out. Thus, the period and frequency are related to the velocity of rotation of the phasor. The velocity of rotation is called the **angular velocity** and is designated ω (the small Greek letter omega).

When a phasor rotates through 2π radians, one complete cycle is traced out. Therefore, the time required for the phasor to go through 2π radians is the period of the sine wave. Because the phasor rotates through 2π radians in a time equal to the period, T, the angular velocity can be expressed as

$$\omega = \frac{2\pi}{T}$$

Since $f = 1/T$,

$$\omega = 2\pi f \qquad\qquad \textbf{Equation 11–18}$$

When a phasor is rotated at an angular velocity ω, then ωt is the angle through which the phasor has passed at any instant. Therefore, the following relationship can be stated:

$$\theta = \omega t \qquad\qquad \textbf{Equation 11–19}$$

Substituting $2\pi f$ for ω results in $\theta = 2\pi ft$. With this relationship between angle and time, the equation for the instantaneous value of a sinusoidal voltage, $v = V_p\sin\theta$, can be written as

$$v = V_p\sin 2\pi ft \qquad\qquad \textbf{Equation 11–20}$$

You can calculate the instantaneous value at any point in time along the sine wave curve if you know the frequency and peak value. The unit of $2\pi ft$ is the radian so your calculator must be in the radian mode.

11–6 ANALYSIS OF AC CIRCUITS

When a time-varying ac voltage such as a sinusoidal voltage is applied to a circuit, the circuit laws and power formulas that you studied earlier still apply. Ohm's law, Kirchhoff's laws, and the power formulas apply to ac circuits in the same way that they apply to dc circuits.

After completing this section, you should be able to

◆ **Apply the basic circuit laws to resistive ac circuits**

  ◆ Apply Ohm's law to resistive circuits with ac sources

  ◆ Apply Kirchhoff's voltage law and current law to resistive circuits with ac sources

  ◆ Determine power in resistive ac circuits

  ◆ Determine total voltages that have both ac and dc components

If a sinusoidal voltage is applied across a resistor as shown in Figure 11–37, there is a sinusoidal current. The current is zero when the voltage is zero and is maximum when the voltage is maximum. When the voltage changes polarity, the current reverses direction. As a result, the voltage and current are said to be in phase with each other.
▶ FIGURE 11–37

A sinusoidal voltage produces a sinusoidal current.
When you use Ohm's law in ac circuits, remember that both the voltage and the current must be expressed consistently, that is, both as peak values, both as rms values, both as average values, and so on. Kirchhoff's voltage and current laws apply to ac circuits as well as to dc circuits. Figure 11–38 illustrates Kirchhoff's voltage law in a resistive circuit that has a sinusoidal voltage source. The source voltage is the sum of all the voltage drops across the resistors, just as in a dc circuit.

▲ FIGURE 11–38

Illustration of Kirchhoff's voltage law in an ac circuit.

Power in resistive ac circuits is determined the same as for dc circuits except that you must use rms values of current and voltage. Recall that the rms value of a sine wave voltage is equivalent to a dc voltage of the same value in terms of its heating effect. The general power formulas are restated for a resistive ac circuit as

$$P = V_{rms}I_{rms}$$
$$P = \frac{V_{rms}^2}{R}$$
$$P = I_{rms}^2 R$$

EXAMPLE 11–13

Determine the rms voltage across each resistor and the rms current in Figure 11–39. The source voltage is given as an rms value. Also determine the total power.

► FIGURE 11–39

Solution The total resistance of the circuit is

$$R_{tot} = R_1 + R_2 = 1.0\,k\Omega + 560\,\Omega = 1.56\,k\Omega$$

Use Ohm's law to find the rms current.

$$I_{rms} = \frac{V_{s(rms)}}{R_{tot}} = \frac{120\,V}{1.56\,k\Omega} = \textbf{76.9 mA}$$

The rms voltage drop across each resistor is

$$V_{1(rms)} = I_{rms}R_1 = (76.9\,mA)(1.0\,k\Omega) = \textbf{76.9\,V}$$
$$V_{2(rms)} = I_{rms}R_2 = (76.9\,mA)(560\,\Omega) = \textbf{43.1\,V}$$

The total power is

$$P_{tot} = I_{rms}^2 R_{tot} = (76.9\,mA)^2(1.56\,k\Omega) = 9.23\,W$$

Superimposed DC and AC Voltages

In many practical circuits, you will find both dc and ac voltages combined. An example of this is in amplifier circuits where ac signal voltages are superimposed on dc operating voltages. This is a common application of the superposition theorem studied in Chapter 8.
◀ FIGURE 11–41

Superimposed dc and ac voltages.

Figure 11–41 shows a dc source and an ac source in series. These two voltages will add algebraically to produce an ac voltage "riding" on a dc level, as measured across the resistor.

If V_{DC} is greater than the peak value of the sinusoidal voltage, the combined voltage is a sine wave that never reverses polarity and is therefore nonalternating. That is, the sine wave is riding on a dc level, as shown in Figure 11–42(a). If V_{DC} is less than the peak value of the sine wave, the sine wave will be negative during a portion of its lower half-cycle, as illustrated in Figure 11–42(b), and is therefore alternating. In either case, the sine wave will reach a maximum voltage equal to $V_{DC} + V_p$, and it will reach a minimum voltage equal to $V_{DC} - V_p$.

(a) $V_{DC} > V_p$. The sine wave never goes negative.

(b) $V_{DC} < V_p$. The sine wave reverses polarity during a portion of its cycle, as indicated by the gray area.

$$V_{max} = V_{DC} + V_p = 12 \text{ V} + 10 \text{ V} = \mathbf{22 \text{ V}}$$

The minimum voltage across R is

$$V_{min} = V_{DC} - V_p = 12 \text{ V} - 10 \text{ V} = \mathbf{2 \text{ V}}$$

Therefore, $V_{R(tot)}$ is a nonalternating sine wave that varies from +22 V to +2 V, as shown in Figure 11–44(a).

In Figure 11–43(b), the maximum voltage across R is

$$V_{max} = V_{DC} + V_p = 6 \text{ V} + 10 \text{ V} = \mathbf{16 \text{ V}}$$

The minimum voltage across R is

$$V_{min} - = V_{DC} - V_p = \mathbf{-4 \text{ V}}$$

Therefore, $V_{R(tot)}$ is an alternating sine wave that varies from +16 V to −4 V, as shown in Figure 11–44(b).

## 11–7   THE ALTERNATOR (AC GENERATOR)

An **alternator** is an ac generator that converts energy of motion into electrical energy. Although it is similar to a dc generator, the alternator is more efficient than the dc generator. Alternators are widely used in vehicles, boats, and other applications even when dc is the final output.

After completing this section, you should be able to

◆ **Describe how an alternator generates electricity**

   ◆ Identify the main parts of an alternator, including the rotor, stator, and slip rings

   ◆ Explain why the output of a rotating-field alternator is taken from the stator

   ◆ Describe the purpose of the slip rings

   ◆ Explain how an alternator can be used to produce dc

Simplified Alternator

Both the dc generator and the alternator, which generates ac voltage, are based on the principle of electromagnetic induction that produces a voltage when there is relative motion between a magnetic field and a conductor. For a simplified alternator, a single rotating loop passes permanent magnetic poles. The natural voltage that is generated by a rotating loop is ac. In an alternator, instead of the split rings used in a dc generator, solid rings called slip rings are used to connect to the rotor, and the output is ac. The simplest form of an alternator has the same appearance as a dc generator (see Figure 10–35) except for the slip rings, as shown in Figure 11–45.

▲ **FIGURE 11–45**

A simplified alternator.

Frequency

In the simplified alternator in Figure 11–45, each revolution of the loop produces one cycle of a sine wave. The positive and negative peaks occur when the loop cuts the maximum number of flux lines. The rate the loop spins determines the time for one complete cycle and the frequency. If it takes 1/60 of a second to make a revolution, the period of the sine wave is 1/60 of a second and the frequency is 60 Hz. Thus, the faster the loop rotates, the higher the frequency.

Another way of achieving a higher frequency is to use more magnetic poles. When four poles are used instead of two, as shown in Figure 11–46, the conductor passes under a north and a south pole during one-half a revolution, which doubles the frequency. Alternators can

▲ FIGURE 11–46

Four poles produce twice the frequency of two poles for the same rotational speed.

have many more poles, depending on the requirements, some have as many as 100. The number of poles and the speed of the rotor determine the frequency in accordance with the following equation:

Equation 11–21

$$f = \frac{Ns}{120}$$

where f is the frequency in hertz, N is the number of poles, and s is the rotational speed in revolutions per minute.

EXAMPLE 11–16

Assume a large alternator is turned by a turbine at 300 rpm and has 24 poles. What is the output frequency?

Solution

$$f = \frac{Ns}{120} = \frac{(24)(300 \text{ rpm})}{120} = \textbf{60 Hz}$$

Related Problem   At what speed must the rotor move to produce a 50 Hz output?

Practical Alternators

The single loop used in our simplified alternator produces only a tiny voltage. In a practical alternator, hundreds of loops are wound on a magnetic core, which forms the rotor. Practical alternators usually have fixed windings surrounding the rotor instead of permanent magnets. Depending on the type of alternator, these fixed windings can either provide the magnetic field (in which case they are called field windings) or act as the fixed conductors that produce the output (in which case they are the armature windings).

Rotating-Armature Alternators   In a rotating-armature alternator, the magnetic field is stationary and is supplied by permanent magnets or electromagnets operated from dc. With electromagnets, field windings are used instead of permanent magnets and provide a fixed magnetic field that interacts with the rotor coils. Power is generated in the rotating assembly and supplied to the load through the slip rings.

In a rotating-armature alternator, the rotor is the component from which power is taken. In addition to hundreds of windings, the practical rotating-armature alternator usually has many pole pairs in the stator that alternate as north and south poles, which serve to increase the output frequency.

Rotating-Field Alternator   The rotating-armature alternator is generally limited to low-power applications because all output current must pass through the slip rings and brushes. To avoid this problem, rotating-field alternators take the output from the stator coils and use

a rotating magnet, hence the name. Small alternators may have a permanent magnet for a rotor, but most use an electromagnet formed by a wound rotor. A relatively small amount of dc is supplied to the rotor (through the slip rings) to power the electromagnet. As the rotating magnetic field sweeps by the stator windings, power is generated in the stator. The stator is therefore the armature in this case.

Figure 11–47 shows how a rotating-field alternator can generate three-phase sine waves. (For simplicity, a permanent magnet is shown for the rotor.) AC is generated in each winding as the north pole and the south pole of the rotor alternately sweep by a stator winding. If the north pole generates the positive portion of the sine wave, the south pole will generate the negative portion; thus, one rotation produces a complete sine wave. Each winding has a sine wave output; but because the windings are separated by 120°, the three sine waves are also shifted by 120°. This produces the three-phase output as shown. Most alternators generate three-phase voltage because it is more efficient to produce and is widely used in industry. If the final output is dc, three-phase is easier to convert to dc.
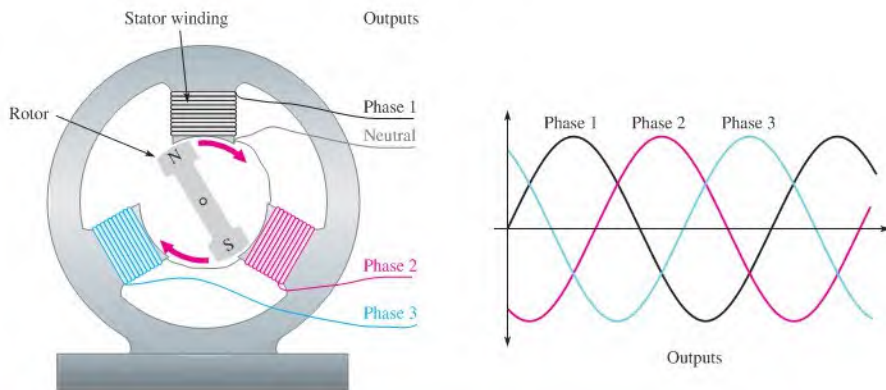

▲ FIGURE 11–47

The rotor shown is a permanent magnet that produces a strong magnetic field. As it sweeps by each stator winding, a sine wave is produced across that winding. The neutral is the reference.

Rotor Current

A wound rotor offers important control advantages to alternators. A wound rotor enables control over the strength of the magnetic field by controlling the rotor current and hence the output voltage. For wound rotors, dc must be supplied to the rotor. This current is usually supplied through brushes and slip rings, which are made of a continuous ring of material, (unlike a commutator, which is segmented). Because the brushes need to pass only the magnetizing rotor current, they last longer and are smaller than the brushes in an equivalent dc generator, which pass all of the output current.

In wound-rotor alternators, the only current through the brushes and slip rings is the dc that is used to maintain its magnetic field. The dc is usually derived from a small portion of the output current, which is taken from the stator and converted to dc. Large alternators, such as in power stations, may have a separate dc generator, called an **exciter**, to supply current to the field coils. An exciter can respond very fast to changes in output voltage to keep the alternator's output constant, an important consideration in high-power alternators. Some exciters are set up using a stationary field with the armature on the rotating main shaft. The result is a brushless system because the exciter output is on the rotating shaft. A brushless system eliminates the primary maintenance issue with large alternators in cleaning, repairing, and replacing brushes.

An Application

Alternators are used in nearly all modern automobiles, trucks, tractors, and other vehicles. In vehicles, the output is usually three-phase ac taken from stator windings and then converted to dc with diodes that are housed inside the alternator case. (Diodes are solid-state devices that allow current in only one direction.) Current to the rotor is controlled by a voltage regulator, which is also internal to the alternator. The voltage regulator keeps the output voltage relatively constant for engine speed changes or changing loads. Alternators have replaced dc generators in automobiles and most other applications because they are more efficient and more reliable.

Important parts of a small alternator, such as you might find in an automobile are shown in Figure 11–48. Like the self-excited generator discussed in Chapter 10, the rotor has a small residual magnetism to begin with, so an ac voltage is generated in the stators as soon as the rotor starts spinning. This ac is converted to dc by a set of diodes. A portion of the dc is used to provide current to the rotor; the rest is available for the loads. The amount of current required by the rotor is much less than the total current from the alternator, so it can easily provide the required current to the load.
▲ FIGURE 11–48

Expanded and simplified view of a rotor, stator, and diode plate for a small alternator that produces dc.

In addition to the fact that three-phase voltage is more efficient to produce, it can produce a stable dc output easily by using two diodes in each winding. Since vehicles require dc for the charging system and loads, the output of the alternator is converted to dc internally using a diode array mounted on a diode plate. Thus, a standard three-phase automotive alternator will normally have six diodes inside to convert the output to dc. (Some alternators have six independent stator coils and twelve diodes.)

11–8   THE AC MOTOR

Motors are electromagnetic devices that represent the most common loads for ac in power applications. AC motors are used to operate household appliances such as heat pumps, refrigerators, washers, dryers, and vacuums. In industry, ac motors are used in many applications to move and process materials as well as refrigeration and heating units, machining operations, pumps, and much more. In this section, the two major types of ac motors, induction motors and synchronous motors, are introduced.

After completing this section, you should be able to

◆ **Explain how ac motors convert electrical energy into rotational motion**

    ◆ Cite the main differences between induction and synchronous motors

    ◆ Explain how the magnetic field rotates in an ac motor

    ◆ Explain how an induction motor develops torque

AC Motor Classification

The two major classifications of ac motors are induction motors and synchronous motors. Several considerations determine which of these types are best for any given application. These considerations include the speed and power requirements, voltage rating, load characteristics (such as starting torque required), efficiency requirements, maintenance requirements, and operating environment (such as underwater operation or temperature).

An **induction motor** is so named because a magnetic field induces current in the rotor, creating a magnetic field that interacts with the stator field. Normally, there is no electrical connection to the rotor, so there is no need for slip rings or brushes, which tend to wear out. The rotor current is caused by electromagnetic induction, which also occurs in transformers (covered in Chapter 14), so induction motors are said to work by transformer action.

In a **synchronous motor**, the rotor moves in sync (at the same rate) as the rotating field of the stator. Synchronous motors are used in applications where maintaining constant speed is important. Synchronous motors are not self-starting and must receive starting torque from an external source or from built-in starting windings. Like alternators, synchronous motors use slip rings and brushes to provide current to the rotor.

Rotating Stator Field

Both synchronous and induction ac motors have a similar arrangement for the stator windings, which allow the magnetic field of the stator to rotate. The rotating stator field is equivalent to moving a magnet in a circle except that the rotating field is produced electrically, with no moving parts.

How can the magnetic field in the stator rotate if the stator itself does not move? The rotating field is created by the changing ac itself. Let's look at a rotating field with a three-phase stator, as shown in Figure 11–49. Notice that one of the three phases "dominates" at different times. When phase 1 is at 90°, the current in the phase 1 winding is at a maximum and current in the other windings is smaller. Therefore, the stator magnetic field will be oriented toward the phase-1 stator winding. As the phase-1 current declines, the phase-2 current increases, and the field rotates toward the phase-2 winding. The magnetic field will be oriented toward the phase-2 winding when current in it is a maximum. As the phase-2 current declines, the phase-3 current increases, and the field rotates toward the phase-3 winding. The process repeats as the field returns to the phase-1 winding. Thus, the field rotates at a rate
▲ FIGURE 11–49

The application of three phases to the stator produces a net magnetic field as shown by the red arrow. The rotor (not shown) moves in response to this field.

determined by the frequency of the applied voltage. With a more detailed analysis, it can be shown that the magnitude of the field is unchanged; only the direction of the field changes.

As the stator field moves, the rotor moves in sync with it in a synchronous motor but lags behind in an induction motor. The rate the stator field moves is called the *synchronous speed* of the motor.

Induction Motors

The theory of operation is essentially the same for both single-phase and three-phase induction motors. Both types use the rotating field described previously, but the single-phase motor requires starting windings or other method to produce torque for starting the motor, whereas the three-phase motor is self-starting. When starting windings are employed in a single-phase motor, they are removed from the circuit by a mechanical centrifugal switch as the motor speeds up.

The core of the induction motor's rotor consists of an aluminum frame that forms the conductors for the circulating current in the rotor. (Some larger induction motors use copper bars.) The aluminum frame is similar in appearance to the exercise wheel for pet squirrels (common in the early 20th century), so it is aptly called a **squirrel cage**, illustrated in Figure 11–50. The aluminum squirrel cage itself is the *electrical* path; it is embedded within a ferromagnetic material to provide a low reluctance *magnetic* path through the rotor. In addition, the rotor has cooling fins that may be molded into the same piece of aluminum as the squirrel cage. The entire assembly must be balanced so that it spins easily and without vibrating.

Operation of an Induction Motor When the magnetic field from the stator moves across the squirrel cage of the inductor, a current is generated in the squirrel cage. This current creates a magnetic field that reacts with the moving field of the stator, causing the

material

rotor to start turning. The rotor will try to "catch-up" with the moving field, but cannot, in a condition known as slip. **Slip** is defined as the difference between the synchronous speed of the stator and the rotor speed. The rotor can never reach the synchronous speed of the stator field because, if it did, it would not cut any field lines and the torque would drop to zero. Without torque, the rotor could not turn itself.

Initially, before the rotor starts moving, there is no back emf, so the stator current is high. As the rotor speeds up, it generates a back emf that opposes the stator current. As the motor speeds up, the torque produced balances the load and the current is just enough to keep the rotor turning. The running current is significantly lower than the initial start-up current because of the back emf. If the load on the motor is then increased, the motor will slow down and generate less back emf. This increases the current to the motor and increases the torque it can apply to the load. Thus, an induction motor can operate over a range of speeds and torque. Maximum torque occurs when the rotor is spinning at about 75% of the synchronous speed.

Synchronous Motors

Recall that an induction motor develops no torque if it runs at the synchronous speed, so it must run slower than the synchronous speed, depending on the load. The synchronous motor will run at the synchronous speed and still develop the required torque for different loads. The only way to change the speed of a synchronous motor is to change the frequency.

The fact that synchronous motors maintain a constant speed for all load conditions is a major advantage in certain industrial operations and in applications where clock or timing requirements are involved (such as a telescope drive motor or a chart recorder). In fact, the first application of synchronous motors was in electric clocks (in 1917).

Another important advantage to large synchronous motors is their efficiency. Although their original cost is higher than a comparable induction motor, the savings in power will often pay for the cost difference in a few years.

Operation of a Synchronous Motor   Essentially, the rotating stator field of the synchronous motor is identical to that of an induction motor. The primary difference in the two motors is in the rotor. The induction motor has a rotor that is electrically isolated from a supply and the synchronous motor uses a magnet to follow the rotating stator field. Small synchronous motors use a permanent magnet for the rotor; larger motors use an electromagnet. When an electromagnet is used, dc is supplied from an external source via slip rings as in the case of the alternator.

11–9   NONSINUSOIDAL WAVEFORMS

Sine waves are important in electronics, but they are by no means the only type of ac or time-varying waveform. Two other major types of waveforms are the pulse waveform and the triangular waveform.

After completing this section, you should be able to

✦ **Identify the characteristics of basic nonsinusoidal waveforms**

   ✦ Discuss the properties of a pulse waveform

   ✦ Define *duty cycle*

   ✦ Discuss the properties of triangular and sawtooth waveforms

   ✦ Discuss the harmonic content of a waveform

Pulse Waveforms

Basically, a **pulse** can be described as a very rapid transition **(leading edge)** from one voltage or current level **(baseline)** to an amplitude level, and then, after an interval of time, a very rapid transition **(trailing edge)** back to the original baseline level. The transitions in level are also called *steps*. An ideal pulse consists of two opposite-going steps of equal amplitude. When the leading or trailing edge is positive-going, it is called a **rising edge**. When the leading or trailing edge is negative-going, it is called a **falling edge**.

Figure 11–51(a) shows an ideal positive-going pulse consisting of two equal but opposite instantaneous steps separated by an interval of time called the *pulse width*. Part (b) of Figure 11–51 shows an ideal negative-going pulse. The height of the pulse measured from the baseline is its voltage (or current) amplitude.

(a) Positive-going pulse   (b) Negative-going pulse
▲ **FIGURE 11–51**

Ideal pulses.

In many applications, analysis is simplified by treating all pulses as ideal (composed of instantaneous steps and perfectly rectangular in shape). Actual pulses, however, are never ideal. All pulses possess certain characteristics that cause them to be different from the ideal.

In practice, pulses cannot change from one level to another instantaneously. Time is always required for a transition (step), as illustrated in Figure 11–52(a). As you can see, there is an interval of time during the rising edge in which the pulse is going from its lower value to its higher value. This interval is called the *rise time, t_r*.

Rise time is the time required for the pulse to go from 10% of its amplitude to 90% of its amplitude.

(a) Rise and fall times   (b) Pulse width
▲ FIGURE 11–52

Nonideal pulse.

The interval of time during the falling edge in which the pulse is going from its higher value to its lower value is called the *fall time, t_f.*

Fall time is the time required for the pulse to go from 90% of its amplitude to 10% of its amplitude.

Pulse width, t_W, also requires a precise definition for the nonideal pulse because the rising and falling edges are not vertical.

Pulse width is the time between the point on the rising edge, where the value is 50% of amplitude, to the point on the falling edge, where the value is 50% of amplitude.

Pulse width is shown in Figure 11–52(b).

Repetitive Pulses   Any waveform that repeats itself at fixed intervals is **periodic**. Some examples of periodic pulse waveforms are shown in Figure 11–53. Notice that, in each case, the pulses repeat at regular intervals. The rate at which the pulses repeat is the **pulse repetition frequency**, which is the fundamental frequency of the waveform. The frequency can be expressed in hertz or in pulses per second. The time from one pulse to the corresponding point on the next pulse is the period, *T*. The relationship between frequency and period is the same as with the sine wave, $f = 1/T$.
▲ FIGURE 11–53

Repetitive pulse waveforms.

An important characteristic of repetitive pulse waveforms is the duty cycle.

The duty cycle is the ratio of the pulse width (t_W) to the period (T) and is usually expressed as a percentage.

$$\text{percent duty cycle} = \left(\frac{t_W}{T}\right)100\%$$

Equation 11–22

EXAMPLE 11–17

Determine the period, frequency, and duty cycle for the pulse waveform in Figure 11–54.

▶ **FIGURE 11–54**

Solution

$$T = 10 \ \mu s$$

$$f = \frac{1}{T} = \frac{1}{10 \ \mu s} = 100 \ \text{kHz}$$

$$\text{percent duty cycle} = \left(\frac{1 \ \mu s}{10 \ \mu s} \right) 100\% = 10\%$$

Related Problem

A certain pulse waveform has a frequency of 200 kHz and a pulse width of 0.25 μs. Determine the duty cycle.

Square Waves   A square wave is a pulse waveform with a duty cycle of 50%. Thus, the pulse width is equal to one-half of the period. A square wave is shown in Figure 11–55.

▶ **FIGURE 11–55**

Square wave.

The Average Value of a Pulse Waveform   The average value (V_{avg}) of a pulse waveform is equal to its baseline value plus its duty cycle times its amplitude. The lower level of a positive-going waveform or the upper level of a negative-going waveform is taken as the baseline. The formula is as follows:

Equation 11–23

$$V_{avg} = \text{baseline} + (\text{duty cycle})(\text{amplitude})$$

The following example illustrates the calculation of the average value.

EXAMPLE 11–18

Determine the average value of each of the waveforms in Figure 11–56.
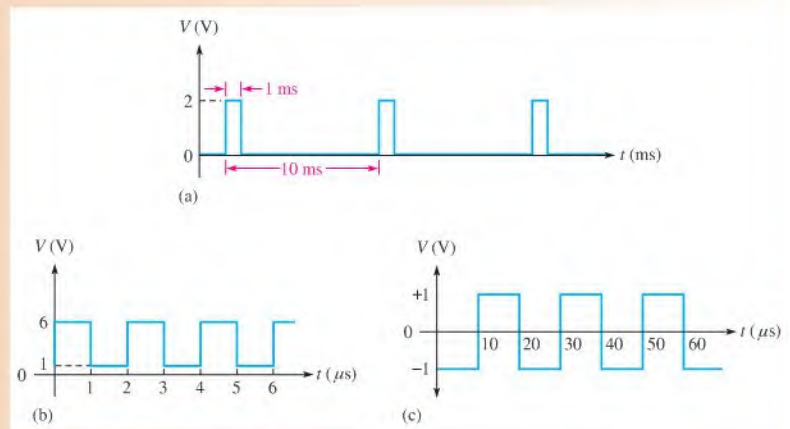

▲ **FIGURE 11–56**

Solution   In Figure 11–56(a), the baseline is at 0 V, the amplitude is 2 V, and the duty cycle is 10%. The average value is

$$V_{avg} = \text{baseline} + (\text{duty cycle})(\text{amplitude})$$
$$= 0\,V + (0.1)(2\,V) = \mathbf{0.2\,V}$$

The waveform in Figure 11–56(b) has a baseline of $+1$ V, an amplitude of 5 V, and a duty cycle of 50%. The average value is

$$V_{avg} = \text{baseline} + (\text{duty cycle})(\text{amplitude})$$
$$= 1\,V + (0.5)(5\,V) = 1\,V + 2.5\,V = \mathbf{3.5\,V}$$

Figure 11–56(c) shows a square wave with a baseline of -1 V and an amplitude of 2 V. The average value is

$$V_{avg} = \text{baseline} + (\text{duty cycle})(\text{amplitude})$$
$$= -1\,V + (0.5)(2\,V) = -1\,V + 1\,V = \mathbf{0\,V}$$

This is an alternating square wave, and, as with an alternating sine wave, it has an average of zero.

Related Problem   If the baseline of the waveform in Figure 11–56(a) is shifted to 1 V, what is the average value?

Triangular and Sawtooth Waveforms

Triangular and sawtooth waveforms are formed by voltage or current ramps. A **ramp** is a linear increase or decrease in the voltage or current. Figure 11–57 shows both positive- and negative-going ramps. In part (a), the ramp has a positive slope; in part (b), the ramp has a negative slope. The slope of a voltage ramp is $\pm V/t$ and is expressed in units of V/s. The slope of a current ramp is $\pm I/t$ and is expressed in units of A/s.

(a) Positive ramp   (b) Negative ramp
▲ **FIGURE 11–57**

Voltage ramps.

EXAMPLE 11–19   What are the slopes of the voltage ramps in Figure 11–58?

▶ **FIGURE 11–58**

(a)   (b)
Solution   In Figure 11–58(a), the voltage increases from 0 V to +10 V in 5 ms. Thus, $V = 10$ V and $t = 5$ ms. The slope is

$$\frac{V}{t} = \frac{10\text{ V}}{5\text{ ms}} = 2\text{ V/ms}$$

In Figure 11–58(b), the voltage decreases from +5 V to 0 V in 100 ms. Thus, $V = -5$ V and $t = 100$ ms. The slope is

$$\frac{V}{t} = \frac{-5\text{ V}}{100\text{ ms}} = -0.05\text{ V/ms}$$

Related Problem   A certain voltage ramp has a slope of $+12$ V/μs. If the ramp starts at zero, what is the voltage at 0.01 ms?

Triangular Waveforms   Figure 11–59 shows that a **triangular waveform** is composed of positive-going and negative-going ramps having equal slopes. The period of this waveform is measured from one peak to the next corresponding peak, as illustrated. This particular triangular waveform is alternating and has an average value of zero.

▶ **FIGURE 11–59**

Alternating triangular waveform with a zero average value.
Figure 11–60 depicts a triangular waveform with a nonzero average value. The frequency for triangular waves is determined in the same way as for sine waves, that is, $f = 1/T$.

▶ **FIGURE 11–60**

Nonalternating triangular waveform with a nonzero average value.
Sawtooth Waveforms   The **sawtooth waveform** is actually a special case of the triangular wave consisting of two ramps, one of much longer duration than the other. Sawtooth waveforms are used in many electronic systems. For example, the electron beam that sweeps across the screen of a CRT TV receiver, creating the picture, is controlled by sawtooth voltages and currents. One sawtooth wave produces the horizontal beam movement, and the other produces the vertical beam movement. A sawtooth voltage is sometimes called a *sweep voltage*.

Figure 11–61 is an example of a sawtooth wave. Notice that it consists of a positive-going ramp of relatively long duration, followed by a negative-going ramp of relatively short duration.
▲ FIGURE 11–61

Alternating sawtooth waveform.

Harmonics

A repetitive nonsinusoidal waveform is composed of a fundamental frequency and harmonic frequencies. The **fundamental frequency** is the repetition rate of the waveform, and the **harmonics** are higher frequency sine waves that are multiples of the fundamental.

Odd Harmonics *Odd harmonics* are frequencies that are odd multiples of the fundamental frequency of a waveform. For example, a 1 kHz square wave consists of a fundamental of 1 kHz and odd harmonics of 3 kHz, 5 kHz, 7 kHz, and so on. The 3 kHz frequency in this case is called the third harmonic, the 5 kHz frequency is the fifth harmonic, and so on.

Even Harmonics *Even harmonics* are frequencies that are even multiples of the fundamental frequency. For example, if a certain wave has a fundamental of 200 Hz, the second harmonic is 400 Hz, the fourth harmonic is 800 Hz, the sixth harmonic is 1200 Hz, and so on. These are even harmonics.

Composite Waveform Any variation from a pure sine wave produces harmonics. A nonsinusoidal wave is a composite of the fundamental and the harmonics. Some types of waveforms have only odd harmonics, some have only even harmonics, and some contain both. The shape of the wave is determined by its harmonic content. Generally, only the fundamental and the first few harmonics are of significant importance in determining the wave shape.

A square wave is an example of a waveform that consists of a fundamental and only odd harmonics. When the instantaneous values of the fundamental and each odd harmonic are added algebraically at each point, the resulting curve will have the shape of a square wave, as illustrated in Figure 11–62. In part (a) of the figure, the fundamental and the third harmonic produce a wave shape that begins to resemble a square wave. In part (b), the fundamental, third, and fifth harmonics produce a closer resemblance. When the seventh harmonic is included, as in part (c), the resulting wave shape becomes even more like a square wave. As more harmonics are included, a periodic square wave is approached.

11–10 THE OSCILLOSCOPE

The oscilloscope (scope for short) is a widely used and versatile test instrument for observing and measuring waveforms.

After completing this section, you should be able to

◆ **Use an oscilloscope to measure waveforms**

   ◆ Recognize common oscilloscope controls

   ◆ Measure the amplitude of a waveform

   ◆ Measure the period and frequency of a waveform

The **oscilloscope** is basically a graph-displaying device that traces a graph of a measured electrical signal on its screen. In most applications, the graph shows how signals change over time. The vertical axis of the display screen represents voltage, and the horizontal axis represents time. You can measure amplitude, period, and frequency of a signal using an oscilloscope. Also, you can determine the pulse width, duty cycle, rise time, and fall time of a pulse waveform. Most scopes can display at least two signals on the screen at one time, enabling you to observe their time relationship. Typical oscilloscopes are shown in Figure 11–64.

Two basic types of oscilloscopes, digital, and analog can be used to view digital waveforms. The digital scope converts the measured waveform to digital information by a sampling process in an analog-to-digital converter (ADC). The digital information is then used to reconstruct the waveform on the screen. The analog scope works by applying the measured waveform directly to control the up and down motion of the electron beam in the cathode-ray

tube (CRT) as it sweeps across the screen. As a result, the beam traces out the waveform pattern on the screen.

The digital scope is more widely used than the analog scope. However, either type can be used in many applications; each has characteristics that make it more suitable for certain situations. An analog scope displays waveforms as they occur in "real time." Digital scopes are useful for measuring transient pulses that may occur randomly or only once. Also, because information about the measured waveform can be stored in a digital scope, it may be viewed at some later time, printed out, or thoroughly analyzed by a computer or other means.

Basic Operation of Analog Oscilloscopes

To measure a voltage, a probe must be connected from the scope to the point in a circuit at which the voltage is present. Generally, a ×10 probe is used that reduces (attenuates) the signal amplitude by ten. The signal goes through the probe into the vertical circuits where it is either further attenuated or amplified, depending on the actual amplitude and on where you set the vertical control of the scope. The vertical circuits then drive the vertical deflection plates of the CRT. Also, the signal goes to the trigger circuits that trigger the horizontal circuits to initiate repetitive horizontal sweeps of the electron beam across the screen using a sawtooth waveform. There are many sweeps per second so that the beam appears to form a solid line across the screen in the shape of the waveform. This basic operation is illustrated in Figure 11–65.

Basic Operation of Digital Oscilloscopes

Some parts of a digital scope are similar to the analog scope. However, the digital scope is more complex than an analog scope and typically has an LCD screen rather than a CRT. Rather than displaying a waveform as it occurs, the digital scope first acquires the measured analog waveform and converts it to a digital format using an analog-to-digital converter (ADC). The digital data is stored and processed. The data then goes to the reconstruction and display circuits for display in its original analog form. Figure 11–66 show a basic block diagram for a digital oscilloscope.

Oscilloscope Controls

A front panel view of a typical dual-channel oscilloscope is shown in Figure 11–67. Instruments vary depending on model and manufacturer, but most have certain common features. For example, the two vertical sections contain a Position control, a channel menu button, and a Volts/Div control. The horizontal section contains a Sec/Div control.

Some of the main controls are now discussed. Refer to the user manual for complete details of your particular scope.

Vertical Controls In the vertical section of the scope in Figure 11–67, there are identical controls for each of the two channels (CH1 and CH2). The Position control lets you move a displayed waveform up or down vertically on the screen. The buttons immediately right of the screen provide for the selection of several items that appear on the screen, such as the coupling modes (ac, dc, or ground), coarse or fine adjustment for the Volts/Div, signal inversion, and other parameters. The Volts/Div control adjusts the number of volts represented by each vertical division on the screen. The Volts/Div setting for each channel is displayed on the bottom of the screen.

Horizontal Controls In the horizontal section, the controls apply to both channels. The Position control lets you move a displayed waveform left or right horizontally on the screen. The Horizontal Menu button provides for the selection of several items that appear on the screen such as the main time base, expanded view of a portion of a waveform, and

other parameters. The Sec/Div control adjusts the time represented by each horizontal division or main time base. The Sec/Div setting is displayed at the bottom of the screen.

Trigger Controls   In the Trigger section, the Level control determines the point on the triggering waveform where triggering occurs to initiate the sweep to display input waveforms. The Trigger Menu button provides for the selection of several items that appear on the screen including edge or slope triggering, trigger source, trigger mode, and other parameters. There is also an input for an external trigger signal.

Triggering stabilizes a waveform on the screen and properly triggers on a pulse that occurs only one time or randomly. Also, it allows you to observe time delays between two waveforms. Figure 11–68 compares a triggered to an untriggered signal. The untriggered signal tends to drift across the screen producing what appears to be multiple waveforms.

Coupling a Signal into the Scope   Coupling is the method used to connect a signal voltage to be measured into the oscilloscope. The DC and AC coupling modes are selected from the Vertical menu. DC coupling allows a waveform including its dc component to be

displayed. AC coupling blocks the dc component of a signal so that you see the waveform centered at 0 V. The Ground mode allows you to connect the channel input to ground to see where the 0 V reference is on the screen. Figure 11–69 illustrates the result of DC and AC coupling using a sinusoidal waveform that has a dc component.

▲ FIGURE 11–69

Displays of the same waveform having a dc component.

The voltage probe, shown in Figure 11–70, is used for connecting a signal to the scope. Since all instruments tend to affect the circuit being measured due to loading, most scope probes provide a high series resistance to minimize loading effects. Probes that have a series resistance ten times larger than the input resistance of the scope are called ×10 (times ten) probes. Probes with no series resistance are called ×1 (times one) probes. The oscilloscope adjusts its calibration for the attenuation of the type of probe being used. For most measurements, the ×10 probe should be used. However, if you are measuring very small signals, a ×1 may be the best choice.

The probe has an adjustment that allows you to compensate for the input capacitance of the scope. Most scopes have a probe compensation output that provides a calibrated square wave for probe compensation. Before making a measurement, you should make sure that the probe is properly compensated to eliminate any distortion introduced. Typically, there is a screw or other means of adjusting compensation on a probe. Figure 11–71 shows scope waveforms for three probe conditions: properly compensated, undercompensated, and overcompensated. If the waveform appears either over- or under-compensated, adjust the probe until the properly compensated square wave is achieved.

Application Activity

As you learned in this chapter, nonsinusoidal waveforms contain a combination of various harmonic frequencies. Each of these harmonics is a sinusoidal waveform with a certain frequency. Certain sinusoidal frequencies are audible; that is, they can be heard by the human ear. A single audible frequency, or pure sine wave, is called a tone and generally falls in the frequency range from about 300 Hz to about 15 kHz. When you hear a tone reproduced through a speaker, its loudness, or volume, depends on its voltage amplitude. You will use your knowledge of sine wave characteristics and the operation of an oscilloscope to measure the frequency and amplitude of signals at various points in a basic radio receiver.

Actual voice or music signals that are picked up by a radio receiver contain many harmonic frequencies with different voltage values. A voice or music signal is continuously changing, so its harmonic content is also changing. However, if a single sinusoidal frequency is transmitted and picked up by the receiver, you will hear a constant tone from the speaker.

Although, at this point you do not have the background to study amplifiers and receiver systems in detail, you can observe
Simplified block diagram of a basic radio receiver. Circled numbers represent test points.

the signals at various points in the receiver. A block diagram of a typical AM receiver is shown in Figure 11–73. AM stands for amplitude modulation, a topic that will be covered in another course. Figure 11–74 shows what a basic AM signal looks like, and for now that's all you need to know. As you can see, the amplitude of the sinusoidal waveform is changing. The higher radio frequency (RF) signal is called the *carrier;* and its amplitude is varied or modulated by a lower frequency signal, which is the audio (a tone in this case). Normally, however, the audio signal is a complex voice or music waveform.

Oscilloscope Measurements

Signals that are indicated by circled numbers at several test points on the receiver block diagram in Figure 11–73 are displayed on the oscilloscope screen in Figure 11–75 as indicated

by the same corresponding circled numbers. In all cases, the upper waveform on the screen is channel 1 and the lower waveform is channel 2. The readings on the bottom of the screen show readings for both channels.

The signal at point 1 is an AM signal, but you can't see the amplitude variation because of the short time base. The waveform is spread out too much to see the modulating audio signal, which causes amplitude variations; so what you see is just one cycle of the carrier. At point 3, the higher carrier frequency is difficult to determine because the time base was selected to allow viewing of one full cycle of the modulating signal. In an AM receiver, this intermediate frequency is 455 kHz. In actual practice, the modulated carrier signal at point 3 cannot easily be viewed on the scope because it contains two frequencies that make it difficult to synchronize in order to obtain a stable

The peaks follow the audio signal as indicated by dashed curve

pattern. Sometimes external triggering using the modulating signal or TV field is used to obtain a stable display. A stable pattern is shown in this case to illustrate what the modulated waveform looks like.

1. For each waveform in Figure 11–75, except point 3, determine the frequency and rms value. The signal at point 4 is the modulating tone extracted by the detector from the higher intermediate frequency (455 kHz).

Amplifier Analysis

2. All voltage amplifiers have a characteristic known as voltage gain. The voltage gain is the amount by which the amplitude of the output signal is greater than the amplitude of the input signal. Using this definition and the appropriate

scope measurements, determine the gain of the audio preamplifier in this particular receiver.

3. When an electrical signal is converted to sound by a speaker, the loudness of the sound depends on the amplitude of the signal applied to the speaker. Based on this, explain how the volume control potentiometer is used to adjust the loudness (volume) of the sound and determine the rms amplitude at the speaker.

SUMMARY

♦ The sine wave is a time-varying, periodic waveform.

♦ Alternating current changes direction in response to changes in the polarity of the source voltage.

♦ One cycle of an alternating sine wave consists of a positive alternation and a negative alternation.

♦ Two common sources of sine waves are the electromagnetic ac generator and the electronic oscillator circuit.

♦ A full cycle of a sine wave is 360°, or 2π radians. A half-cycle is 180°, or π radian. A quarter-cycle is 90°, or $\pi/2$ radians.

♦ A sinusoidal voltage can be generated by a conductor rotating in a magnetic field.

♦ Phase angle is the difference in degrees or radians between a given sine wave and a reference sine wave.

♦ The angular position of a phasor represents the angle of the sine wave with respect to a 0° reference, and the length or magnitude of a phasor represents the amplitude.

♦ Alternators (ac generators) produce power when there is relative motion between a magnetic field and a conductor.

♦ Most alternators take the output from the stator. The rotor provides a moving magnetic field.

♦ Two major types of ac motors are induction motors and synchronous motors.

♦ Induction motors have a rotor that turns in response to a rotating field from the stator.

♦ Synchronous motors move at a constant speed in sync with the field of the stator.

♦ A pulse consists of a transition from a baseline level to an amplitude level, followed by a transition back to the baseline level.

♦ A triangle or sawtooth wave consists of positive-going and negative-going ramps.

♦ Harmonic frequencies are odd or even multiples of the repetition rate of a nonsinusoidal waveform.

♦ Conversions of sine wave values are summarized in Table 11–2.

INTRODUCTION

In previous chapters, the resistor has been the only passive electrical component that you have studied. Capacitors and inductors are other types of basic passive electrical components. You will study inductors in Chapter 13.

In this chapter, you will learn about the capacitor and its characteristics. The physical construction and electrical properties are examined, and the effects of connecting capacitors in series and in parallel are analyzed. How a capacitor works in both dc and ac circuits is an important part of this coverage and forms the basis for the study of reactive circuits in terms of both frequency response and time response.

The *capacitor* is an electrical device that can store electrical charge, thereby creating an electric field that, in turn, stores energy. The measure of the energy-storing ability of a capacitor is its *capacitance*. When a sinusoidal signal is applied to a capacitor, it reacts in a certain way and produces an opposition to current, which depends on the frequency of the applied signal. This opposition to current is called *capacitive reactance*.

12–1 THE BASIC CAPACITOR

A **capacitor** is a passive electrical component that stores electrical charge and has the property of capacitance.

After completing this section, you should be able to

◆ **Describe the basic construction and characteristics of a capacitor**

  ◆ Explain how a capacitor stores charge

  ◆ Define *capacitance* and state its unit

  ◆ Explain how a capacitor stores energy

  ◆ Explain capacitor leakage

  ◆ Specify how the physical characteristics affect the capacitance

Basic Construction

In its simplest form, a capacitor is an electrical device that stores electrical charge and is constructed of two parallel conductive plates separated by an insulating material called the **dielectric**. Connecting leads are attached to the parallel plates. A basic capacitor is shown in Figure 12–1(a), and a schematic symbol is shown in part (b).

How a Capacitor Stores Charge

In the neutral state, both plates of a capacitor have an equal number of free electrons, as indicated in Figure 12–2(a). When the capacitor is connected to a voltage source through a resistor, as shown in part (b), electrons (negative charge) are removed from plate *A*, and an equal number are deposited on plate *B*. As plate *A* loses electrons and plate *B* gains electrons, plate *A* becomes positive with respect to plate *B*. During this charging process, electrons flow only through the connecting leads. No electrons flow through the dielectric of the capacitor because it is an insulator. The movement of electrons ceases when the voltage across the capacitor equals the source voltage, as indicated in Figure 12–2(c). If the capacitor is disconnected from the source, it retains the stored charge for a long period of time (the length of time depends on the type of capacitor) and still has the voltage across it, as shown in Figure 12–2(d). A charged capacitor can act as a temporary battery.

SAFETY NOTE

Capacitors are capable of storing electrical charge for a long time after power has been turned off in a circuit. Be careful when touching or handling capacitors in or out of a circuit. If you touch the leads, you may be in for a shock as the capacitor discharges through you! It is usually good practice to discharge a capacitor using a shorting tool with an insulated grip of some sort before handling the capacitor.

(a) Neutral (uncharged) capacitor
    (same charge on both plates)

(b) Electrons flow from plate A to plate B as the capacitor
    charges when connected to a voltage source.

(c) After the capacitor charges to V_S, no electrons flow
    while connected to the voltage source.

(d) Ideally, the capacitor retains charge when
    disconnected from the voltage source.
▲ **FIGURE 12–2**

Illustration of a capacitor storing charge.

Capacitance

The amount of charge that a capacitor can store per unit of voltage across its plates is its capacitance, designated C. That is, **capacitance** is a measure of a capacitor's ability to store charge. The more charge per unit of voltage that a capacitor can store, the greater its capacitance, as expressed by the following formula:

Equation 12–1
$$C = \frac{Q}{V}$$

where C is capacitance, Q is charge, and V is voltage.

By rearranging the terms in Equation 12–1, you can obtain two other formulas.

Equation 12–2
$$Q = CV$$

Equation 12–3
$$V = \frac{Q}{C}$$

The Unit of Capacitance   The farad (F) is the basic unit of capacitance. Recall that the coulomb (C) is the unit of electrical charge.

One farad is the amount of capacitance when one coulomb (C) of charge is stored with one volt across the plates.

Most capacitors that are used in electronics work have capacitance values that are specified in microfarads (μF) and picofarads (pF). A microfarad is one-millionth of a farad

$(1\,\mu\text{F} = 1 \times 10^{-6}\,\text{F})$, and a picofarad is one-trillionth of a farad $(1\,\text{pF} = 1 \times 10^{-12}\,\text{F})$. Conversions for farads, microfarads, and picofarads are given in Table 12–1.

How a Capacitor Stores Energy

A capacitor stores energy in the form of an electric field that is established by the opposite charges stored on the two plates. The electric field is represented by lines of force between the positive and negative charges and is concentrated within the dielectric, as shown in Figure 12–3.

The electric field stores energy in a capacitor.
The plates in Figure 12–3 have acquired a charge because they are connected to a battery. This creates an electric field between the plates, which stores energy. The energy stored in the electric field is directly related to the size of the capacitor and to the square of the voltage as given by the following equation for the energy stored:

Equation 12–4

$$W = \frac{1}{2}CV^2$$

When capacitance (C) is in farads and voltage (V) is in volts, the energy (W) is in joules.

Voltage Rating

Every capacitor has a limit on the amount of voltage that it can withstand across its plates. The voltage rating specifies the maximum dc voltage that can be applied without risk of damage to the device. If this maximum voltage, commonly called the *breakdown voltage* or *working voltage,* is exceeded, permanent damage to the capacitor can result.

You must consider both the capacitance and the voltage rating before you use a capacitor in a circuit application. The choice of capacitance value is based on particular circuit requirements. The voltage rating should always be above the maximum voltage expected in a particular application.

Dielectric Strength   The breakdown voltage of a capacitor is determined by the **dielectric strength** of the dielectric material used. The dielectric strength is expressed in V/mil (1 mil = 0.001 in. = 2.54×10^{-5} m). Table 12–2 lists typical values for several materials. Exact values vary depending on the specific composition of the material.

► TABLE 12–2

Some common dielectric materials and their dielectric strengths.

MATERIAL	DIELECTRIC STRENGTH (V/MIL)
Air	80
Oil	375
Ceramic	1000
Paper (paraffined)	1200
Teflon®	1500
Mica	1500
Glass	2000

A capacitor's dielectric strength can best be explained by an example. Assume that a certain capacitor has a plate separation of 1 mil and that the dielectric material is ceramic. This particular capacitor can withstand a maximum voltage of 1000 V because its dielectric strength is 1000 V/mil. If the maximum voltage is exceeded, the dielectric may break down and conduct current, causing permanent damage to the capacitor. Similarly, if the ceramic capacitor has a plate separation of 2 mils, its breakdown voltage is 2000 V.

Temperature Coefficient

The **temperature coefficient** indicates the amount and direction of a change in capacitance value with temperature. A positive temperature coefficient means that the capacitance increases with an increase in temperature or decreases with a decrease in temperature. A negative coefficient means that the capacitance decreases with an increase in temperature or increases with a decrease in temperature.

Temperature coefficients are typically specified in parts per million per Celsius degree (ppm/°C). For example, a negative temperature coefficient of 150 ppm/°C for a 1 μF capacitor means that for every degree rise in temperature, the capacitance decreases by 150 pF (there are one million picofarads in one microfarad).

Leakage

No insulating material is perfect. The dielectric of any capacitor will conduct some very small amount of current. Thus, the charge on a capacitor will eventually leak off. Some types of capacitors, such as large electrolytic types, have higher leakages than others. An equivalent circuit for a nonideal capacitor is shown in Figure 12–4. The parallel resistor R_{leak} represents the extremely high resistance (several hundred kilohms or more) of the dielectric material through which there is leakage current.
▲ **FIGURE 12–4**

Equivalent circuit for a nonideal capacitor.

Physical Characteristics of a Capacitor

The following parameters are important in establishing the capacitance and the voltage rating of a capacitor: plate area, plate separation, and dielectric constant.

Plate Area   Capacitance is directly proportional to the physical size of the plates as determined by the plate area, A. A larger plate area produces more capacitance, and a smaller plate area produces less capacitance. Figure 12–5(a) shows that the plate area of a parallel plate capacitor is the area of one of the plates. If the plates are moved in relation to each other, as shown in Figure 12–5(b), the overlapping area determines the effective plate area. This variation in effective plate area is the basis for a certain type of variable capacitor.

▶ **FIGURE 12–5**

Capacitance is directly proportional to plate area (*A*).

(a) Full plate area: more capacitance

(b) Reduced plate area: less capacitance
Plate Separation   Capacitance is inversely proportional to the distance between the plates. The plate separation is designated *d*, as shown in Figure 12–6. A greater separation of the plates produces a smaller capacitance, as illustrated in the figure. As previously

Capacitance is inversely proportional to the distance between the plates.

(a) Plates closer together: more capacitance

(b) Plates further apart: less capacitance
discussed, the breakdown voltage is directly proportional to the plate separation. The further the plates are separated, the greater the breakdown voltage.

Dielectric Constant   As you know, the insulating material between the plates of a capacitor is called the *dielectric*. Dielectric materials tend to reduce the voltage between plates for a given charge and thus increase the capacitance. If the voltage is fixed, more charge can be stored due to the presence of a dielectric than can be stored without a dielectric. The measure of a material's ability to establish an electric field is called the **dielectric constant** or *relative permittivity*, symbolized by ε_r. (ε is the Greek letter epsilon.)

Capacitance is directly proportional to the dielectric constant. The dielectric constant of a vacuum is defined as 1 and that of air is very close to 1. These values are used as a reference, and all other materials have values of ε_r specified with respect to that of a vacuum or air. For example, a material with $\varepsilon_r = 8$ can result in a capacitance eight times greater than that of air with all other factors being equal.

Table 12–3 lists several common dielectric materials and a typical dielectric constant for each. The values can vary because it depends on the specific composition of the material.

▶ TABLE 12–3

Some common dielectric materials and their typical dielectric constants.

MATERIAL	TYPICAL ε_r VALUE
Air (vacuum)	1.0
Teflon®2.0	
Paper (paraffined)	2.5
Oil	4.0
Mica	5.0
Glass	7.5
Ceramic	1200

The dielectric constant (relative permittivity) is dimensionless because it is a relative measure. It is a ratio of the absolute permittivity of a material, ε, to the absolute permittivity of a vacuum, ε_0, as expressed by the following formula:

Equation 12–5

$$\varepsilon_r = \frac{\varepsilon}{\varepsilon_0}$$

The value of ε_0 is 8.85×10^{-12} F/m (farads per meter).

Formula   You have seen how capacitance is directly related to plate area, A, and the dielectric constant, ε_r, and inversely related to plate separation, d. An exact formula for calculating the capacitance in terms of these three quantities is

Equation 12–6

$$C = \frac{A\varepsilon_r(8.85 \times 10^{-12} \text{ F/m})}{d}$$

where A is in square meters (m^2), d is in meters (m), and C is in farads (F). Recall that the absolute permittivity of a vacuum, ε_0, is 8.85×10^{-12} F/m and that the absolute permittivity of a dielectric (ε), as derived from Equation (12–5), is

$$\varepsilon = \varepsilon_r(8.85 \times 10^{-12} \text{ F/m})$$

EXAMPLE 12–4

Determine the capacitance of a parallel plate capacitor having a plate area of 0.01 m^2 and a plate separation of 0.5 mil (1.27×10^{-5} m). The dielectric is mica, which has a dielectric constant of 5.0.

Solution

Use Equation 12–6.

$$C = \frac{A\varepsilon_r(8.85 \times 10^{-12} \text{ F/m})}{d} = \frac{(0.01 \text{ m}^2)(5.0)(8.85 \times 10^{-12} \text{ F/m})}{1.27 \times 10^{-5} \text{ m}} = \mathbf{0.035 \ \mu F}$$

Related Problem

Determine C where $A = 3.6 \times 10^{-5}$ m^2, $d = 1$ mil (2.54×10^{-5} m), and ceramic is the dielectric.

12–2 TYPES OF CAPACITORS

Capacitors normally are classified according to the type of dielectric material and whether they are polarized or nonpolarized. The most common types of dielectric materials are mica, ceramic, plastic-film, and electrolytic (aluminum oxide and tantalum oxide).

After completing this section, you should be able to

◆ **Discuss various types of capacitors**

   ◆ Describe the characteristics of mica, ceramic, plastic-film, and electrolytic capacitors

   ◆ Describe types of variable capacitors

   ◆ Identify capacitor labeling

   ◆ Discuss capacitance measurement

Fixed Capacitors

Mica Capacitors   Two types of mica capacitors are stacked-foil and silver-mica. The basic construction of the stacked-foil type is shown in Figure 12–7. It consists of alternate layers of metal foil and thin sheets of mica. The metal foil forms the plate, with alternate foil sheets connected together to increase the plate area. More layers are used to increase the plate area, thus increasing the capacitance. The mica/foil stack is encapsulated in an insulating material such as Bakelite®, as shown in Figure 12–7(b). A silver-mica capacitor is formed in a similar way by stacking mica sheets with silver electrode material screened on them.

Mica capacitors are available with capacitance values ranging from 1 pF to 0.1 μF and voltage ratings from 100 V dc to 2500 V dc. Mica has a typical dielectric constant of 5.

Ceramic Capacitors   Ceramic dielectrics provide very high dielectric constants (1200 is typical). As a result, comparatively high capacitance values can be achieved in a small physical size. Ceramic capacitors are commonly available in a ceramic disk form, as shown in Figure 12–8, in a multilayer radial-lead configuration, as shown in Figure 12–9, or in a leadless ceramic chip, as shown in Figure 12–10, for surface mounting on printed circuit boards.

Ceramic capacitors typically are available in capacitance values ranging from 1 pF to 100 μF with voltage ratings up to 6 kV.

Plastic-Film Capacitors Common dielectric materials used in plastic-film capacitors include polycarbonate, propylene, polyester, polystyrene, polypropylene, and mylar. Some of these types have capacitance values up to 100 μF but most are less than 1 μF.

Figure 12–11 shows a common basic construction used in many plastic-film capacitors. A thin strip of plastic-film dielectric is sandwiched between two thin metal strips that act

TECH NOTE

Scientists are working with graphene, a carbon-based material that may be used for improved charge storage in rechargeable batteries and ultra-capacitors. The ability to store large amounts of charge is important in many applications from office copiers to improving the efficiency of electric and hybrid vehicles. The new technology may speed development of renewable energies such as wind and solar power, which need to be able to store large amounts of energy.

as plates. One lead is connected to the inner plate and one is connected to the outer plate as indicated. The strips are then rolled in a spiral configuration and encapsulated in a molded case. Thus, a large plate area can be packaged in a relatively small physical size, thereby achieving large capacitance values. Another method uses metal deposited directly on the film dielectric to form the plates.

SAFETY NOTE

Be extremely careful with electrolytic capacitors because it does make a difference which way an electrolytic capacitor is connected. Always observe the proper polarity. If a polarized capacitor is connected backwards, it may explode and cause injury.

Electrolytic Capacitors   Electrolytic capacitors are polarized so that one plate is positive and the other negative. These capacitors are used for capacitance values from 1 μF up to over 200,000 μF, but they have relatively low breakdown voltages (350 V is a typical maximum) and high amounts of leakage. In this text, capacitors with values of 1 μF or greater are considered to be polarized.

In recent years, manufacturers have developed new electrolytic capacitors with much larger capacitance values; however, these new capacitors have lower voltage ratings than smaller-value capacitors and tend to be expensive. Super capacitors with capacitances of hundreds of farads are available. These capacitors are useful for battery backup and for applications like small motor starters that require a very large capacitance.

Electrolytic capacitors offer much higher capacitance values than mica or ceramic capacitors, but their voltage ratings are typically lower. Aluminum electrolytics are probably the most commonly used type. While other capacitors use two similar plates, the electrolytic consists of one plate of aluminum foil and another plate made of a conducting electrolyte applied to a material such as plastic film. These two "plates" are separated by a layer of aluminum oxide that forms on the surface of the aluminum plate. Figure 12–13(a) illustrates the basic construction of a typical aluminum electrolytic capacitor with axial leads. Other electrolytics with radial leads are shown in Figure 12–13(b); the symbol for an electrolytic capacitor is shown in part (c).

Tantalum electrolytics can be in either a tubular configuration similar to Figure 12–13 or "tear drop" shape as shown in Figure 12–14. In the tear drop configuration, the positive plate is actually a pellet of tantalum powder rather than a sheet of foil. Tantalum pentoxide forms the dielectric, and manganese dioxide forms the negative plate.

Because of the process used for the insulating oxide dielectric, the metallic (aluminum or tantalum) plate must be connected so that it is always positive with respect to the electrolyte

Examples of electrolytic capacitors.
▲ FIGURE 12–14

Construction view of a typical "tear drop" shaped tantalum electrolytic capacitor.

plate, and, thus all electrolytic capacitors are polarized. The metal plate (positive lead) is usually indicated by a plus sign or some other obvious marking and must always be connected in a dc circuit where the voltage across the capacitor does not change polarity regardless of any ac present. Reversal of the polarity of the voltage will usually result in complete destruction of the capacitor.

The problem of dielectric absorption occurs mostly in electrolytic capacitors when they do not completely discharge during use and retain a residual charge. Approximately 25% of defective capacitors exhibit this condition.
Schematic symbol for a variable capacitor.

Variable Capacitors

Variable capacitors are used in a circuit when there is a need to adjust the capacitance value either manually or automatically. These capacitors are generally less than 300 pF but are available in larger values for specialized applications. The schematic symbol for a variable capacitor is shown in Figure 12–15.

Adjustable capacitors that normally have slotted screw-type adjustments and are used for very fine adjustments in a circuit are called **trimmers**. Ceramic or mica is a common dielectric in these types of capacitors, and the capacitance usually is changed by adjusting the plate separation. Generally, trimmer capacitors have values less than 100 pF. Figure 12–16 shows some typical devices.

▶ FIGURE 12–16

Examples of trimmer capacitors.
The **varactor** is a semiconductor device that exhibits a capacitance characteristic that is varied by changing the voltage across its terminals. This device usually is covered in detail in a course on electronic devices.

Capacitor Labeling

Capacitor values are indicated on the body of the capacitor either by typographical labels or by color codes. Typographical labels consist of letters and numbers that indicate various parameters such as capacitance, voltage rating, and tolerance.

Some capacitors carry no unit designation for capacitance. In these cases, the units are implied by the value indicated and are recognized by experience. For example, a ceramic capacitor marked .001 or .01 has units of microfarads because picofarad values that small are not available. As another example, a ceramic capacitor labeled 50 or 330 has units of picofarads because microfarad units that large normally are not available in this type. In some cases, a 3-digit designation is used. The first two digits are the first two digits of the capacitance value. The third digit is the number of zeros after the second digit. For example, 103 means 10,000 pF. In some instances, the units are labeled as pF or μF; sometimes the microfarad unit is labeled as MF or MFD.

A voltage rating appears on some types of capacitors with WV or WVDC and is omitted on others. When it is omitted, the voltage rating can be determined from information supplied by the manufacturer. The tolerance of the capacitor is usually labeled as a percentage, such as $\pm 10\%$. The temperature coefficient is indicated by a *parts per million* marking. This type of label consists of a P or N followed by a number. For example, N750 means a negative temperature coefficient of 750 ppm/°C, and P30 means a positive temperature coefficient of 30 ppm/°C. An NP0 designation means that the positive and negative coefficients are zero; thus the capacitance does not change with temperature. Certain types of capacitors are color coded. Refer to Appendix C for additional capacitor labeling and color code information.

Capacitance Measurement

A capacitance meter such as the one shown in Figure 12–17 can be used to check the value of a capacitor. Also, many DMMs provide a capacitance measurement feature. Most capacitors change value over a period of time, some more than others. Ceramic capacitors, for example, often exhibit a 10% to 15% change in value during the first year. Electrolytic capacitors are

A typical capacitance meter. (Courtesy of B+K Precision)

particularly subject to value change due to drying of the electrolytic solution. In other cases, capacitors may be labeled incorrectly or the wrong value may have been installed in the circuit. Although a value change represents less than 25% of defective capacitors, a value check can quickly eliminate this as a source of trouble when troubleshooting a circuit.

Typically, values from 200 pF to 200,000 μF can be measured on a capacitance meter by simply connecting the capacitor, setting the switch, and reading the value on the display. Some capacitance meters can also be used to check for leakage current in capacitors. In order to check for leakage, a sufficient voltage must be applied across the capacitor to simulate operating conditions. This is automatically done by the test instrument. Over 40% of all defective capacitors have excessive leakage current and electrolytics are particularly susceptible to this problem.

12–3 SERIES CAPACITORS

The total capacitance of a series connection of capacitors is less than the individual capacitance of any of the capacitors. Capacitors in series divide voltage across them in proportion to their capacitance.

After completing this section, you should be able to

◆ **Analyze series capacitors**

  ◆ Determine total capacitance

  ◆ Determine capacitor voltages

Total Capacitance

When capacitors are connected in series, the total capacitance is less than the smallest capacitance value because the effective plate separation increases. The calculation of total series capacitance is analogous to the calculation of total resistance of parallel resistors (Chapter 6).

Consider the generalized circuit in Figure 12–18(a), which has *n* capacitors in series with a voltage source and a switch. When the switch is closed, the capacitors charge as
(a) Charging current is same for each capacitor, $I = Q/t$.

(b) All capacitors store same amount of charge and $V = Q/C$.

▲ **FIGURE 12–18**

A series capacitive circuit.

current is established through the circuit. Since this is a series circuit, the current must be the same at all points, as illustrated. Since current is the rate of flow of charge, the amount of charge stored by each capacitor is equal to the total charge, expressed as

Equation 12–7

$$Q_T = Q_1 = Q_2 = Q_3 = \cdots = Q_n$$

Next, according to Kirchhoff's voltage law, the sum of the voltages across the charged capacitors must equal the total voltage, V_T, as shown in Figure 12–18(b). This is expressed in equation form as

$$V_T = V_1 + V_2 + V_3 + \cdots + V_n$$

From Equation 12–3, $V = Q/C$. When this relationship is substituted into each term of the voltage equation, the following result is obtained:

$$\frac{Q_T}{C_T} = \frac{Q_1}{C_1} + \frac{Q_2}{C_2} + \frac{Q_3}{C_3} + \cdots + \frac{Q_n}{C_n}$$

Since the charges on all the capacitors are equal, the Q terms can be factored and canceled, resulting in

Equation 12–8

$$\frac{1}{C_T} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots + \frac{1}{C_n}$$

Taking the reciprocal of both sides of Equation 12–8 yields the following general formula for total series capacitance:

Equation 12–9

$$C_T = \frac{1}{\dfrac{1}{C_1} + \dfrac{1}{C_2} + \dfrac{1}{C_3} + \cdots + \dfrac{1}{C_n}}$$

Remember,

The total series capacitance is always less than the smallest capacitance.

Two Capacitors in Series When only two capacitors are in series, a special form of Equation 12–8 can be used.

$$\frac{1}{C_T} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{C_1 + C_2}{C_1 C_2}$$

Taking the reciprocal of the left and right terms gives the formula for total capacitance of two capacitors in series.

Equation 12–10

$$C_T = \frac{C_1 C_2}{C_1 + C_2}$$

Capacitors of Equal Value in Series This special case is another in which a formula can be developed from Equation 12–8. When all capacitor values are the same and equal to C, the formula is

$$\frac{1}{C_T} = \frac{1}{C} + \frac{1}{C} + \frac{1}{C} + \cdots + \frac{1}{C}$$

Adding all the terms on the right yields

$$\frac{1}{C_T} = \frac{n}{C}$$

where n is the number of equal-value capacitors. Taking the reciprocal of both sides yields

Equation 12–11

$$C_T = \frac{C}{n}$$

The capacitance value of the equal capacitors divided by the number of equal series capacitors gives the total capacitance.

You can also use Equation 12–9.

$$C_T = \cfrac{1}{\cfrac{1}{100\,\text{pF}} + \cfrac{1}{330\,\text{pF}}} = \mathbf{76.7\ pF}$$

Related Problem   Determine C_T if C_1 = 470 pF and C_2 = 680 pF in Figure 12–20.

▶ **FIGURE 12–21**
Solution   Since $C_1 = C_2 = C_3 = C_4 = C$, use Equation 12–11,

$$C_T = \frac{C}{n} = \frac{0.022\,\mu F}{4} = \mathbf{0.0055\ \mu F}$$

Related Problem   Determine C_T if the capacitor values in Figure 12–21 are doubled.

Capacitor Voltages

A series connection of charged capacitors acts as a voltage divider. The voltage across each capacitor in series is inversely proportional to its capacitance value, as shown by the formula $V = Q/C$. You can determine the voltage across any individual capacitor in series with the following formula:

Equation 12–12

$$V_x = \left(\frac{C_T}{C_x}\right)V_T$$

where C_x is any capacitor in series (such as C_1, C_2, or C_3), V_x is the voltage across C_x, and V_T is the total voltage across the capacitors. The derivation is as follows: Since the charge on any capacitor in series is the same as the total charge ($Q_x = Q_T$), and since $Q_x = V_xC_x$ and $Q_T = V_TC_T$, then

$$V_xC_x = V_TC_T$$

Solving for V_x yields

$$V_x = \frac{C_TV_T}{C_x}$$

The largest-value capacitor in a series connection will have the smallest voltage across it. The smallest-value capacitor will have the largest voltage across it.

EXAMPLE 12–8   Find the voltage across each capacitor in Figure 12–22.

▶ **FIGURE 12–22**
Solution   Calculate the total capacitance.

$$C_T = \cfrac{1}{\cfrac{1}{C_1} + \cfrac{1}{C_2} + \cfrac{1}{C_3}} = \cfrac{1}{\cfrac{1}{0.1\,\mu F} + \cfrac{1}{0.47\,\mu F} + \cfrac{1}{0.22\,\mu F}} = 0.06\,\mu F$$

From Figure 12–22, $V_S = V_T = 25$ V. Therefore, use Equation 12–12 to calculate the voltage across each capacitor.

$$V_1 = \left(\frac{C_T}{C_1}\right)V_T = \left(\frac{0.06\ \mu\text{F}}{0.1\ \mu\text{F}}\right)25\ \text{V} = \textbf{15.0 V}$$

$$V_2 = \left(\frac{C_T}{C_2}\right)V_T = \left(\frac{0.06\ \mu\text{F}}{0.47\ \mu\text{F}}\right)25\ \text{V} = \textbf{3.19 V}$$

$$V_3 = \left(\frac{C_T}{C_3}\right)V_T = \left(\frac{0.06\ \mu\text{F}}{0.22\ \mu\text{F}}\right)25\ \text{V} = \textbf{6.82 V}$$

12–4 PARALLEL CAPACITORS

Capacitances add when capacitors are connected in parallel.

After completing this section, you should be able to

◆ **Analyze parallel capacitors**
   ◆ Determine total capacitance

When capacitors are connected in parallel, the total capacitance is the sum of the individual capacitances because the effective plate area increases. The calculation of total parallel capacitance is analogous to the calculation of total series resistance (Chapter 5).

Consider what happens when the switch in Figure 12–24 is closed. The total charging current from the source divides at the junction of the parallel branches. There is a separate charging current through each branch so that a different charge can be stored by each capacitor. By Kirchhoff's current law, the sum of all of the charging currents is equal to the
▲ FIGURE 12–24

Capacitors in parallel.

total current. Therefore, the sum of the charges on the capacitors is equal to the total charge. Also, the voltages across all of the parallel branches are equal. These observations are used to develop a formula for total parallel capacitance as follows for the general case of n capacitors in parallel.

Equation 12–13

$$Q_T = Q_1 + Q_2 + Q_3 + \cdots + Q_n$$

From Equation 12–2, $Q = CV$. When this relationship is substituted into each term of Equation 12–13, the following result is obtained:

$$C_T V_T = C_1 V_1 + C_2 V_2 + C_3 V_3 + \cdots + C_n V_n$$

Since $V_T = V_1 = V_2 = V_3 = \cdots = V_n$, the voltages can be factored and canceled, giving

Equation 12–14

$$C_T = C_1 + C_2 + C_3 + \cdots + C_n$$

Equation 12–14 is the general formula for total parallel capacitance where n is the number of capacitors. Remember,

The total parallel capacitance is the sum of all the capacitors in parallel.

For the special case when all of the capacitors have the same value, C, multiply the value by the number (n) of capacitors in parallel.

12–5   CAPACITORS IN DC CIRCUITS

A capacitor will charge up when it is connected to a dc voltage source. The buildup of charge across the plates occurs in a predictable manner that is dependent on the capacitance and the resistance in a circuit.

After completing this section, you should be able to

◆ **Analyze capacitive dc switching circuits**

  ◆ Describe the charging and discharging of a capacitor

  ◆ Define *RC time constant*

  ◆ Relate the time constant to charging and discharging of a capacitor

  ◆ Write equations for the charging and discharging curves

  ◆ Explain why a capacitor blocks dc

Charging a Capacitor

A capacitor will charge when it is connected to a dc voltage source, as shown in Figure 12–27. The capacitor in part (a) of the figure is uncharged; that is, plate *A* and plate *B* have equal numbers of free electrons. When the switch is closed, as shown in part (b), the source moves electrons away from plate *A* through the circuit to plate *B* as the arrows indicate. As

(d) Retains charge
▲ **FIGURE 12–27**

Charging a capacitor.

plate A loses electrons and plate B gains electrons, plate A becomes positive with respect to plate B. As this charging process continues, the voltage across the plates builds up rapidly until it is equal to the applied voltage, V_S, but opposite in polarity, as shown in part (c). When the capacitor is fully charged, there is no current.

A capacitor blocks constant dc.

When the charged capacitor is disconnected from the source, as shown in Figure 12–27(d), it remains charged for long periods of time, depending on its leakage resistance, and can cause severe electrical shock. The charge on an electrolytic capacitor generally leaks off more rapidly than in other types of capacitors.

Discharging a Capacitor

When a wire is connected across a charged capacitor, as shown in Figure 12–28, the capacitor will discharge. In this particular case, a very low resistance path (the wire) is connected across the capacitor with a switch. Before the switch is closed, the capacitor is charged to 50 V, as indicated in part (a). When the switch is closed, as shown in part (b), the excess electrons on plate B move through the circuit to plate A (indicated by the arrows); as a result of the electrons moving through the low resistance of the wire, the energy stored by the capacitor is dissipated in the wire. The charge is neutralized when the numbers of free electrons on both plates are again equal. At this time, the voltage across the capacitor is zero, and the capacitor is completely discharged, as shown in part (c).

Discharging a charged capacitor.

Current and Voltage During Charging and Discharging

Notice in Figures 12–27 and 12–28 that the direction of electron flow during discharge is opposite to that during charging. It is important to understand that ideally *there is no current through the dielectric of the capacitor during charging or discharging because the*

dielectric is an insulating material. There is current from one plate to the other only through the external circuit.

Figure 12–29(a) shows a capacitor connected in series with a resistor and a switch to a dc voltage source. Initially, the switch is open and the capacitor is uncharged with zero volts across its plates. At the instant the switch is closed, the current jumps to its maximum value and the capacitor begins to charge. The current is maximum initially because the capacitor has zero volts across it and, therefore, effectively acts as a short; thus, the current is limited only by the resistance. As time passes and the capacitor charges, the current decreases and the voltage across the capacitor (V_C) increases. The resistor voltage is proportional to the current during this charging period.

After a certain period of time, the capacitor reaches full charge. At this point, the current is zero and the capacitor voltage is equal to the dc source voltage, as shown in Figure 12–29(b). If the switch were opened now, the capacitor would retain its full charge (neglecting any leakage).

In Figure 12–29(c), the voltage source has been removed. When the switch is closed, the capacitor begins to discharge. Initially, the current jumps to a maximum but in a direction opposite to its direction during charging. As time passes, the current and capacitor voltage decrease. The resistor voltage is always proportional to the current. When the capacitor has fully discharged, the current and the capacitor voltage are zero.

Remember the following rules about capacitors in dc circuits:

1. A capacitor appears as an *open* to constant voltage.

2. A capacitor appears as a *short* to an instantaneous change in voltage.

Now let's examine in more detail how the voltage and current change with time in a capacitive circuit.

(a) Charging: Capacitor voltage increases as the current and resistor voltage decrease.

(b) Fully charged: Capacitor voltage equals source voltage. The current is zero.

(c) Discharging: Capacitor voltage, resistor voltage, and the current decrease from their initial maximum values. Note that the discharge current is opposite to the charge current.

Current and voltage in a charging and discharging capacitor.

The *RC* Time Constant

In a practical situation, there cannot be capacitance without some resistance in a circuit. It may simply be the small resistance of a wire, a Thevenin source resistance, or it may be a physical resistor. Because of this, the charging and discharging characteristics of a capacitor must always be considered with the associated resistance. The resistance introduces the element of *time* in the charging and discharging of a capacitor.

When a capacitor charges or discharges through a resistance, a certain time is required for the capacitor to charge fully or discharge fully. The voltage across a capacitor cannot change instantaneously because a finite time is required to move charge from one point to another. The time constant of a series *RC* circuit determines the rate at which the capacitor charges or discharges.

The ***RC* time constant is a fixed time interval that equals the product of the resistance and the capacitance in a series *RC* circuit.**

The time constant is expressed in seconds when resistance is in ohms and capacitance is in farads. It is symbolized by τ (Greek letter tau), and the formula is

Equation 12–16
$$\tau = RC$$

Recall that $I = Q/t$. The current depends on the amount of charge moved in a given time. When the resistance is increased, the charging current is reduced, thus increasing the charging time of the capacitor. When the capacitance is increased, the amount of charge increases; thus, for the same current, more time is required to charge the capacitor.

EXAMPLE 12–11

A series *RC* circuit has a resistance of 1.0 MΩ and a capacitance of 4.7 μF. What is the time constant?

Solution
$$\tau = RC = (1.0 \times 10^6 \, \Omega)(4.7 \times 10^{-6} \, \text{F}) = \textbf{4.7 s}$$

Related Problem A series *RC* circuit has a 270 kΩ resistor and a 3300 pF capacitor. What is the time constant?

When a capacitor is charging or discharging between two voltage levels, the charge on the capacitor changes by approximately 63% of the difference in the levels in one time constant. An uncharged capacitor charges to 63% of its fully charged voltage in one time constant. When a capacitor is discharging, its voltage drops to approximately $100\% - 63\% = 37\%$ of its initial value in one time constant, which is a 63% change.

The Charging and Discharging Curves

A capacitor charges and discharges following a nonlinear curve, as shown in Figure 12–30. In these graphs, the approximate percentage of full charge is shown at each time-constant interval. This type of curve follows a precise mathematical formula and is called an *exponential curve*. The charging curve is an increasing exponential, and the discharging curve is a decreasing exponential. It takes five time constants to change the voltage by 99% (considered 100%). This five time-constant interval is generally accepted as the time to fully charge or discharge a capacitor and is called the *transient time*.

General Formula The general expressions for either increasing or decreasing exponential curves are given in the following equations for both instantaneous voltage and instantaneous current.

Equation 12–17
$$v = V_F + (V_i - V_F)e^{-t/\tau}$$

Equation 12–18
$$i = I_F + (I_i - I_F)e^{-t/\tau}$$

where V_F and I_F are the final values of voltage and current, and V_i and I_i are the initial values of voltage and current. The lowercase italic letters v and i are the instantaneous values of the capacitor voltage and current at time t, and e is the base of natural logarithms. The e^x key on a calculator makes it easy to work with this exponential term.

Charging from Zero The formula for the special case in which an increasing exponential voltage curve begins at zero ($V_i = 0$), as shown in Figure 12–30(a), is given in Equation 12–19. It is developed as follows, starting with the general formula, Equation 12–17.

$$v = V_F + (V_i - V_F)e^{-t/\tau} = V_F + (0 - V_F)e^{-t/RC} = V_F - V_F e^{-t/RC}$$

Factoring out V_F, you have

$$v = V_F(1 - e^{-t/RC})$$

<div align="right">Equation 12–19</div>

Using Equation 12–19, you can calculate the value of the charging voltage of a capacitor at any instant of time if it is initially uncharged. You can calculate an increasing current by substituting i for v and I_F for V_F in Equation 12–19.

EXAMPLE 12–12

In Figure 12–31, determine the capacitor voltage 50 μs after the switch is closed if the capacitor is initially uncharged. Draw the charging curve.

▶ FIGURE 12–31
Solution　The time constant is $RC = (8.2 \text{ k}\Omega)(0.01 \text{ }\mu\text{F}) = 82 \text{ }\mu\text{s}$. The voltage to which the capacitor will fully charge is 50 V (this is V_F). The initial voltage is zero. Notice that 50 μs is less than one time constant; so the capacitor will charge less than 63% of the full voltage in that time.

$$v_C = V_F(1 - e^{-t/RC}) = (50 \text{ V})(1 - e^{-50\mu s/82\mu s})$$
$$= (50 \text{ V})(1 - e^{-0.61}) = (50 \text{ V})(1 - 0.543) = \textbf{22.8 V}$$

The charging curve for the capacitor is shown in Figure 12–32.
You can determine an exponential function on your calculator by using the e^x key and entering the value of the exponent of e.

Related Problem   Determine the capacitor voltage 15 μs after switch closure in Figure 12–31.

Use Multisim file E12-12 to verify the calculated results in this example and to confirm your calculation for the related problem.

Discharging to Zero   The formula for the special case in which a decreasing exponential voltage curve ends at zero ($V_F = 0$), as shown in Figure 12–30(b), is derived from the general formula as follows:

$$v = V_F + (V_i - V_F)e^{-t/\tau} = 0 + (V_i - 0)e^{-t/RC}$$

This reduces to

Equation 12–20

$$v = V_i e^{-t/RC}$$

where V_i is the voltage at the beginning of the discharge. You can use this formula to calculate the discharging voltage at any instant, as Example 12–13 illustrates.

EXAMPLE 12–13

Determine the capacitor voltage in Figure 12–33 at a point in time 6 ms after the switch is closed. Draw the discharging curve.

Solution   The discharge time constant is $RC = (10\ \text{k}\Omega)(2.2\ \mu\text{F}) = 22$ ms. The initial capacitor voltage is 10 V. Notice that 6 ms is less than one time constant, so the capacitor will discharge less than 63%. Therefore, it will have a voltage greater than 37% of the initial voltage at 6 ms.

$$v_C = V_i e^{-t/RC} = (10\ \text{V})e^{-6\text{ms}/22\text{ms}} = (10\ \text{V})e^{-0.27} = (10\ \text{V})(0.761) = \mathbf{7.61\ V}$$

The discharging curve for the capacitor is shown in Figure 12–34.

Graphical Method Using Universal Exponential Curves   The universal curves in Figure 12–35 provide a graphic solution of the charge and discharge of capacitors. Example 12–14 illustrates this graphical method.

Normalized universal exponential curves.

EXAMPLE 12–14

How long will it take the initially uncharged capacitor in Figure 12–36 to charge to 75 V? What is the capacitor voltage 2 ms after the switch is closed? Use the normalized universal exponential curves in Figure 12–35 to determine the answers.

► FIGURE 12–36
Solution   The full charge voltage is 100 V, which is at the 100% level (1.0) on the normalized vertical scale of the graph. The value 75 V is 75% of maximum, or 0.75 on the graph. You can see that this value occurs at 1.4 time constants. In this circuit, one time constant is $RC = (100\,\text{k}\Omega)(0.01\,\mu\text{F}) = 1$ ms. Therefore, the capacitor voltage reaches 75 V at 1.4 ms after the switch is closed.

On the universal exponential curve, you see that the capacitor is at approximately 86 V (0.86 on the vertical axis) in 2 ms, which is 2 time constants. These graphic solutions are shown in Figure 12–37.

Solving for Time

Occasionally, it is necessary to determine how long it will take a capacitor to charge or discharge to a specified voltage. Equations 12–17 and 12–19 can be solved for t if v is specified. The natural logarithm (abbreviated ln) of $e^{-t/RC}$ is the exponent $-t/RC$. Therefore, taking the natural logarithm of both sides of the equation allows you to solve for time. This procedure is done as follows for the decreasing exponential formula when $V_F = 0$ (Equation 12–20).

$$v = V_i e^{-t/RC}$$

$$\frac{v}{V_i} = e^{-t/RC}$$

$$\ln\left(\frac{v}{V_i}\right) = \ln e^{-t/RC}$$

$$\ln\left(\frac{v}{V_i}\right) = \frac{-t}{RC}$$

$$t = -RC \ln\left(\frac{v}{V_i}\right)$$

Equation 12–21

The same procedure can be used for the increasing exponential formula in Equation 12–19 as follows:

$$v = V_F(1 - e^{-t/RC})$$

$$\frac{v}{V_F} = 1 - e^{-t/RC}$$

$$1 - \frac{v}{V_F} = e^{-t/RC}$$

$$\ln\left(1 - \frac{v}{V_F}\right) = \ln e^{-t/RC}$$

$$\ln\left(1 - \frac{v}{V_F}\right) = \frac{-t}{RC}$$

$$t = -RC \ln\left(1 - \frac{v}{V_F}\right)$$

In Figure 12–38, how long will it take the capacitor to discharge to 25 V when the switch is closed?

► **FIGURE 12–38**
Solution   Use Equation 12–21 to find the discharge time.

$$t = -RC\ln\left(\frac{v}{V_i}\right) = -(2.2\,\text{k}\Omega)(1\,\mu\text{F})\ln\left(\frac{25\,\text{V}}{100\,\text{V}}\right)$$

$$= -(2.2\,\text{ms})\ln(0.25) = -(2.2\,\text{ms})(-1.39) = \textbf{3.05 ms}$$

You can determine ln(0.25) with your calculator by using the LN key.

Response to a Square Wave

A common case that illustrates the rising and falling exponential occurs when an *RC* circuit is driven with a square wave that has a long period compared to the time constant. The square wave provides on and off action but, unlike a single switch, it provides a discharge path back through the generator when the wave drops back to zero.

When the square wave rises, the voltage across the capacitor rises exponentially toward the maximum value of the square wave in a time that depends on the time constant. When the square wave returns to the zero level, the capacitor voltage decreases exponentially, again depending on the time constant. The Thevenin resistance of the generator is part of the *RC* time constant; however, it can be ignored if it is small compared to *R*. Example 12–16 shows the waveforms for the case where the period is long compared to the time constant; other cases will be covered in detail in Chapter 20.

EXAMPLE 12–16   In Figure 12–39, calculate the voltage across the capacitor every 0.1 ms for one complete period of the input. Then sketch the capacitor waveform. Assume the Thevenin resistance of the generator is negligible.
▲ **FIGURE 12–39**

Solution

$$\tau = RC = (15\,\text{k}\Omega)(0.0056\,\mu\text{F}) = 0.084\,\text{ms}$$

The period of the square wave is 1 ms, which is approximately 12τ. This means that 6τ will elapse after each change of the pulse, allowing the capacitor to fully charge and fully discharge.

For the increasing exponential,

$$v = V_F(1 - e^{-t/RC}) = V_F(1 - e^{-t/\tau})$$

At 0.1 ms: $v = 2.5\,V(1 - e^{-0.1ms/0.084ms}) = 1.74\,V$

At 0.2 ms: $v = 2.5\,V(1 - e^{-0.2ms/0.084ms}) = 2.27\,V$

At 0.3 ms: $v = 2.5\,V(1 - e^{-0.3ms/0.084ms}) = 2.43\,V$

At 0.4 ms: $v = 2.5\,V(1 - e^{-0.4ms/0.084ms}) = 2.48\,V$

At 0.5 ms: $v = 2.5\,V(1 - e^{-0.5ms/0.084ms}) = 2.49\,V$

For the decreasing exponential,

$$v = V_i(e^{-t/RC}) = V_i(e^{-t/\tau})$$

In the equation, time is shown from the point when the change occurs (subtracting 0.5 ms from the actual time). For example, at 0.6 ms, $t = 0.6\,ms - 0.5\,ms = 0.1\,ms$.

At 0.6 ms: $v = 2.5\,V(e^{-0.1ms/0.084ms}) = 0.76\,V$

At 0.7 ms: $v = 2.5\,V(e^{-0.2ms/0.084ms}) = 0.23\,V$

At 0.8 ms: $v = 2.5\,V(e^{-0.3ms/0.084ms}) = 0.07\,V$

At 0.9 ms: $v = 2.5\,V(e^{-0.4ms/0.084ms}) = 0.02\,V$

At 1.0 ms: $v = 2.5\,V(e^{-0.5ms/0.084ms}) = 0.01\,V$

Figure 12–40 is a plot of these results.

12–6 Capacitors in AC Circuits

As you know, a capacitor blocks dc. A capacitor passes ac but with an amount of opposition, called capacitive reactance, that depends on the frequency of the ac.

After completing this section, you should be able to

◆ **Analyze capacitive ac circuits**

 ◆ Explain why a capacitor causes a phase shift between voltage and current

 ◆ Define *capacitive reactance*

 ◆ Determine the value of capacitive reactance in a given circuit

 ◆ Discuss instantaneous, true, and reactive power in a capacitor

To explain fully how capacitors work in ac circuits, the concept of the derivative must be introduced. *The derivative of a time-varying quantity is the instantaneous rate of change of that quantity.*

Recall that current is the rate of flow of charge (electrons). Therefore, instantaneous current, *i*, can be expressed as the instantaneous rate of change of charge, *q*, with respect to time, *t*.

Equation 12–23

$$i = \frac{dq}{dt}$$

The term dq/dt is the derivative of q with respect to time and represents the instantaneous rate of change of q. Also, in terms of instantaneous quantities, $q = Cv$. Therefore, from a basic rule of differential calculus, the derivative of q with respect to time is $dq/dt = C(dv/dt)$. Since $i = dq/dt$, we get the following relationship:

Equation 12–24

$$i = C\left(\frac{dv}{dt}\right)$$

This formula states

> **The instantaneous capacitor current is equal to the capacitance times the instantaneous rate of change of the voltage across the capacitor.**

The faster the voltage across a capacitor changes, the greater the current.

Phase Relationship of Current and Voltage in a Capacitor

Consider what happens when a sinusoidal voltage is applied across a capacitor, as shown in Figure 12–41(a). The voltage waveform has a maximum rate of change (dv/dt = max) at the zero crossings and a zero rate of change (dv/dt = 0) at the peaks, as indicated in Figure 12–41(b).

The phase relationship between the current and the voltage for the capacitor can be established from Equation 12–24. When $dv/dt = 0$, i is also zero because $i = C(dv/dt) = C(0) = 0$. When dv/dt is a positive-going maximum, i is a positive maximum; when dv/dt is a negative-going maximum, i is a negative maximum.

A sinusoidal voltage always produces a sinusoidal current in a capacitive circuit. Therefore, you can plot the current with respect to the voltage if you know the points on the voltage curve at which the current is zero and those at which it is maximum. This relationship is shown in Figure 12–42(a). Notice that the current leads the voltage in phase by 90°. This is always true in a purely capacitive circuit. The relationship between the voltage and current phasors is shown in Figure 12–42(b).

(b) Phasor diagram
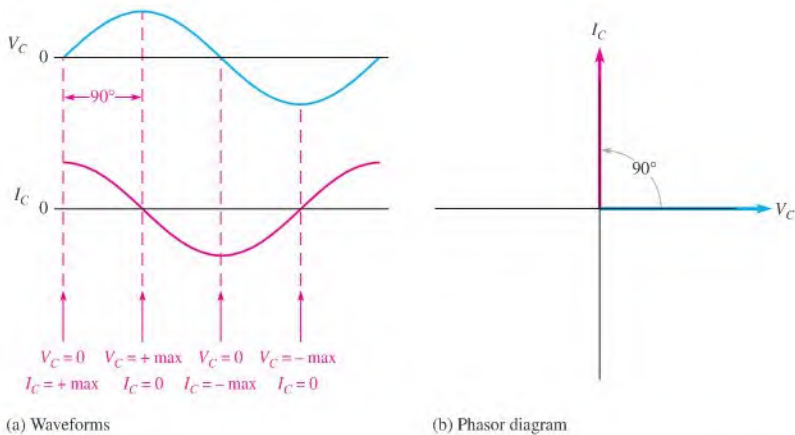

▲ FIGURE 12–42

Phase relation of V_C and I_C in a capacitor. Current always leads the capacitor voltage by 90°.

Capacitive Reactance, X_C

Capacitive reactance is the opposition to sinusoidal current, expressed in ohms. The symbol for capacitive reactance is X_C.

To develop a formula for X_C, we use the relationship $i = C(dv/dt)$ and the curves in Figure 12–43. The rate of change of voltage is directly related to frequency. The faster the voltage changes, the higher the frequency. For example, you can see that in Figure 12–43
▲ FIGURE 12–43

The higher frequency waveform (A) has a greater slope at its zero crossings, corresponding to a higher rate of change.

the slope of sine wave A at the zero crossings is steeper than that of sine wave B. The slope of a curve at a point indicates the rate of change at that point. Sine wave A has a higher frequency than sine wave B, as indicated by a greater maximum rate of change (dv/dt is greater at the zero crossings).

When frequency increases, dv/dt increases, and thus i increases. When frequency decreases, dv/dt decreases, and thus i decreases.

$$i = C(dv/dt) \quad \text{and} \quad i = C(dv/dt)$$

An increase in i means that there is less opposition to current (X_C is less), and a decrease in i means a greater opposition to current (X_C is greater). Therefore, X_C is inversely proportional to i and thus inversely proportional to frequency.

X_C **is inversely proportional to** f, **shown as** $\dfrac{1}{f}$.

From the same relationship $i = C(dv/dt)$, you can see that if dv/dt is constant and C is varied, an increase in C produces an increase in i, and a decrease in C produces a decrease in i.

$$i = C(dv/dt) \quad \text{and} \quad i = C(dv/dt)$$

Again, an increase in i means less opposition (X_C is less), and a decrease in i means greater opposition (X_C is greater). Therefore, X_C is inversely proportional to i and thus inversely proportional to capacitance.

The capacitive reactance is inversely proportional to both f and C.

X_C **is inversely proportional to** fC, **shown as** $\dfrac{1}{fC}$.

Thus far, we have determined a proportional relationship between X_C and $1/fC$. Equation 12–25 is the complete formula for calculating X_C. The derivation is given in Appendix B.

Equation 12–25

$$X_C = \frac{1}{2\pi fC}$$

Capacitive reactance, X_C, is in ohms when f is in hertz and C is in farads. Notice that 2π appears in the denominator as a constant of proportionality. This term is derived from the relationship of a sine wave to rotational motion.

Reactance for Series Capacitors

When capacitors are in series in an ac circuit, the total capacitance is smaller than the smallest individual capacitance. Because the total capacitance is smaller, the total capacitive reactance (opposition to current) must be larger than any individual capacitive reactance. With series capacitors, the total capacitive reactance ($X_{C(tot)}$) is the sum of the individual reactances.

$$X_{C(tot)} = X_{C1} + X_{C2} + X_{C3} + \cdots + X_{Cn}$$

Equation 12–26

Compare this formula with Equation 5–1 for finding the total resistance of series resistors. In both cases, you simply add the individual oppositions.

Reactance for Parallel Capacitors

In ac circuits with parallel capacitors, the total capacitance is the sum of the capacitances. Recall that the capacitive reactance is inversely proportional to the capacitance. Because the total parallel capacitance is larger than any individual capacitances, the total capacitive reactance must be smaller than the reactance of any individual capacitor. With parallel capacitors, the total reactance is found by

$$X_{C(tot)} = \cfrac{1}{\cfrac{1}{X_{C1}} + \cfrac{1}{X_{C2}} + \cfrac{1}{X_{C3}} + \cdots + \cfrac{1}{X_{Cn}}}$$

Equation 12–27

Compare this formula with Equation 6–2 for parallel resistors. As in the case of parallel resistors, the total opposition (resistance or reactance) is the reciprocal of the sum of the reciprocals of the individual oppositions.

For two capacitors in parallel, Equation 12–27 can be reduced to the product-over-sum form. This is useful because, for most practical circuits, more than two capacitors in parallel is not common.

$$X_{C(tot)} = \frac{X_{C1}X_{C2}}{X_{C1} + X_{C2}}$$

EXAMPLE 12–18   What is the total capacitive reactance of each circuit in Figure 12–45?
▲ **FIGURE 12–45**

Solution   The reactances of the individual capacitors are the same in both circuits.

$$X_{C1} = \frac{1}{2\pi f C_1} = \frac{1}{2\pi(5.0\,\text{kHz})(0.01\,\mu\text{F})} = 3.18\,\text{k}\Omega$$

$$X_{C2} = \frac{1}{2\pi f C_2} = \frac{1}{2\pi(5.0\,\text{kHz})(0.068\,\mu\text{F})} = 468\,\Omega$$

The Series Circuit: For the capacitors in series in Figure 12–45 (a), the total reactance is the sum of X_{C1} and X_{C2}, as given in Equation 12–26.

$$X_{C(tot)} = X_{C1} + X_{C2} = 3.18\,\text{k}\Omega + 468\,\Omega = \mathbf{3.65\,k\Omega}$$

Alternatively, you can obtain the total series reactance by first finding the total capacitance using Equation 12–10. Then calculate the total reactance.

$$C_{tot} = \frac{C_1 C_2}{C_1 + C_2} = \frac{(0.01\,\mu\text{F})(0.068\,\mu\text{F})}{0.01\,\mu\text{F} + 0.068\,\mu\text{F}} = 0.0087\,\mu\text{F}$$

$$X_{C(tot)} = \frac{1}{2\pi f C_{tot}} = \frac{1}{2\pi(5.0\,\text{kHz})(0.0087\,\mu\text{F})} = \mathbf{3.65\,k\Omega}$$

The Parallel Circuit: For the capacitors in parallel in Figure 12–45(b), determine the total reactance from the product-over-sum rule using X_{C1} and X_{C2}.

$$X_{C(tot)} = \frac{X_{C1} X_{C2}}{X_{C1} + X_{C2}} = \frac{(3.18\,\text{k}\Omega)(468\,\Omega)}{3.18\,\text{k}\Omega + 468\,\Omega} = \mathbf{408\,\Omega}$$

Related Problem   Determine the total parallel capacitive reactance by first finding the total parallel capacitance.
Ohm's Law   The reactance of a capacitor is analogous to the resistance of a resistor. In fact, both are expressed in ohms. Since both R and X_C are forms of opposition to current. Ohm's law applies to capacitive circuits as well as to resistive circuits; and it is stated as follows for Figure 12–46:

$$I = \frac{V_s}{X_C}$$

When applying Ohm's law in ac circuits, you must express both the current and the voltage in the same way, that is, both in rms, both in peak, and so on.

EXAMPLE 12–19   Determine the rms current in Figure 12–47.
Solution   First, determine the capacitive reactance.

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(10 \times 10^3 \, \text{Hz})(0.0056 \times 10^{-6} \, \text{F})} = 2.84 \, \text{k}\Omega$$

Then apply Ohm's law.

$$I_{\text{rms}} = \frac{V_{\text{rms}}}{X_C} = \frac{5 \, \text{V}}{2.84 \, \text{k}\Omega} = \mathbf{1.76 \, \text{mA}}$$

Related Problem   Change the frequency in Figure 12–47 to 25 kHz and determine the rms current.

Use Multisim file E12-19 to verify the calculated results in this example and to confirm your calculation for the related problem.

Capacitive Voltage Divider

In ac circuits, capacitors can be used in applications that require a voltage divider. (Some oscillator circuits use this method to tap off a fraction of the output.) The voltage across a series capacitor was given as Equation 12–12, which is repeated here ($V_T = V_s$).

$$V_x = \left(\frac{C_T}{C_x}\right)V_s$$

A resistive voltage divider is expressed in terms of a resistance ratio, which is a ratio of oppositions. You can think of the capacitive voltage divider by applying this idea from a resistive divider, but using reactance in place of resistance. The equation for the voltage across a capacitor in a capacitive voltage divider can be written as

$$V_x = \left(\frac{X_{Cx}}{X_{C(tot)}}\right)V_s$$

Equation 12–28

where X_{Cx} is the reactance of capacitor C_x, $X_{C(tot)}$ is the total capacitive reactance, and V_x is the voltage across capacitor C_x. Either Equation 12–12 or Equation 12–28 can be used to find the voltage from a divider, as illustrated in Example 12–20.

EXAMPLE 12–20   What is the voltage across C_2 in the circuit of Figure 12–48?

▶ **FIGURE 12–48**
Solution   The reactance of the individual capacitors and the total reactance were determined in Example 12–18. Substituting into Equation 12–28.

$$V_2 = \left(\frac{X_{C2}}{X_{C(tot)}}\right)V_s = \left(\frac{468 \, \Omega}{3.65 \, \text{k}\Omega}\right)10 \, \text{V} = \mathbf{1.28 \, \text{V}}$$

Notice that the voltage across the larger capacitor is the smaller fraction of the total. You can obtain the same result from Equation 12–12.

$$V_2 = \left(\frac{C_T}{C_2}\right)V_s = \left(\frac{0.0087\ \mu\text{F}}{0.068\ \mu\text{F}}\right)10\ \text{V} = \textbf{1.28 V}$$

Related Problem   Use Equation 12–28 to determine the voltage across C_1.

Power in a Capacitor

As discussed earlier in this chapter, a charged capacitor stores energy in the electric field within the dielectric. An ideal capacitor does not dissipate energy; it only stores it temporarily. When an ac voltage is applied to a capacitor, energy is stored by the capacitor during a portion of the voltage cycle; then the stored energy is returned to the source during another portion of the cycle. There is no net energy loss. Figure 12–49 shows the power curve that results from one cycle of capacitor voltage and current.
▲ **FIGURE 12–49**

Power curve.

Instantaneous Power (p)   The product of v and i gives **instantaneous power**. At points where v or i is zero, p is also zero. When both v and i are positive, p is also positive. When either v or i is positive and the other is negative, p is negative. When both v and i are negative, p is positive. As you can see, the power follows a sinusoidal-shaped curve. Positive values of power indicate that energy is stored by the capacitor. Negative values of power indicate that energy is returned from the capacitor to the source. Note that the power fluctuates at a frequency twice that of the voltage or current as energy is alternately stored and returned to the source.

True Power (P_{true})   Ideally, all of the energy stored by a capacitor during the positive portion of the power cycle is returned to the source during the negative portion. No net energy is lost due to conversion to heat in the capacitor, so the **true power** is zero. Actually, because of leakage and foil resistance in a practical capacitor, a small percentage of the total power is dissipated in the form of true power.

Reactive Power (P_r) The rate at which a capacitor stores or returns energy is called its **reactive power**. The reactive power is a nonzero quantity, because at any instant in time, the capacitor is actually taking energy from the source or returning energy to it. Reactive power does not represent an energy loss. The following formulas apply:

$$P_r = V_{rms}I_{rms}$$

Equation 12–29

$$P_r = \frac{V_{rms}^2}{X_C}$$

Equation 12–30

$$P_r = I_{rms}^2 X_C$$

Equation 12–31

Notice that these equations are of the same form as those introduced in Chapter 4 for power in a resistor. The voltage and current are expressed in rms. The unit of reactive power is **VAR (volt-ampere reactive)**.

EXAMPLE 12–21

Determine the true power and the reactive power in Figure 12–50.

▶ **FIGURE 12–50**
Solution The true power, P_{true}, is *always* **zero** for an ideal capacitor. The reactive power is determined by first finding the value for the capacitive reactance and then using Equation 12–30.

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(2 \times 10^3 \text{ Hz})(0.01 \times 10^{-6} \text{ F})} = 7.96 \text{ k}\Omega$$

$$P_r = \frac{V_{rms}^2}{X_C} = \frac{(2 \text{ V})^2}{7.96 \text{ k}\Omega} = 503 \times 10^{-6} \text{ VAR} = \textbf{503 } \mu\textbf{VAR}$$

12–7 CAPACITOR APPLICATIONS

Capacitors are widely used in many electrical and electronic applications.

After completing this section, you should be able to

　　◆ Describe a power supply filter

　　◆ Explain the purpose of coupling and bypass capacitors

　　◆ Discuss the basics of capacitors applied to tuned circuits, timing circuits, and computer memories

If you pick up any circuit board, open any power supply, or look inside any piece of electronic equipment, chances are you will find capacitors of one type or another. These components are used for a variety of reasons in both dc and ac applications.

Electrical Storage

One of the most basic applications of a capacitor is as a backup voltage source for low-power circuits such as certain types of semiconductor memories in computers. This particular application requires a very high capacitance value and negligible leakage.

The storage capacitor is connected between the dc power supply input to the circuit and ground. When the circuit is operating from its normal power supply, the capacitor remains fully charged to the dc power supply voltage. If the normal power source is disrupted, effectively removing the power supply from the circuit, the storage capacitor temporarily becomes the power source for the circuit.

A capacitor provides voltage and current to a circuit as long as its charge remains sufficient. As current is drawn by the circuit, charge is removed from the capacitor and the voltage decreases. For this reason, the storage capacitor can only be used as a temporary power source. The length of time that a capacitor can provide sufficient power to the circuit depends on the capacitance and the amount of current drawn by the circuit. The smaller the current and the higher the capacitance, the longer the time a capacitor can provide power to a circuit.

Power Supply Filtering

A basic dc power supply consists of a circuit known as a **rectifier** followed by a **filter**. The rectifier converts the 120 V, 60 Hz sinusoidal voltage available at a standard outlet to a pulsating dc voltage that can be either a half-wave rectified voltage or a full-wave rectified voltage, depending on the type of rectifier circuit. As shown in Figure 12–52(a), a half-wave rectifier removes each negative half-cycle of the sinusoidal voltage. As shown in Figure 12–52(b), a full-wave rectifier actually reverses the polarity of the negative portion of each cycle. Both half-wave and full-wave rectified voltages are dc because, even though they are changing, they do not alternate polarity.

To be useful for powering electronic circuits, the rectified voltage must be changed to constant dc voltage because all circuits require constant power. The filter nearly eliminates the fluctuations in the rectified voltage and ideally provides a smooth constant-value dc voltage to the load that is the electronic circuit, as indicated in Figure 12–53.

The Capacitor as a Power Supply Filter　Capacitors are used as filters in dc power supplies because of their ability to store electrical charge. Figure 12–54(a) shows a dc power supply with a full-wave rectifier and a capacitor filter. The operation can be described from a charging and discharging point of view as follows. Assume the capacitor is initially uncharged. When the power supply is first turned on and the first cycle of the rectified voltage
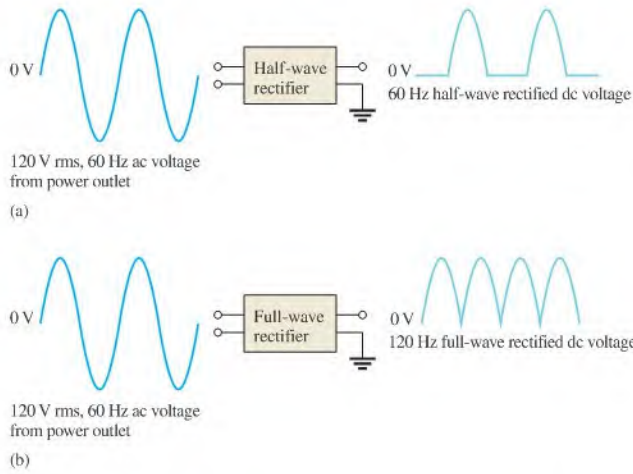

◀ FIGURE 12–52

▲ FIGURE 12–54

Basic operation of a power supply filter capacitor.

occurs, the capacitor will quickly charge through the low forward resistance of the rectifier. The capacitor voltage will follow the rectified voltage curve up to the peak of the rectified voltage. As the rectified voltage passes the peak and begins to decrease, the capacitor will begin to discharge very slowly through the high resistance of the load circuit, as indicated in Figure 12–54(b). The amount of discharge is typically very small and is exaggerated in the figure for purposes of illustration. The next cycle of the rectified voltage will recharge the capacitor back to the peak value by replenishing the small amount of charge lost since the previous peak. This pattern of a small amount of charging and discharging continues as long as the power is on.

A rectifier is designed so that it allows current only in the direction to charge the capacitor. The capacitor will not discharge back through the rectifier but will only discharge a small amount through the relatively high resistance of the load. The small fluctuation in voltage due to the charging and discharging of the capacitor is called the **ripple voltage**. A good dc power supply has a very small amount of ripple on its dc output. The discharge time constant of a power supply filter capacitor depends on its capacitance and the resistance of the load; consequently, the higher the capacitance value, the longer the discharge time and therefore, the smaller the ripple voltage.

DC Blocking and AC Coupling

Capacitors are commonly used to block the constant dc voltage in one part of a circuit from getting to another part. As an example of this, a capacitor is connected between two stages of an amplifier to prevent the dc voltage at the output of stage 1 from affecting the dc voltage at the input of stage 2, as illustrated in Figure 12–55. Assume that, for proper operation, the output of stage 1 has a zero dc voltage and the input to stage 2 has a 3 V dc voltage. The capacitor prevents the 3 V dc at stage 2 from getting to the stage 1 output and affecting its zero value, and vice versa.

An application of a capacitor to block dc and couple ac in an amplifier.
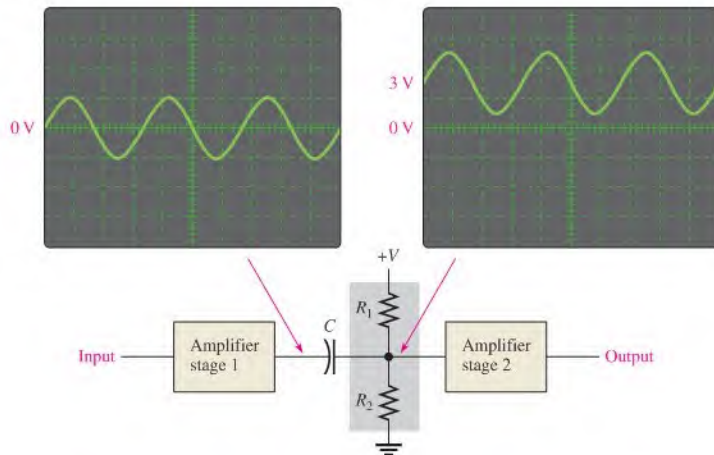

If a sinusoidal signal voltage is applied to the input to stage 1, the signal voltage is increased (amplified) and appears on the ouput of stage 1, as shown in Figure 12–55. The amplified signal voltage is then coupled through the capacitor to the input of stage 2 where it is superimposed on the 3 V dc level and then again amplified by stage 2. In order for the signal voltage to be passed through the capacitor without being reduced, the capacitor must be large enough so that its reactance at the frequency of the signal voltage is negligible. In

this type of application, the capacitor is known as a *coupling capacitor,* which ideally appears as an open to dc and as a short to ac. As the signal frequency is reduced, the capacitive reactance increases and, at some point, the capacitive reactance becomes large enough to cause a significant reduction in ac voltage between stage 1 and stage 2.

Power Line Decoupling

Capacitors connected from the dc supply voltage line to ground are used on circuit boards to decouple unwanted voltage transients or spikes that occur on the dc supply voltage because of fast switching digital circuits. A voltage transient contains high frequencies that may affect the operation of the circuits. These transients are shorted to ground through the very low reactance of the decoupling capacitors. Several decoupling capacitors are often used at various points along the supply voltage line on a circuit board.

Bypassing

Another capacitor application is to bypass an ac voltage around a resistor in a circuit without affecting the dc voltage across the resistor. In amplifier circuits, for example, dc voltages called *bias voltages* are required at various points. For the amplifier to operate properly, certain bias voltages must remain constant and, therefore, any ac voltages must be removed. A sufficiently large capacitor connected from a bias point to ground provides a low reactance path to ground for ac voltages, leaving the constant dc bias voltage at the given point. At lower frequencies, the bypass capacitor becomes less effective because of its increased reactance. This bypass application is illustrated in Figure 12–56.
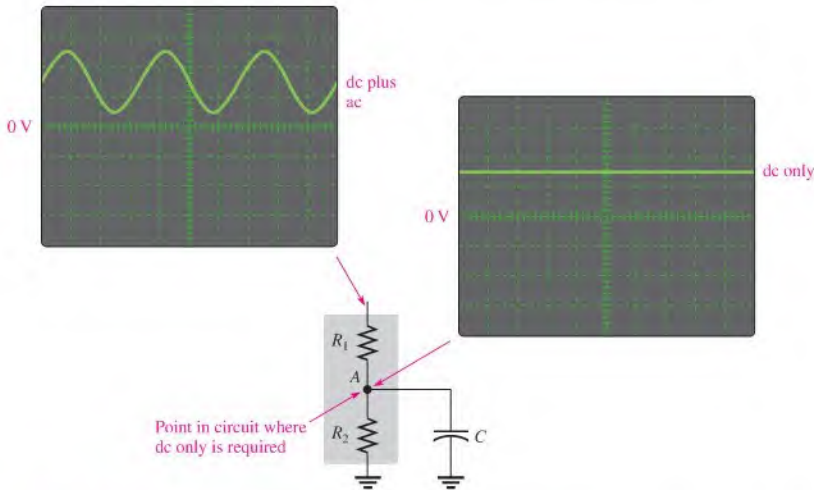

▲ **FIGURE 12–56**

Example of the operation of a bypass capacitor. Point *A* is at ac ground due to the low reactance path through the capacitor.

Signal Filters

Capacitors are essential to the operation of a class of circuits called *filters* that are used for selecting one ac signal with a certain specified frequency from a wide range of signals with many different frequencies or for selecting a certain band of frequencies and eliminating all others. A common example of this application is in radio and television receivers where it

is necessary to select the signal transmitted from a given station and eliminate or filter out the signals transmitted from all the other stations in the area.

When you tune your radio or TV, you are actually changing the capacitance in the tuner circuit (which is a type of filter) so that only the signal from the station or channel you want passes through to the receiver circuitry. Capacitors are used in conjunction with resistors, inductors (covered in the next chapter), and other components in these types of filters. The topic of filters will be covered in Chapter 18.

The main characteristic of a filter is its frequency selectivity, which is based on the fact that the reactance of a capacitor depends on frequency ($X_C = 1/2\pi fC$).

Timing Circuits

Another important area in which capacitors are used is in timing circuits that generate specified time delays or produce waveforms with specific characteristics. Recall that the time constant of a circuit with resistance and capacitance can be controlled by selecting appropriate values for R and C. The charging time of a capacitor can be used as a basic time delay in various types of circuits. An example is the circuit that controls the turn indicators on your car where the light flashes on and off at regular intervals.

Computer Memories

Dynamic memories in computers use very tiny capacitors as the basic storage element for binary information, which consists of two binary digits, 1 and 0. A charged capacitor can represent a stored 1 and a discharged capacitor can represent a stored 0. Patterns of 1s and 0s that make up binary data are stored in a memory that consists of an array of capacitors with associated circuitry. You will study this topic in a computer or digital fundamentals course.

12–8   SWITCHED-CAPACITOR CIRCUITS

Another important application of capacitors is in programmable analog arrays, which are implemented in integrated circuit (IC) form. Switched-capacitors are used to implement various types of programmable analog circuits in which capacitors take the place of resistors. Capacitors can be implemented on an IC chip more easily than a resistor can, and they offer other advantages such as zero power dissipation. When a resistance is required in a circuit, the switched capacitor can be made to emulate a resistor. Using switched-capacitor emulation, resistor values can be readily changed by reprogramming and accurate and stable resistance values can be achieved.

After completing this section, you should be able to

◆ **Describe the basic operation of switched-capacitor circuits**

  ◆ Explain how switched-capacitor circuits emulate resistors

Recall that current is defined in terms of charge Q and time t as

$$I = \frac{Q}{t}$$

This formula states that current is the rate at which charge flows through a circuit. Also recall that the basic definition of charge in terms of capacitance and voltage is

$$Q = CV$$

Substituting CV for Q, the current can be expressed as

$$I = \frac{CV}{t}$$

Basic Operation

A general model of a switched-capacitor circuit is shown in Figure 12–57. It consists of a capacitor, two arbitrary voltage sources (V_1 and V_2), and a two-pole switch. In actual circuits, the switch is implemented with transistors. Let's examine this circuit for a specified period of time, T, which is then repeated. Assume that V_1 and V_2 are constant during the time period T. Of particular interest is the average current I_1 from the source V_1 during the period of time, T.

(a)

(b)
▲ FIGURE 12–57

Basic operation of a switched-capacitor circuit. The voltage source symbol represents a time-varying symbol.

During the first half of the time period T, the switch is in position 1, as indicated in Figure 12–57. Therefore, there is a current I_1 due to V_1 that is charging the capacitor during the interval from $t = 0$ to $t = T/2$. During the second half of the time period, the switch is in position 2, as indicated, and there is no current from V_1; therefore, the average current from the source V_1 over the time period T is

$$I_{1(\text{avg})} = \frac{Q_{1(T/2)} - Q_{1(0)}}{T}$$

$Q_{1(0)}$ is the charge at $t = 0$ and $Q_{1(T/2)}$ is the charge at $t = T/2$. So, $Q_{1(T/2)} - Q_{1(0)}$ is the net charge transferred while the switch is in position 1.

The capacitor voltage at $T/2$ is equal to V_1, and the capacitor voltage at 0 or T is equal to V_2. Using the formula $Q = CV$ and substituting into the previous equation, you obtain

$$I_{1(\text{avg})} = \frac{CV_{1(T/2)} - CV_{2(0)}}{T} = \frac{C(V_{1(T/2)} - V_{2(0)})}{T}$$

Since V_1 and V_2 are assumed to be constant during T, the average current can be expressed as

$$I_{1(\text{avg})} = \frac{C(V_1 - V_2)}{T}$$

Equation 12–32
Figure 12–58 shows an equivalent circuit with a resistor instead of the capacitor and switches. Applying Ohm's law to the resistive circuit, the current is

$$I_1 = \frac{V_1 - V_2}{R}$$

Setting $I_{1(\text{avg})}$ in the switched-capacitor circuit equal to current in the resistive circuit, you have

$$\frac{C(V_1 - V_2)}{T} = \frac{V_1 - V_2}{R}$$

Canceling the $V_1 - V_2$ terms and solving for R gives the equivalent resistance.

Equation 12–33

$$R = \frac{T}{C}$$

This important result shows that a switched-capacitor circuit can emulate a resistor with a value determined by the time T and the capacitance C. Remember that the switch is in each position for one-half of the time period T and that T can be varied by varying the frequency at which the switches are operated. In a programmable analog device, the switching frequency is a programmable parameter for each emulated resistor and can be set to achieve a precise resistor value. Since $T = 1/f$, the resistance in terms of frequency is

Equation 12–34

$$R = \frac{1}{fC}$$

EXAMPLE 12–22

The input resistor, R, of an amplifier circuit is to be replaced with a switched-capacitor circuit. Assume that the switched capacitor value is 1000 pF. You want the switched-capacitor to emulate a 10 kΩ resistor. Determine the frequency at which the capacitor must be switched.

Solution   Using the formula $R = T/C$,

$$T = RC = (10\,\text{k}\Omega)(1000\,\text{pF}) = 10\,\mu\text{s}$$

This means that the switch must be operated at a frequency of

$$f = \frac{1}{T} = \frac{1}{10\,\mu\text{s}} = \textbf{100 kHz}$$

The duty cycle is 50% so that the switch is in each position half of the period.

Related Problem   At what frequency must the 1000 pF capacitor be switched to emulate a 5.6 kΩ resistor?

Application Activity

Capacitors are used in certain types of amplifiers to couple the ac signal while blocking the dc voltage. Capacitors are used in many other applications, but in this application, you will focus on the coupling capacitors in an amplifier circuit. This topic was introduced in Section 12–7. A knowledge of amplifier circuits is not necessary for this assignment.

All amplifier circuits contain transistors that require dc voltages to establish proper operating conditions for amplifying ac signals. These dc voltages are referred to as bias voltages. As indicated in Figure 12–59(a), a common type of dc bias circuit used in amplifiers is the voltage divider formed by R_1 and R_2, which sets up the proper dc voltage at the input to the amplifier.

When an ac signal voltage is applied to the amplifier, the input coupling capacitor, C_1, prevents the internal resistance of the ac source from changing the dc bias voltage. Without the capacitor, the internal source resistance would appear in parallel with R_2 and drastically change the value of the dc voltage.

The coupling capacitance is chosen so that its reactance (X_C) at the frequency of the ac signal is very small compared to the bias resistor values. The coupling capacitance therefore efficiently couples the ac signal from the source to the input of the amplifier. On the source side of the input coupling capacitor there is only ac but on the amplifier side there is ac plus dc (the signal voltage is riding on the dc bias voltage set by the voltage divider), as indicated in Figure 12–59(a). Capacitor C_2 is the output coupling capacitor, which couples the amplified ac signal to another amplifier stage that would be connected to the output.

You will check three amplifier boards like the one in Figure 12–59(b) for the proper input voltages using an oscilloscope. If the voltages are incorrect, you will determine the most likely fault. For all measurements, assume the amplifier has no dc loading effect on the voltage-divider bias circuit.

INTRODUCTION

You have learned about the resistor and the capacitor. In this chapter, you will learn about a third type of basic passive component, the *inductor*, and study its characteristics.

The basic construction and electrical properties of inductors are discussed, and the effects of connecting them in series and in parallel are analyzed. How an inductor works in both dc and ac circuits is an important part of this coverage and forms the basis for the study of reactive circuits in terms of both frequency response and time response. You will also learn how to check for a faulty inductor.

The inductor, which is basically a coil of wire, is based on the principle of electromagnetic induction, which you studied in Chapter 10. Inductance is the property of a coil of wire that opposes a change in current. The basis for inductance is the electromagnetic field that surrounds any conductor when there is current through it. The electrical component designed to have the property of inductance is called an *inductor, coil,* or in certain applications a *choke.* All of these terms refer to the same type of device.

13–1 THE BASIC INDUCTOR

An **inductor** is a passive electrical component formed by a coil of wire and which exhibits the property of inductance.

After completing this section, you should be able to

- ◆ **Describe the basic construction and characteristics of an inductor**

  - ◆ Define *inductance* and state its unit

  - ◆ Discuss induced voltage

  - ◆ Explain how an inductor stores energy

  - ◆ Specify how the physical characteristics affect inductance

  - ◆ Discuss winding resistance and winding capacitance

  - ◆ State Faraday's law

  - ◆ State Lenz's law

When a length of wire is formed into a coil, as shown in Figure 13–1, it becomes an inductor. The terms *coil* and *inductor* are used interchangeably. Current through the coil produces an electromagnetic field, as illustrated. The magnetic lines of force around each loop (turn) in the **winding** of the coil effectively add to the lines of force around the adjoining loops, forming a strong electromagnetic field within and around the coil. The net direction of the total electromagnetic field creates a north and a south pole.
◀ **FIGURE 13–1**

A coil of wire forms an inductor. When there is current through it, a three-dimensional electromagnetic field is created, surrounding the coil in all directions.

To understand the formation of the total electromagnetic field in a coil, consider the interaction of the electromagnetic fields around two adjacent loops. The magnetic lines of force around adjacent loops are each deflected into a single outer path when the loops are brought close together. This effect occurs because the magnetic lines of force are in opposing directions between adjacent loops and therefore cancel out when the loops are close together, as illustrated in Figure 13–2. The total electromagnetic field for the two loops is

Opposing fields between loops

(a) Separated

(b) Closely adjacent loops; opposing fields between loops cancel.

depicted in part (b). This effect is additive for many closely adjacent loops in a coil; that is, each additional loop adds to the strength of the electromagnetic field. For simplicity, only single lines of force are shown, although there are many. Figure 13–3 shows a schematic symbol for an inductor.

Inductance

When there is current through an inductor, an electromagnetic field is established. When the current changes, the electromagnetic field also changes. An increase in current expands the electromagnetic field, and a decrease in current reduces it. Therefore, a changing current produces a changing electromagnetic field around the inductor. In turn, the changing electromagnetic field causes an **induced voltage** across the coil in a direction to oppose the change in current. This property is called *self-inductance* but is usually referred to as simply *inductance,* symbolized by L.

> **Inductance is a measure of a coil's ability to establish an induced voltage as a result of a change in its current, and that induced voltage is in a direction to oppose the change in current.**

The inductance (L) of a coil and the time rate of change of the current (di/dt) determine the induced voltage (v_{ind}). A change in current causes a change in the electromagnetic field, which, in turn, induces a voltage across the coil, as you know. The induced voltage is directly proportional to L and di/dt, as stated by the following formula:

Equation 13–1

$$v_{ind} = L\left(\frac{di}{dt}\right)$$

This formula indicates that the greater the inductance, the greater the induced voltage. Also, it shows that the faster the coil current changes (greater di/dt), the greater the induced voltage. Notice the similarity of Equation 13–1 to Equation 12–24: $i = C(dv/dt)$.

The Unit of Inductance The **henry (H)** is the basic unit of inductance. By definition, the inductance of a coil is one henry when current through the coil, changing at the rate of one ampere per second, induces one volt across the coil. The henry is a large unit, so in practical applications, millihenries (mH) and microhenries (μH) are the more common units.

EXAMPLE 13–1

Determine the induced voltage across a 1 henry (1 H) inductor when the current is changing at a rate of 2 A/s.

Solution

$$v_{ind} = L\left(\frac{di}{dt}\right) = (1\ H)(2\ A/s) = \textbf{2 V}$$

Related Problem* Determine the inductance when a current changing at a rate of 10 A/s causes 50 V to be induced.

*Answers are at the end of the chapter.

Energy Storage An inductor stores energy in the electromagnetic field created by the current. The energy stored is expressed as follows:

Equation 13–2

$$W = \frac{1}{2}LI^2$$

As you can see, the energy stored is proportional to the inductance and the square of the current. When current (I) is in amperes and inductance (L) is in henries, energy (W) is in joules.

Physical Characteristics of an Inductor

The following parameters are important in establishing the inductance of a coil: permeability of the core material, number of turns of wire, core length, and cross-sectional area of the core.

Core Material   As discussed earlier, an inductor is basically a coil of wire that surrounds a magnetic or nonmagnetic material called the **core**. Examples of magnetic materials are iron, nickel, steel, cobalt, or alloys. These materials have permeabilities that are hundreds or thousands of times greater than that of a vacuum and are classified as *ferromagnetic*. A ferromagnetic core provides a better path for the magnetic lines of force and thus permits a stronger magnetic field. Examples of nonmagnetic materials are air, copper, plastic, and glass. The permeabilities of these materials are the same as for a vacuum.

   As you learned in Chapter 10, the permeability (μ) of the core material determines how easily a magnetic field can be established, and is measured in Wb/At · m, which is the same as H/m. The inductance is directly proportional to the permeability of the core material.

Physical Parameters   As indicated in Figure 13–4, the number of turns of wire, the length, and the cross-sectional area of the core are factors in setting the value of inductance. The inductance is inversely proportional to the length of the core and directly proportional to the cross-sectional area. Also, the inductance is directly related to the number of turns squared. This relationship is as follows:

$$L = \frac{N^2 \mu A}{l}$$

Equation 13–3

where L is the inductance in henries (H), N is the number of turns of wire, μ is the permeability in henries per meter (H/m), A is the cross-sectional area in meters squared, and l is the core length in meters (m).
◄ FIGURE 13–4

Physical parameters of an inductor.

EXAMPLE 13–2

Determine the inductance of the coil in Figure 13–5. The permeability of the core is 0.25×10^{-3} H/m.

► FIGURE 13–5
Solution   First determine the length and area in meters.

$$l = 1.5 \,\text{cm} = 0.015 \,\text{m}$$
$$A = \pi r^2 = \pi (0.25 \times 10^{-2} \,\text{m})^2 = 1.96 \times 10^{-5} \,\text{m}^2$$

The inductance of the coil is

$$L = \frac{N^2 \mu A}{l} = \frac{(350)^2 (0.25 \times 10^{-3}\,\text{H/m})(1.96 \times 10^{-5}\,\text{m}^2)}{0.015\,\text{m}} = \mathbf{40\,mH}$$

Related Problem   Determine the inductance of a coil with 90 turns around a core that is 1.0 cm long and has a diameter of 0.8 cm. The permeability is 0.25×10^{-3} H/m.

Winding Resistance

When a coil is made of a certain material, for example, insulated copper wire, that wire has a certain resistance per unit of length. When many turns of wire are used to construct a coil, the total resistance may be significant. This inherent resistance is called the *dc resistance* or the *winding resistance* (R_W).

Although this resistance is distributed along the length of the wire, it effectively appears in series with the inductance of the coil, as shown in Figure 13–6. In many applications, the winding resistance may be small enough to be ignored and the coil can be considered an ideal inductor. In other cases, the resistance must be considered.

(a) The wire has resistance distributed along its length.

(b) Equivalent circuit

▲ **FIGURE 13–6**

Winding resistance of a coil.

Winding Capacitance

When two conductors are placed side by side, there is always some capacitance between them. Thus, when many turns of wire are placed close together in a coil, a certain amount of stray capacitance, called *winding capacitance* (C_W), is a natural side effect. In many applications, this winding capacitance is very small and has no significant effect. In other cases, particularly at high frequencies, it may become quite important.

The equivalent circuit for an inductor with both its winding resistance (R_W) and its winding capacitance (C_W) is shown in Figure 13–7. The capacitance effectively acts in parallel. The total of the stray capacitances between each loop of the winding is indicated in a schematic as a capacitance appearing in parallel with the coil and its winding resistance, as shown in Figure 13–7(b).

(a) Stray capacitance between each loop appears as a total parallel capacitance (C_W).

Review of Faraday's Law

Faraday's law was introduced in Chapter 10 and is reviewed here because of its importance in the study of inductors. Michael Faraday found that by moving a magnet through a coil of wire, a voltage was induced across the coil and that when a complete path was provided, the induced voltage caused an induced current. Faraday observed that

The amount of voltage induced in a coil is directly proportional to the rate of change of the magnetic field with respect to the coil.

This principle is illustrated in Figure 13–8, where a bar magnet is moved through a coil of wire. An induced voltage is indicated by the voltmeter connected across the coil. The faster the magnet is moved, the greater the induced voltage.
Induced voltage created by a changing magnetic field.

When a wire is formed into a certain number of loops or turns and is exposed to a changing magnetic field, a voltage is induced across the coil. The induced voltage is proportional to the number of turns of wire in the coil, N, and to the rate at which the magnetic field changes. The rate of change of the magnetic field is designated $d\phi/dt$, where ϕ is the magnetic flux. The ratio $d\phi/dt$ is expressed in webers/second (Wb/s). Faraday's law states that the induced voltage across a coil is equal to the number of turns (loops) times the rate of flux change. It was given in Equation 10–8 and is restated here.

$$v_{ind} = N\left(\frac{d\phi}{dt}\right)$$

EXAMPLE 13–3

Apply Faraday's law to find the induced voltage across a coil with 500 turns located in a magnetic field that is changing at a rate of 5 Wb/s.

Solution

$$v_{ind} = N\left(\frac{d\phi}{dt}\right) = (500\ t)(5\ Wb/s) = \mathbf{2.5\ kV}$$

Lenz's Law

Lenz's law was introduced in Chapter 10 and is restated here.

When the current through a coil changes, an induced voltage is created as a result of the changing electromagnetic field and the polarity of the induced voltage is such that it always opposes the change in current.

Figure 13–9 illustrates Lenz's law. In part (a), the current is constant and is limited by R_1. There is no induced voltage because the electromagnetic field is unchanging. In part (b), the

(a) Switch open: Constant current and constant magnetic field; no induced voltage.

(b) At instant of switch closure: Expanding magnetic field induces voltage, which opposes an increase in total current. The total current remains the same at this instant.

(c) Right after switch closure: The rate of expansion of the magnetic field decreases, allowing the current to increase exponentially as induced voltage decreases.

(d) Switch remains closed: Current and magnetic field reach constant value.

(e) At instant of switch opening: Magnetic field begins to collapse, creating an induced voltage, which opposes a decrease in current.

(f) After switch opening: Rate of collapse of magnetic field decreases, allowing current to decrease exponentially back to original value.

▲ FIGURE 13–9

Demonstration of Lenz's law in an inductive circuit: When the current tries to change suddenly, the electromagnetic field changes and induces a voltage in a direction that opposes that change in current.

switch suddenly is closed, placing R_2 in parallel with R_1 and thus reducing the resistance. Naturally, the current tries to increase and the electromagnetic field begins to expand, but the induced voltage opposes this attempted increase in current for an instant.

In Figure 13–9(c), the induced voltage gradually decreases, allowing the current to increase. In part (d), the current has reached a constant value as determined by the parallel resistors, and the induced voltage is zero. In part (e), the switch has been suddenly opened,

and, for an instant, the induced voltage prevents any decrease in current, and arcing between the switch contacts results. In part (f), the induced voltage gradually decreases, allowing the current to decrease back to a value determined by R_1. Notice that the induced voltage has a polarity that opposes any current change. The polarity of the induced voltage is opposite that of the battery voltage for an increase in current and aids the battery voltage for a decrease in current.

13–2 TYPES OF INDUCTORS

Inductors normally are classified according to the type of core material.

After completing this section, you should be able to

◆ **Discuss various types of inductors**

   ◆ Describe the basic types of fixed inductors

   ◆ Distinguish between fixed and variable inductors

Inductors are made in a variety of shapes and sizes. Basically, they fall into two general categories: fixed and variable. The standard schematic symbols are shown in Figure 13–10.

Both fixed and variable inductors can be classified according to the type of core material. Three common types are the air core, the iron core, and the ferrite core. Each has a unique symbol, as shown in Figure 13–11.

Adjustable (variable) inductors usually have a screw-type adjustment that moves a sliding core in and out, thus changing the inductance. A wide variety of inductors exist, and some are shown in Figure 13–12. Small fixed inductors are frequently encapsulated in an insulating material that protects the fine wire in the coil. Encapsulated inductors have an appearance similar to a resistor.

Total Series Inductance

When inductors are connected in series, as in Figure 13–14, the total inductance, L_T, is the sum of the individual inductances. The formula for L_T is expressed in the following equation for the general case of n inductors in series:

Equation 13–4

$$L_T = L_1 + L_2 + L_3 + \cdots + L_n$$

Notice that the calculation of total inductance in series is analogous to the calculations of total resistance in series (Chapter 5) and total capacitance in parallel (Chapter 12).

In Figure 13–15(b),

Related Problem

Total Parallel Inductance

When inductors are connected in parallel, as in Figure 13–16, the total inductance is less than the smallest inductance. The general formula states that the reciprocal of the total inductance is equal to the sum of the reciprocals of the individual inductances.

$$\frac{1}{L_T} = \frac{1}{L_1} + \frac{1}{L_2} + \frac{1}{L_3} + \cdots + \frac{1}{L_n}$$

Equation 13–5

You can calculate total inductance, L_T, by taking the reciprocal of both sides of Equation 13–5.

$$L_T = \frac{1}{\left(\dfrac{1}{L_1}\right) + \left(\dfrac{1}{L_2}\right) + \left(\dfrac{1}{L_3}\right) + \cdots + \left(\dfrac{1}{L_n}\right)}$$

Equation 13–6

The calculation for total inductance in parallel is analogous to the calculations for total parallel resistance (Chapter 6) and total series capacitance (Chapter 12). For series-parallel combinations of inductors, determine the total inductance in the same way as total resistance in series-parallel resistive circuits (Chapter 7).

13–4 INDUCTORS IN DC CIRCUITS

Energy is stored in the electromagnetic field of an inductor when it is connected to a dc voltage source. The buildup of current through the inductor occurs in a predictable manner, which is dependent on the time constant of the circuit. The time constant is determined by the inductance and the resistance in a circuit.

After completing this section, you should be able to

◆ **Analyze inductive dc switching circuits**

   ◆ Describe the increase and decrease of current an inductor

   ◆ Define *RL time constant*

   ◆ Describe induced voltage

   ◆ Write the exponential equations for current in an inductor

When there is constant direct current in an inductor, there is no induced voltage. There is, however, a voltage drop due to the winding resistance of the coil. The inductance itself appears as a short to dc. Energy is stored in the electromagnetic field according to

the formula previously stated in Equation 13–2, $W = \frac{1}{2}LI^2$. The only energy conversion to heat occurs in the winding resistance ($P = I^2R_W$). This condition is illustrated in Figure 13–18.

$P = I^2R_W$
Conversion of electrical energy to heat due to winding resistance

Energy stored in magnetic field
$W = \frac{1}{2}LI^2$
Energy storage and conversion to heat in an inductor in a dc circuit.

The *RL* Time Constant

Because the inductor's basic action is to develop a voltage that opposes a change in its current, it follows that current cannot change instantaneously in an inductor. A certain time is required for the current to make a change from one value to another. The rate at which the current changes is determined by the *RL* time constant.

The *RL* time constant is a fixed time interval that equals the ratio of the inductance to the resistance.

The formula is

$$\tau = \frac{L}{R}$$

Equation 13–7

where τ is in seconds when inductance (L) is in henries and resistance (R) is in ohms.

EXAMPLE 13–6

A series *RL* circuit has a resistance of $1.0\ k\Omega$ and an inductance of 1 mH. What is the time constant?

Solution

$$\tau = \frac{L}{R} = \frac{1\ \text{mH}}{1.0\ k\Omega} = \frac{1 \times 10^{-3}\ \text{H}}{1 \times 10^3\ \Omega} = 1 \times 10^{-6}\ \text{s} = \mathbf{1\ \mu s}$$

Related Problem   Find the time constant for $R = 2.2\ k\Omega$ and $L = 500\ \mu\text{H}$.

Current in an Inductor

Increasing Current   In a series *RL* circuit, the current will increase to approximately 63% of its full value in one time-constant interval after voltage is applied. This buildup of current is analogous to the buildup of capacitor voltage during the charging in an *RC* circuit; they both follow an exponential curve and reach the approximate percentages of the final current as indicated in Table 13–1 and as illustrated in Figure 13–19.

The change in current over five time-constant intervals is illustrated in Figure 13–20. When the current reaches its final value at 5τ, it ceases to change. At this time, the inductor acts as a short (except for winding resistance) to the constant current. The final value of the current is

$$I_F = \frac{V_S}{R} = \frac{10\ \text{V}}{1.0\ k\Omega} = 10\ \text{mA}$$

$$\tau = \frac{L}{R} = \frac{10\,\text{mH}}{1.2\,\text{k}\Omega} = \mathbf{8.33\ \mu s}$$

the switch is opened, the current through L is at a constant value of 10 mA, which is determined by R_1 because L acts ideally as a short. When the switch is opened, the induced inductor voltage initially provides 10 mA through R_2. The current then decreases by 63% during each time constant interval.

Response to a Square Wave

A good way to demonstrate both increasing and decreasing current in an RL circuit is to use a square wave voltage as the input. The square wave is a useful signal for observing the dc response of a circuit because it automatically provides on and off action similar to a switch. (Time response will be covered further in Chapter 20.) When the square wave goes from its low level to its high level, the current in the circuit responds by exponentially rising to its final value. When the square wave returns to the zero level, the current in the circuit responds by exponentially decreasing to its zero value. Figure 13–24 shows input voltage and current waveforms.
▲ **FIGURE 13–24**

EXAMPLE 13–8

For the circuit in Figure 13–24, what is the current at 0.1 ms and 0.6 ms?

Solution   The *RL* time constant for the circuit is

$$\tau = \frac{L}{R} = \frac{1.0\,\text{H}}{10\,\text{k}\Omega} = 0.1\,\text{ms}$$

If the square-wave generator period is long enough for the current to reach its maximum value in 5τ, the current will increase exponentially and during each time constant interval will have a value equal to the percentage of the final current given in Table 13–1. The final current is

$$I_F = \frac{V_S}{R} = \frac{2.5\,\text{V}}{10\,\text{k}\Omega} = 0.25\,\text{mA}$$

The current at 0.1 ms is

$$i = 0.63(0.25\,\text{mA}) = \textbf{0.158 mA}$$

At 0.6 ms, the square-wave input has been at the 0 V level for 0.1 ms, or 1τ; and the current decreases from the maximum value toward its final value of 0 mA by 63%. Therefore,

$$i = 0.25\,\text{mA} - 0.63(0.25\,\text{mA}) = \textbf{0.092 mA}$$

Related Problem   What is the current at 0.2 ms and 0.8 ms?

Open the Multisim file E13-08. Notice that the inductor and resistor are reversed in order to ground one side of the resistor and make the measurement of the resistor voltage simpler. The shape of the current in the circuit is the same as the shape of the resistor voltage. By applying Ohm's law to the resistor voltage, you can find the current in the circuit at any instant in time. Confirm that the current at a time 0.1 ms is close to the calculated value.

Voltages in a Series *RL* Circuit

As you know, when current changes in an inductor, a voltage is induced. Let's examine what happens to the induced voltage across the inductor in the series circuit in Figure 13–25 during one complete cycle of a square wave input. Keep in mind that the generator produces a level that is like switching a dc source on and then puts an "automatic" low resistance (ideally zero) path across the source when it returns to its zero level.

An ammeter placed in the circuit shows the current in the circuit at any instant in time. The V_L waveform is the voltage across the inductor. In Figure 13–25(a), the square wave
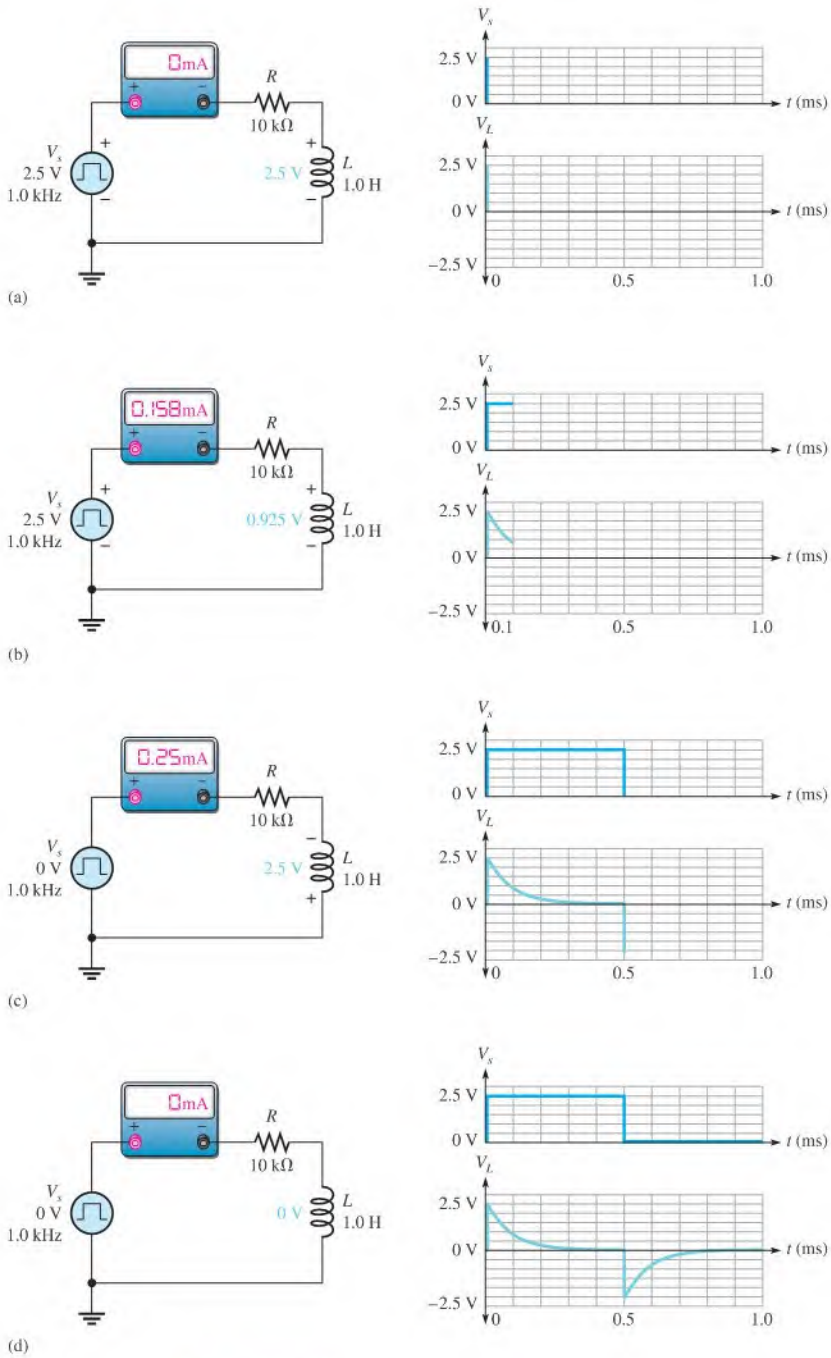

▲ FIGURE 13–25

has just transitioned from zero to its maximum value of 2.5 V. In accordance with Lenz's law, a voltage is induced across the inductor that opposes this *change* as the magnetic field surrounding the inductor builds up. There is no current in the circuit due to the equal but opposing voltages.

As the magnetic field builds up, the induced voltage across the inductor decreases, and current is in the circuit. After 1τ, the induced voltage across the inductor has decreased by 63%, which causes the current to increase by 63% to 0.158 mA. This is shown in Figure 13–25(b) at the end of one time constant (0.1 ms).

The voltage on the inductor continues to exponentially decrease to zero, at which point the current is limited only by the circuit resistance. Then the square wave goes back to zero (at $t = 0.5$ ms) as shown in Figure 13–25(c). Again a voltage is induced across the inductor opposing this change. This time, the polarity of the inductor voltage is reversed due to the collapsing magnetic field. Although the source voltage is 0, the collapsing magnetic field maintains current in the same direction until the current decreases to zero, as shown in Figure 13–25(d).

EXAMPLE 13–9

(a) The circuit in Figure 13–26 has a square wave input. What is the highest frequency that can be used and still observe the complete waveform across the inductor?

(b) Assume the generator is set to the frequency determined in (a). Describe the voltage waveform across the resistor?

The period needs to be 10 times longer than τ to observe the entire wave.

$$T = 10\tau = 4.54\ \mu s$$

$$f = \frac{1}{T} = \frac{1}{4.54\ \mu s} = \textbf{220 kHz}$$

(b) The voltage across the resistor has the same shape as the current waveform. The general shape was shown in Figure 13–24 and has a maximum value of 10 V (the same V_s assuming no winding resistance).

The Exponential Formulas

The formulas for the exponential current and voltage in an RL circuit are similar to those used in Chapter 12 for the RC circuit, and the universal exponential curves in Figure 12–35 apply to inductors as well as capacitors. The general formulas for RL circuits are stated as follows:

Equation 13–8
$$v = V_F + (V_i - V_F)e^{-Rt/L}$$

Equation 13–9
$$i = I_F + (I_i - I_F)e^{-Rt/L}$$

where V_F and I_F are the final values of voltage and current, V_i and I_i are the initial values of voltage and current. The lowercase italic letters v and i are the instantaneous values of the inductor voltage and current at time t.

Increasing Current   The formula for the special case in which an increasing exponential current curve begins at zero is derived by setting $I_i = 0$ in Equation 13–9.

Equation 13–10
$$i = I_F(1 - e^{-Rt/L})$$

Using Equation 13–10, you can calculate the value of the increasing inductor current at any instant of time. You can calculate voltage by substituting v for i and V_F for I_F in Equation 13–10. Notice that the exponent Rt/L can also be written as $t/(L/R) = t/\tau$.

EXAMPLE 13–10

In Figure 13–27, determine the inductor current 30 μs after the switch is closed.
▲ **FIGURE 13–27**

Solution   The RL time constant is

$$\tau = \frac{L}{R} = \frac{100\,mH}{2.2\,k\Omega} = 45.5\,\mu s$$

The final current is

$$I_F = \frac{V_S}{R} = \frac{12\,V}{2.2\,k\Omega} = 5.45\,mA$$

The initial current is zero. Notice that 30 μs is less than one time constant, so the current will reach less than 63% of its final value in that time.

$$i_L = I_F(1 - e^{-Rt/L}) = 5.45\,mA(1 - e^{-0.66}) = 5.45\,mA(1 - 0.517) = \textbf{2.63 mA}$$

Related Problem   In Figure 13–27, determine the inductor current 55 μs after the switch is closed.

Decreasing Current   The formula for the special case in which a decreasing exponential current has a final value of zero is derived by setting $I_F = 0$ in Equation 13–9.

$$i = I_i e^{-Rt/L}$$

This formula can be used to calculate the decreasing inductor current at any instant, as the next example shows.

EXAMPLE 13–11

In Figure 13–28, what is the current at each microsecond interval for one complete cycle of the input square wave, V_s After calculating the current at each time, sketch the current waveform.
▲ **FIGURE 13–28**

Solution

$$\tau = \frac{L}{R} = \frac{560\ \mu H}{680\ \Omega} = 0.824\ \mu s$$

When the pulse goes from 0 V to 10 V at $t = 0$, the final current is

$$I_F = \frac{V_s}{R} = \frac{10\ V}{680\ \Omega} = 14.7\ mA$$

For the increasing current,

$$i = I_F(1 - e^{-Rt/L}) = I_F(1 - e^{-t/\tau})$$

At 1 μs: $i = 14.7\ mA(1 - e^{-1\mu s/0.824\mu s}) = \mathbf{10.3\ mA}$

At 2 μs: $i = 14.7\ mA(1 - e^{-2\mu s/0.824\mu s}) = \mathbf{13.4\ mA}$

At 3 μs: $i = 14.7\ mA(1 - e^{-3\mu s/0.824\mu s}) = \mathbf{14.3\ mA}$

At 4 μs: $i = 14.7\ mA(1 - e^{-4\mu s/0.824\mu s}) = \mathbf{14.6\ mA}$

At 5 μs: $i = 14.7\ mA(1 - e^{-5\mu s/0.824\mu s}) = \mathbf{14.7\ mA}$

When the pulse goes from 10 V to 0 V at $t = 5\ \mu s$, the current decreases exponentially. For the decreasing current,

$$i = I_i(e^{-Rt/L}) = I_i(e^{-t/\tau})$$

The initial current is the value at 5 μs, which is 14.7 mA.

At 6 μs: $i = 14.7\ mA(e^{-1\mu s/0.824\mu s})\ = \mathbf{4.37\ mA}$

At 7 μs: $i = 14.7\ mA(e^{-2\mu s/0.824\mu s})\ = \mathbf{1.30\ mA}$

At 8 μs: $i = 14.7\ mA(e^{-3\mu s/0.824\mu s})\ = \mathbf{0.38\ mA}$

At 9 μs: $i = 14.7\ mA(e^{-4\mu s/0.824\mu s})\ = \mathbf{0.11\ mA}$

At 10 μs: $i = 14.7\ mA(e^{-5\ \mu s/0.824\ \mu s})\ = \mathbf{0.03\ mA}$

Figure 13–29 is a graph of these results.

13–5 INDUCTORS IN AC CIRCUITS

An inductor passes ac with an amount of opposition called inductive reactance that depends on the frequency of the ac. The concept of the derivative was introduced in Chapter 12, and the expression for induced voltage in an inductor was stated earlier in Equation 13–1. These are used again in this section.

After completing this section, you should be able to

◆ **Analyze inductive ac circuits**

  ◆ Explain why an inductor causes a phase shift between voltage and current

  ◆ Define *inductive reactance*

  ◆ Determine the value of inductive reactance in a given circuit

  ◆ Discuss instantaneous, true, and reactive power in an inductor

Phase Relationship of Current and Voltage in an Inductor

From Equation 13–1, the formula for induced voltage, you can see that the faster the current through an inductor changes, the greater the induced voltage will be. For example, if

the rate of change of current is zero, the voltage is zero [$v_{ind} = L(di/dt) = L(0) = 0$ V]. When di/dt is a positive-going maximum, v_{ind} is a positive maximum; when di/dt is a negative-going maximum, v_{ind} is a negative maximum.

A sinusoidal current always induces a sinusoidal voltage in inductive circuits. Therefore, you can plot the voltage with respect to the current if you know the points on the current curve at which the voltage is zero and those at which it is maximum. This phase relationship is shown in Figure 13–30(a). Notice that the voltage leads the current by 90°. This is always true in a purely inductive circuit. The current and voltage of this relationship is shown by the phasors in Figure 13–30(b).
▲ FIGURE 13–30

Phase relation of V_L and I_L in an inductor. Current always lags the inductor voltage by 90°.

Inductive Reactance, X_L

Inductive reactance is the opposition to sinusoidal current, expressed in ohms. The symbol for inductive reactance is X_L.

To develop a formula for X_L, we use the relationship $v_{ind} = L(di/dt)$ and the curves in Figure 13–31. The rate of change of current is directly related to frequency. The faster the current changes, the higher the frequency. For example, you can see that in Figure 13–31, the slope of sine wave A at the zero crossings is steeper than that of sine wave B. Recall that the slope of a curve at a point indicates the rate of change at that point. Sine wave A has a higher frequency than sine wave B, as indicated by a greater maximum rate of change (di/dt is greater at the zero crossings).
◄ FIGURE 13–31

Slope indicates rate of change. Sine wave A has a greater rate of change at the zero crossing than B, and thus A has a higher frequency.

When frequency increases, di/dt increases, and thus v_{ind} increases. When frequency decreases, di/dt decreases, and thus v_{ind} decreases. The induced voltage is directly dependent on frequency.

$$\overset{\uparrow}{v_{ind}} = L(\overset{\uparrow}{di/dt}) \quad \text{and} \quad v_{ind} = L(di/dt) \underset{\downarrow}{} \underset{\downarrow}{}$$

An increase in induced voltage means more opposition (X_L is greater). Therefore, X_L is directly proportional to induced voltage and thus directly proportional to frequency.

X_L is proportional to f.

Now, if di/dt is constant and the inductance is varied, an increase in L produces an increase in v_{ind}, and a decrease in L produces a decrease in v_{ind}.

$$\overset{\uparrow}{v_{ind}} = L(di/dt) \quad \text{and} \quad v_{ind} = L(di/dt) \underset{\downarrow}{} \underset{\downarrow}{}$$

Again, an increase in v_{ind} means more opposition (greater X_L). Therefore, X_L is directly proportional to induced voltage and thus directly proportional to inductance. The inductive reactance is directly proportional to both f and L.

X_L is proportional to fL.

The formula (derived in Appendix B) for inductive reactance, X_L, is

Equation 13–12

$$X_L = 2\pi fL$$

Inductive reactance, X_L, is in ohms when f is in hertz and L is in henries. As with capacitive reactance, the 2π term is a constant factor in the equation, which comes from the relationship of a sine wave to rotational motion.

EXAMPLE 13–12

A sinusoidal voltage is applied to the circuit in Figure 13–32. The frequency is 10 kHz. Determine the inductive reactance.

▶ **FIGURE 13–32**

Solution   Convert 10 kHz to 10×10^3 Hz and 5 mH to 5×10^{-3} H. Therefore, the inductive reactance is

$$X_L = 2\pi fL = 2\pi(10 \times 10^3 \text{ Hz})(5 \times 10^{-3} \text{ H}) = \textbf{314 } \boldsymbol{\Omega}$$

Related Problem   What is X_L in Figure 13–32 if the frequency is increased to 35 kHz?

Reactance for Series Inductors

As given in Equation 13–4, the total inductance of series inductors is the sum of the individual inductances. Because reactance is directly proportional to the inductance, the total reactance of series inductors is the sum of the individual reactances.

Equation 13–13

$$X_{L(tot)} = X_{L1} + X_{L2} + X_{L3} + \cdots + X_{Ln}$$

Notice that Equation 13–13 has the same form as Equation 13–4. It also has the same form as the formulas for finding the total opposition to current such as the total resistance of series resistors or the total reactance of series capacitors. When combining the resistance or reactance of the same type of component in series (resistors, inductors, or capacitors), you simply add the individual oppositions to obtain the total.

Reactance for Parallel Inductors

In an ac circuit with parallel inductors, Equation 13–6 was given to find the total inductance. It stated that the total inductance is the reciprocal of the sum of the reciprocals of the inductors. Likewise, the total inductive reactance is the reciprocal of the sum of the reciprocals of the individual reactances.

$$X_{L(tot)} = \frac{1}{\dfrac{1}{X_{L1}} + \dfrac{1}{X_{L2}} + \dfrac{1}{X_{L3}} + \cdots + \dfrac{1}{X_{Ln}}}$$

Equation 13–14

Notice that Equation 13–14 has the same form as Equation 13–6. It also has the same form as the formulas for finding the total resistance of parallel resistors or the total reactance of parallel capacitors. When combining the resistance or reactance of the same type of component in parallel (resistors, inductors, or capacitors), you take the reciprocal of the sum of the reciprocals to obtain the total opposition.

For two inductors in parallel, Equation 13–14 can be reduced to the product-over-sum form. Thus,

$$X_{L(tot)} = \frac{X_{L1}X_{L2}}{X_{L1} + X_{L2}}$$

EXAMPLE 13–13

What is the total inductive reactance of each circuit of Figure 13–33?

(a) (b)
▲ **FIGURE 13–33**

Solution The reactances of the individual inductors are the same in both circuits. From Equation 13–12,

$$X_{L1} = 2\pi f L_1 = 2\pi(200\,\text{kHz})(2.7\,\text{mH}) = 3.39\,\text{k}\Omega$$
$$X_{L2} = 2\pi f L_2 = 2\pi(200\,\text{kHz})(4.7\,\text{mH}) = 5.91\,\text{k}\Omega$$

For the series inductors in Figure 13–33(a), the total reactance is the sum of X_{L1} and X_{L2}, as given in Equation 13–13.

$$X_{L(tot)} = X_{L1} + X_{L2} = 3.39\,\text{k}\Omega + 5.91\,\text{k}\Omega = \textbf{9.30 k}\boldsymbol{\Omega}$$

For the inductors in parallel in Figure 13–33(b), determine the total reactance by Equation 13–14 or from the product-over-sum rule using X_{L1} and X_{L2}.

$$X_{L(tot)} = \frac{X_{L1}X_{L2}}{X_{L1} + X_{L2}} = \frac{(3.39\,\text{k}\Omega)(5.91\,\text{k}\Omega)}{3.39\,\text{k}\Omega + 5.91\,\text{k}\Omega} = \mathbf{2.15\,k\Omega}$$

You can also obtain the total reactance for either series or parallel inductors by first finding the total inductance and then substituting in Equation 13–12 to find the total reactance.

Related Problem   What is the total inductive reactance for each circuit in Figure 13–33 if $L_1 = 1$ mH and L_2 is unchanged?

▲ **FIGURE 13–34**

Ohm's Law   The reactance of an inductor is analogous to the resistance of a resistor. In fact, X_L, just like X_C and R, is expressed in ohms. Since inductive reactance is a form of opposition to current, Ohm's law applies to inductive circuits as well as to resistive circuits and capacitive circuits; and it is stated as follows for Figure 13–34.

$$I = \frac{V_s}{X_L}$$

When applying Ohm's law in ac circuits, you must express both the current and the voltage in the same way, that is, both in rms, both in peak, and so on.

EXAMPLE 13–14

Determine the rms current in Figure 13–35.

▶ **FIGURE 13–35**
Solution   Convert 10 kHz to 10×10^3 Hz and 100 mH to 100×10^{-3} H. Then calculate X_L.

$$X_L = 2\pi fL = 2\pi(10 \times 10^3\,\text{Hz})(100 \times 10^{-3}\,\text{H}) = 6283\,\Omega$$

Apply Ohm's law to determine the rms current.

$$I_{rms} = \frac{V_{rms}}{X_L} = \frac{5\,\text{V}}{6283\,\Omega} = \mathbf{796\,\mu A}$$

Related Problem   Determine the rms current in Figure 13–35 for the following values: $V_{rms} = 12$ V, $f = 4.9$ kHz, and $L = 680$ mH.

Power in an Inductor

As discussed earlier, an inductor stores energy in its magnetic field when there is current through it. An ideal inductor (assuming no winding resistance) does not dissipate energy; it only stores it. When an ac voltage is applied to an ideal inductor, energy is stored by the inductor during a portion of the cycle; then the stored energy is returned to the source during another portion of the cycle. No net energy is lost in an ideal inductor due to conversion to heat. Figure 13–36 shows the power curve that results from one cycle of inductor current and voltage.
▲ **FIGURE 13–36**

Power curve.

Instantaneous Power (p)   The product of v and i gives instantaneous power. At points where v or i is zero, p is also zero. When both v and i are positive, p is also positive. When either v or i is positive and the other negative, p is negative. When both v and i are negative, p is positive. As you can see in Figure 13–36, the power follows a sinusoidal-shaped curve. Positive values of power indicate that energy is stored by the inductor. Negative values of power indicate that energy is returned from the inductor to the source. Note that the power fluctuates at a frequency twice that of the voltage or current as energy is alternately stored and returned to the source.

True Power (P$_{true}$)   Ideally, all of the energy stored by an inductor during the positive portion of the power cycle is returned to the source during the negative portion. No net energy is lost due to conversion to heat in the inductor, so the true power is zero. Actually, because of winding resistance in a practical inductor, some power is always dissipated; and there is a very small amount of true power, which can normally be neglected.

$$P_{\text{true}} = (I_{\text{rms}})^2 R_W$$

Reactive Power (P$_r$)   The rate at which an inductor stores or returns energy is called its **reactive power**, with the unit of VAR (volt-ampere reactive). The reactive power is a nonzero quantity because at any instant in time the inductor is actually taking energy from the source or returning energy to it. Reactive power does not represent an energy loss due to conversion to heat. The following formulas apply:

$$P_r = V_{\text{rms}} I_{\text{rms}}$$

$$P_r = \frac{V_{\text{rms}}^2}{X_L}$$

$$P_r = I_{\text{rms}}^2 X_L$$

EXAMPLE 13–15

A 10 V rms signal with a frequency of 1 kHz is applied to a 10 mH coil with a negligible winding resistance. Determine the reactive power (P_r).

Solution First, calculate the inductive reactance and current values.

$$X_L = 2\pi fL = 2\pi(1\,\text{kHz})(10\,\text{mH}) = 62.8\,\Omega$$

$$I = \frac{V_s}{X_L} = \frac{10\,\text{V}}{62.8\,\Omega} = 159\,\text{mA}$$

Then, use Equation 13–18.

$$P_r = I^2X_L = (159\,\text{mA})^2(62.8\,\Omega) = \textbf{1.59 VAR}$$

Related Problem What happens to the reactive power if the frequency increases?

The Quality Factor (Q) of a Coil

The **quality factor (Q)** is the ratio of the reactive power in an inductor to the true power in the winding resistance of the coil or the resistance in series with the coil. It is a ratio of the power in L to the power in R_W. The quality factor is important in resonant circuits, which are studied in Chapter 17. A formula for Q is developed as follows:

$$Q = \frac{\text{reactive power}}{\text{true power}} = \frac{I^2X_L}{I^2R_W}$$

The current is the same in L and R_W; thus, the I^2 terms cancel, leaving

Equation 13–19

$$Q = \frac{X_L}{R_W}$$

When the resistance is just the winding resistance of the coil, the circuit Q and the coil Q are the same. Note that Q is a ratio of like units and, therefore, has no unit itself. The quality factor is also known as unloaded Q because it is defined with no load across the coil.

13–6   INDUCTOR APPLICATIONS

Inductors are not as versatile as capacitors and tend to be more limited in their application due, in part, to size, cost factors, and nonideal behavior (internal resistance, etc.). One of the most common applications for inductors is noise reduction applications.

After completing this section, you should be able to

◆ **Discuss some inductor applications**

   ◆ Discuss two ways in which noise enters a circuit

   ◆ Describe the suppression of electromagnetic interference (EMI)

   ◆ Explain how a ferrite bead is used

   ◆ Discuss the basics of tuned circuits

Noise Suppression

One of the most important applications of inductors has to do with suppressing unwanted electrical noise. The inductors used in these applications are generally wound on a closed core to avoid having the inductor become a source of radiated noise itself. Two types of noise are conductive noise and radiated noise.

Conductive Noise   Many systems have common conductive paths connecting different parts of the system, which can conduct high frequency noise from one part of the system to another. Consider the case of two circuits connected with common lines as shown in Figure 13–38(a). A path for high frequency noise exists though the common grounds, creating a condition known as a *ground loop*. Ground loops are particularly a problem in instrumentation systems, where a transducer may be located a distance from the recording system and noise current in the ground can affect the signal.

If the signal of interest changes slowly, a special inductor, called a *longitudinal choke,* can be installed in the signal line as shown in Figure 13–38(b). The longitudinal choke is a form of transformer (covered in Chapter 14) that acts as inductors in each signal line. The ground loop sees a high impedance path, thus reducing the noise, while the low-frequency signal is coupled through the low impedance of the choke.

Switching circuits also tend to generate high-frequency noise (above 10 MHz) by virtue of the high-frequency components present. (Recall from Section 11–9 that a pulse waveform

(a)   (b)
▲ **FIGURE 13–38**

contains many high-frequency harmonics). Certain types of power supplies use high-speed switching circuits that are a source of conductive and radiated noise.

Because an inductor's impedance increases with frequency, inductors are good for blocking electrical noise from these supplies, which should carry only dc. Inductors are frequently installed in the power supply lines to suppress this conductive noise, so that one circuit does not adversely affect another circuit. One or more capacitors may also be used in conjunction with the inductor to improve filtering action.

Radiated Noise   Noise can also enter a circuit by way of an electromagnetic field. The noise source can be an adjacent circuit or a nearby power supply. There are several approaches to reducing the effects of radiated noise. Usually, the first step is to determine the cause of the noise and isolate it using shielding or filtering.

Inductors are widely employed in filters that are used to suppress radio-frequency noise. The inductor used for noise suppression must be carefully selected so as not to become a source of radiated noise itself. For high frequencies(>20 MHz), inductors wound on highly permeable toroidal cores are widely used, as they tend to keep the magnetic flux restricted to the core.

RF Chokes

Inductors used for the purpose of blocking very high frequencies are called *radio frequency (RF) chokes*. RF chokes are used for conductive or radiated noise. They are special inductors designed to block high frequencies from getting into or leaving parts of a system by providing a high impedance path for high frequencies. In general, the choke is placed in series with the line for which RF suppression is required. Depending on the frequency of the interference, different types of chokes are required. A common type of electromagnetic interference (EMI) filter wraps the signal line on a toroidal core several times. The toroidal configuration is desired because it contains the magnetic field so that the choke does not become a source of noise itself.

Another common type of RF choke is a ferrite bead. All wires have inductance, and the ferrite bead is a small ferromagnetic material that is strung onto the wire to increase its inductance. The impedance presented by the bead is a function of both the material and the frequency, as well as the size of the bead. It is an effective and inexpensive "choke" for high frequencies. Ferrite beads are common in highfrequency communication systems. Sometimes several are strung together in series to increase the effective inductance.

Tuned Circuits

Inductors are used in conjunction with capacitors to provide frequency selection in communications systems. These tuned circuits allow a narrow band of frequencies to be selected while all other frequencies are rejected. The tuners in your TV and radio receivers are based on this principle and permit you to select one channel or station out of the many that are available.

Frequency selectivity is based on the fact that the reactances of both capacitors and inductors depend on the frequency and on the interaction of these two components when connected in series or parallel. Since the capacitor and the inductor produce opposite phase shifts, their combined opposition to current can be used to obtain a desired response at a selected frequency. Tuned *RLC* circuits are covered in Chapter 17.

Application Activity

In this application, you will see how you can test coils for their unknown inductance values using a test setup consisting of a square wave generator and an oscilloscope. Two coils for which the inductance values are not known are tested using simple laboratory instruments to determine the inductance values. The method is to place the coil in series with a resistor with a known value and measure the time constant. Knowing the time constant and the resistance value, the value of L can be calculated.

The method of determining the time constant is to apply a square wave to the circuit and measure the resulting voltage across the resistor. Each time the square wave input voltage goes high, the inductor is energized and each time the square wave goes back to zero, the inductor is deenergized. The time it takes for the exponential resistor voltage to increase to approximately its final value equals five time constants. This operation is illustrated in Figure 13–39. To make sure that the winding resistance of the coil can be neglected, it must be measured and the value of the resistor used in the circuit must

be selected to be considerably larger than the winding and source resistances.

The Winding Resistance

Assume that the winding resistance of the coil in Figure 13–40 has been measured with an ohmmeter and found to be 85 Ω. To make the winding and source resistances negligible for time constant measurement, a 10 kΩ series resistor is used in the circuit.

INTRODUCTION

In Chapter 13, you learned about self-inductance. In this chapter, you will study mutual inductance, which is the basis for the operation of transformers. Transformers are used in all types of applications such as power supplies, electrical power distribution, and signal coupling in communications systems.

The operation of the transformer is based on the principle of mutual inductance, which occurs when two or more coils are in close proximity. A simple transformer is actually two coils that are electromagnetically coupled by their mutual inductance. Because there is no electrical contact between two magnetically coupled coils, the transfer of energy from one coil to the other can be achieved in a situation of complete electrical isolation. In relation to transformers, the term *winding* or *coil* is commonly used to describe the primary and secondary.

14–1 MUTUAL INDUCTANCE

When two coils are placed close to each other, a changing electromagnetic field produced by the current in one coil will cause an induced voltage in the second coil because of the mutual inductance between the two coils.

After completing this section, you should be able to

- **Explain mutual inductance**
  - Discuss magnetic coupling
  - Define *electrical isolation*
  - Define *coefficient of coupling*
  - Identify the factors that affect mutual inductance and state the formula

Recall from Chapter 10 that the electromagnetic field surrounding a coil of wire expands, collapses, and reverses as the current increases, decreases, and reverses.

When a second coil is placed very close to the first coil so that the changing magnetic lines of force cut through the second coil, the coils are magnetically coupled and a voltage is induced, as indicated in Figure 14–1. When two coils are magnetically coupled, they provide **electrical isolation**, a condition in which two circuits have no common electrically conductive path between them. If the current in the first coil is sinusoidal, the voltage induced in the second coil is also sinusoidal. The amount of voltage induced in the second coil as a result of the current in the first coil is dependent on the **mutual inductance, (L_M)**, which is the inductance between the two coils. The mutual inductance is established by the inductance of each coil and by the amount of coupling (k) between the two coils. To maximize coupling, the two coils are wound on a common core.

Lines of force cutting second coil as the electromagnetic field expands, collapses, and reverses in response to the sinusoidal input.
◄ **FIGURE 14–1**

A voltage is induced in the second coil as a result of the changing current in the first coil, producing a changing electromagnetic field that links the second coil.

Coefficient of Coupling

The **coefficient of coupling**, k, between two coils is the ratio of the magnetic lines of force (flux) produced by coil 1 linking coil 2 (ϕ_{1-2}) to the total flux produced by coil 1 (ϕ_1).

$$k = \frac{\phi_{1-2}}{\phi_1}$$

Equation 14–1

For example, if half of the total flux produced by coil 1 links coil 2, then $k = 0.5$. A greater value of k means that more voltage is induced in coil 2 for a certain rate of change of current in coil 1. Note that k has no units. Recall that the unit of magnetic lines of force (flux) is the weber, abbreviated Wb.

The coefficient of coupling, k, depends on the physical closeness of the coils and the type of core material on which they are wound. Also, the construction and shape of the cores are factors.

Formula for Mutual Inductance

The three factors influencing mutual inductance (k, L_1, and L_2) are shown in Figure 14–2. The formula for mutual inductance is

Equation 14–2

$$L_M = k\sqrt{L_1 L_2}$$

▶ **FIGURE 14–2**

The mutual inductance of two coils.
EXAMPLE 14–1

One coil produces a total magnetic flux of 50 μWb, and 20 μWb link coil 2. What is the coefficient of coupling, k?

Solution

$$k = \frac{\phi_{1-2}}{\phi_1} = \frac{20\,\mu\text{Wb}}{50\,\mu\text{Wb}} = \textbf{0.4}$$

*Related Problem**

Determine k when $\phi_1 = 500\,\mu$Wb and $\phi_{1-2} = 375\,\mu$Wb.

*Answers are at the end of the chapter.

EXAMPLE 14–2

Two coils are wound on a single core, and the coefficient of coupling is 0.3. The inductance of coil 1 is 10 μH, and the inductance of coil 2 is 15 μH. What is L_M?

Solution

$$L_M = k\sqrt{L_1 L_2} = 0.3\sqrt{(10\,\mu\text{H})(15\,\mu\text{H})} = \textbf{3.67 } \boldsymbol{\mu}\textbf{H}$$

Related Problem

Determine the mutual inductance when $k = 0.5$, $L_1 = 1$ mH, and $L_2 = 600\,\mu$H.

14–2 THE BASIC TRANSFORMER

A **transformer** is an electrical device constructed of two or more coils of wire (windings) magnetically coupled to each other so that there is a mutual inductance for the transfer of power from one winding to the other. Although many transformers have more than two windings, the coverage in this section is restricted to a basic two-winding transformer. Later, more complicated transformers are introduced.

⊕ *This icon indicates selected websites for further information on topics in this section. See the Companion Website provided with this text.*

After completing this section, you should be able to

◆ **Describe how a transformer is constructed and how it operates**

  ◆ Identify the parts of a basic transformer

  ◆ Discuss the importance of the core material

  ◆ Define *primary winding* and *secondary winding*

  ◆ Define *turns ratio*

  ◆ Discuss how the direction of windings affects voltage polarities

A schematic of a transformer is shown in Figure 14–3(a). As shown, one coil is called the **primary winding**, and the other is called the **secondary winding**. The source voltage is applied to the primary winding, and the load is connected to the secondary winding, as shown in Figure 14–3(b). The primary winding is the input winding, and the secondary winding is the output winding. It is common to refer to the side of the transformer that has the source voltage as the *primary,* and the side that has the induced voltage as the *secondary.*

▲ **FIGURE 14–3**

The basic transformer.

The windings of a transformer are formed around the core. The core provides both a physical structure for placement of the windings and a magnetic path so that the magnetic flux is concentrated close to the coils. There are three general categories of core material: air, ferrite, and iron. The schematic symbol for each type is shown in Figure 14–4.

(a) Air core   (b) Ferrite core   (c) Iron core
▲ **FIGURE 14–4**

Schematic symbols based on type of core.

Iron-core transformers generally are used for audio frequency (AF) and power applications. These transformers consist of windings on a core constructed from laminated sheets of ferromagnetic material insulated from each other, as shown in Figure 14–5. This construction provides an easy path for the magnetic flux and increases the amount of coupling between the windings. Figure 14–5 shows the basic construction of two major configurations of
(a) Core type has each winding on a separate leg.

(b) Shell type has both windings on the same leg.

Iron-core transformer construction with multilayer windings.

iron-core transformers. In the core-type construction, shown in part (a), the windings are on separate legs of the laminated core. In the shell-type construction, shown in part (b), both windings are on the same leg. Each type has certain advantages. Generally, the core type has more room for insulation and can handle higher voltages. The shell type can produce higher magnetic fluxes in the core, resulting in the need for fewer turns.

Air-core and ferrite-core transformers generally are used for high-frequency applications and consist of windings on an insulating shell which is hollow (air) or constructed of ferrite, such as depicted in Figure 14–6. The wire is typically covered by a varnish-type coating to prevent the windings from shorting together. The amount of **magnetic coupling** between the primary winding and the secondary winding is set by the type of core material and by the relative positions of the windings. In Figure 14–6(a), the windings are loosely coupled because they are separated, and in part (b) they are tightly coupled because they are overlapping. The tighter the coupling, the greater the induced voltage in the secondary for a given current in the primary.

▶ FIGURE 14–6

Transformers with cylindrical-shaped cores.
(a) Loosely coupled windings

(b) Tightly coupled windings. Cutaway view shows both windings.

High-frequency transformers tend to have fewer windings and smaller inductances than power transformers. A type of high-frequency transformer that has become popular in recent years is the planar transformer. Planar transformers are constructed with printed circuit (PC) board assembly methods (rather than wire winding) that enable them to be produced with high precision and low cost. The windings are actually traces laid out on stacked PC boards. Planar transformers are available in a variety of sizes and wattage ratings. The low profile of a planar transformer (typically less than 0.5 inches) makes it particularly suited to cases where space is critical.

A representative planar transformer is shown in Figure 14–7(a). The transformer in Figure 14–7(b) is a low-voltage transformer commonly used in power supplies. Parts (c) and (d) show other common types of small transformers.

Some common types of transformers.

Turns Ratio

A transformer parameter that is useful in understanding how a transformer operates is the turns ratio. In this text, the **turns ratio (n)** is defined as the ratio of the number of turns in the secondary winding (N_{sec}) to the number of turns in the primary winding (N_{pri}).

$$n = \frac{N_{sec}}{N_{pri}}$$

Equation 14–3

This definition of turns ratio is based on the IEEE standard for electronics power transformers as specified in the IEEE dictionary. Other categories of transformer may have a different definition, so some sources define the turns ratio as N_{pri}/N_{sec}. Either definition is correct as long as it is clearly stated and used consistently. The turns ratio of a transformer is rarely if ever given as a transformer specification. Generally, the input and output voltages and the power rating are the key specifications. However, the turns ratio is useful in studying the operating principle of a transformer.

EXAMPLE 14–3

A transformer primary winding has 100 turns, and the secondary winding has 400 turns. What is the turns ratio?

Solution $N_{sec} = 400$ and $N_{pri} = 100$; therefore, the turns ratio is

$$n = \frac{N_{sec}}{N_{pri}} = \frac{400}{100} = 4$$

Related Problem   A certain transformer has a turns ratio of 10. If $N_{pri} = 500$, what is N_{sec}?

Direction of Windings

Another important transformer parameter is the direction in which the windings are placed around the core. As illustrated in Figure 14–8, the direction of the windings determines the polarity of the voltage across the secondary winding (secondary voltage) with respect to the voltage across the primary winding (primary voltage). Phase dots are sometimes used on the schematic symbols to indicate polarities, as shown in Figure 14–9.

The direction of the windings determines the relative polarities of the voltages.

14–3 STEP-UP AND STEP-DOWN TRANSFORMERS

A step-up transformer has more turns in its secondary winding than in its primary winding and is used to increase ac voltage. A step-down transformer has more turns in its primary winding than in its secondary winding and is used to decrease ac voltage.

After completing this section, you should be able to

◆ **Describe how transformers increase and decrease voltage**

◆ Explain how a step-up transformer works

◆ Identify a step-up transformer by its turns ratio

◆ State the relationship between primary and secondary voltages and the turns ratio

◆ Explain how a step-down transformer works

◆ Identify a step-down transformer by its turns ratio

◆ Describe dc isolation

The Step-Up Transformer

A transformer in which the secondary voltage is greater than the primary voltage is called a **step-up transformer**. The amount that the voltage is stepped up depends on the turns ratio.

> The ratio of secondary voltage (V_{sec}) to primary voltage (V_{pri}) is equal to the ratio of the number of turns in the secondary winding (N_{sec}) to the number of turns in the primary winding (N_{pri}).

$$\frac{V_{sec}}{V_{pri}} = \frac{N_{sec}}{N_{pri}}$$

<div align="right">**Equation 14–4**</div>

Recall that N_{sec}/N_{pri} defines the turns ratio, n. Therefore, from this relationship,

$$V_{sec} = nV_{pri}$$

<div align="right">**Equation 14–5**</div>

Equation 14–5 shows that the secondary voltage is equal to the turns ratio times the primary voltage. This condition assumes that the coefficient of coupling is 1, and a good iron-core transformer approaches this value.

The turns ratio for a step-up transformer is always greater than 1 because the number of turns in the secondary winding (N_{sec}) is always greater than the number of turns in the primary winding (N_{pri}).

EXAMPLE 14–4

The transformer in Figure 14–10 has a turns ratio of 3. What is the voltage across the secondary winding? RMS voltage is assumed.

▶ **FIGURE 14–10**

Solution   The secondary voltage is

$$V_{sec} = nV_{pri} = (3)120 \text{ V} = \textbf{360 V}$$

Note that the turns ratio of 3 is indicated on the schematic as 1:3, meaning that there are three secondary turns for each primary turn.

Related Problem   The transformer in Figure 14–10 is changed to one with a turns ratio of 4. Determine V_{sec}.

Use Multisim file E14-04 to verify the calculated results in this example and to confirm your calculation for the related problem.

The Step-Down Transformer

A transformer in which the secondary voltage is less than the primary voltage is called a **step-down transformer**. The amount by which the voltage is stepped down depends on the turns ratio. Equation 14–5 also applies to a step-down transformer.

The turns ratio of a step-down transformer is always less than 1 because the number of turns in the secondary winding is always fewer than the number of turns in the primary winding.

EXAMPLE 14–5

The transformer in Figure 14–11 has a turns ratio of 0.2. What is the secondary voltage?

▶ **FIGURE 14–11**

Solution The secondary voltage is

$$V_{sec} = nV_{pri} = (0.2)120 \text{ V} = \textbf{24 V}$$

Related Problem The transformer in Figure 14–11 is changed to one with a turns ratio of 0.48. Determine the secondary voltage.

Use Multisim file E14-05 to verify the calculated results in this example and to confirm your calculation for the related problem.

DC Isolation

As illustrated in Figure 14–12(a), if there is dc in the primary of a transformer, nothing happens in the secondary. The reason is that a changing current in the primary winding is necessary to induce a voltage in the secondary winding, as shown in part (b). Therefore, the transformer isolates the secondary circuit from any dc in the primary circuit. A transformer that is used strictly for isolation has a turns ratio of 1.

(a)   (b)
▲ **FIGURE 14–12**

DC isolation and ac coupling.

Isolation transformers are often packaged as part of a total ac line-conditioning device. In addition to the isolation transformer, the line conditioning includes surge protection, filters to eliminate interference, and sometimes automatic voltage regulation. Line conditioning is useful to isolate sensitive equipment such as microprocessor-based controllers. Specialized line conditioners for patient-monitoring equipment in hospitals provide a high degree of electrical isolation and protection from shock.

Small transformers that are used to isolate the dc bias from one stage of an amplifier to the next stage are called coupling transformers because the ac signal is passed ("coupled") but the dc is blocked. Coupling transformers are widely used at high frequencies where they are designed to pass only a selected band of frequencies by making the primary and secondary coils part of a parallel tuned circuit (resonant circuit). (Tuned circuits are discussed in Chapter 17.) A typical transformer-coupled amplifier arrangement is shown in Figure 14–13. Frequently, the core of a coupling transformer can be adjusted to fine-tune the frequency response. Coupling transformers are also commonly used to couple a signal from an amplifier to a speaker.

14–4 LOADING THE SECONDARY

When a resistive load is connected to the secondary winding of a transformer, the relationship of the load (secondary) current and the current in the primary circuit is determined by the turns ratio.

After completing this section, you should be able to

♦ **Discuss the effect of a resistive load across the secondary**

♦ Determine the current delivered by the secondary when a step-up transformer is loaded

♦ Determine the current delivered by the secondary when a step-down transformer is loaded

♦ Discuss power in a transformer

When a load resistor is connected to the secondary winding, as shown in Figure 14–14, there is current through the resulting secondary circuit because of the voltage induced in the secondary coil. It can be shown that the ratio of the primary current, I_{pri}, to the secondary current, I_{sec}, is equal to the turns ratio, as expressed in the following equation:

$$\frac{I_{pri}}{I_{sec}} = n$$

Equation 14–6

◀ FIGURE 14–14

R_L
I_{pri}

I_{sec}

A manipulation of the terms in Equation 14–6 gives Equation 14–7, which shows that I_{sec} is equal to I_{pri} times the reciprocal of the turns ratio.

Equation 14–7

$$I_{sec} = \left(\frac{1}{n}\right)I_{pri}$$

Thus, for a step-up transformer, in which n is greater than 1, the secondary current is less than the primary current. For a step-down transformer, n is less than 1, and I_{sec} is greater than I_{pri}. When the secondary voltage is greater than the primary voltage, the secondary current is lower than the primary current and vice versa.

EXAMPLE 14–6

The two ideal transformers in Figure 14–15 have loaded secondary windings. If the primary current is 100 mA in each case, what is the load current?

▸ **FIGURE 14–15**

(b)   2:1
Solution   In Figure 14–15(a), the turns ratio is 10. The current through the load is

$$I_{sec} = \left(\frac{1}{n}\right)I_{pri} = (0.1)100\,\text{mA} = \mathbf{10\,mA}$$

In Figure 14–15(b), the turns ratio is 0.5. The current through the load is

$$I_{sec} = \left(\frac{1}{n}\right)I_{pri} = (2)100\,\text{mA} = \mathbf{200\,mA}$$

Related Problem   What is the secondary current in Figure 14–15(a) if the turns ratio is doubled? What is the secondary current in Figure 14–15(b) if the turns ratio is halved? Assume I_{pri} remains the same in both circuits.

Primary Power Equals Load Power

When a load is connected to the secondary winding of a transformer, the power transferred to the load can never be greater than the power in the primary winding. For an ideal transformer, the power delivered to the primary equals the power delivered by the secondary to the load. When losses are considered, some of the power is dissipated in the transformer rather than the load; therefore, the load power is always less than the power in the primary.

Power is dependent on voltage and current, and there can be no increase in power in a transformer. Therefore, if the voltage is stepped up, the current is stepped down and vice versa. In an ideal transformer, the secondary power is equal to the primary power regardless of the turns ratio, as the following equations show. The power delivered to the primary is

$$P_{pri} = V_{pri}I_{pri}$$

and the power delivered to the load is

$$P_{sec} = V_{sec}I_{sec}$$

From Equations 14–7 and 14–5,

$$I_{sec} = \left(\frac{1}{n}\right)I_{pri} \qquad \text{and} \qquad V_{sec} = nV_{pri}$$

By substitution,

$$P_{sec} = \left(\frac{1}{n}\right) n V_{pri} I_{pri}$$

Canceling terms yields

$$P_{sec} = V_{pri} I_{pri} = P_{pri}$$

This result is closely approached in practice by power transformers because of the very high efficiencies.

SECTION 14–4 **CHECKUP**	1. If the turns ratio of a transformer is 2, is the secondary current greater than or less than the primary current? By how much? 2. A transformer has 1000 turns in its primary winding and 250 turns in its secondary winding, and I_{pri} is 0.5 A. What is the value of I_{sec}? 3. In Problem 2, how much primary current is necessary to produce a secondary load current of 10 A?

14–5 REFLECTED LOAD

From the viewpoint of the primary, a load connected across the secondary winding of a transformer appears to have a resistance that is not necessarily equal to the actual resistance of the load. The actual load is "reflected" into the primary as determined by the turns ratio. This reflected load is what the primary source effectively sees, and it determines the amount of primary current.

After completing this section, you should be able to

◆ **Discuss the concept of a reflected load in a transformer**

   ◆ Define *reflected resistance*

   ◆ Explain how the turns ratio affects the reflected resistance

   ◆ Calculate reflected resistance

The concept of the **reflected load** is illustrated in Figure 14–16. The load (R_L) in the secondary of a transformer is reflected into the primary by transformer action. Ideally, the load appears to the source in the primary to be a resistance (R_{pri}) with a value determined by the turns ratio and the actual value of the load resistance. The resistance R_{pri} is called the **reflected resistance**.

V_s $I_{pri} = \dfrac{V_{pri}}{R_{pri}}$ $R_{pri} = \left(\dfrac{1}{n}\right)^2 R_L$

Actual load   Reflected load

The resistance in the primary of Figure 14–16 is $R_{pri} = V_{pri}/I_{pri}$. The resistance in the secondary is $R_L = V_{sec}/I_{sec}$. From Equations 14–4 and 14–6, you know that $V_{sec}/V_{pri} = n$ and $I_{pri}/I_{sec} = n$. Using these relationships, a formula for R_{pri} in terms of R_L is determined as follows:

$$\frac{R_{pri}}{R_L} = \frac{V_{pri}/I_{pri}}{V_{sec}/I_{sec}} = \left(\frac{V_{pri}}{V_{sec}}\right)\left(\frac{I_{sec}}{I_{pri}}\right) = \left(\frac{1}{n}\right)\left(\frac{1}{n}\right) = \left(\frac{1}{n}\right)^2$$

Solving for R_{pri} yields

Equation 14–8

$$R_{pri} = \left(\frac{1}{n}\right)^2 R_L$$

Equation 14–8 shows that the resistance reflected into the primary circuit is the square of the reciprocal of the turns ratio times the load resistance.

EXAMPLE 14–7

Figure 14–17 shows a source that is transformer-coupled to a load resistor of 100 Ω. The transformer has a turns ratio of 4. What is the reflected resistance seen by the source?

▶ **FIGURE 14–17**
Solution   The reflected resistance is determined by Equation 14–8.

$$R_{pri} = \left(\frac{1}{n}\right)^2 R_L = \left(\frac{1}{4}\right)^2 R_L = \left(\frac{1}{16}\right)100 \ \Omega = \textbf{6.25 } \boldsymbol{\Omega}$$

The source sees a resistance of 6.25 Ω just as if it were connected directly, as shown in the equivalent circuit of Figure 14–18.

▶ **FIGURE 14–18**

Related Problem   If the turns ratio in Figure 14–17 is 10 and R_L is 600 Ω, what is the reflected resistance?

EXAMPLE 14–8

In Figure 14–17, if a transformer is used having a turns ratio of 0.25, what is the reflected resistance?

Solution   The reflected resistance is

$$R_{pri} = \left(\frac{1}{n}\right)^2 R_L = \left(\frac{1}{0.25}\right)^2 100 \ \Omega = (4)^2 100 \ \Omega = \textbf{1600 } \boldsymbol{\Omega}$$

This result illustrates the difference that the turns ratio makes.

Related Problem   To achieve a reflected resistance of 800 Ω, what turns ratio is required in Figure 14–17?

In a step-up transformer ($n > 1$), the reflected resistance is less than the actual load resistance; in a step-down transformer ($n < 1$), the reflected resistance is greater than the load resistance. This was illustrated in Examples 14–7 and 14–8, respectively.

14–6   IMPEDANCE MATCHING

One application of transformers is in the matching of a load impedance to a source impedance to achieve maximum transfer of power or other results. This technique is called impedance matching. In audio systems, special wide-band transformers are often used to get the maximum amount of available power from the amplifier to the speaker by proper selection of the turns ratio. Transformers designed specifically for impedance matching usually show the input and output impedance they are designed to match. A special type of impedance-matching transformer called the balun is introduced.

After completing this section, you should be able to

◆ **Discuss impedance matching with transformers**

  ◆ Discuss the maximum power transfer theorem

  ◆ Define *impedance matching*

  ◆ Explain the purpose of impedance matching

  ◆ Describe a balun transformer

Recall that the maximum power transfer theorem (discussed in Section 8–7) states that maximum power is transferred from a source to a load when the load resistance is equal to the source resistance. In ac circuits, the total opposition to current is referred to as impedance, which can be resistance, reactance, or a combination of both. The term **impedance matching** is used to show that the source and load impedances are effectively equal. For this section, we will confine our usage to resistance only.

Figure 14–19(a) shows an ac source with a fixed internal resistance. Some fixed internal resistance is inherent in all sources due to their internal circuitry. Part (b) shows a load connected to the source. In this case, the objective is often to transfer as much power to the load as possible.

In most practical situations, the internal source resistance of various types of sources is fixed. Also, in many cases, the resistance of a device that acts as a load is fixed and cannot be altered. If you need to connect a given source to a given load, remember that only by chance will their resistances match. In this situation, a special type of wide band transformer comes in handy. You can use the reflected-resistance characteristic provided by a transformer to make the load resistance appear to have the same value as the source resistance. This technique is called impedance matching, and the transformer is called an impedance-matching transformer because it also transforms reactances as well as resistances.

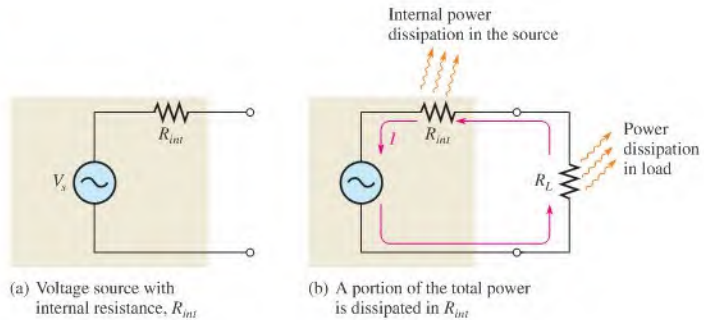

Figure 14–20 illustrates a specific example of an impedance-matching transformer. In this example, a source with an internal resistance of 75 Ω is driving a 300 Ω load. The impedance-matching transformer needs to make the load resistance look like a 75 Ω resistance to the source in order to deliver maximum power to the load. To select the right transformer, you need to know how the turns ratio affects the impedance. You can use Equation 14–8 to determine the turns ratio, n, to achieve impedance matching when you know the values for R_L and R_{pri}.

$$R_{pri} = \left(\frac{1}{n}\right)^2 R_L$$

Transpose terms and divide both sides by R_L.

$$\left(\frac{1}{n}\right)^2 = \frac{R_{pri}}{R_L}$$

Then take the square root of both sides.

$$\frac{1}{n} = \sqrt{\frac{R_{pri}}{R_L}}$$

Invert both sides to get the following formula for the turns ratio:

Equation 14–9

$$n = \sqrt{\frac{R_L}{R_{pri}}}$$

Finally, solve for the particular turns ratio to match a 300 Ω load to a 75 Ω source.

$$n = \sqrt{\frac{300\ \Omega}{75\ \Omega}} = \sqrt{4} = 2$$

Therefore, a matching transformer with a turns ratio of 2 must be used in this application.

EXAMPLE 14–9

An amplifier has an 800 Ω internal resistance. In order to provide maximum power to an 8 Ω speaker, what turns ratio must be used in the coupling transformer?

Solution

The reflected resistance must equal 800 Ω. Thus, from Equation 14–9, the turns ratio can be determined.

$$n = \sqrt{\frac{R_L}{R_{pri}}} = \sqrt{\frac{8\ \Omega}{800\ \Omega}} = \sqrt{0.01} = \mathbf{0.1}$$

The diagram and its equivalent reflected circuit are shown in Figure 14–21.

The Balun Transformer An application for impedance matching is used in high-frequency antennas. In addition to impedance matching, many transmitting antennas also require that an unbalanced signal from the transmitter be converted to a balanced signal. A *balanced signal* is composed of two equal-amplitude signals that are 180° out-of-phase with each other. An *unbalanced signal* is one that is referenced to ground. A special type of transformer called a **balun**, a contraction of the words "*bal*anced-*un*balanced" is used to convert the unbalanced signal from the transmitter to a balanced signal at the antenna, as shown in Figure 14–22.
◀ **FIGURE 14–22**

Illustration of a balun transformer converting an unbalanced signal to a balanced signal.

The transmitter is usually connected to the balun with a coaxial cable (coax). A coax is basically a conductor surrounded by an insulating region and an outer conductor called the shield. In Figure 14–22, the signal from the transmitter is referenced to ground, which is connected to the outer shield of the coax, so it is an unbalanced signal. The shield on the coax minimizes pickup of radiated noise.

The coax has a certain characteristic impedance associated with it. The turns ratio of the balun is set to match the coax impedance to the antenna impedance. For example, if the transmitting antenna represents a 300 Ω impedance and the coax has a characteristic impedance of 75 Ω, the balun can provide the impedance match with a turns ratio of two, as was shown earlier. Baluns can also be used to convert from balanced signals to unbalanced signals.

14–7 TRANSFORMER RATINGS AND CHARACTERISTICS

Transformer operation has been discussed from an ideal point of view. That is, the winding resistance, the winding capacitance, and nonideal core characteristics were all neglected and the transformer was treated as if it had an efficiency of 100%. For studying the basic concepts and in many applications, the ideal model is valid. However, the practical transformer has several nonideal characteristics.

After completing this section, you should be able to

◆ **Describe a practical transformer**

   ◆ List and describe the nonideal characteristics

   ◆ Explain power rating of a transformer

   ◆ Define *efficiency* of a transformer

Ratings

Power Rating A power transformer is typically rated in volt-amperes (VA), primary/secondary voltage, and operating frequency. For example, a given transformer rating may be specified as 2 kVA, 500/50, 60 Hz. The 2 kVA value is the **apparent power rating**. The 500 and the 50 can be either secondary or primary voltages. The 60 Hz is the operating frequency.

The transformer rating can be helpful in selecting the proper transformer for a given application. Let's assume, for example, that 50 V is the secondary voltage. In this case the load current is

$$I_L = \frac{P_{sec}}{V_{sec}} = \frac{2\text{ kVA}}{50\text{ V}} = 40\text{ A}$$

On the other hand, if 500 V is the secondary voltage, then

$$I_L = \frac{P_{sec}}{V_{sec}} = \frac{2\text{ kVA}}{500\text{ V}} = 4\text{ A}$$

These are the maximum currents that the secondary can handle in either case.

The reason that the power rating is in volt-amperes (apparent power) rather than in watts (true power) is as follows: If the transformer load is purely capacitive or purely inductive, the true power (watts) delivered to the load is zero. However, the current for $V_{sec} = 500$ V and $X_C = 100$ Ω at 60 Hz, for example, is 5 A. This current exceeds the maximum that the 2 kVA secondary can handle, and the transformer may be damaged. So it is meaningless to specify power in watts for transformers.

Voltage and Frequency Ratings In addition to the apparent power rating, most power transformers will have voltage and frequency ratings placed on the transformer. The voltage

ratings include the primary voltage for which it is designed and the secondary voltage that is present when the rated load is connected to the secondary and the primary is connected to the rated input voltage. Frequently, there will be a small schematic drawing showing the windings and voltage rating for each winding. The frequency for which the transformer is designed will also be specified. A transformer operated on the wrong frequency can be damaged, so it is important to note the frequency specification. These are minimum specifications you need to know in order to select a power transformer for an application.

Characteristics

Winding Resistance   Both the primary and the secondary windings of a practical transformer have winding resistance. You learned about the winding resistance of inductors in Chapter 13. The winding resistances of a practical transformer are represented as resistors in series with the windings as shown in Figure 14–23.

Winding resistance in a practical transformer results in less voltage across a secondary load. Voltage drops due to the winding resistance effectively subtract from the primary and secondary voltages and result in load voltage that is less than that predicted by the relationship $V_{sec} = nV_{pri}$. In many cases, the effect is relatively small and can be neglected.

Losses in the Core   There is always some energy conversion in the core material of a practical transformer. This conversion is seen as a heating of ferrite and iron cores, but it does not occur in air cores. Part of this energy conversion is because of the continuous reversal of the magnetic field due to the changing direction of the primary current; this component of the energy conversion is called *hysteresis loss*. The rest of the energy conversion to heat is caused by eddy currents produced when voltage is induced in the core material by the changing magnetic flux, according to Faraday's law. The eddy currents occur in circular patterns in the core resistance, thus producing heat. This conversion to heat is greatly reduced by the use of laminated construction of iron cores. The thin layers of ferromagnetic material are insulated from each other to minimize the buildup of eddy currents by confining them to a small area and to keep core losses to a minimum.

Magnetic Flux Leakage   In an ideal transformer, all of the magnetic flux produced by the primary current is assumed to pass through the core to the secondary winding, and vice versa. In a practical transformer, some of the magnetic flux lines break out of the core and pass through the surrounding air back to the other end of the winding, as illustrated in Figure 14–24 for the magnetic field produced by the primary current. Magnetic flux leakage results in a reduced secondary voltage.

The percentage of magnetic flux that actually reaches the secondary winding determines the coefficient of coupling of the transformer. For example, if nine out of ten flux lines remain inside the core, the coefficient of coupling is 0.90 or 90%. Most iron-core transformers have very high coefficients of coupling (greater than 0.99), while ferrite-core and air-core devices have lower values.

Winding resistances in a practical transformer.
Leakage flux

◀ FIGURE 14–24

Flux leakage in a practical transformer.

Winding Capacitance   As you learned in Chapter 13, there is always some stray capacitance between adjacent turns of a winding. These stray capacitances result in an effective capacitance in parallel with each winding of a transformer, as indicated in Figure 14–25.

Winding capacitance in a practical transformer.
These stray capacitances have very little effect on the transformer's operation at low frequencies (such as power line frequencies) because the reactances (X_C) are very high. However, at higher frequencies, the reactances decrease and begin to produce a bypassing effect across the primary winding and across the secondary load. As a result, less of the total primary current is through the primary winding, and less of the total secondary current is through the load. This effect reduces the load voltage as the frequency goes up.

Transformer Efficiency   Recall that the power delivered to the load is equal to the power delivered to the primary in an ideal transformer. Because the nonideal characteristics just discussed result in a power loss in the transformer, the secondary (output) power is always less than the primary (input) power. The **efficiency** (η) of a transformer is a measure of the percentage of the input power that is delivered to the output.

Equation 14–10

$$\eta = \left(\frac{P_{out}}{P_{in}}\right)100\%$$

Most power transformers have efficiencies in excess of 95% under load.

EXAMPLE 14–10

A certain type of transformer has a primary current of 5 A and a primary voltage of 4800 V. The secondary current is 90 A, and the secondary voltage is 240 V. Determine the efficiency of this transformer.

Solution   The input power is

$$P_{in} = V_{pri}I_{pri} = (4800\,\text{V})(5\,\text{A}) = 24\,\text{kVA}$$

The output power is

$$P_{out} = V_{sec}I_{sec} = (240\,\text{V})(90\,\text{A}) = 21.6\,\text{kVA}$$

The efficiency is

$$\eta = \left(\frac{P_{out}}{P_{in}}\right)100\% = \left(\frac{21.6\,\text{kVA}}{24\,\text{kVA}}\right)100\% = \mathbf{90\%}$$

Related Problem   A transformer has a primary current of 8 A with a primary voltage of 440 V. The secondary current is 30 A and the secondary voltage is 100 V. What is the efficiency?

14–8 TAPPED AND MULTIPLE-WINDING TRANSFORMERS

The basic transformer has several important variations. They include tapped transformers, multiple-winding transformers, and autotransformers. Three-phase transformers, which are types of multiple-winding transformers, are introduced in this section.

After completing this section, you should be able to

• **Describe several types of transformers**

  ♦ Describe center-tapped transformers

  ♦ Describe multiple-winding transformers

  ♦ Describe autotransformers

  ♦ Describe three-phase transformers

Tapped Transformers

A schematic of a transformer with a center-tapped secondary winding is shown in Figure 14–26(a). The **center tap (CT)** is equivalent to two secondary windings with half the total voltage across each.

(a) Center-tapped transformer

(b) Output voltages with respect to the center tap are 180° out of phase with each other and are one-half the magnitude of the secondary voltage.
▲ **FIGURE 14–26**

Operation of a center-tapped transformer.

The voltages between either end of the secondary winding and the center tap are, at any instant, equal in magnitude but opposite in polarity, as illustrated in Figure 14–26(b). Here, for example, at some instant on the sinusoidal voltage, the polarity across the entire secondary winding is as shown (top end $+$, bottom end $-$). At the center tap, the voltage is less positive than the top end but more positive than the bottom end of the secondary. Therefore, measured with respect to the center tap, the top end of the secondary is positive, and the bottom end is negative. This center-tapped feature is used in many power supply rectifiers in which the ac voltage is converted to dc, as illustrated in Figure 14–27.
◄ **FIGURE 14–27**

Application of a center-tapped transformer in ac-to-dc conversion.

Some tapped transformers have taps on the secondary winding at points other than the electrical center. Also, single and multiple primary and secondary taps are sometimes used in certain applications, such as impedance-matching transformers that normally have a center-tapped primary. Examples of these types of transformers are shown in Figure 14–28.

(a)   (b)   (c)
Utility companies use many tapped transformers in distribution systems. Normally, power is generated and transmitted as three-phase power. At some point, the three-phase power is converted to single-phase for residential use. An example of a utility-pole transformer is shown in Figure 14–29 for the case where the high-voltage three-phase power has previously been converted to single-phase power (by tapping one of the three phases). It still needs to be converted to 120 V/240 V for residential customers, so a single-phase tapped transformer is used. By selecting the appropriate tap on the primary side, the utility company can make minor adjustments in the voltage that is delivered to the customer. The center tap on the secondary side is the neutral (usually uninsulated) conductor.

Multiple-Winding Transformers

Some transformers are designed to operate from either 120 V ac or 240 V ac lines. These transformers usually have two primary windings, each of which is designed for 120 V ac. When the two are connected in series, the transformer can be used for 240 V ac operations, as illustrated in Figure 14–30.

More than one secondary can be wound on a common core. Transformers with several secondary windings are often used to achieve several voltages by either stepping up or stepping

(a) Two primary windings

(b) Primary windings in parallel for 120 V ac operation

(c) Primary windings in series for 240 V ac operation
down the primary voltage. These types are commonly used in power supply applications in which several voltage levels are required for the operation of an electronic instrument.

A typical schematic of a multiple-secondary transformer is shown in Figure 14–31; this transformer has three secondaries. Sometimes you will find combinations of multiple-primary, multiple-secondary, and tapped transformers all in one unit.
◀ FIGURE 14–31

A multiple-secondary transformer.

EXAMPLE 14–11

The transformer shown in Figure 14–32 has the numbers of turns indicated. One of the secondaries is also center tapped. If 120 V ac are connected to the primary, determine each secondary voltage and the voltages with respect to the center tap (CT) on the middle secondary.

▶ FIGURE 14–32
Solution

$$V_{AB} = n_{AB}V_{pri} = (0.05)120 \text{ V} = \textbf{6.0 V}$$
$$V_{CD} = n_{CD}V_{pri} = (2)120 \text{ V} = \textbf{240 V}$$
$$V_{(CT)C} = V_{(CT)D} = \frac{240 \text{ V}}{2} = \textbf{120 V}$$
$$V_{EF} = n_{EF}V_{pri} = (0.1)120 \text{ V} = \textbf{12 V}$$

Related Problem   Repeat the calculations for a primary with 500 turns.

Autotransformers

In an **autotransformer**, one winding serves as both the primary and the secondary. The winding is tapped at the proper points to achieve the desired turns ratio for stepping up or stepping down the voltage.

Autotransformers differ from conventional transformers in that there is no electrical isolation between the primary and the secondary because both are on one winding. Autotransformers normally are smaller and lighter than equivalent conventional transformers because they require a much lower kVA rating for a given load. Many autotransformers provide an adjustable tap using a sliding contact mechanism so that the output voltage can be varied (these are often called *variacs*). Figure 14–33 shows schematic symbols for various types of autotransformers. Autotransformers are used in starting industrial induction motors and regulating transmission line voltages.

Example 14–12 illustrates why an autotransformer has a kVA requirement that is less than the input or output kVA.

▶ **FIGURE 14–33**

Types of autotransformers.

(a) Step-up   (b) Step-down   (c) Variable
EXAMPLE 14–12

A certain autotransformer is used to change a source voltage of 240 V to a load voltage of 170 V across an 8 Ω load resistance. Determine the input and output power in kilovolt-amperes, and show that the actual kVA requirement is less than this value. Assume that this transformer is ideal.

Solution   The circuit is shown in Figure 14–34 with voltages and currents indicated.

▶ **FIGURE 14–34**
The load current, I_3, is determined as

$$I_3 = \frac{V_3}{R_L} = \frac{170 \text{ V}}{8 \ \Omega} = 21.3 \text{ A}$$

The input power is the total source voltage (V_1) times the total current from the source (I_1).

$$P_{in} = V_1 I_1$$

The output power is the load voltage, V_3, times the load current, I_3.

$$P_{out} = V_3 I_3$$

For an ideal transformer, $P_{in} = P_{out}$; thus,

$$V_1 I_1 = V_3 I_3$$

Solving for I_1 yields

$$I_1 = \frac{V_3 I_3}{V_1} = \frac{(170\ \text{V})(21.3\ \text{A})}{240\ \text{V}} = 15.1\ \text{A}$$

Applying Kirchhoff's current law at the tap junction,

$$I_1 = I_2 + I_3$$

Solving for I_2, the current through winding B, yields

$$I_2 = I_1 - I_3 = 15.1\ \text{A} - 21.3\ \text{A} = -6.2\ \text{A}$$

The minus sign indicates I_2 is out of phase with I_1.

The input and output power are

$$P_{in} = P_{out} = V_3 I_3 = (170\ \text{V})(21.3\ \text{A}) = \textbf{3.62 kVA}$$

The power in winding A is

$$P_A = V_2 I_1 = (70\ \text{V})(15.1\ \text{A}) = 1057\ \text{VA} = 1.057\ \text{kVA}$$

The power in winding B is

$$P_B = V_3 I_2 = (170\ \text{V})(6.2\ \text{A}) = 1054\ \text{VA} = 1.054\ \text{kVA}$$

Thus, the power rating required for each winding is less than the power that is delivered to the load. The slight difference in the calculated powers in windings A and B is due to rounding.

Related Problem   What happens to the kVA requirement if the load is changed to 4 Ω ?

Three-Phase Transformers

Three-phase power was introduced in Chapter 11 in relation to generators and motors. Three-phase transformers are widely used in power distribution systems. Three-phase is the most common way in which power is produced, transmitted, and used. Although widely used in commercial and industrial applications, three-phase power is generally not used in residential applications.

A three-phase transformer consists of three sets of primary and secondary windings. Each set is wound on one leg of an iron-core assembly. Basically, it is three single-phase transformers sharing a common core, as shown in Figure 14–35. It is possible (but more expensive) to connect three single-phase transformers together to achieve the same result.
◀ **FIGURE 14–35**

Three-phase transformer.

In a three-phase transformer, the three identical primary windings and the three identical secondary windings are connected in either of two ways, a delta (Δ) configuration or a wye (Y) configuration, to form a complete transformer unit. Delta and wye connections are shown in Figure 14–36.

▶ **FIGURE 14–36**

Delta and wye configurations.

(a)   (b)
In a three-phase transformer the possible combinations of delta and wye configurations are

1. *Delta-to-wye* (Δ-Y). The primary winding is a delta and the secondary winding is a wye. This common configuration is used in commercial and industrial applications.

2. *Delta-to-delta* (Δ-Δ). The primary and secondary windings are both connected in the delta configuration. This is also commonly used in industrial applications.

3. *Wye-to-delta* (Y-Δ). The primary winding is a wye and the secondary winding is a delta. This is used in high-voltage transmission applications.

4. *Wye-to-wye* (Y-Y). The primary and secondary windings are both connected in the wye configuration. It is used in high-voltage, low kVA applications.

The delta-to-wye connections are shown in Figure 14–37. The proper winding phasing must be observed when connecting the transformers. The windings in the delta must be + to −; the polarity for each winding in the wye must be the same at the center point.
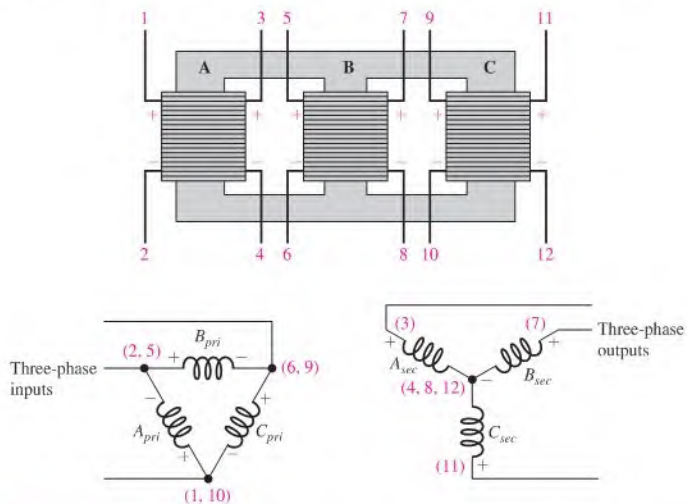

▲ **FIGURE 14–37**

Connections for a delta-to-wye transformer. The primary windings are designated A_{pri}, B_{pri}, and C_{pri}, the secondary windings are designated A_{sec}, B_{sec}, and C_{sec}. The numbers in parentheses correspond to the transformer leads.

The wye configuration has an advantage in that a neutral connection can be made at the center junction point. The delta configuration normally does not have a neutral. One exception is the special case for changing three-phase transmission-line voltage to single-phase power for residential use. In this case, a Y-Δ transformer with a center-tapped delta configuration is used, as shown in Figure 14–38. This configuration is referred to as a four-wire delta and can be used in applications where single phase is not available.

14–9 TROUBLESHOOTING

Transformers are reliable devices when they are operated within their specified range. Common failures in transformers are opens in either the primary or the secondary windings. One cause of such failures is the operation of the device under conditions that exceed its ratings. Normally, when a transformer fails, it is difficult to repair and therefore the simplest procedure is to replace it. A few transformer failures and the associated symptoms are covered in this section.

After completing this section, you should be able to

◆ **Troubleshoot transformers**

   ◆ Find an open primary or secondary winding

   ◆ Find a shorted or partially shorted primary or secondary winding

Open Primary Winding

When there is an open primary winding, there is no primary current and, therefore, no induced voltage or current in the secondary. This condition is illustrated in Figure 14–39(a), and the method of checking with an ohmmeter is shown in part (b).

(a) Conditions when the primary winding is open

Disconnect source from primary winding.
(b) Checking the primary winding with an ohmmeter
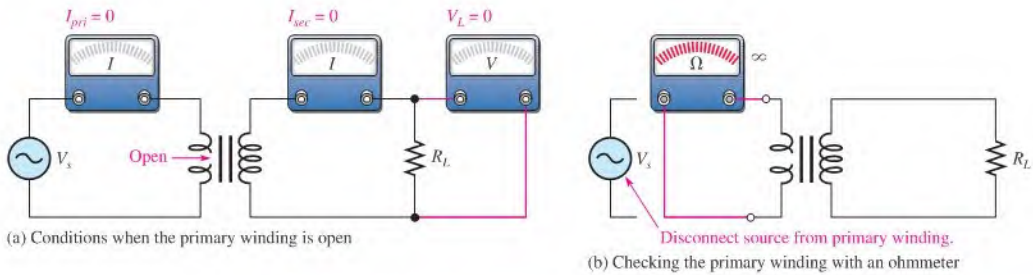

▲ **FIGURE 14–39**

Open primary winding.

Open Secondary Winding

When there is an open secondary winding, there is no current in the secondary circuit and, as a result, no voltage across the load. Also, an open secondary causes the primary current to be very small (there is only a small magnetizing current). In fact, the primary current may be practically zero. This condition is illustrated in Figure 14–40(a), and the ohmmeter check is shown in part (b).

(a) Conditions when the secondary winding is open

(b) Checking the secondary winding with the ohmmeter
▲ **FIGURE 14–40**

Open secondary winding.

Shorted or Partially Shorted Windings

Shorted windings are very rare and if they do occur are very difficult to find unless there is a visual indication or a large number of windings are shorted. A completely shorted primary winding will draw excessive current from the source; and unless there is a breaker or a fuse in the circuit, either the source or the transformer or both will burn out. A partial short in the primary winding can cause higher than normal or even excessive primary current.

In the case of a shorted or partially shorted secondary winding, there is an excessive primary current because of the low reflected resistance due to the short. Often, this excessive current will burn out the primary winding and result in an open. The short-circuit current in the secondary winding causes the load current to be zero (full short) or smaller than normal (partial short), as demonstrated in Figure 14–41(a) and (b). The ohmmeter check for this condition is shown in part (c).

CHECKUP

2. What is often the cause of transformer failure?

Application Activity

A common application of the transformer is in dc power supplies. The transformer is used to change and couple the ac line voltage into the power supply circuitry where it is converted to a dc voltage. You will troubleshoot four identical transformer-coupled dc power supplies

and, based on a series of measurements, determine the fault, if any, in each.

The transformer (T_1) in the power supply schematic of Figure 14–42 steps the 120 V from the ac outlet down to 10 V that can be converted by the diode bridge rectifier, filtered, and regulated to obtain a 6 V dc output. The diode rectifier changes the ac
◀ FIGURE 14–42

to a pulsating full-wave dc voltage that is smoothed by the capacitor filter C_1. The voltage regulator is an integrated circuit that takes the filtered voltage and provides a constant 6 V dc over a range of load values and line voltage variations. Additional filtering is provided by capacitor C_2. You will learn about these circuits in a later course. The circled numbers in Figure 14–42 correspond to measurement points on the power supply board.

The Power Supply

There are four identical power supply boards to troubleshoot like the one shown in Figure 14–43. The power line to the primary winding of transformer T_1 is protected by the fuse. The secondary winding is connected to the circuit board containing the rectifier, filter, and regulator. Measurement points are indicated by the circled numbers.

Measuring Voltages on Power Supply Board 1

After plugging the power supply into a standard wall outlet, an autoranging portable multimeter is used to measure the voltages. In an autoranging meter, the appropriate measurement range is automatically selected instead of being manually selected as in a standard multimeter.

1. Determine from the meter readings in Figure 14–44 whether or not the power supply is operating properly. If it is not,

isolate the problem to one of the following: the circuit board containing the rectifier, filter, and regulator; the transformer; the fuse; or the power source. The circled numbers on the meter inputs correspond to the numbered points on the power supply in Figure 14–43.

2. Determine from the meter readings for boards 2, 3, and 4 in Figure 14–45 whether or not each power supply is operating properly. If it is not, isolate the problem to one of the

following: the circuit board containing the rectifier, filter, and regulator; the transformer; the fuse; or the power source. Only the meter displays and corresponding measurement points are shown.

SUMMARY

♦ A normal transformer consists of two or more coils that are magnetically coupled on a common core.

♦ There is mutual inductance between two magnetically coupled coils.

♦ When current in one coil changes, voltage is induced in the other coil.

♦ The primary is the winding connected to the source, and the secondary is the winding connected to the load.

♦ The number of turns in the primary and the number of turns in the secondary determine the turns ratio.

♦ The relative polarities of the primary and secondary voltages are determined by the direction of the windings around the core.

♦ A step-up transformer has a turns ratio greater than 1.

♦ A step-down transformer has a turns ratio less than 1.

♦ A transformer cannot increase power.

♦ In an ideal transformer, the power from the source (input power) is equal to the power delivered to the load (output power).

♦ If the voltage is stepped up, the current is stepped down, and vice versa.

♦ A load across the secondary winding of a transformer appears to the source as a reflected load having a value dependent on the reciprocal of the turns ratio squared.

♦ Certain transformers can match a load resistance to a source resistance to achieve maximum power transfer to the load by selecting the proper turns ratio.

♦ A balun is a type of transformer used to convert a balanced line (such as twisted pair wiring) to an unbalanced line (such as coaxial cable) or vice versa.

♦ A typical transformer does not respond to dc.

♦ Conversion of electrical energy to heat in an actual transformer results from winding resistances, hysteresis loss in the core, eddy currents in the core, and flux leakage.

♦ Three-phase transformers are commonly used in power distribution applications.

INTRODUCTION

An *RC* circuit contains both resistance and capacitance. In this chapter, basic series and parallel *RC* circuits and their responses to sinusoidal ac voltages are presented. Series-parallel combinations are also analyzed. True, reactive, and apparent power in *RC* circuits are discussed and some basic *RC* circuit applications are introduced. Applications of *RC* circuits include filters, amplifier coupling, oscillators, and wave-shaping circuits. Troubleshooting is also covered in this chapter.

Section 15–1 provides an introduction to complex numbers, an important tool for the analysis of ac circuits. The complex number system is a way to mathematically express a phasor quantity and allows phasor quantities to be added, subtracted, multiplied, and divided. You will use complex numbers throughout Chapters 15, 16, and 17.

COVERAGE OPTIONS

Following Section 15–1, The Complex Number System, this chapter and Chapters 16 and 17 are each divided into four parts: Series Circuits, Parallel Circuits, Series-Parallel Circuits, and Special Topics. This organization facilitates either of two options to the coverage of reactive circuits in Chapters 15, 16, and 17.

Option 1   Study the complex number system first; then study all *RC* circuit topics (Chapter 15), followed by all *RL* circuit topics (Chapter 16), and then all *RLC* circuit topics (Chapter 17). Using this approach, you simply cover Chapters 15, 16, and 17 in sequence.

Option 2   After studying the complex number system, study *series* reactive circuits. Then study *parallel* reactive circuits, followed by *series-parallel* reactive circuits and finally *special topics*. Using this approach, you cover Section 15–1; then Part 1: Series Circuits in Chapters 15, 16, and 17; then Part 2: Parallel Circuits in Chapters 15, 16, and 17; then Part 3: Series-Parallel Circuits in Chapters 15, 16, and 17. Finally, Part 4: Special Topics can be covered in each of the chapters.

15–1 THE COMPLEX NUMBER SYSTEM

Complex numbers allow mathematical operations with phasor quantities and are useful in the analysis of ac circuits. With the complex number system, you can add, subtract, multiply, and divide quantities that have both magnitude and angle, such as sine waves and other ac circuit quantities. Most scientific calculators can perform operations with complex numbers. Consult your user's manual for the exact procedure.

After completing this section, you should be able to

◆ **Use complex numbers to express phasor quantities**

  ◆ Describe the complex plane

  ◆ Represent a point on the complex plane

  ◆ Discuss real and imaginary numbers

  ◆ Express phasor quantities in both rectangular and polar forms

  ◆ Convert between rectangular and polar forms

  ◆ Do arithmetic operations with complex numbers

Positive and Negative Numbers

Positive numbers are represented by points to the right of the origin on the horizontal axis of a graph, and negative numbers are represented by points to the left of the origin, as illustrated in Figure 15–1(a). Also, positive numbers are represented by points on the vertical axis above the origin, and negative numbers are represented by points below the origin, as shown in Figure 15–1(b).

◆ **FIGURE 15–1**

Graphic representation of positive and negative numbers.

(b)
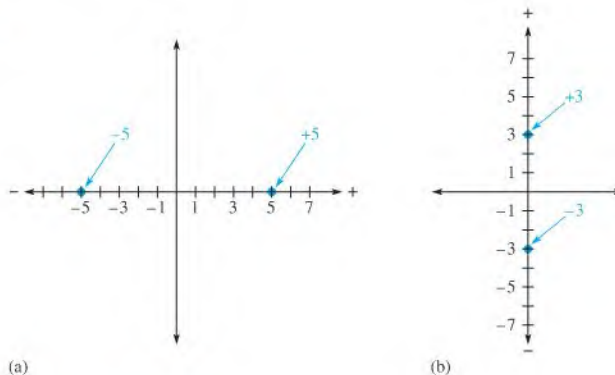

The Complex Plane

To distinguish between values on the horizontal axis and values on the vertical axis, a **complex plane** is used. In the complex plane, the horizontal axis is called the *real axis,* and the vertical axis is called the *imaginary axis,* as shown in Figure 15–2. In electrical circuit work, a $\pm j$ prefix is used to designate numbers that lie on the imaginary axis in order to distinguish them from numbers lying on the real axis. This prefix is known as the *j*

operator. In mathematics, an i is used instead of a j, but in electric circuits, the i can be confused with instantaneous current, so j is used.

Angular Position on the Complex Plane Angular positions are represented on the complex plane, as shown in Figure 15–3. The positive real axis represents zero degrees. Proceeding counterclockwise, the $+j$ axis represents 90°, the negative real axis represents 180°, the $-j$ axis is the 270° point, and, after a full rotation of 360°, you are back to the positive real axis. Notice that the plane is divided into four quadrants.
◄ FIGURE 15–3

Angles on the complex plane.

Representing a Point on the Complex Plane A point located on the complex plane is classified as real, imaginary ($\pm j$), or a combination of the two. For example, a point located 4 units from the origin on the positive real axis is the positive **real number**, $+4$, as shown in Figure 15–4(a). A point 2 units from the origin on the negative real

axis is the negative real number, −2, as shown in part (b). A point on the +*j* axis 6 units from the origin, as shown in part (c), is the positive **imaginary number**, +*j*6. Finally, a point 5 units along the −*j* axis is the negative imaginary number, −*j*5, as shown in part (d).

When a point lies not on any axis but somewhere in one of the four quadrants, it is a complex number and is defined by its coordinates. For example, in Figure 15–5, the point located in the first quadrant has a real value of +4 and a *j* value of +*j*4 and is expressed as +4, +*j*4. The point located in the second quadrant has coordinates −3 and +*j*2. The point located in the third quadrant has coordinates −3 and −*j*5. The point located in the fourth quadrant has coordinates of +6 and −*j*4.

Coordinate points on the complex plane.
EXAMPLE 15–1

    E: $-1, -j9$ F: $-5, -j5$ G: $-6, j5$ H: $-2, j11$

Related Problem   In what quadrant is each of the following points located?

    (a) $+2.5, +j1$ **(b)** $7, -j5$ **(c)** $-10, -j5$ **(d)** $-11, +j6.8$

*Answers are at the end of the chapter.

Value of *j*

If you multiply the positive real value of $+2$ by j, the result is $+j2$. This multiplication has effectively moved the $+2$ through a $90°$ angle to the $+j$ axis. Similarly, multiplying $+2$ by $-j$ rotates it $-90°$ to the $-j$ axis. Thus, j is considered a rotational operator.

Mathematically, the j operator has a value of $\sqrt{-1}$. If $+j2$ is multiplied by j, you get

$$j^2 2 = (\sqrt{-1})(\sqrt{-1})(2) = (-1)(2) = -2$$

This calculation effectively places the value on the negative real axis. Therefore, multiplying a positive real number by j^2 converts it to a negative real number, which, in effect, is a rotation of $180°$ on the complex plane. This operation is illustrated in Figure 15–8.
◄ **FIGURE 15–8**

Effect of the *j* operator on location of a number on the complex plane.

Rectangular and Polar Forms

Rectangular and polar are two forms of complex numbers that are used to represent phasor quantities. Each has certain advantages when used in circuit analysis, depending on the particular application. A phasor quantity contains both *magnitude* and angular position or *phase*. In this text, italic letters such as V and I are used to represent magnitude only, and boldfaced nonitalic letters such as **V** and **I** are used to represent complete phasor quantities.

Rectangular Form A phasor quantity is represented in **rectangular form** by the algebraic sum of the real value (A) of the coordinate and the j value (B) of the coordinate, expressed in the following general form:

$$A + jB$$

Examples of phasor quantities are $1 + j2$, $5 - j3$, $-4 + j4$, and $-2 - j6$, which are shown on the complex plane in Figure 15–9. As you can see, the rectangular coordinates describe the phasor in terms of its values projected onto the real axis and the j axis. An "arrow" drawn from the origin to the coordinate point in the complex plane represents graphically the phasor quantity.

▶ **FIGURE 15–9**

Examples of phasors specified by rectangular coordinates.
Polar Form Phasor quantities can also be expressed in **polar form**, which consists of the phasor magnitude (C) and the angular position relative to the positive real axis (θ), expressed in the following general form:

$$C\angle\pm\theta$$

Examples are $2\angle45°$, $5\angle120°$, $4\angle-110°$, and $8\angle-30°$. The first number is the magnitude, and the symbol $\angle$ precedes the value of the angle. Figure 15–10 shows these phasors on the complex plane. The length of the phasor, of course, represents the magnitude of the

▶ **FIGURE 15–10**

Examples of phasors specified by polar values.
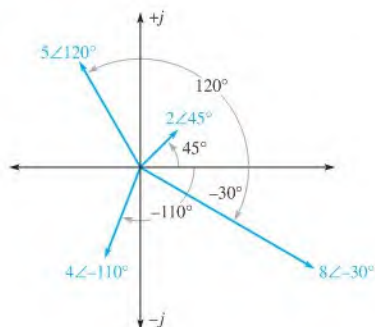

quantity. Keep in mind that for every phasor expressed in polar form, there is also an equivalent expression in rectangular form.

Conversion from Rectangular to Polar Form   A phasor can exist in any of the four quadrants of the complex plane, as indicated in Figure 15–11. The phase angle θ in each case is measured relative to the positive real axis ($0°$), and ϕ (phi) is the angle in the 2nd and 3rd quadrants relative to the negative real axis, as shown.
▲ **FIGURE 15–11**

All possible phasor quadrant locations.

The first step to convert from rectangular form to polar form is to determine the magnitude of the phasor. A phasor can be visualized as forming a right triangle in the complex plane, as indicated in Figure 15–12, for each quadrant location. The horizontal side of the triangle is the real value, A, and the vertical side is the j value, B. The hypotenuse of the triangle is the length of the phasor, C, representing the magnitude, and can be expressed, using the Pythagorean theorem, as

$$C = \sqrt{A^2 + B^2}$$

Next, the angle θ indicated in parts (a) and (d) of Figure 15–12 is expressed as an inverse tangent function.

$$\theta = \tan^{-1}\left(\frac{\pm B}{A}\right)$$

The angle θ indicated in parts (b) and (c) of Figure 15–12 is

$$\theta = \pm 180° \mp \phi$$

which includes both conditions as indicated by the dual signs.

$$\theta = \pm 180° \mp \tan^{-1}\left(\frac{B}{A}\right)$$
▲ **FIGURE 15–12**

Right angle relationships in the complex plane.

In each case the appropriate signs must be used in the calculation.

The general formula for converting from rectangular to polar is

Equation 15–3
$$\pm A \pm jB = C\angle \pm \theta$$

Example 15–2 illustrates the conversion procedure.

EXAMPLE 15–2

Convert the following complex numbers from rectangular form to polar form by determining the magnitude and angle:

(a) $8 + j6$ **(b)** $10 - j5$

Solution **(a)** The magnitude of the phasor represented by $8 + j6$ is

$$C = \sqrt{A^2 + B^2} = \sqrt{8^2 + 6^2} = \sqrt{100} = 10$$

Since the phasor is in the first quadrant, use Equation 15–2. The angle is

$$\theta = \tan^{-1}\left(\frac{\pm B}{A}\right) = \tan^{-1}\left(\frac{6}{8}\right) = 36.9°$$

θ is the angle relative to the positive real axis. The polar form of $8 + j6$ is

$$C\angle\theta = \mathbf{10\angle 36.9°}$$

(b) The magnitude of the phasor represented by $10 - j5$ is

$$C = \sqrt{10^2 + (-5)^2} = \sqrt{125} = 11.2$$

Since the phasor is in the fourth quadrant, use Equation 15–2. The angle is

$$\theta = \tan^{-1}\left(\frac{-5}{10}\right) = -26.6°$$

θ is the angle relative to the positive real axis. The polar form of $10 - j5$ is

$$C\angle\theta = \mathbf{11.2\angle -26.6°}$$

Related Problem Convert $18 + j23$ to polar form.

Conversion from Polar to Rectangular Form The polar form gives the magnitude and angle of a phasor quantity, as indicated in Figure 15–13.

▶ **FIGURE 15–13**

Polar components of a phasor.
To get the rectangular form, you must find sides A and B of the triangle, using the rules from trigonometry stated below:

Equation 15–4
$$A = C\cos\theta$$

Equation 15–5
$$B = C\sin\theta$$

The polar-to-rectangular conversion formula is

Equation 15–6
$$C\angle\theta = A + jB$$

The following example demonstrates this conversion.

EXAMPLE 15–3

Convert the following polar quantities to rectangular form:

(a) $10\angle 30°$ **(b)** $200\angle -45°$

Solution   **(a)** The real part of the phasor represented by $10\angle 30°$ is

$$A = C\cos\theta = 10\cos 30° = 10(0.866) = 8.66$$

The *j* part of this phasor is

$$jB = jC\sin\theta = j10\sin 30° = j10(0.5) = j5$$

The rectangular form of $10\angle 30°$ is

$$A + jB = \mathbf{8.66 + j5}$$

(b) The real part of the phasor represented by $200\angle -45°$ is

$$A = 200\cos(-45°) = 200(0.707) = 141$$

The *j* part is

$$jB = j200\sin(-45°) = j200(-0.707) = -j141$$

The rectangular form of $200\angle -45°$ is

$$A + jB = \mathbf{141 - j141}$$

Related Problem   Convert $78\angle -26°$ to rectangular form.

Mathematical Operations

Addition   Complex numbers must be in rectangular form in order to add them. The rule is

Add the real parts of each complex number to get the real part of the sum. Then add the *j* parts of each complex number to get the *j* part of the sum.

EXAMPLE 15–4

Add the following sets of complex numbers:

(a) $8 + j5$ and $2 + j1$ **(b)** $20 - j10$ and $12 + j6$

Solution   **(a)** $(8 + j5) + (2 + j1) = (8 + 2) + j(5 + 1) = \mathbf{10 + j6}$

(b) $(20 - j10) + (12 + j6) = (20 + 12) + j(-10 + 6) = 32 + j(-4) = \mathbf{32 - j4}$

Related Problem   Add $5 - j11$ and $-6 + j3$.

Subtraction   As in addition, the numbers must be in rectangular form to be subtracted. The rule is

Subtract the real parts of the numbers to get the real part of the difference. Then subtract the *j* parts of the numbers to get the *j* part of the difference.

EXAMPLE 15–5

Perform the following subtractions:

(a) Subtract $1 + j2$ from $3 + j4$.

(b) Subtract $10 - j8$ from $15 + j15$.

Solution   (a) $(3 + j4) - (1 + j2) = (3 - 1) + j(4 - 2) = $ **$2 + j2$**

(b) $(15 + j15) - (10 - j8) = (15 - 10) + j[15 - (-8)] = $ **$5 + j23$**

Related Problem   Subtract $3.5 - j4.5$ from $-10 - j9$.

Multiplication   Multiplication of two complex numbers in rectangular form is accomplished by multiplying, in turn, each term in one number by both terms in the other number and then combining the resulting real terms and the resulting j terms (recall that $j \times j = -1$). As an example,

$$(5 + j3)(2 - j4) = 10 - j20 + j6 + 12 = 22 - j14$$

Multiplication of two complex numbers is easier when both numbers are in polar form, so it is best to convert to polar form before multiplying. The rule is

Multiply the magnitudes, and add the angles algebraically.

EXAMPLE 15–6

Perform the following multiplications:

(a) $10\angle 45°$ times $5\angle 20°$ (b) $2\angle 60°$ times $4\angle -30°$

Solution   (a) $(10\angle 45°)(5\angle 20°) = (10)(5)\angle(45° + 20°) = $ **$50\angle 65°$**

(b) $(2\angle 60°)(4\angle -30°) = (2)(4)\angle[60° + (-30°)] = $ **$8\angle 30°$**

Related Problem   Multiply $50\angle 10°$ times $30\angle -60°$.

Division   Division of two complex numbers in rectangular form is accomplished by multiplying both the numerator and the denominator by the **complex conjugate** of the denominator and then combining terms and simplifying. The complex conjugate of a number is found by changing the sign of the j term. As an example,

$$\frac{10 + j5}{2 + j4} = \frac{(10 + j5)(2 - j4)}{(2 + j4)(2 - j4)} = \frac{20 - j30 + 20}{4 + 16} = \frac{40 - j30}{20} = 2 - j1.5$$

Like multiplication, division is easier when the numbers are in polar form, so it is best to convert to polar form before dividing. The rule is

Divide the magnitude of the numerator by the magnitude of the denominator to get the magnitude of the quotient. Then subtract the denominator angle from the numerator angle to get the angle of the quotient.

EXAMPLE 15–7

Perform the following divisions:

(a) Divide $100\angle 50°$ by $25\angle 20°$.

(b) Divide $15\angle 10°$ by $3\angle -30°$.

Solution   **(a)** $\dfrac{100\angle 50°}{25\angle 20°} = \left(\dfrac{100}{25}\right)\angle(50° - 20°) = \mathbf{4\angle 30°}$

(b) $\dfrac{15\angle 10°}{3\angle -30°} = \left(\dfrac{15}{3}\right)\angle[10° - (-30°)] = \mathbf{5\angle 40°}$

Related Problem   Divide $24\angle -30°$ by $6\angle 12°$.

15–2 SINUSOIDAL RESPONSE OF SERIES *RC* CIRCUITS

When a sinusoidal voltage is applied to a series *RC* circuit, each resulting voltage drop and the current in the circuit are also sinusoidal and have the same frequency as the applied voltage. The capacitance causes a phase shift between the voltage and current that depends on the relative values of the resistance and the capacitive reactance.

After completing this section, you should be able to

- ◆ **Describe the relationship between current and voltage in a series *RC* circuit**
  - ◆ Discuss voltage and current waveforms
  - ◆ Discuss phase shift

As shown in Figure 15–14, the resistor voltage (V_R), the capacitor voltage (V_C), and the current (*I*) are all sine waves with the frequency of the source. Phase shifts are introduced because of the capacitance. The resistor voltage and current *lead* the source voltage, and the capacitor voltage *lags* the source voltage. The phase angle between the current and the capacitor voltage is always 90°. These generalized phase relationships are indicated in Figure 15–14.

▶ **FIGURE 15–14**

Illustration of sinusoidal response with general phase relationships of V_R, V_C, and *I* relative to the source voltage. V_R and *I* are in phase while V_R and V_C are 90° out of phase.
The amplitudes and the phase relationships of the voltages and current depend on the values of the resistance and the **capacitive reactance**. When a circuit is purely resistive, the phase angle between the applied (source) voltage and the total current is zero. When a circuit is purely capacitive, the phase angle between the applied voltage and the total current is 90°, with the current leading the voltage. When there is a combination of both resistance and capacitive reactance in a circuit, the phase angle between the applied voltage and the total current is somewhere between 0° and 90°, depending on the relative values of the resistance and the capacitive reactance.

1. A 60 Hz sinusoidal voltage is applied to an *RC* circuit. What is the frequency of the capacitor voltage? What is the frequency of the current?

2. What causes the phase shift between V_s and I in a series *RC* circuit?

3. When the resistance in a series *RC* circuit is greater than the capacitive reactance, is the phase angle between the applied voltage and the total current closer to 0° or to 90°?

15–3 IMPEDANCE OF SERIES *RC* CIRCUITS

Impedance is the total opposition to sinusoidal current. Its unit is the ohm. The impedance of a series *RC* circuit consists of resistance and capacitive reactance. It causes a phase difference between the total current and the source voltage. Therefore, the impedance consists of a magnitude component and a phase angle component.

After completing this section, you should be able to

◆ **Determine the impedance of a series *RC* circuit**

  ◆ Define *impedance*

  ◆ Express capacitive reactance in complex form

  ◆ Express total impedance in complex form

  ◆ Draw an impedance triangle

  ◆ Calculate impedance magnitude and the phase angle

In a purely resistive circuit, the impedance is simply equal to the total resistance. In a purely capacitive circuit, the impedance is equal to the total capacitive reactance. The impedance of a series *RC* circuit is determined by both the resistance and the capacitive reactance. These cases are illustrated in Figure 15–15. The magnitude of the impedance is symbolized by *Z*.

(a) $Z = R$ (b) $Z = X_C$ (c) Z includes both R and X_C
▲ **FIGURE 15–15**

Three cases of impedance.

Capacitive reactance is a phasor quantity and is expressed as a complex number in rectangular form as

$$\mathbf{X}_C = -jX_C$$

where boldface $\mathbf{X}_C$ designates a phasor quantity (representing both magnitude and angle) and X_C is just the magnitude.

In the series RC circuit of Figure 15–16, the total impedance is the phasor sum of R and $-jX_C$ and is expressed as

$$\mathbf{Z} = R - jX_C$$
▲ FIGURE 15–16

Impedance in a series RC circuit.

In ac analysis, both R and X_C are as shown in the phasor diagram of Figure 15–17(a), with X_C appearing at a $-90°$ angle with respect to R. This relationship comes from the fact that the capacitor voltage in a series RC circuit lags the current, and thus the resistor voltage, by 90°. Since $\mathbf{Z}$ is the phasor sum of R and $-jX_C$, its phasor representation is as shown in Figure 15–17(b). A repositioning of the phasors, as shown in part (c), forms a right triangle called the *impedance triangle*. The length of each phasor represents the magnitude in ohms, and the angle θ is the phase angle of the RC circuit and represents the phase difference between the applied voltage and the current.
▲ FIGURE 15–17

Development of the impedance triangle for a series RC circuit.

From right-angle trigonometry (Pythagorean theorem), the magnitude (length) of the impedance can be expressed in terms of the resistance and reactance as

$$Z = \sqrt{R^2 + X_C^2}$$

The italic letter Z represents the magnitude of the phasor quantity $\mathbf{Z}$ and is expressed in ohms.

The phase angle, θ, is expressed as

$$\theta = -\tan^{-1}\left(\frac{X_C}{R}\right)$$

The symbol $\tan^{-1}$ stands for inverse tangent. You can find the $\tan^{-1}$ value on your calculator. Combining the magnitude and angle, the phasor expression for impedance in polar form is

$$\mathbf{Z} = \sqrt{R^2 + X_C^2}\angle-\tan^{-1}\left(\frac{X_C}{R}\right)$$

EXAMPLE 15–8

For each circuit in Figure 15–18, write the phasor expression for the impedance in both rectangular form and polar form.
▲ **FIGURE 15–18**

Solution For the circuit in Figure 15–18(a), the impedance is

$$\mathbf{Z} = R - j0 = R = \mathbf{56\ \Omega} \qquad \text{in rectangular form } (X_C = 0)$$

$$\mathbf{Z} = R\angle 0° = \mathbf{56\angle 0°\ \Omega} \qquad \text{in polar form}$$

The impedance is simply the resistance, and the phase angle is zero because pure resistance does not cause a phase shift between the voltage and current.

For the circuit in Figure 15–18(b), the impedance is

$$\mathbf{Z} = 0 - jX_C = \mathbf{-j100\ \Omega} \qquad \text{in rectangular form } (R = 0)$$

$$\mathbf{Z} = X_C\angle -90° = \mathbf{100\angle -90°\ \Omega} \qquad \text{in polar form}$$

The impedance is simply the capacitive reactance, and the phase angle is $-90°$ because the capacitance causes the current to lead the voltage by 90°.

For the circuit in Figure 15–18(c), the impedance in rectangular form is

$$\mathbf{Z} = R - jX_C = \mathbf{56\ \Omega\ - j100\ \Omega}$$

The impedance in polar form is

$$\mathbf{Z} = \sqrt{R^2 + X_C^2}\angle -\tan^{-1}\left(\frac{X_C}{R}\right)$$

$$= \sqrt{(56\ \Omega)^2 + (100\ \Omega)^2}\angle -\tan^{-1}\left(\frac{100\ \Omega}{56\ \Omega}\right) = \mathbf{115\angle -60.8°\ \Omega}$$

In this case, the impedance is the phasor sum of the resistance and the capacitive reactance. The phase angle is fixed by the relative values of X_C and R. Rectangular to polar conversion can be done on a calculator (refer to your user's manual).

Related Problem Use your calculator to convert the impedance in Figure 15–18(c) from rectangular to polar form. Draw the impedance phasor diagram.

15–4 ANALYSIS OF SERIES *RC* CIRCUITS

Ohm's law and Kirchhoff's voltage law are used in the analysis of series *RC* circuits to determine voltage, currents and impedance. Also, in this section *RC* lead and lag circuits are examined.

After completing this section, you should be able to

◆ **Analyze a series *RC* circuit**

  ◆ Apply Ohm's law and Kirchhoff's voltage law to series *RC* circuits

  ◆ Express the voltages and current as phasor quantities

  ◆ Show how impedance and phase angle vary with frequency

  ◆ Analyze the *RC* lag circuit

  ◆ Analyze the *RC* lead circuit

Ohm's Law

The application of Ohm's law to series *RC* circuits involves the use of the phasor quantities of **Z**, **V**, and **I**. Keep in mind that the use of boldface nonitalic letters indicates phasor quantities where both magnitude and angle are included. The three equivalent forms of Ohm's law are as follows:

Equation 15–9
$$\mathbf{V} = \mathbf{IZ}$$

Equation 15–10
$$\mathbf{I} = \frac{\mathbf{V}}{\mathbf{Z}}$$

Equation 15–11
$$\mathbf{Z} = \frac{\mathbf{V}}{\mathbf{I}}$$

Recall that multiplication and division are most easily accomplished with the polar forms. Since Ohm's law calculations involve multiplications and divisions, you should express the voltage, current, and impedance in polar form. The following two examples show the relationship between the source voltage and source current. In Example 15–9, the current is the reference and in Example 15–10, the voltage is the reference. Notice that the reference is drawn along the x-axis in both cases.

EXAMPLE 15–9

The current in Figure 15–19 is expressed in polar form as $\mathbf{I} = 0.2\angle0°$ mA. Determine the source voltage expressed in polar form, and draw a phasor diagram showing the relation between source voltage and current.

▶ **FIGURE 15–19**
Solution   The magnitude of the capacitive reactance is

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi (1000\,\text{Hz})(0.01\,\mu\text{F})} = 15.9\,\text{k}\Omega$$

The total impedance in rectangular form is

$$\mathbf{Z} = R - jX_C = 10\,\text{k}\Omega - j15.9\,\text{k}\Omega$$

Converting to polar form yields

$$\mathbf{Z} = \sqrt{R^2 + X_C^2}\angle -\tan^{-1}\left(\frac{X_C}{R}\right)$$

$$= \sqrt{(10\,\text{k}\Omega)^2 + (15.9\,\text{k}\Omega)^2}\angle -\tan^{-1}\left(\frac{15.9\,\text{k}\Omega}{10\,\text{k}\Omega}\right) = 18.8\angle -57.8^\circ\,\text{k}\Omega$$

Use Ohm's law to determine the source voltage.

$$\mathbf{V}_s = \mathbf{IZ} = (0.2\angle 0^\circ\,\text{mA})(18.8\angle -57.8^\circ\,\text{k}\Omega) = \mathbf{3.76}\angle -\mathbf{57.8^\circ}\,\text{V}$$

The magnitude of the source voltage is 3.76 V at an angle of -57.8° with respect to the current; that is, the voltage lags the current by 57.8°, as shown in the phasor diagram of Figure 15–20.

▶ **FIGURE 15–20**
Related Problem   Determine $\mathbf{V}_s$ in Figure 15–19 if $f = 2\,\text{kHz}$ and $\mathbf{I} = 0.2\angle 0^\circ\,\text{A}$.

EXAMPLE 15–10   Determine the current in the circuit of Figure 15–21, and draw a phasor diagram showing the relation between source voltage and current.

▶ **FIGURE 15–21**
Solution   The magnitude of the capacitive reactance is

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi (1.5\,\text{kHz})(0.022\,\mu\text{F})} = 4.82\,\text{k}\Omega$$

The total impedance in rectangular form is

$$\mathbf{Z} = R - jX_C = 2.2\,\text{k}\Omega - j4.82\,\text{k}\Omega$$

Converting to polar form yields

$$\mathbf{Z} = \sqrt{R^2 + X_C^2}\angle -\tan^{-1}\left(\frac{X_C}{R}\right)$$

$$= \sqrt{(2.2\,\text{k}\Omega)^2 + (4.82\,\text{k}\Omega)^2}\angle -\tan^{-1}\left(\frac{4.82\,\text{k}\Omega}{2.2\,\text{k}\Omega}\right) = 5.30\angle -65.5°\,\text{k}\Omega$$

Use Ohm's law to determine the current.

$$\mathbf{I} = \frac{\mathbf{V}}{\mathbf{Z}} = \frac{10\angle 0°\,\text{V}}{5.30\angle -65.5°\,\text{k}\Omega} = \mathbf{1.89\angle 65.5°\,mA}$$

The magnitude of the current is 1.89 mA. The positive phase angle of 65.5° indicates that the current leads the voltage by that amount, as shown in the phasor diagram of Figure 15–22.

▶ **FIGURE 15–22**

Phase Relationships of Current and Voltages

In a series RC circuit, the current is the same through both the resistor and the capacitor. Thus, the resistor voltage is in phase with the current, and the capacitor voltage lags the current by 90°. Therefore, there is a phase difference of 90° between the resistor voltage, V_R, and the capacitor voltage, V_C, as shown in the waveform diagram of Figure 15–23.

▶ **FIGURE 15–23**

Phase relation of voltages and current in a series RC circuit.
I leads V_C by 90°.
V_R and I are in phase.
Amplitudes depend on the particular circuit.

From Kirchhoff's voltage law, the sum of the voltage drops must equal the applied voltage. However, since V_R and V_C are not in phase with each other, they must be added as phasor quantities, with V_C lagging V_R by 90°, as shown in Figure 15–24(a). As shown in
Voltage phasor diagram for a series *RC* circuit.

Figure 15–24(b), $\mathbf{V}_s$ is the phasor sum of V_R and V_C, as expressed in rectangular form in the following equation:

$$\mathbf{V}_s = V_R - jV_C$$

Equation 15–12

This equation can be expressed in polar form as

$$\mathbf{V}_s = \sqrt{V_R^2 + V_C^2}\angle-\tan^{-1}\left(\frac{V_C}{V_R}\right)$$

Equation 15–13

where the magnitude of the source voltage is

$$V_s = \sqrt{V_R^2 + V_C^2}$$

and the phase angle between the resistor voltage and the source voltage is

$$\theta = -\tan^{-1}\left(\frac{V_C}{V_R}\right)$$

Since the resistor voltage and the current are in phase, θ also represents the phase angle between the source voltage and the current. Figure 15–25 shows a complete voltage and current phasor diagram that represents the waveform diagram of Figure 15–23.
Variation of Impedance and Phase Angle with Frequency

As you know, capacitive reactance varies inversely with frequency. Since $Z = \sqrt{R^2 + X_C^2}$, you can see that when X_C increases, the entire term under the square root sign increases and thus the magnitude of the total impedance also increases; and when X_C decreases, the magnitude of the total impedance also decreases. Therefore, *in a series RC circuit, Z is inversely dependent on frequency.*

Figure 15–26 illustrates how the voltages and current in a series *RC* circuit vary as the frequency increases or decreases, with the source voltage held at a constant value. In part (a), as the frequency is increased, X_C decreases; so less voltage is dropped across the capacitor. Also, Z decreases as X_C decreases, causing the current to increase. An increase in the current causes more voltage across R.

In Figure 15–26(b), as the frequency is decreased, X_C increases; so more voltage is dropped across the capacitor. Also, Z increases as X_C increases, causing the current to decrease. A decrease in the current causes less voltage across R.

Changes in Z and X_C can be observed as shown in Figure 15–27. As the frequency increases, the voltage across Z remains constant because V_s is constant. Also, the voltage across C decreases. The increasing current indicates that Z is decreasing. It does so because of the inverse relationship stated in Ohm's law ($Z = V_Z/I$). The increasing current also indicates that X_C is decreasing ($X_C = V_C/I$). The decrease in V_C corresponds to the decrease in X_C.

Since X_C is the factor that introduces the phase angle in a series *RC* circuit, a change in X_C produces a change in the phase angle. As the frequency is increased, X_C becomes

Voltage and current phasor diagram for the waveforms in Figure 15–23.

(a) As frequency is increased, Z decreases as X_C decreases, causing I and V_R to increase and V_C to decrease.

(b) As frequency is decreased, Z increases as X_C increases, causing I and V_R to decrease and V_C to increase.
▲ **FIGURE 15–26**

An illustration of how the variation of impedance affects the voltages and current as the source frequency is varied. The source voltage is held at a constant amplitude.

By watching these two meters, you can see what Z is doing: I is increasing and V_Z is constant. Thus, Z is decreasing.

$Z = \dfrac{V_Z}{I}$

By watching these two meters, you can see what X_C is doing: I is increasing and V_C is decreasing. Thus, X_C is decreasing.

$X_C = \dfrac{V_C}{I}$

Frequency is increasing.

V_s is constant.
▲ **FIGURE 15–27**

An illustration of how Z and X_C change with frequency.

smaller, and thus the phase angle decreases. As the frequency is decreased, X_C becomes larger, and thus the phase angle increases. The angle between V_s and V_R is the phase angle of the circuit because I is in phase with V_R. By measuring the phase of V_R, you are effectively measuring the phase of I. An oscilloscope is normally used to observe the phase angle by measuring the phase angle between V_s and one of the component voltages.

Figure 15–28 uses the impedance triangle to illustrate the variations in X_C, Z, and θ as the frequency changes. Of course, R remains constant. The main point is that because X_C varies inversely with the frequency, so also do the magnitude of the total impedance and the phase angle. Example 15–11 illustrates this.
▲ FIGURE 15–28

As the frequency increases, X_C decreases, Z decreases, and θ decreases. Each value of frequency can be visualized as forming a different impedance triangle.

EXAMPLE 15–11

For the series *RC* circuit in Figure 15–29, determine the magnitude of the total impedance and the phase angle for each of the following values of input frequency:

(a) 10 kHz   **(b)** 20 kHz   **(c)** 30 kHz

▶ **FIGURE 15–29**
Solution   **(a)** For $f = 10$ kHz,

$$X_C = \frac{1}{2\pi f C} = \frac{1}{2\pi(10\text{ kHz})(0.01\ \mu\text{F})} = 1.59\text{ k}\Omega$$

$$\mathbf{Z} = \sqrt{R^2 + X_C^2}\angle -\tan^{-1}\left(\frac{X_C}{R}\right)$$

$$= \sqrt{(1.0\text{ k}\Omega)^2 + (1.59\text{ k}\Omega)^2}\angle -\tan^{-1}\left(\frac{1.59\text{ k}\Omega}{1.0\text{ k}\Omega}\right) = 1.88\angle -57.8°\text{ k}\Omega$$

Thus, $Z = \mathbf{1.88\text{ k}\Omega}$ and $\theta = \mathbf{-57.8°}$.

(b) For $f = 20$ kHz,

$$X_C = \frac{1}{2\pi(20\text{ kHz})(0.01\ \mu\text{F})} = 796\ \Omega$$

$$\mathbf{Z} = \sqrt{(1.0\text{ k}\Omega)^2 + (796\ \Omega)^2}\angle -\tan^{-1}\left(\frac{796\ \Omega}{1.0\text{ k}\Omega}\right) = 1.28\angle -38.5°\text{ k}\Omega$$

Thus, $Z = \mathbf{1.28\text{ k}\Omega}$ and $\theta = \mathbf{-38.5°}$.

(c) For $f = 30\,\text{kHz}$,

$$X_C = \frac{1}{2\pi(30\,\text{kHz})(0.01\,\mu\text{F})} = 531\,\Omega$$

$$\mathbf{Z} = \sqrt{(1.0\,\text{k}\Omega)^2 + (531\,\Omega)^2}\angle-\tan^{-1}\left(\frac{531\,\Omega}{1.0\,\text{k}\Omega}\right) = 1.13\angle-28.0°\,\text{k}\Omega$$

Thus, $Z = \mathbf{1.13\,k\Omega}$ and $\theta = \mathbf{-28.0°}$.

Notice that as the frequency increases, X_C, Z, and θ decrease.

The *RC* Lag Circuit

An ***RC* lag circuit** is a phase shift circuit in which the output voltage lags the input voltage by a specified amount. Figure 15–30(a) shows a series *RC* circuit with the output voltage taken across the capacitor. The source voltage is the input, V_{in}. As you know, θ, the phase angle between the current and the input voltage, is also the phase angle between the resistor voltage and the input voltage because V_R and I are in phase with each other.

(a) A basic *RC* lag circuit

(b) Phasor voltage diagram showing the phase lag between V_{in} and V_{out}

(c) Input and output voltage waveforms
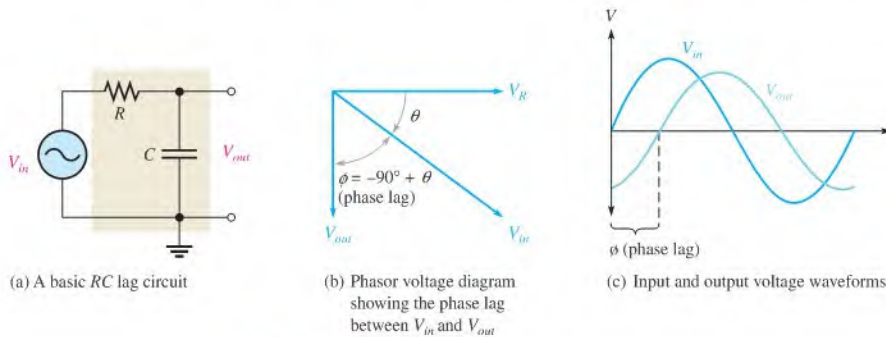

▲ **FIGURE 15–30**

RC lag circuit ($V_{out} = V_C$).

Since V_C lags V_R by 90°, the phase angle between the capacitor voltage and the input voltage is the difference between $-90°$ and θ, as shown in Figure 15–30(b). The capacitor voltage is the output, and it lags the input, thus creating a basic lag circuit.

The input and output voltage waveforms of the lag circuit are shown in Figure 15–30(c). The amount of phase difference, designated ϕ, between the input and the output is dependent on the relative sizes of the capacitive reactance and the resistance, as is the magnitude of the output voltage.

Phase Difference Between Input and Output   As already established, θ is the phase angle between I and V_{in}. The angle between V_{out} and V_{in} is designated ϕ (phi) and is developed as follows.

The polar expressions for the input voltage and the current are $V_{in}\angle0°$ and $I\angle\theta$, respectively. The output voltage in polar form is

$$\mathbf{V}_{out} = (I\angle\theta)(X_C\angle-90°) = IX_C\angle(-90° + \theta)$$

The preceding equation states that the output voltage is at an angle of $-90° + \theta$ with respect to the input voltage. Since $\theta = -\tan^{-1}(X_C/R)$, the angle ϕ between the input and output is

$$\phi = -90° + \tan^{-1}\left(\frac{X_C}{R}\right)$$

Equivalently, this angle can be expressed as

$$\phi = -\tan^{-1}\left(\frac{R}{X_C}\right)$$

This angle is always negative, indicating that the output voltage lags the input voltage, as shown in Figure 15–31.

　　For the lag circuit in Figure 15–32(b), first determine the capacitive reactance.

$$\phi = -\tan^{-1}\left(\frac{R}{X_C}\right) = -\tan^{-1}\left(\frac{680\,\Omega}{1.59\,k\Omega}\right) = \mathbf{-23.2°}$$

The output lags the input by 23.2°.

Magnitude of the Output Voltage   To evaluate the output voltage in terms of its magnitude, visualize the *RC* lag circuit as a voltage divider. A portion of the total input voltage is dropped across the resistor and a portion across the capacitor. Because the output voltage is the voltage across the capacitor, it can be calculated using either Ohm's law ($V_{out} = IX_C$) or the voltage divider formula.

The *RC* Lead Circuit

An **RC lead circuit** is a phase shift circuit in which the output voltage leads the input voltage by a specified amount. When the output of a series *RC* circuit is taken across the resistor rather than across the capacitor, as shown in Figure 15–34(a), it becomes a lead circuit.

(b) Phasor voltage diagram showing the phase lead between V_{in} and V_{out}

(c) Input and output voltage waveforms
▲ FIGURE 15–34

RC lead circuit ($V_{out} = V_R$).

Phase Difference Between Input and Output   In a series *RC* circuit, the current leads the input voltage. Also, as you know, the resistor voltage is in phase with the current. Since the output voltage is taken across the resistor, the output leads the input, as indicated by the phasor diagram in Figure 15–34(b). The waveforms are shown in Figure 15–34(c).

As in the lag circuit, the amount of phase difference between the input and output and the magnitude of the output voltage in the lead circuit are dependent on the relative values of the resistance and the capacitive reactance. When the input voltage is assigned a reference angle of 0°, the angle of the output voltage is the same as θ (the angle between total current and applied voltage) because the resistor voltage (output) and the current are in phase with each other. Therefore, since $\phi = \theta$ in this case, the expression is

$$\phi = \tan^{-1}\left(\frac{X_C}{R}\right)$$

Equation 15–16

This angle is positive because the output leads the input.

EXAMPLE 15–14

Calculate the output phase angle for each circuit in Figure 15–35.

(b)
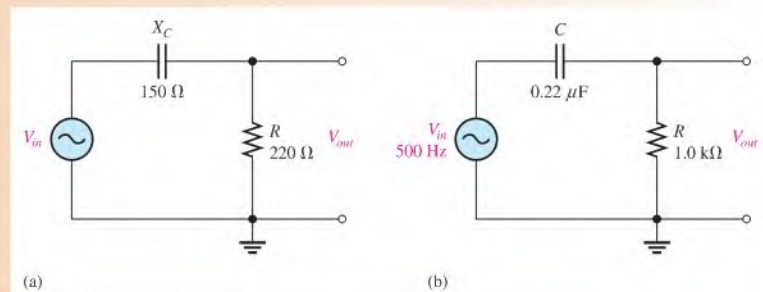

▲ FIGURE 15–35

Solution For the lead circuit in Figure 15–35(a),

$$\phi = \tan^{-1}\left(\frac{X_C}{R}\right) = \tan^{-1}\left(\frac{150\,\Omega}{220\,\Omega}\right) = \mathbf{34.3°}$$

The output leads the input by 34.3°.

For the lead circuit in Figure 15–35(b), first determine the capacitive reactance.

$$X_C = \frac{1}{2\pi f C} = \frac{1}{2\pi(500\,\text{Hz})(0.22\,\mu\text{F})} = 1.45\,\text{k}\Omega$$

$$\phi = \tan^{-1}\left(\frac{X_C}{R}\right) = \tan^{-1}\left(\frac{1.45\,\text{k}\Omega}{1.0\,\text{k}\Omega}\right) = \mathbf{55.4°}$$

The output leads the input by 55.4°.

Related Problem In a lead circuit, what happens to the phase lead if the frequency increases?

Magnitude of the Output Voltage Since the output voltage of an *RC* lead circuit is taken across the resistor, the magnitude can be calculated using either Ohm's law ($V_{out} = IR$) or the voltage-divider formula.

Equation 15–17

$$V_{out} = \left(\frac{R}{\sqrt{R^2 + X_C^2}}\right)V_{in}$$

The expression for the output voltage in phasor form is

$$\mathbf{V}_{out} = V_{out}\angle\phi$$

EXAMPLE 15–15

The input voltage in Figure 15–35(b) (Example 15–14) has an rms value of 10 V. Determine the phasor expression for the output voltage. Draw the waveform relationships for the input and output voltages showing peak values. The phase angle (55.4°) and X_C (1.45 kΩ) were found in Example 15–14.

Solution The phasor expression for the output voltage is

$$\mathbf{V}_{out} = V_{out}\angle\phi = \left(\frac{R}{\sqrt{R^2 + X_C^2}}\right)V_{in}\angle\phi$$

$$= \left(\frac{1.0\,\text{k}\Omega}{1.76\,\text{k}\Omega}\right)10\angle55.4°\,\text{V} = \mathbf{5.68\angle55.4°\,V\ rms}$$

The peak value of the input voltage is

$$V_{in(p)} = 1.414V_{in(rms)} = 1.414(10\,\text{V}) = 14.14\,\text{V}$$

The peak value of the output voltage is

$$V_{out(p)} = 1.414V_{out(rms)} = 1.414(5.68\,\text{V}) = 8.03\,\text{V}$$

The waveforms are shown in Figure 15–36.

15–5 IMPEDANCE AND ADMITTANCE OF PARALLEL *RC* CIRCUITS

In this section, you will learn how to determine the impedance and phase angle of a parallel *RC* circuit. The impedance consists of a magnitude component and a phase angle component. Also, capacitive susceptance and admittance of a parallel *RC* circuit are introduced.

After completing this section, you should be able to

 ◆ **Determine impedance and admittance in a parallel *RC* circuit**

  ◆ Express total impedance in complex form

  ◆ Define and calculate *conductance, capacitive susceptance,* and *admittance*

Figure 15–37 shows a basic parallel *RC* circuit connected to an ac voltage source.

▶ **FIGURE 15–37**

Basic parallel *RC* circuit.
The expression for the total impedance is developed as follows, using complex numbers. Since there are only two circuit components, *R* and *C*, the total impedance can be found from the product-over-sum rule.

$$\mathbf{Z} = \frac{(R\angle 0°)(X_C\angle -90°)}{R - jX_C}$$

By multiplying the magnitudes, adding the angles in the numerator, and converting the denominator to polar form, you get

$$\mathbf{Z} = \frac{RX_C\angle(0° - 90°)}{\sqrt{R^2 + X_C^2}\angle -\tan^{-1}\left(\dfrac{X_C}{R}\right)}$$

Now, by dividing the magnitude expression in the numerator by that in the denominator, and by subtracting the angle in the denominator from that in the numerator, you get

$$\mathbf{Z} = \left(\frac{RX_C}{\sqrt{R^2 + X_C^2}}\right)\angle\left(-90° + \tan^{-1}\left(\frac{X_C}{R}\right)\right)$$

Equivalently, this expression can be written as

$$\mathbf{Z} = \frac{RX_C}{\sqrt{R^2 + X_C^2}} \angle -\tan^{-1}\left(\frac{R}{X_C}\right)$$

EXAMPLE 15–16

For each circuit in Figure 15–38, determine the magnitude and phase angle of the total impedance.

(a)   (b)
▲ **FIGURE 15–38**

Solution   For the circuit in Figure 15–38(a), the total impedance is

$$\mathbf{Z} = \left(\frac{RX_C}{\sqrt{R^2 + X_C^2}}\right) \angle -\tan^{-1}\left(\frac{R}{X_C}\right)$$

$$= \left(\frac{(100\,\Omega)(50\,\Omega)}{\sqrt{(100\,\Omega)^2 + (50\,\Omega)^2}}\right) \angle -\tan^{-1}\left(\frac{100\,\Omega}{50\,\Omega}\right) = \mathbf{44.7 \angle -63.4°\ \Omega}$$

Thus, $Z = 44.7\,\Omega$ and $\theta = -63.4°$.
For the circuit in Figure 15–38(b), the total impedance is

$$\mathbf{Z} = \left(\frac{(1.0\,k\Omega)(2\,k\Omega)}{\sqrt{(1.0\,k\Omega)^2 + (2\,k\Omega)^2}}\right) \angle -\tan^{-1}\left(\frac{1.0\,k\Omega}{2\,k\Omega}\right) = \mathbf{894 \angle -26.6°\ \Omega}$$

Thus, $Z = 894\,\Omega$ and $\theta = -26.6°$.

Related Problem   Determine **Z** in Figure 15–38(a) if the frequency is doubled.

Conductance, Susceptance, and Admittance

Recall that **conductance, *G*,** is the reciprocal of resistance. The phasor expression for conductance is expressed as

$$\mathbf{G} = \frac{1}{R\angle 0°} = G\angle 0°$$

Two new terms are now introduced for use in parallel *RC* circuits. **Capacitive susceptance (B_C)** is the reciprocal of capacitive reactance. The phasor expression for capacitive susceptance is

$$\mathbf{B}_C = \frac{1}{X_C\angle -90°} = B_C\angle 90° = +jB_C$$

Admittance (Y) is the reciprocal of impedance. The phasor expression for admittance is

$$\mathbf{Y} = \frac{1}{Z\angle \pm \theta} = Y\angle \mp \theta$$

The unit of each of these terms is the siemens (S), which is the reciprocal of the ohm.

In working with parallel circuits, it is often easier to use conductance (G), capacitive susceptance (B_C), and admittance (Y) rather than resistance (R), capacitive reactance (X_C), and impedance (Z). In a parallel RC circuit, as shown in Figure 15–39, the total admittance is simply the phasor sum of the conductance and the capacitive susceptance.

Equation 15–19

$$\mathbf{Y} = G + jB_C$$

▶ **FIGURE 15–40**
Solution   From Figure 15–40, $R = 330\ \Omega$; thus $G = 1/R = 1/330\ \Omega = 3.03$ mS. The capacitive reactance is

$$X_C = \frac{1}{2\pi f C} = \frac{1}{2\pi(1000\ \text{Hz})(0.22\ \mu\text{F})} = 723\ \Omega$$

The capacitive susceptance magnitude is

$$B_C = \frac{1}{X_C} = \frac{1}{723\ \Omega} = 1.38\ \text{mS}$$

The total admittance is

$$\mathbf{Y}_{tot} = G + jB_C = \mathbf{3.03\ mS} + j\mathbf{1.38\ mS}$$

which can be expressed in polar form as

$$\mathbf{Y}_{tot} = \sqrt{G^2 + B_C^2}\angle \tan^{-1}\left(\frac{B_C}{G}\right)$$

$$= \sqrt{(3.03\ \text{mS})^2 + (1.38\ \text{mS})^2}\angle \tan^{-1}\left(\frac{1.38\ \text{mS}}{3.03\ \text{mS}}\right) = \mathbf{3.33\angle 24.5°\ mS}$$

The admittance phasor diagram is shown in Figure 15–41.

🌐 15–6   ANALYSIS OF PARALLEL *RC* CIRCUITS

Ohm's law and Kirchhoff's current law are used in the analysis of *RC* circuits. Current and voltage relationships in a parallel *RC* circuit are examined.

◆ **Analyze a parallel *RC* circuit**

  ◆ Apply Ohm's law and Kirchhoff's current law to parallel *RC* circuits

  ◆ Express the voltages and currents as phasor quantities

  ◆ Show how impedance and phase angle vary with frequency

  ◆ Convert from a parallel circuit to an equivalent series circuit

EXAMPLE 15–18

Determine the total current and phase angle in Figure 15–42. Draw a phasor diagram showing the relationship of $\mathbf{V}_s$ and $\mathbf{I}_{tot}$.
Solution   The capacitive reactance is

$$X_C = \frac{1}{2\pi f C} = \frac{1}{2\pi(1.5\text{ kHz})(0.022\ \mu\text{F})} = 4.82\text{ k}\Omega$$

The capacitive susceptance magnitude is

$$B_C = \frac{1}{X_C} = \frac{1}{4.82\text{ k}\Omega} = 207\ \mu\text{S}$$

The conductance magnitude is

$$G = \frac{1}{R} = \frac{1}{2.2\text{ k}\Omega} = 455\ \mu\text{S}$$

The total admittance is

$$\mathbf{Y}_{tot} = G + jB_C = 455\ \mu\text{S} + j207\ \mu\text{S}$$

Converting to polar form yields

$$\mathbf{Y}_{tot} = \sqrt{G^2 + B_C^2}\angle\tan^{-1}\left(\frac{B_C}{G}\right)$$

$$= \sqrt{(455\ \mu\text{S})^2 + (207\ \mu\text{S})^2}\angle\tan^{-1}\left(\frac{207\ \mu\text{S}}{455\ \mu\text{S}}\right) = 500\angle24.5°\ \mu\text{S}$$

The phase angle is 24.5°.

Use Ohm's law to determine the total current.

$$\mathbf{I}_{tot} = \mathbf{V}_s\mathbf{Y}_{tot} = (10\angle0°\text{ V})(500\angle24.5°\ \mu\text{S}) = \mathbf{5.00\angle24.5°\ mA}$$

The magnitude of the total current is 5.00 mA, and it leads the applied voltage by **24.5°**, as the phasor diagram in Figure 15–43 indicates.

Phase Relationships of Currents and Voltages

Figure 15–44(a) shows all the currents in a basic parallel *RC* circuit. The total current, I_{tot}, consists of the two branch currents, I_R and I_C. The applied voltage, V_s, appears across both the resistive and the capacitive branches, so V_s, V_R, and V_C are all in phase and of the same magnitude.
▲ **FIGURE 15–44**

Currents in a parallel *RC* circuit. The current directions shown in (a) are instantaneous and, of course, reverse when the source voltage reverses.

The current through the resistor is in phase with the voltage. The current through the capacitor leads the voltage, and thus the resistive current, by 90°. By Kirchhoff's current law, the total current is the phasor sum of the two branch currents, as shown by the phasor diagram in Figure 15–44(b). The total current is expressed as

$$\mathbf{I}_{tot} = I_R + jI_C$$

Equation 15–23

This equation can be expressed in polar form as

$$\mathbf{I}_{tot} = \sqrt{I_R^2 + I_C^2} \angle \tan^{-1}\left(\frac{I_C}{I_R}\right)$$

Equation 15–24

where the magnitude of the total current is

$$I_{tot} = \sqrt{I_R^2 + I_C^2}$$

and the phase angle between the resistor current and the total current is

$$\theta = \tan^{-1}\left(\frac{I_C}{I_R}\right)$$

Since the resistor current and the applied voltage are in phase, θ also represents the phase angle between the total current and the applied voltage. Figure 15–45 shows a complete current and voltage phasor diagram.
▲ **FIGURE 15–45**

Current and voltage phasor diagram for a parallel *RC* circuit (amplitudes depend on the particular circuit).

EXAMPLE 15–19

Determine the value of each current in Figure 15–46, and describe the phase relationship of each with the applied voltage. Draw the current phasor diagram.
Solution   The resistor current, the capacitor current, and the total current are expressed as follows:

$$\mathbf{I}_R = \frac{\mathbf{V}_s}{\mathbf{R}} = \frac{12\angle 0° \text{ V}}{220\angle 0° \ \Omega} = \mathbf{54.5\angle 0° \text{ mA}}$$

$$\mathbf{I}_C = \frac{\mathbf{V}_s}{\mathbf{X}_C} = \frac{12\angle 0° \text{ V}}{150\angle -90° \ \Omega} = \mathbf{80\angle 90° \text{ mA}}$$

$$\mathbf{I}_{tot} = I_R + jI_C = 54.5 \text{ mA} + j80 \text{ mA}$$

Converting $\mathbf{I}_{tot}$ to polar form yields

$$\mathbf{I}_{tot} = \sqrt{I_R^2 + I_C^2}\angle \tan^{-1}\!\left(\frac{I_C}{I_R}\right)$$

$$= \sqrt{(54.5 \text{ mA})^2 + (80 \text{ mA})^2}\angle \tan^{-1}\!\left(\frac{80 \text{ mA}}{54.5 \text{ mA}}\right) = \mathbf{96.8\angle 55.7° \text{ mA}}$$

As the results show, the resistor current is 54.5 mA and is in phase with the voltage. The capacitor current is 80 mA and leads the voltage by 90°. The total current is 96.8 mA and leads the voltage by 55.7°. The phasor diagram in Figure 15–47 illustrates these relationships.
Related Problem   In a parallel circuit, $\mathbf{I}_R = 100\angle 0°$ mA and $\mathbf{I}_C = 60\angle 90°$ mA. Determine the total current.

Conversion from Parallel to Series Form

For every parallel *RC* circuit, there is an equivalent series *RC* circuit for a given frequency. Two circuits are considered equivalent when they both present an equal impedance at their terminals; that is, the magnitude of impedance and the phase angle are identical.

To obtain the equivalent series circuit for a given parallel *RC* circuit, first find the impedance and phase angle of the parallel circuit. Then use the values of Z and θ to construct an impedance triangle, shown in Figure 15–48. The vertical and horizontal sides of the triangle represent the equivalent series resistance and capacitive reactance as indicated. These values can be found using the following trigonometric relationships:

$$R_{eq} = Z \cos \theta \qquad\qquad\qquad \text{Equation 15–25}$$
$$X_{C(eq)} = Z \sin \theta \qquad\qquad\qquad \text{Equation 15–26}$$
◀ **FIGURE 15–48**

EXAMPLE 15–20

Convert the parallel circuit in Figure 15–49 to a series form.

▶ **FIGURE 15–49**
Solution   First, find the admittance of the parallel circuit as follows:

$$G = \frac{1}{R} = \frac{1}{18 \text{ k}\Omega} = 55.6 \ \mu\text{S}$$

$$B_C = \frac{1}{X_C} = \frac{1}{27 \text{ k}\Omega} = 37.0 \ \mu\text{S}$$

$$\mathbf{Y} = G + jB_C = 55.6 \ \mu\text{S} + j37.0 \ \mu\text{S}$$

Converting to polar form yields

$$\mathbf{Y} = \sqrt{G^2 + B_C^2} \angle \tan^{-1}\left(\frac{B_C}{G}\right)$$

$$= \sqrt{(55.6 \ \mu\text{S})^2 + (37.0 \ \mu\text{S})^2} \angle \tan^{-1}\left(\frac{37.0 \ \mu\text{S}}{55.6 \ \mu\text{S}}\right) = 66.8 \angle 33.6° \ \mu\text{S}$$

Then, the total impedance is

$$\mathbf{Z}_{tot} = \frac{1}{\mathbf{Y}} = \frac{1}{66.8 \angle 33.6° \ \mu\text{S}} = 15.0 \angle -33.6° \text{ k}\Omega$$

Converting to rectangular form yields

$$\mathbf{Z}_{tot} = Z\cos\theta - jZ\sin\theta = R_{eq} - jX_{C(eq)}$$
$$= 15.0\text{ k}\Omega\cos(-33.6°) - j15.0\text{ k}\Omega\sin(-33.6°) = 12.5\text{ k}\Omega - j8.31\text{ k}\Omega$$

The equivalent series *RC* circuit is a 12.5 kΩ resistor in series with a capacitive reactance of 8.31 kΩ. This is shown in Figure 15–50.

SERIES-PARALLEL CIRCUITS

15–7 ANALYSIS OF SERIES-PARALLEL *RC* CIRCUITS

The concepts studied with respect to series and parallel circuits are used to analyze circuits with combinations of both series and parallel R and C components.

After completing this section, you should be able to

- **Analyze series-parallel *RC* circuits**
  - Determine total impedance
  - Calculate currents and voltages
  - Measure impedance and phase angle

The impedance of series components is most easily expressed in rectangular form, and the impedance of parallel components is best found by using polar form. The steps for analyzing a circuit with a series and a parallel component are illustrated in Example 15–21. First express the impedance of the series part of the circuit in rectangular form and the impedance of the parallel part in polar form. Next, convert the impedance of the parallel part to rectangular form and add it to the impedance of the series part. Once you determine the rectangular form of the total impedance, you can convert it to polar form in order to see the magnitude and phase angle and to calculate the current.

EXAMPLE 15–21

In the series-parallel *RC* circuit of Figure 15–51, determine the following:

(a) total impedance   **(b)** total current   **(c)** phase angle by which I_{tot} leads V_s

FIGURE 15–51
Solution (a) First, calculate the magnitudes of capacitive reactance.

$$X_{C1} = \frac{1}{2\pi fC} = \frac{1}{2\pi(5 \text{ kHz})(0.1 \ \mu\text{F})} = 318 \ \Omega$$

$$X_{C2} = \frac{1}{2\pi fC} = \frac{1}{2\pi(5 \text{ kHz})(0.047 \ \mu\text{F})} = 677 \ \Omega$$

One approach is to find the impedance of the series portion and the impedance of the parallel portion and combine them to get the total impedance. The impedance of the series combination of R_1 and C_1 is

$$\mathbf{Z}_1 = R_1 - jX_{C1} = 1.0 \text{ k}\Omega - j318 \ \Omega$$

To determine the impedance of the parallel portion, first determine the admittance of the parallel combination of R_2 and C_2.

$$G_2 = \frac{1}{R_2} = \frac{1}{680 \ \Omega} = 1.47 \text{ mS}$$

$$B_{C2} = \frac{1}{X_{C2}} = \frac{1}{677 \ \Omega} = 1.48 \text{ mS}$$

$$\mathbf{Y}_2 = G_2 + jB_{C2} = 1.47 \text{ mS} + j1.48 \text{ mS}$$

Converting to polar form yields

$$\mathbf{Y}_2 = \sqrt{G_2^2 + B_{C2}^2} \angle \tan^{-1}\left(\frac{B_{C2}}{G_2}\right)$$

$$= \sqrt{(1.47 \text{ mS})^2 + (1.48 \text{ mS})^2} \angle \tan^{-1}\left(\frac{1.48 \text{ mS}}{1.47 \text{ mS}}\right) = 2.09\angle 45.2° \text{ mS}$$

Then, the impedance of the parallel portion is

$$\mathbf{Z}_2 = \frac{1}{\mathbf{Y}_2} = \frac{1}{2.09\angle 45.2° \text{ mS}} = 478\angle -45.2° \ \Omega$$

Converting to rectangular form yields

$$\mathbf{Z}_2 = Z_2\cos\theta - jZ_2\sin\theta$$
$$= (478 \ \Omega)\cos(-45.2°) - j(478 \ \Omega)\sin(-45.2°) = 337 \ \Omega - j339 \ \Omega$$

The series portion and the parallel portion are in series with each other. Combine $\mathbf{Z}_1$ and $\mathbf{Z}_2$ to get the total impedance.

$$\mathbf{Z}_{tot} = \mathbf{Z}_1 + \mathbf{Z}_2$$
$$= (1.0 \text{ k}\Omega - j318 \ \Omega) + (337 \ \Omega - j339 \ \Omega) = 1337 \ \Omega - j657 \ \Omega$$

Expressing $\mathbf{Z}_{tot}$ in polar form yields

$$\mathbf{Z}_{tot} = \sqrt{Z_1^2 + Z_2^2} \angle -\tan^{-1}\left(\frac{Z_2}{Z_1}\right)$$

$$= \sqrt{(1338 \ \Omega)^2 + (657 \ \Omega)^2} \angle -\tan^{-1}\left(\frac{657 \ \Omega}{1337 \ \Omega}\right) = \mathbf{1.49 \angle -26.2° \text{ k}\Omega}$$

(b) Use Ohm's law to determine the total current.

$$\mathbf{I}_{tot} = \frac{\mathbf{V}_s}{\mathbf{Z}_{tot}} = \frac{10\angle 0° \text{ V}}{1.49\angle -26.2° \text{ k}\Omega} = \mathbf{6.71\angle 26.2° \text{ mA}}$$

(c) The total current leads the applied voltage by **26.2°**.

Use Multisim files E15-21A, E15-21B, and E15-21C to verify the calculated results in the (b) part of this example and to confirm your calculation for the related problem.

Example 15–22 shows two sets of series components in parallel. The approach is to first express each branch impedance in rectangular form and then convert each of these impedances to polar form. Next, calculate each branch current using polar notation. Once you know the branch currents, you can find the total current by adding the two branch currents in rectangular form. In this particular case, the total impedance is not required.

▲ **FIGURE 15–52**

Solution   First, calculate X_{C1} and X_{C2}.

$$X_{C1} = \frac{1}{2\pi fC} = \frac{1}{2\pi(2 \text{ MHz})(0.001 \ \mu\text{F})} = 79.6 \ \Omega$$

$$X_{C2} = \frac{1}{2\pi fC} = \frac{1}{2\pi(2 \text{ MHz})(0.0022 \ \mu\text{F})} = 36.2 \ \Omega$$

Next, determine the impedance of each of the two parallel branches.

$$\mathbf{Z}_1 = R_1 - jX_{C1} = 33 \ \Omega - j79.6 \ \Omega$$
$$\mathbf{Z}_2 = R_2 - jX_{C2} = 47 \ \Omega - j36.2 \ \Omega$$

Convert these impedances to polar form.

$$\mathbf{Z}_1 = \sqrt{R_1^2 + X_{C1}^2} \angle -\tan^{-1}\left(\frac{X_{C1}}{R_1}\right)$$

$$= \sqrt{(33 \ \Omega)^2 + (79.6 \ \Omega)^2} \angle -\tan^{-1}\left(\frac{79.6 \ \Omega}{33 \ \Omega}\right) = 86.2 \angle -67.5° \ \Omega$$

$$\mathbf{Z}_2 = \sqrt{R_2^2 + X_{C2}^2} \angle -\tan^{-1}\left(\frac{X_{C2}}{R_2}\right)$$

$$= \sqrt{(47 \ \Omega)^2 + (36.2 \ \Omega)^2} \angle -\tan^{-1}\left(\frac{36.2 \ \Omega}{47 \ \Omega}\right) = 59.3 \angle -37.6° \ \Omega$$

Calculate each branch current.

$$\mathbf{I}_1 = \frac{\mathbf{V}_s}{\mathbf{Z}_1} = \frac{2\angle 0° \text{ V}}{86.2\angle -67.5° \ \Omega} = \mathbf{23.2\angle 67.5° \ mA}$$

$$\mathbf{I}_2 = \frac{\mathbf{V}_s}{\mathbf{Z}_2} = \frac{2\angle 0° \text{ V}}{59.3\angle -37.6° \ \Omega} = \mathbf{33.7\angle 37.6° \ mA}$$

To get the total current, express each branch current in rectangular form so that they can be added.

$$\mathbf{I}_1 = 8.89 \text{ mA} + j21.4 \text{ mA}$$
$$\mathbf{I}_2 = 26.7 \text{ mA} + j20.6 \text{ mA}$$

The total current is

$$\mathbf{I}_{tot} = \mathbf{I}_1 + \mathbf{I}_2$$
$$= (8.89 \text{ mA} + j21.4 \text{ mA}) + (26.7 \text{ mA} + j20.6 \text{ mA}) = 35.6 \text{ mA} + j42.0 \text{ mA}$$

Converting $\mathbf{I}_{tot}$ to polar form yields

$$\mathbf{I}_{tot} = \sqrt{(35.6 \text{ mA})^2 + (42.0 \text{ mA})^2}\angle \tan^{-1}\left(\frac{42.0 \ \Omega}{35.6 \ \Omega}\right) = \mathbf{55.1\angle 49.7° \ mA}$$

The current phasor diagram is shown in Figure 15–53.

Measurement of Z_{tot}

Now, let's see how the value of Z_{tot} for the circuit in Example 15–21 can be determined by measurement. First, the total impedance is measured as outlined in the following steps and as illustrated in Figure 15–54 (other ways are also possible):

Step 1: Using a sine wave generator, set the source voltage to a known value (10 V) and the frequency to 5 kHz. If your generator is not accurate, then it is advisable to check the voltage with an ac voltmeter and the frequency with a frequency counter rather than relying on the marked values on the generator controls.
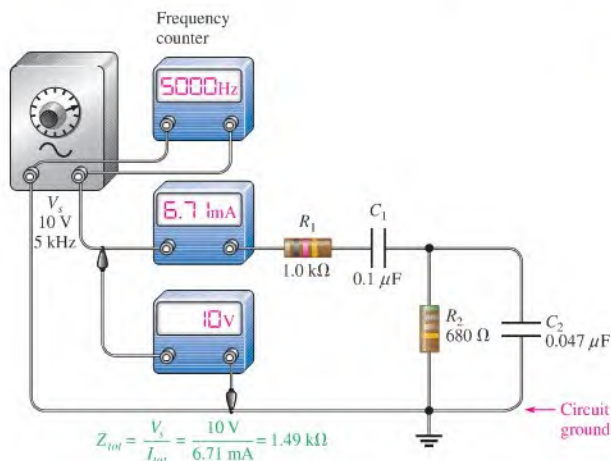

◀ FIGURE 15–54

Determining Z_{tot} by measurement of V_s and I_{tot}.

Step 2: Connect an ac ammeter as shown in Figure 15–54, and measure the total current. Alternatively, you can measure the voltage across R_1 with a voltmeter and calculate the current.

Step 3: Calculate the total impedance by using Ohm's law.

Measurement of Phase Angle, θ

To measure the phase angle, the source voltage and the total current must be displayed on an oscilloscope screen in the proper time relationship. Two basic types of scope probes are available to measure the quantities with an oscilloscope: the voltage probe and the current probe. The current probe is a convenient device, but it is often not as readily available as a voltage probe. We will confine our phase measurement technique to the use of voltage probes in conjunction with the oscilloscope. Although there are special isolation methods, a typical oscilloscope voltage probe has two points that are connected to the circuit: the probe tip and the ground lead. Thus, all voltage measurements must be referenced to ground.

Since only voltage probes are to be used, the total current cannot be measured directly. However, for phase measurement, the voltage across R_1 is in phase with the total current and can be used to establish the phase angle of the current.

Before proceeding with the actual phase measurement, there is a problem with displaying V_{R1}. If the scope probe is connected across the resistor, as indicated in Figure 15–55(a), the ground lead of the scope will short point *B* to ground, thus bypassing the rest of the components and effectively removing them from the circuit electrically, as illustrated in Figure 15–55(b) (assuming that the scope is not isolated from power line ground).

To avoid this problem, you can switch the generator output terminals so that one end of R_1 is connected to the ground terminal, as shown in Figure 15–56(a). Now the scope can be connected across it to display V_{R1}, as indicated in Figure 15–56(b). The other probe is connected across the voltage source to display V_s as indicated. Now channel 1 of the scope has V_{R1} as an input, and channel 2 has V_s. The scope should be triggered from the source voltage (channel 2 in this case).

Before connecting the probes to the circuit, you should align the two horizontal lines (traces) so that they appear as a single line across the center of the scope screen. To do so, ground the probe tips and adjust the vertical position knobs to move the traces toward the center line of the screen until they are superimposed. This procedure ensures that both waveforms have the same zero crossing so that an accurate phase measurement can be made.

(a) Ground lead on scope probe grounds point B.

(b) The effect of grounding point B is to short out the rest of the circuit.

Effects of measuring directly across a component when the instrument and the circuit are grounded.

(b) The scope displays V_{R1} and V_s. V_{R1} represents the phase of the total current.
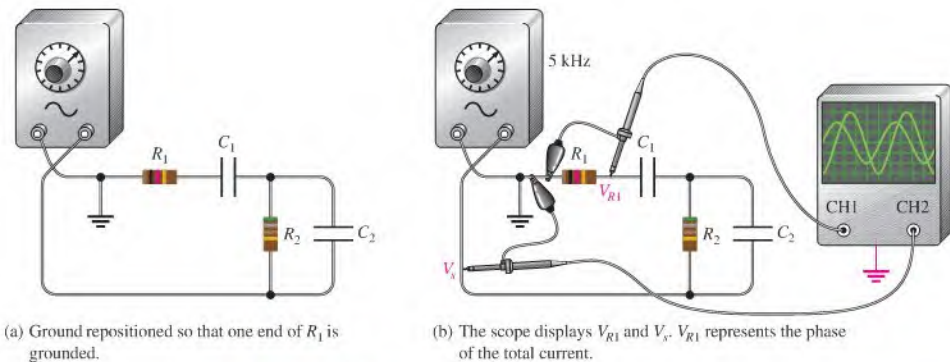

▲ FIGURE 15–56

Repositioning ground so that a direct voltage measurement can be made with respect to ground without shorting out part of the circuit.

Once you have stabilized the waveforms on the scope screen, you can measure the period of the source voltage. Next, use the Volts/Div controls to adjust the amplitudes of the waveforms until they both appear to have the same amplitude. Now, spread the waveforms horizontally by using the Sec/Div control to expand the distance between them. This horizontal distance represents the time between the two waveforms. The number of divisions between the waveforms along any horizontal lines times the Sec/Div setting is equal to the time between them, Δt. Also, you can use the cursors to determine Δt if your oscilloscope has this feature.

Once you have determined the period, T, and the time between the waveforms, Δt, you can calculate the phase angle with the following equation:

Equation 15–27

$$\theta = \left(\frac{\Delta t}{T}\right)360°$$

Figure 15–57 shows simulated screen displays for an oscilloscope in Multisim. In Figure 15–57(a), the waveforms are aligned and set to the same apparent amplitude by adjusting the fine Volts/Div control. The period of these waveforms is 200 μs. The Sec/Div control is adjusted to spread the waveforms out to read Δt more accurately. As shown in part (b), there are 3.0 divisions between the crossings on the center line. The Sec/Div control is set to 5.0 μs and there are 3.0 divisions between the waveforms.

$$\Delta t = 3.0 \text{ divisions} \times 5.0 \,\mu\text{s/division} = 15 \,\mu\text{s}$$

The phase angle is

$$\theta = \left(\frac{\Delta t}{T}\right)360° = \left(\frac{15 \,\mu\text{s}}{200 \,\mu\text{s}}\right)360° = 27°$$

$\Delta t = 3.0 \text{ divisions} \times 5 \,\mu\text{s/division} = 15 \,\mu\text{s}$

OPTION 2 NOTE

15–8 POWER IN *RC* CIRCUITS

In a purely resistive ac circuit, all of the energy delivered by the source is dissipated in the form of heat by the resistance. In a purely capacitive ac circuit, all of the energy delivered by the source is stored by the capacitor during a portion of the voltage cycle and then returned to the source during another portion of the cycle so that there is no net energy conversion to heat. When there is both resistance and capacitance, some of the energy is alternately stored and returned by the capacitance and some is dissipated by the resistance. The amount of energy converted to heat is determined by the relative values of the resistance and the capacitive reactance.

After completing this section, you should be able to

* **Determine power in *RC* circuits**
  * Explain true and reactive power
  * Draw the power triangle
  * Define *power factor*
  * Explain apparent power
  * Calculate power in an *RC* circuit

When the resistance in a series *RC* circuit is greater than the capacitive reactance, more of the total energy delivered by the source is converted to heat by the resistance than is stored by the capacitor. Likewise, when the reactance is greater than the resistance, more of the total energy is stored and returned than is converted to heat.

The formulas for power in a resistor, sometimes called *true power* (P_{true}), and the power in a capacitor, called *reactive power* (P_r), are restated here. The unit of true power is the watt, and the unit of reactive power is the VAR (volt-ampere reactive).

Equation 15–28

$$P_{\text{true}} = I^2 R$$

Equation 15–29

$$P_r = I^2 X_C$$

Power Triangle for *RC* Circuits

The generalized impedance phasor diagram for a series *RC* circuit is shown in Figure 15–58(a). A phasor relationship for the powers can also be represented by a similar diagram because the respective magnitudes of the powers, P_{true} and P_r, differ from R and X_C by a factor of I^2. This is shown in Figure 15–58(b).

The resultant power phasor, I^2Z, represents the **apparent power** P_a. At any instant in time P_a is the total power that appears to be transferred between the source and the *RC*
▲ **FIGURE 15–58**

Development of the power triangle for a series *RC* circuit.

circuit. The unit of apparent power is the volt-ampere, VA. The expression for apparent power is

$$P_a = I^2 Z$$

The power phasor diagram in Figure 15–58(b) can be rearranged in the form of a right triangle, as shown in Figure 15–58(c). This is called the *power triangle*. Using the rules of trigonometry, P_{true} can be expressed as

$$P_{\text{true}} = P_a \cos \theta$$

Since P_a equals $I^2 Z$ or VI, the equation for the true power dissipation in an *RC* circuit can be written as

$$P_{\text{true}} = VI \cos \theta$$

where *V* is the applied voltage and *I* is the total current.

For the case of a purely resistive current, $\theta = 0°$ and $\cos 0° = 1$, so P_{true} equals *VI*. For the case of a purely capacitive circuit, $\theta = 90°$ and $\cos 90° = 0$, so P_{true} is zero. As you already know, there is no power dissipation in an ideal capacitor.

Power Factor

The term $\cos \theta$ is called the **power factor** and is stated as

$$PF = \cos \theta$$

As the phase angle between applied voltage and total current increases, the power factor decreases, indicating an increasingly reactive circuit. The smaller the power factor, the smaller the power dissipation.

The power factor can vary from 0 for a purely reactive circuit to 1 for a purely resistive circuit. In an *RC* circuit, the power factor is referred to as a leading power factor because the current leads the voltage.

EXAMPLE 15–23

Determine the power factor and the true power in the circuit of Figure 15–59.

▶ **FIGURE 15–59**
Solution   The capacitive reactance is

$$X_C = \frac{1}{2\pi f C} = \frac{1}{2\pi (10 \text{ kHz})(0.0047 \ \mu\text{F})} = 3.39 \text{ k}\Omega$$

The total impedance of the circuit in rectangular form is

$$\mathbf{Z} = R - jX_C = 1.0 \text{ k}\Omega - j3.39 \text{ k}\Omega$$

Converting to polar form yields

$$\mathbf{Z} = \sqrt{R^2 + X_C^2} \angle -\tan^{-1}\left(\frac{X_C}{R}\right)$$

$$= \sqrt{(1.0 \text{ k}\Omega)^2 + (3.39 \text{ k}\Omega)^2} \angle -\tan^{-1}\left(\frac{3.39 \text{ k}\Omega}{1.0 \text{ k}\Omega}\right) = 3.53 \angle -73.6° \text{ k}\Omega$$

The angle associated with the impedance is θ, the angle between the applied voltage and the total current; therefore, the power factor is

$$PF = \cos\theta = \cos(-73.6°) = \mathbf{0.282}$$

The current magnitude is

$$I = \frac{V_s}{Z} = \frac{15 \text{ V}}{3.53 \text{ k}\Omega} = 4.25 \text{ mA}$$

The true power is

$$P_{\text{true}} = V_s I \cos\theta = (15 \text{ V})(4.25 \text{ mA})(0.282) = \mathbf{18.0 \ mW}$$

Related Problem   What is the power factor if f is reduced by half in Figure 15–59?

Significance of Apparent Power

As mentioned, apparent power is the power that appears to be transferred between the source and the load, and it consists of two components—a true power component and a reactive power component.

In all electrical and electronic systems, it is the true power that does the work. The reactive power is simply shuttled back and forth between the source and load. Ideally, in terms of performing useful work, all of the power transferred to the load should be true power and none of it reactive power. However, in most practical situations the load has some reactance associated with it, and therefore you must deal with both power components.

In Chapter 14, the use of apparent power in relation to transformers was discussed. For any reactive load, there are two components of the total current: the resistive component and the reactive component. If you consider only the true power (watts) in a load, you are dealing with only a portion of the total current that the load demands from a source. In order to have a realistic picture of the actual current that a load will draw, you must consider apparent power (VA).

A source such as an ac generator can provide current to a load up to some maximum value. If the load draws more than this maximum value, the source can be damaged. Figure 15–60(a) shows a 120 V generator that can deliver a maximum current of 5 A to a load. Assume that the generator is rated at 600 W and is connected to a purely resistive load of 24 Ω (power factor of 1). The ammeter shows that the current is 5 A, and the wattmeter indicates that the power is 600 W. The generator has no problem under these conditions, although it is operating at maximum current and power.

Now, consider what happens if the load is changed to a reactive one with an impedance of 18 Ω and a power factor of 0.6, as indicated in Figure 15–60(b). The current is
▲ FIGURE 15–60

Wattage rating of a source is inappropriate when the load is reactive. The rating should be in VA rather than in watts.

120 V/18 Ω = 6.67 A, which *exceeds* the maximum. Even though the wattmeter reads 480 W, which is less than the power rating of the generator, the excessive current probably will cause damage. This illustration shows that a true power rating can be deceiving and is inappropriate for ac sources. The ac generator should be rated at 600 VA, a rating that manufacturers generally use, rather than 600 W.

EXAMPLE 15–24

For the circuit in Figure 15–61, find the true power, the reactive power, and the apparent power.

▶ FIGURE 15–61
Solution The capacitive reactance and currents through *R* and *C* are

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(1000 \text{ Hz})(0.15 \text{ }\mu\text{F})} = 1061 \text{ }\Omega$$

$$I_R = \frac{V_s}{R} = \frac{10 \text{ V}}{470 \text{ }\Omega} = 21.3 \text{ mA}$$

$$I_C = \frac{V_s}{X_C} = \frac{10 \text{ V}}{1061 \text{ }\Omega} = 9.43 \text{ mA}$$

The true power is

$$P_{\text{true}} = I_R^2 R = (21.3 \text{ mA})^2(470 \text{ }\Omega) = \textbf{213 mW}$$

The reactive power is

$$P_r = I_C^2 X_C = (9.43 \text{ mA})^2 (1061 \, \Omega) = \textbf{94.3 mVAR}$$

The apparent power is

$$P_a = \sqrt{P_{\text{true}}^2 + P_r^2} = \sqrt{(213 \text{ mW})^2 + (94.3 \text{ mVAR})^2} = \textbf{233 mVA}$$

15–9   BASIC APPLICATIONS

RC circuits are found in a variety of applications, often as part of a more complex circuit. Three applications are phase shift oscillators, frequency-selective circuits (filters), and ac coupling.

After completing this section, you should be able to

◆ **Discuss some basic *RC* applications**

  ◆ Discuss how the *RC* circuit is used as an oscillator

  ◆ Discuss how the *RC* circuit operates as a filter

  ◆ Discuss ac coupling

The Phase Shift Oscillator

As you know, a series *RC* circuit will shift the phase of the output voltage by an amount that depends on the values of *R* and *C* and the frequency of the signal. This ability to shift phase depending on frequency is vital in certain feedback oscillator circuits. An **oscillator** is a circuit that generates a periodic waveform and is an important circuit for many electronic systems. You will study oscillators in a devices course, so the focus here is on the application of *RC* circuits for shifting phase. The requirement is that a fraction of the output of the oscillator is returned to the input (called "feedback") in the proper phase to reinforce the input and sustain oscillations. Generally, the requirement is to feed back the signal with a total of 180° of phase shift.

A single *RC* circuit is limited to phase shifts that are smaller than 90°. The basic *RC* lag circuit discussed in Section 15–4 can be "stacked" to form a complex *RC* network as shown in Figure 15–62, which shows a specific circuit called a phase-shift oscillator. The phase shift oscillator typically uses three equal-component *RC* circuits that produce the required 180° phase shift at a certain frequency, which will be the frequency at which the oscillator
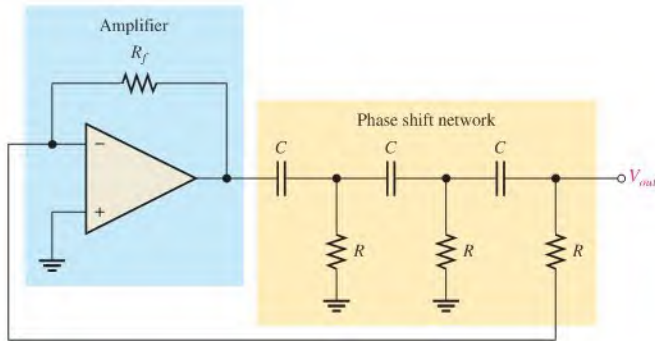

▲ FIGURE 15–62

Phase shift oscillator.

works. The output of the amplifier is phase shifted by the RC network and returned to the input of the amplifier, which provides sufficient gain to maintain oscillations.

The process of putting several RC circuits together results in a loading effect, so the overall phase shift is not the same as simply adding the phase shifts of the individual RC circuits. The detailed calculation for this circuit is shown in Appendix B. With equal components, the frequency at which a 180° phase shift occurs is given by the equation

$$f_r = \frac{1}{2\pi\sqrt{6}\,RC}$$

Equation 15–33

It also turns out that the RC network attenuates (reduces) the signal from the amplifier by a factor of 29; the amplifier must make up for this attenuation by having a gain of -29 (the minus sign takes into account the phase shift).

EXAMPLE 15–25

In Figure 15–63, calculate the output frequency.

◆ FIGURE 15–63
Solution

$$f_r = \frac{1}{2\pi\sqrt{6}\,RC} = \frac{1}{2\pi\sqrt{6}\,(15\ \text{k}\Omega)(0.001\ \mu\text{F})} = 4.33\ \text{kHz}$$

Related Problem   If all of the capacitors are changed to 0.0027 μF, what is the oscillator frequency?

The *RC* Circuit as a Filter

Filters are frequency-selective circuits that permit signals of certain frequencies to pass from the input to the output while blocking all others. That is, all frequencies but the selected ones are filtered out. Filters are covered in greater depth in Chapter 18 but are introduced here as an application example.

Series *RC* circuits exhibit a frequency-selective characteristic and therefore act as basic filters. There are two types. The first one that we examine, called a **low-pass filter**, is realized by taking the output across the capacitor, just as in a lag circuit. The second type, called a **high-pass filter**, is implemented by taking the output across the resistor, as in a lead circuit.

Low-Pass Filter   You have already seen what happens to the output magnitude and phase angle in a lag circuit. In terms of its filtering action, we are interested primarily in the variation of the output magnitude with frequency.

Figure 15–64 shows the filtering action of a series *RC* circuit using specific values for illustration. In part (a) of the figure, the input is zero frequency (dc). Since the capacitor blocks constant direct current, the output voltage equals the full value of the input voltage because there is no voltage dropped across *R*. Therefore, the circuit passes all of the input voltage to the output (10 V in, 10 V out).

In Figure 15–64(b), the frequency of the input voltage has been increased to 1 kHz, causing the capacitive reactance to decrease to 159 Ω. For an input voltage of 10 V rms, the
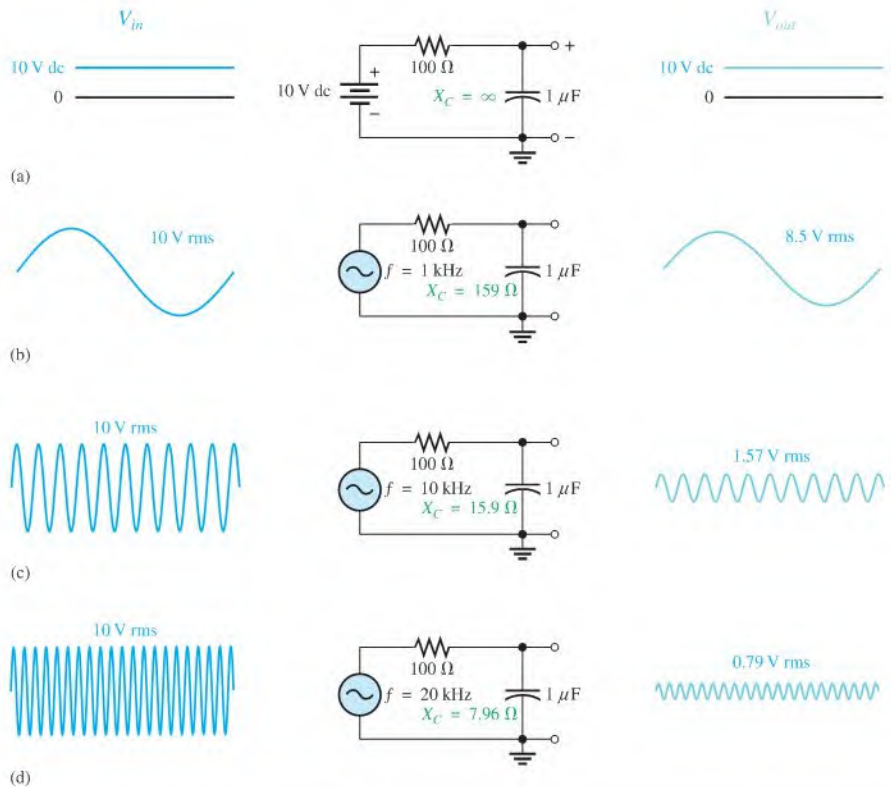

▲ **FIGURE 15–64**

Low-pass filtering action (phase shifts are not indicated).

output voltage is approximately 8.5 V rms, which can be calculated using the voltage-divider approach or Ohm's law.

In Figure 15–64(c), the input frequency has been increased to 10 kHz, causing the capacitive reactance to decrease further to 15.9 Ω. For a constant input voltage of 10 V rms, the output voltage is now 1.57 V rms.

As the input frequency is increased further, the output voltage continues to decrease and approaches zero as the frequency becomes very high, as shown in Figure 15–64(d).

A description of the circuit action is as follows: As the frequency of the input increases, the capacitive reactance decreases. Because the resistance is constant and the capacitive reactance decreases, the voltage across the capacitor (output voltage) also decreases according to the voltage-divider principle. The input frequency can be increased until it reaches a value at which the reactance is so small compared to the resistance that the output voltage can be neglected because it is very small compared to the input voltage. At this value of frequency, the circuit is essentially completely blocking the input signal.

As shown in Figure 15–64, the circuit passes dc (zero frequency) completely. As the frequency of the input increases, less of the input voltage is passed through to the output; that is, the output voltage decreases as the frequency increases. It is apparent that the lower frequencies pass through the circuit much better than the higher frequencies. This *RC* circuit is therefore a very basic form of low-pass filter.

The **frequency response** of the low-pass filter circuit in Figure 15–64 is shown in Figure 15–65 with a graph of output voltage magnitude versus frequency. This graph, called a *response curve,* indicates that the output decreases as the frequency increases.
▲ **FIGURE 15–65**

Frequency response curve for the low-pass filter in Figure 15–64.

High-Pass Filter   Figure 15–66 illustrates high-pass filtering action, where the output is taken across the resistor, just as in a lead circuit. When the input voltage is dc (zero frequency) in part (a), the output is zero volts because the capacitor blocks direct current; therefore, no voltage is developed across *R*.

In Figure 15–66(b), the frequency of the input signal has been increased to 100 Hz with an rms value of 10 V. The output voltage is 0.63 V rms. Thus, only a small percentage of the input voltage appears on the output at this frequency.

In Figure 15–66(c), the input frequency is increased further to 1 kHz, causing more voltage to be developed across the resistor because of the further decrease in the capacitive reactance. The output voltage at this frequency is 5.32 V rms. As you can see, the output
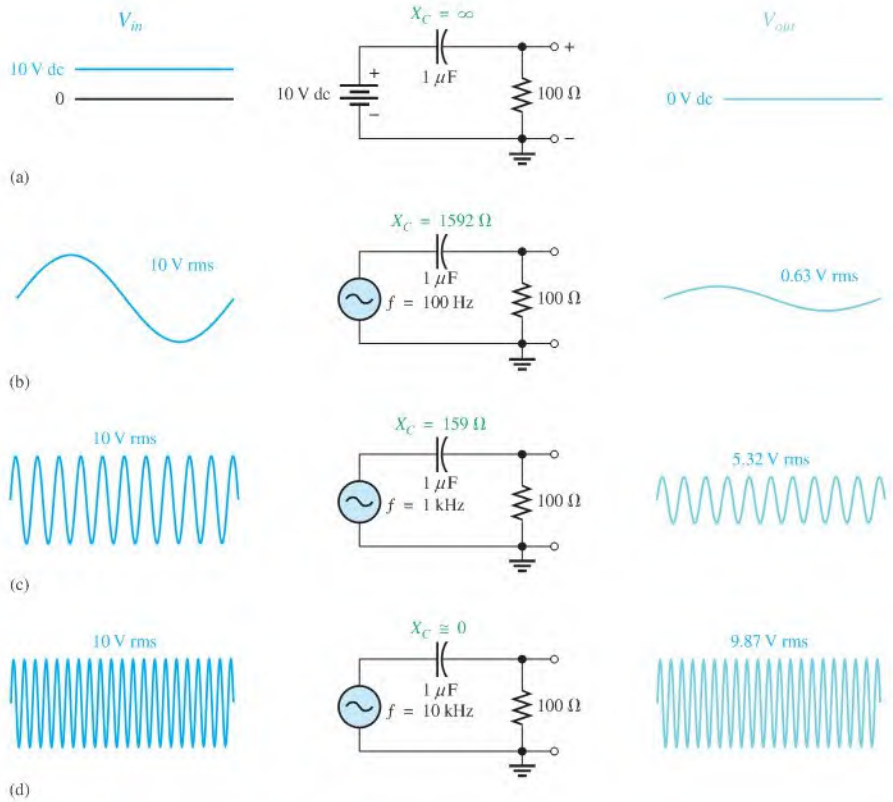

▲ FIGURE 15–66

High-pass filtering action (phase shifts are not indicated).

voltage increases as the frequency increases. A value of frequency is reached at which the reactance is negligible compared to the resistance, and most of the input voltage appears across the resistor, as shown in Figure 15–66(d).

As illustrated, this circuit tends to prevent lower frequencies from appearing on the output but allows higher frequencies to pass through from input to output. Therefore, this RC circuit is a basic form of high-pass filter.

The frequency response of the high-pass filter circuit in Figure 15–66 is shown in Figure 15–67 with a graph of output voltage magnitude versus frequency. This response curve shows that the output increases as the frequency increases and then levels off and approaches the value of the input voltage.

The Cutoff Frequency and the Bandwidth of a Filter The frequency at which the capacitive reactance equals the resistance in a low-pass or high-pass RC filter is called the **cutoff frequency** and is designated f_c. This condition is expressed as $1/(2\pi f_c C) = R$. Solving for f_c results in the following formula:

Equation 15–34

$$f_c = \frac{1}{2\pi RC}$$

At f_c, the output voltage of the filter is 70.7% of its maximum value. It is standard practice to consider the cutoff frequency as the limit of a filter's performance in terms of
▲ FIGURE 15–67

Frequency response curve for the high-pass filter in Figure 15–66.
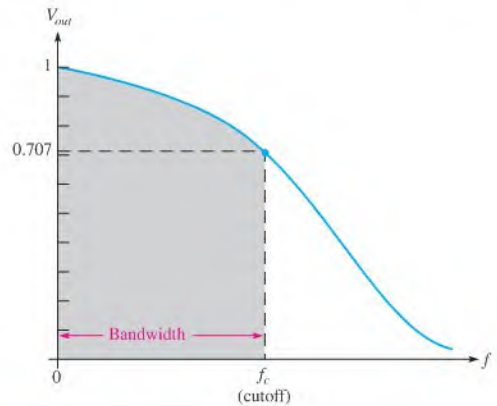

▲ FIGURE 15–68

Normalized general response curve of a low-pass filter showing the cutoff frequency and the bandwidth.

passing or rejecting frequencies. For example, in a high-pass filter, all frequencies above f_c are considered to be passed by the filter, and all those below f_c are considered to be rejected. The reverse is true for a low-pass filter.

The range of frequencies that is considered to be passed by a filter is called the **bandwidth**. Figure 15–68 illustrates the bandwidth and the cutoff frequency for a low-pass filter.

Coupling an AC Signal into a DC Bias Circuit

Figure 15–69 shows an *RC* circuit that is used to create a dc voltage level with an ac voltage superimposed on it. This type of circuit is commonly found in amplifiers in which the dc voltage is required to **bias** the amplifier to the proper operating point and the signal voltage to be amplified is coupled through a capacitor and superimposed on the dc level. The capacitor prevents the low internal resistance of the signal source from affecting the dc bias voltage.
◄ FIGURE 15–69

Amplifier bias and signal-coupling circuit.

In this type of application, a relatively large value of capacitance is selected so that for the frequencies to be amplified, the reactance is very small compared to the resistance of the bias network. When the reactance is very small (ideally zero), there is practically no phase shift or signal voltage dropped across the capacitor. Therefore, all of the signal voltage passes from the source to the input of the amplifier.

Figure 15–70 illustrates the application of the superposition principle to the circuit in Figure 15–69. In part (a), the ac source has been effectively removed from the circuit and replaced with a short to represent its ideal internal resistance (actual generators typically have 50 Ω or 600 Ω of internal resistance). Since *C* is open to dc, the voltage at point *A* is determined by the voltage-divider action of R_1 and R_2 and the dc voltage source.

(a) dc equivalent: ac source replaced by short. *C* is open to dc. R_1 and R_2 act as dc voltage divider.

(b) ac equivalent: dc source is replaced by short. *C* is short to ac. All of V_{ac} is coupled to point *A*.

(c) dc + ac: Voltages are superimposed at point *A*.
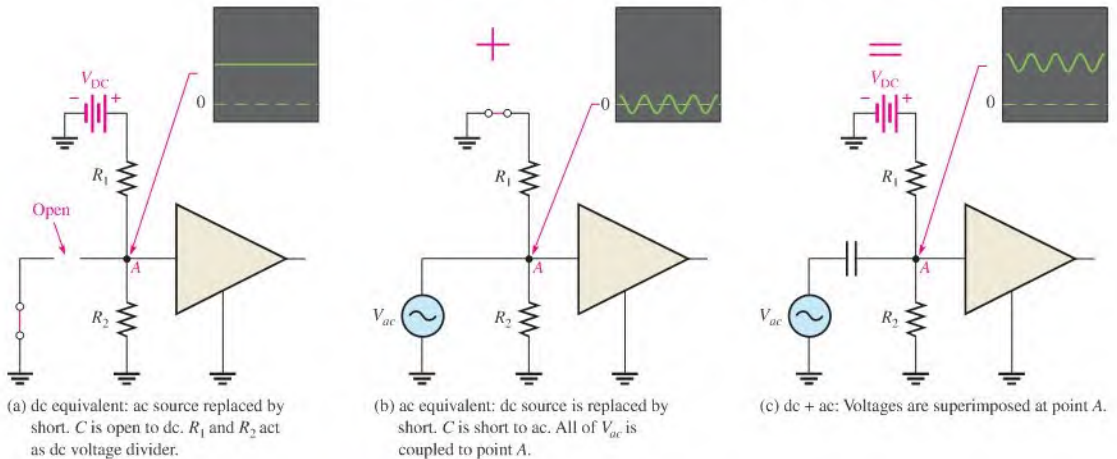

▲ **FIGURE 15–70**

The superposition of dc and ac voltages in an *RC* bias and coupling circuit.

In Figure 15–70(b), the dc source has been effectively removed from the circuit and re- placed with a short to represent its ideal internal resistance. Since *C* appears as a short at the frequency of the ac, the signal voltage is coupled directly to point *A* and appears across the parallel combination of R_1 and R_2.

Figure 15–70(c) illustrates that the combined effect of the superposition of the dc and the ac voltages results in the signal voltage "riding" on the dc level.

   ◆ Find a shorted capacitor

   ◆ Find a leaky capacitor

Effect of an Open Resistor It is easy to see how an open resistor affects the operation of a basic series *RC* circuit, as shown in Figure 15–71. Obviously, there is no path for current, so the capacitor voltage remains at zero; thus, the total voltage, V_s, appears across the open resistor.
Effect of an Open Capacitor When the capacitor is open, there is no current; thus, the resistor voltage remains at zero. The total source voltage is across the open capacitor, as shown in Figure 15–72.
Effect of a Shorted Capacitor Capacitors rarely short; but when a capacitor does short out, the voltage across it is zero, the current equals V_s/R, and the total voltage appears across the resistor, as shown in Figure 15–73.
Effect of a Leaky Capacitor When a large electrolytic capacitor exhibits a high leakage current, the leakage resistance effectively appears in parallel with the capacitor, as shown in Figure 15–74(a). When the leakage resistance is comparable in value to the circuit resistance, *R*, the circuit response is drastically affected. The circuit, looking from the capacitor toward the source, can be thevenized, as shown in Figure 15–74(b). The Thevenin
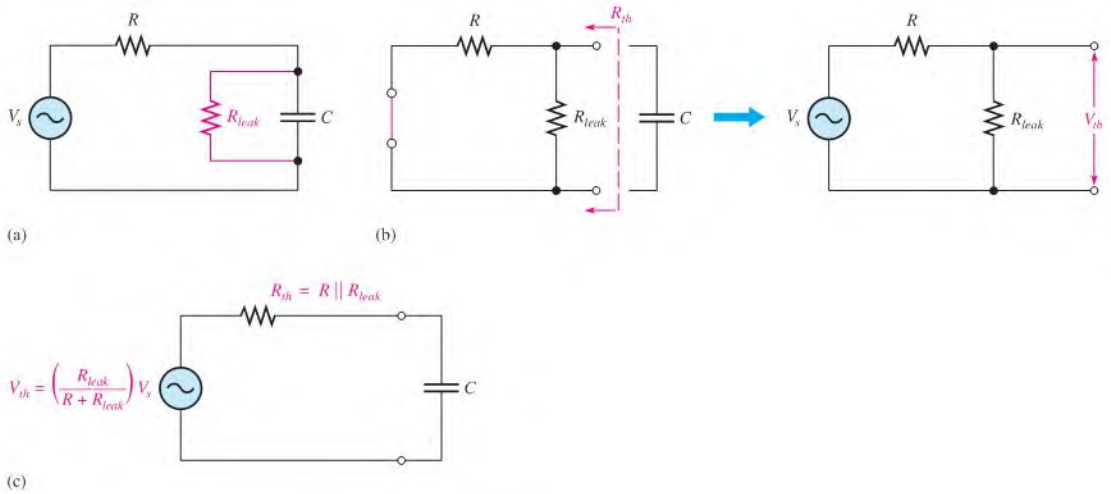

▲ FIGURE 15–74

Effect of a leaky capacitor.

equivalent resistance is R in parallel with R_{leak} (the source appears as a short), and the Thevenin equivalent voltage is determined by the voltage-divider action of R and R_{leak}.

$$R_{th} = R \| R_{leak} = \frac{RR_{leak}}{R + R_{leak}}$$

$$V_{th} = \left(\frac{R_{leak}}{R + R_{leak}}\right)V_s$$

As you can see, the voltage across the capacitor is reduced since $V_{th} < V_s$. Also, the circuit time constant is reduced, and the current is increased. The Thevenin equivalent circuit is shown in Figure 15–74(c).

EXAMPLE 15–26

Assume that the capacitor in Figure 15–75 is degraded to a point where its leakage resistance is 10 kΩ. Determine the output voltage under the degraded condition.
▲ FIGURE 15–75

Solution   The effective circuit resistance is

$$R_{th} = \frac{RR_{leak}}{R + R_{leak}} = \frac{(4.7\,\text{k}\Omega)(10\,\text{k}\Omega)}{14.7\,\text{k}\Omega} = 3.20\,\text{k}\Omega$$

To determine the output voltage, find the Thevenin equivalent voltage.

$$V_{th} = \left(\frac{R_{leak}}{R + R_{leak}} \right) V_s = \left(\frac{10\,k\Omega}{14.7\,k\Omega} \right) 10\,V = 6.80\,V$$

Then,

$$V_{out} = \left(\frac{X_C}{\sqrt{R_{th}^2 + X_C^2}} \right) V_{th} = \left(\frac{5.0\,k\Omega}{\sqrt{(3.2\,k\Omega)^2 + (5.0\,k\Omega)^2}} \right) 6.80\,V = \mathbf{5.73\,V}$$

Related Problem   What would the output voltage be if the capacitor were not leaky?

Other Troubleshooting Considerations

So far, you have learned about specific component failures and the associated voltage measurements. Many times, however, the failure of a circuit to work properly is not the result of a faulty component. A loose wire, a bad contact, or a poor solder joint can cause an open circuit. A short can be caused by a wire clipping or solder splash. Things as simple as not plugging in a power supply or a function generator happen more often than you might think. Wrong values in a circuit (such as an incorrect resistor value), the function generator set at the wrong frequency, or the wrong output connected to the circuit can cause improper operation.

When you have problems with a circuit, always check to make sure that the instruments are properly connected to the circuits and to a power outlet. Also, look for obvious things such as a broken or loose contact, a connector that is not completely plugged in, or a piece of wire or a solder bridge that could be shorting something out.

The point is that you should consider all possibilities, not just faulty components, when a circuit is not working properly. The following example illustrates this approach with a simple circuit using the APM (analysis, planning, and measurement) method.

EXAMPLE 15–27   The circuit represented by the schematic in Figure 15–76 has no output voltage, which is the voltage across the capacitor. You expect to see about 7.4 V at the output. The circuit is physically constructed on a protoboard. Use your troubleshooting skills to find the problem.

▶ **FIGURE 15–76**
Solution   Apply the APM method to this troubleshooting problem.

Analysis: First think of the possible causes for the circuit to have no output voltage.

1. There is no source voltage or the frequency is so high that the capacitive reactance is almost zero.

2. There is a short between the output terminals. Either the capacitor could be internally shorted, or there could be some physical short in the circuit.

3. There is an open between the source and the output. This would prevent current and thus cause the output voltage to be zero. The resistor could be open, or the conductive path could be open due to a broken or loose connecting wire or a bad protoboard contact.

4. There is an incorrect component value. The resistor could be so large that the current and, therefore, the output voltage are negligible. The capacitor could be so large that its reactance at the input frequency is near zero.

Planning: You decide to make some visual checks for problems such as the function generator power cord not plugged in or the frequency set at an incorrect value. Also, broken leads, shorted leads, as well as an incorrect resistor color code or capacitor label often can be found visually. If nothing is discovered after a visual check, then you will make voltage measurements to track down the cause of the problem. You decide to use a digital oscilloscope and a DMM to make the measurements.

Measurement: Assume that you find that the function generator is plugged in and the frequency setting appears to be correct. Also, you find no visible opens or shorts during your visual check, and the component values are correct.

The first step in the measurement process is to check the voltage from the source with the scope. Assume a 10 V rms sine wave with a frequency of 5 kHz is observed at the circuit input as shown in Figure 15–77(a). The correct voltage is present, so *the first possible cause has been eliminated.*

Next, check for a shorted capacitor by disconnecting the source and placing a DMM (set on the ohmmeter function) across the capacitor. If the capacitor is good, an open will be indicated by an OL (overload) in the meter display after a short charging time. Assume the capacitor checks okay, as shown in Figure 15–77(b). *The second possible cause has been eliminated.*

Since the voltage has been "lost" somewhere between the input and the output, you must now look for the voltage. Reconnect the source and measure the voltage across the resistor with the DMM (set on the voltmeter function) from one resistor lead to the other. The voltage across the resistor is zero. This means there is no current, which indicates an open somewhere in the circuit.

Now, begin tracing the circuit back toward the source looking for the voltage (you could also start from the source and work forward). You can use either the scope or the DMM but decide to use the multimeter with one lead connected to ground and the other used to probe the circuit. As shown in Figure 15–77(c), the voltage on the right lead of the resistor, point ①, reads zero. Since you already have measured zero voltage across the resistor, the voltage on the left resistor lead at point ② must be zero as the meter indicates. Next, moving the meter probe to point ③, you read 10 V. You have found the voltage! Since there is zero volts on the left resistor lead, and there is 10 V at point ③, one of the two contacts in the protoboard hole into which the wire leads are inserted is bad. It could be that the small contacts were pushed in too far and were bent or broken so that the circuit lead does not make contact.

Move either or both the resistor lead and the wire to another hole in the same row. Assume that when the resistor lead is moved to the hole just above, you have voltage at the output of the circuit (across the capacitor).

Related Problem   Suppose you had measured 10 V across the resistor before the capacitor was checked. What would this have indicated?
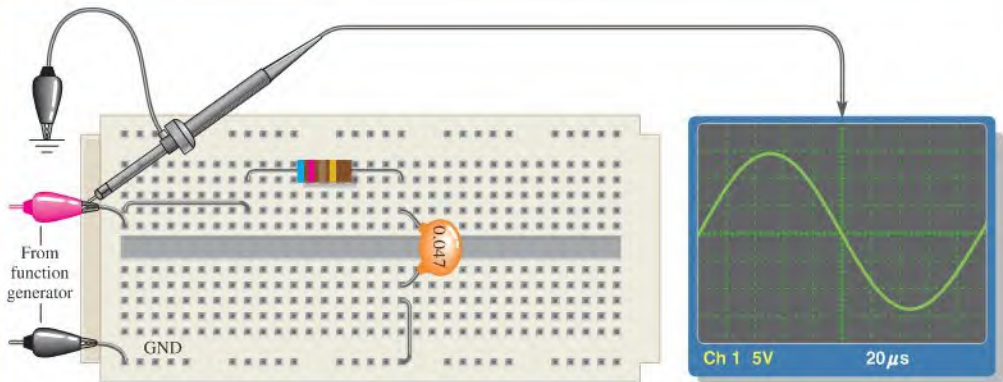

(a) Scope shows the correct voltage at the input.
(b) With function generator disconnected, the meter indicates the capacitor is not shorted.
(c) The voltage is found at point ③, indicating that one of the two used protoboard contacts in that row is bad.

Application Activity

In Chapter 12, you studied the capacitively coupled input to an amplifier with voltage-divider bias. In this application, the output voltage and phase lag of a similar amplifier's input circuit are examined to determine how they change with frequency. If too much voltage is dropped across the coupling capacitor, the overall performance of the amplifier is adversely affected.

As you learned in Chapter 12, the coupling capacitor (C_1) in Figure 15–78 passes the input signal voltage to the input of the amplifier (point A to point B) without affecting the dc level at point B produced by the resistive voltage divider (R_1 and R_2). If the input frequency is high enough so that the reactance of the

coupling capacitor is negligibly small, essentially no ac signal voltage is dropped across the capacitor. As the signal frequency is reduced, the capacitive reactance increases and more of the signal voltage is dropped across the capacitor. This lowers the overall voltage gain of the amplifier and thus degrades its performance.

The amount of signal voltage that is coupled from the input source (point A) to the amplifier input (point B) is determined by the values of the capacitor and the dc bias resistors (assuming the amplifier has no loading effect) in Figure 15–78. These components actually form a high-pass RC filter, as shown in Figure 15–79. The voltage-divider bias resistors are effectively in parallel with each other as far as the ac source is concerned because the power supply has zero internal resistance. The lower end of

The RC input circuit acts effectively like a high-pass RC filter.

R_2 goes to ground and the upper end of R_1 goes to the dc supply voltage as shown in Figure 15–79(a). Since there is no ac voltage at the +18 V dc terminal, the upper end of R_1 is at 0 V ac, which is referred to as *ac ground*. The development of the circuit into an effective high-pass RC filter is shown in parts (b) and (c).

INTRODUCTION

In this chapter you will study series and parallel *RL* circuits. The analyses of *RL* and *RC* circuits are similar. The major difference is that the phase responses are opposite; inductive reactance increases with frequency, while capacitive reactance decreases with frequency.

An *RL* circuit contains both resistance and inductance. In this chapter, basic series and parallel *RL* circuits and their responses to sinusoidal ac voltages are presented. Series-parallel combinations are also analyzed. True, reactive, and apparent power in *RL* circuits are discussed and some basic *RL* circuit applications are introduced. Applications of *RL* circuits include filters and switching regulators. Troubleshooting is also covered in this chapter.

COVERAGE OPTIONS

If you chose Option 1 to cover all of Chapter 15 on *RC* circuits, then all of this chapter should be covered next.

If you chose Option 2 to cover reactive circuits beginning in Chapter 15 on the basis of the four major parts, then the appropriate part of this chapter should be covered next, followed by the corresponding part in Chapter 17.

SERIES CIRCUITS

16–1 SINUSOIDAL RESPONSE OF SERIES *RL* CIRCUITS

As with the *RC* circuit, all currents and voltages in a series *RL* circuit are sinusoidal when the input voltage is sinusoidal. The inductance causes a phase shift between the voltage and the current that depends on the relative values of the resistance and the inductive reactance.

After completing this section, you should be able to

♦ **Describe the relationship between current and voltage in a series *RL* circuit**

  ♦ Discuss voltage and current waveforms

  ♦ Discuss phase shift

In an *RL* circuit, the resistor voltage and the current lag the source voltage. The inductor voltage leads the source voltage. Ideally, the phase angle between the current and the inductor voltage is always 90°. These generalized phase relationships are indicated in Figure 16–1. Notice how they differ from those of the *RC* circuit that was discussed in Chapter 15.

The amplitudes and the phase relationships of the voltages and current depend on the values of the resistance and the **inductive reactance**. When a circuit is purely inductive, the phase angle between the applied voltage and the total current is 90°, with the current lagging the voltage. When there is a combination of both resistance and inductive reactance in a circuit, the phase angle is somewhere between 0° and 90°, depending on the relative values of the resistance and the inductive reactance.

Recall that practical inductors have winding resistance, capacitance between windings, and other factors that prevent an inductor from behaving as an ideal component. In practical
▲ FIGURE 16–1

Illustration of sinusoidal response with general phase relationships of V_R, V_L, and I relative to the source voltage. V_R and I are in phase, while V_R and V_L are 90° out of phase with each other.

circuits, these effects can be significant; however, for the purpose of isolating the inductive effects, we will treat inductors in this chapter as ideal (except in the Application Activity).

16–2 IMPEDANCE OF SERIES *RL* CIRCUITS

The impedance of a series *RL* circuit consists of resistance and inductive reactance and is the total opposition to sinusoidal current. Its unit is the ohm. The impedance also results in a phase difference between the total current and the source voltage. Therefore, the impedance consists of a magnitude component and a phase angle component and is represented as a phasor quantity.

After completing this section, you should be able to

◆ **Determine the impedance of a series *RL* circuit**

   ◆ Express inductive reactance in complex form

   ◆ Express total impedance in complex form

   ◆ Calculate impedance magnitude and the phase angle

The impedance of a series *RL* circuit is determined by the resistance and the inductive reactance. Inductive reactance is expressed as a phasor quantity in rectangular form as

$$\mathbf{X}_L = jX_L$$

In the series *RL* circuit of Figure 16–2, the total impedance is the phasor sum of R and jX_L and is expressed as

$$\mathbf{Z} = R + jX_L$$

<div style="text-align:right">**Equation 16–1**</div>
◀ **FIGURE 16–2**

Impedance in a series *RL* circuit.

In ac analysis, both R and X_L are as shown in the phasor diagram of Figure 16–3(a), with X_L appearing at a +90° angle with respect to R. This relationship comes from the fact that the inductor voltage leads the current, and thus the resistor voltage, by 90°. Since **Z** is the phasor sum of R and jX_L, its phasor representation is as shown in Figure 16–3(b). A repositioning of the phasors, as shown in part (c), forms a right triangle called the *impedance triangle*. The length of each phasor represents the magnitude of the quantity, and θ is the phase angle between the applied voltage and the current in the *RL* circuit.
▲ **FIGURE 16–3**

Development of the impedance triangle for a series *RL* circuit.

The impedance magnitude of the series *RL* circuit can be expressed in terms of the resistance and reactance as

$$Z = \sqrt{R^2 + X_L^2}$$

The magnitude of the impedance is expressed in ohms.

The phase angle, θ, is expressed as

$$\theta = \tan^{-1}\left(\frac{X_L}{R}\right)$$

Combining the magnitude and the angle, the impedance can be expressed in polar form as

Equation 16–2

$$\mathbf{Z} = \sqrt{R^2 + X_L^2}\angle\tan^{-1}\left(\frac{X_L}{R}\right)$$

EXAMPLE 16–1

For each circuit in Figure 16–4, write the phasor expression for the impedance in both rectangular and polar forms.
▲ **FIGURE 16–4**

Solution For the circuit in Figure 16–4(a), the impedance is

$$\mathbf{Z} = R + j0 = R = \mathbf{56\,\Omega} \quad \text{in rectangular form } (X_L = 0)$$
$$\mathbf{Z} = R\angle 0° = \mathbf{56\angle 0°\,\Omega} \quad \text{in polar form}$$

The impedance is simply equal to the resistance, and the phase angle is zero because pure resistance does not introduce a phase shift.

For the circuit in Figure 16–4(b), the impedance is

$$\mathbf{Z} = 0 + jX_L = \mathbf{j100}\ \Omega \qquad \text{in rectangular form } (R = 0)$$
$$\mathbf{Z} = X_L\angle 90° = \mathbf{100}\angle\mathbf{90°}\ \Omega \qquad \text{in polar form}$$

The impedance equals the inductive reactance in this case, and the phase angle is +90° because the inductance causes the current to lag the voltage by 90°.

For the circuit in Figure 16–4(c), the impedance in rectangular form is

$$\mathbf{Z} = R + jX_L = \mathbf{56}\ \Omega + \mathbf{j100}\ \Omega$$

The impedance in polar form is

$$\mathbf{Z} = \sqrt{R^2 + X_L^2}\angle\tan^{-1}\left(\frac{X_L}{R}\right)$$

$$= \sqrt{(56\ \Omega)^2 + (100\ \Omega)^2}\angle\tan^{-1}\left(\frac{100\ \Omega}{56\ \Omega}\right) = \mathbf{115}\angle\mathbf{60.8°}\ \Omega$$

In this case, the impedance is the phasor sum of the resistance and the inductive reactance. The phase angle is fixed by the relative values of X_L and R.

*Related Problem** In a series *RL* circuit, $R = 1.8\ \text{k}\Omega$ and $X_L = 950\ \Omega$. Express the impedance in both rectangular and polar forms.

Ohm's Law

The application of Ohm's law to series *RL* circuits involves the use of the phasor quantities of **Z**, **V**, and **I**. The three equivalent forms of Ohm's law were stated in Chapter 15 for *RC* circuits. They apply also to *RL* circuits and are restated here:

$$\mathbf{V} = \mathbf{IZ} \qquad \mathbf{I} = \frac{\mathbf{V}}{\mathbf{Z}} \qquad \mathbf{Z} = \frac{\mathbf{V}}{\mathbf{I}}$$

Recall that since Ohm's law calculations involve multiplication and division operations, you should express the voltage, current, and impedance in polar form.

EXAMPLE 16–2

The current in Figure 16–5 is expressed in polar form as $\mathbf{I} = 0.2\angle 0°$ mA. Determine the source voltage expressed in polar form, and draw a phasor diagram showing the relationship between the source voltage and the current.
▲ FIGURE 16–5

Solution   The magnitude of the inductive reactance is

$$X_L = 2\pi fL = 2\pi(10 \text{ kHz})(100 \text{ mH}) = 6.28 \text{ k}\Omega$$

The impedance in rectangular form is

$$\mathbf{Z} = R + jX_L = 10 \text{ k}\Omega + j6.28 \text{ k}\Omega$$

Converting to polar form yields

$$\mathbf{Z} = \sqrt{R^2 + X_L^2} \angle \tan^{-1}\left(\frac{X_L}{R}\right)$$

$$= \sqrt{(10 \text{ k}\Omega)^2 + (6.28 \text{ k}\Omega)^2} \angle \tan^{-1}\left(\frac{6.28 \text{ k}\Omega}{10 \text{ k}\Omega}\right) = \mathbf{11.8 \angle 32.1° \text{ k}\Omega}$$

Use Ohm's law to determine the source voltage.

$$\mathbf{V}_s = \mathbf{IZ} = (0.2\angle 0° \text{ mA})(11.8\angle 32.1° \text{ k}\Omega) = \mathbf{2.36 \angle 32.1° \text{ V}}$$

The magnitude of the source voltage is 2.36 V at an angle of 32.1° with respect to the current; that is, the voltage leads the current by 32.1°, as shown in the phasor diagram of Figure 16–6.

▶ FIGURE 16–6
Phase Relationships of Current and Voltages

In a series *RL* circuit, the current is the same through both the resistor and the inductor. Thus, the resistor voltage is in phase with the current, and the inductor voltage leads the current by 90°. Therefore, there is a phase difference of 90° between the resistor voltage, V_R, and the inductor voltage, V_L, as shown in the waveform diagram of Figure 16–7.
◄ **FIGURE 16–7**

Phase relation of voltages and current in a series *RL* circuit.

From Kirchhoff's voltage law, the sum of the voltage drops must equal the applied voltage. However, since V_R and V_L are not in phase with each other, they must be added as phasor quantities with V_L leading V_R by 90°, as shown in Figure 16–8(a). As shown in part (b), $\mathbf{V}_s$ is the phasor sum of V_R and V_L.

$$\mathbf{V}_s = V_R + jV_L$$

Equation 16–3

This equation can be expressed in polar form as

$$\mathbf{V}_s = \sqrt{V_R^2 + V_L^2} \angle \tan^{-1}\left(\frac{V_L}{V_R}\right)$$

Equation 16–4

where the magnitude of the source voltage is

$$V_s = \sqrt{V_R^2 + V_L^2}$$

and the phase angle between the resistor voltage and the source voltage is

$$\theta = \tan^{-1}\left(\frac{V_L}{V_R}\right)$$
◄ **FIGURE 16–8**

Voltage phasor diagram for a series *RL* circuit.
Since the resistor voltage and the current are in phase, θ is also the phase angle between the source voltage and the current. Figure 16–9 shows a voltage and current phasor diagram that represents the waveform diagram of Figure 16–7.

Variation of Impedance and Phase Angle with Frequency

The impedance triangle is useful in visualizing how the frequency of the applied voltage affects the *RL* circuit response. As you know, inductive reactance varies directly with frequency. When X_L increases, the magnitude of the total impedance also increases; and when X_L decreases, the magnitude of the total impedance decreases. Thus, Z is directly dependent on frequency. The phase angle θ also varies directly with frequency because $\theta = \tan^{-1}(X_L/R)$. As X_L increases with frequency, so does θ, and vice versa.

The impedance triangle is used in Figure 16–10 to illustrate the variations in X_L, Z, and θ as the frequency changes. Of course, R remains constant. The main point is that because X_L varies directly with the frequency, so also do the magnitude of the total impedance and the phase angle. Example 16–3 illustrates this.

▶ FIGURE 16–10

As the frequency increases, X_L increases, Z increases, and θ increases. Each value of frequency can be visualized as forming a different impedance triangle.
EXAMPLE 16–3

For the series *RL* circuit in Figure 16–11, determine the magnitude of the total impedance and the phase angle for each of the following frequencies:

(a) 10 kHz   **(b)** 20 kHz   **(c)** 30 kHz

▶ FIGURE 16–11
Solution   **(a)** For $f = 10$ kHz,

$$X_L = 2\pi f L = 2\pi(10\text{ kHz})(20\text{ mH}) = 1.26\text{ k}\Omega$$

$$\mathbf{Z} = \sqrt{R^2 + X_L^2}\angle\tan^{-1}\left(\frac{X_L}{R}\right)$$

$$= \sqrt{(1.0\text{ k}\Omega)^2 + (1.26\text{ k}\Omega)^2}\angle\tan^{-1}\left(\frac{1.26\text{ k}\Omega}{1.0\text{ k}\Omega}\right) = 1.61\angle 51.6°\text{ k}\Omega$$

Thus, $Z = \mathbf{1.61\text{ k}\Omega}$ and $\theta = \mathbf{51.6°}$.

(b) For $f = 20$ kHz,

$$X_L = 2\pi(20\text{ kHz})(20\text{ mH}) = 2.51\text{ k}\Omega$$

$$\mathbf{Z} = \sqrt{(1.0\text{ k}\Omega)^2 + (2.51\text{ k}\Omega)^2}\angle\tan^{-1}\left(\frac{2.51\text{ k}\Omega}{1.0\text{ k}\Omega}\right) = 2.70\angle 68.3°\text{ k}\Omega$$

Thus, $Z = \mathbf{2.70\text{ k}\Omega}$ and $\theta = \mathbf{68.3°}$.

(c) For $f = 30$ kHz,

$$X_L = 2\pi(30\text{ kHz})(20\text{ mH}) = 3.77\text{ k}\Omega$$

$$\mathbf{Z} = \sqrt{(1.0\text{ k}\Omega)^2 + (3.77\text{ k}\Omega)^2}\angle\tan^{-1}\left(\frac{3.77\text{ k}\Omega}{1.0\text{ k}\Omega}\right) = \mathbf{3.90\angle 75.1°\text{ k}\Omega}$$

Thus, $Z = \mathbf{3.90\text{ k}\Omega}$ and $\theta = \mathbf{75.1°}$.

Notice that as the frequency increases, X_L, Z, and θ also increase.

Related Problem Determine Z and θ in Figure 16–11 if f is 100 kHz.

The *RL* Lead Circuit

An **RL lead circuit** is a phase shift circuit in which the output voltage leads the input voltage by a specified amount. Figure 16–12(a) shows a series *RL* circuit with the output voltage taken across the inductor. Note that in the *RC* lead circuit, the output was taken across the resistor. The source voltage is the input, V_{in}. As you know, θ is the angle between the current and the input voltage; it is also the angle between the resistor voltage and the input voltage because V_R and I are in phase.

(a) A basic *RL* lead circuit

(b) Phasor voltage diagram showing V_{out} leading V_{in}

(c) Input and output voltage waveforms
▲ **FIGURE 16–12**

The *RL* lead circuit ($V_{out} = V_L$).

Since V_L leads V_R by 90°, the phase angle between the inductor voltage and the input voltage is the difference between 90° and θ, as shown in Figure 16–12(b). The inductor voltage is the output; it leads the input, thus creating a basic lead circuit.

The input and output voltage waveforms of the lead circuit are shown in Figure 16–12(c). The amount of phase difference, designated ϕ, between the input and the output is dependent on the relative values of the inductive reactance and the resistance, as is the magnitude of the output voltage.

Phase Difference Between Input and Output The angle between V_{out} and V_{in} is designated ϕ (phi) and is developed as follows. The polar expressions for the input voltage and the current are $V_{in}\angle 0°$ and $I\angle{-\theta}$, respectively. The output voltage in polar form is

$$\mathbf{V}_{out} = (I\angle{-\theta})(X_L\angle 90°) = IX_L\angle(90° - \theta)$$

This expression shows that the output voltage is at an angle of $90° - \theta$ with respect to the input voltage. Since $\theta = \tan^{-1}(X_L/R)$, the angle ϕ between the input and output is

$$\phi = 90° - \tan^{-1}\left(\frac{X_L}{R}\right)$$

Equivalently, this angle can be expressed as

Equation 16–5

$$\phi = \tan^{-1}\left(\frac{R}{X_L}\right)$$

The angle ϕ between the output and input is always positive, indicating that the output voltage leads the input voltage, as indicated in Figure 16–13.

Solution For the lead circuit in Figure 16–14(a),

$$\phi = \tan^{-1}\left(\frac{R}{X_L}\right) = \tan^{-1}\left(\frac{15 \text{ k}\Omega}{5 \text{ k}\Omega}\right) = \mathbf{71.6°}$$

The output leads the input by 71.6°.
    For the lead circuit in Figure 16–14(b), first determine the inductive reactance.

$$X_L = 2\pi f L = 2\pi(1 \text{ kHz})(50 \text{ mH}) = 314 \text{ }\Omega$$

$$\phi = \tan^{-1}\left(\frac{R}{X_L}\right) = \tan^{-1}\left(\frac{680 \text{ }\Omega}{314 \text{ }\Omega}\right) = \mathbf{65.2°}$$

The output leads the input by 65.2°.

Magnitude of the Output Voltage To evaluate the output voltage in terms of its magnitude, visualize the *RL* lead circuit as a voltage divider. A portion of the total input voltage is dropped across the resistor and a portion across the inductor. Because the output voltage is the voltage across the inductor, it can be calculated using either Ohm's law ($V_{out} = IX_L$) or the voltage-divider formula.

$$V_{out} = \left(\frac{X_L}{\sqrt{R^2 + X_L^2}} \right) V_{in}$$

Solution The output voltage in phasor form is

$$\mathbf{V}_{out} = V_{out} \angle \phi = \left(\frac{X_L}{\sqrt{R^2 + X_L^2}} \right) V_{in} \angle \phi$$

$$= \left(\frac{314\,\Omega}{\sqrt{(680\,\Omega)^2 + (314\,\Omega)^2}} \right) 5 \angle 65.2°\,\text{V} = \mathbf{2.10 \angle 65.2°\ V}$$

The peak values of voltage are

$$V_{in(p)} = 1.414 V_{in(rms)} = 1.414(5\,\text{V}) = 7.07\,\text{V}$$
$$V_{out(p)} = 1.414 V_{out(rms)} = 1.414(2.10\,\text{V}) = 2.97\,\text{V}$$

The waveforms with their peak values are shown in Figure 16–15. Notice that the output voltage leads the input voltage by 65.2°.

The *RL* Lag Circuit

An *RL* lag circuit is a phase shift circuit in which the output voltage lags the input voltage by a specified amount. When the output of a series *RL* circuit is taken across the resistor rather than the inductor, as shown in Figure 16–16(a), it becomes a lag circuit.

(a) A basic *RL* lag circuit

(b) Phasor voltage diagram showing phase lag between V_{in} and V_{out}

(c) Input and output waveforms
▲ **FIGURE 16–16**

The *RL* lag circuit ($V_{out} = V_R$).

Phase Difference Between Input and Output   In a series *RL* circuit, the current lags the input voltage. Since the output voltage is taken across the resistor, the output lags the input, as indicated by the phasor diagram in Figure 16-16(b). The waveforms are shown in Figure 16–16(c).

As in the lead circuit, the amount of phase difference between the input and output and the magnitude of the output voltage in the lag circuit are dependent on the relative values of the resistance and the inductive reactance. When the input voltage is assigned a reference angle of 0°, the angle of the output voltage (ϕ) with respect to the input voltage equals θ because the resistor voltage (output) and the current are in phase with each other. The expression for the angle between the input voltage and the output voltage is

Equation 16–7

$$\phi = -\tan^{-1}\left(\frac{X_L}{R}\right)$$

This angle is negative because the output lags the input.

For the lag circuit in Figure 16–17(b), first determine the inductive reactance.

$$X_L = 2\pi fL = 2\pi(1 \text{ kHz})(100 \text{ mH}) = 628 \text{ }\Omega$$

$$\phi = -\tan^{-1}\left(\frac{X_L}{R}\right) = -\tan^{-1}\left(\frac{628 \text{ }\Omega}{1.0 \text{ k}\Omega}\right) = -32.1°$$

The output lags the input by 32.1°.

PARALLEL CIRCUITS

16–4 IMPEDANCE AND ADMITTANCE OF PARALLEL *RL* CIRCUITS

In this section, you will learn how to determine the impedance and phase angle of a parallel *RL* circuit. The impedance consists of a magnitude component and a phase angle component. Also, inductive susceptance and admittance of a parallel *RL* circuit are introduced.

After completing this section, you should be able to

◆ **Determine impedance and admittance in a parallel *RL* circuit**

  ◆ Express total impedance in complex form

  ◆ Define and calculate *inductive susceptance* and *admittance*

Figure 16–19 shows a basic parallel *RL* circuit connected to an ac voltage source.
▲ **FIGURE 16–19**

Parallel *RL* circuit.

The expression for the total impedance of a two-component parallel *RL* circuit is developed as follows, using the product-over-sum rule.

$$\mathbf{Z} = \frac{(R\angle 0°)(X_L\angle 90°)}{R + jX_L} = \frac{RX_L\angle(0° + 90°)}{\sqrt{R^2 + X_L^2}\angle\tan^{-1}\left(\dfrac{X_L}{R}\right)}$$

$$= \left(\frac{RX_L}{\sqrt{R^2 + X_L^2}}\right)\angle\left(90° - \tan^{-1}\left(\frac{X_L}{R}\right)\right)$$

Equivalently, this equation can be expressed as

$$\mathbf{Z} = \left(\frac{RX_L}{\sqrt{R^2 + X_L^2}}\right)\angle\tan^{-1}\left(\frac{R}{X_L}\right)$$

Equation 16–9

EXAMPLE 16–8

For each circuit in Figure 16–20, determine the magnitude and phase angle of the total impedance.

(a)   (b)
Solution For the circuit in Figure 16–20(a), the total impedance is

$$\mathbf{Z} = \left(\frac{RX_L}{\sqrt{R^2 + X_L^2}}\right)\angle\tan^{-1}\left(\frac{R}{X_L}\right)$$

$$= \left(\frac{(100\ \Omega)(50\ \Omega)}{\sqrt{(100\ \Omega)^2 + (50\ \Omega)^2}}\right)\angle\tan^{-1}\left(\frac{100\ \Omega}{50\ \Omega}\right) = \mathbf{44.7\angle 63.4°\ \Omega}$$

Thus, $Z = 44.7\ \Omega$ and $\theta = 63.4°$.

For the circuit in Figure 16–20(b), the total impedance is

$$\mathbf{Z} = \left(\frac{(1.0\ \text{k}\Omega)(2\ \text{k}\Omega)}{\sqrt{(1.0\ \text{k}\Omega)^2 + (2\ \text{k}\Omega)^2}}\right)\angle\tan^{-1}\left(\frac{1.0\ \text{k}\Omega}{2\ \text{k}\Omega}\right) = \mathbf{894\angle 26.6°\ \Omega}$$

Thus, $Z = 894\ \Omega$ and $\theta = 26.6°$.

Notice that the positive angle indicates that the voltage leads the current, in contrast to the *RC* case where the voltage lags the current.

Related Problem In a parallel circuit, $R = 10\ \text{k}\Omega$ and $X_L = 14\ \text{k}\Omega$. Determine the total impedance in polar form.

Conductance, Susceptance, and Admittance

As you know from the previous chapter, conductance (*G*) is the reciprocal of resistance, susceptance (*B*) is the reciprocal of reactance, and admittance (*Y*) is the reciprocal of impedance.

For parallel *RL* circuits, the phasor expression for **inductive susceptance (B_L)** is

$$\mathbf{B}_L = \frac{1}{X_L\angle 90°} = B_L\angle -90° = -jB_L$$

and the phasor expression for **admittance** is

$$\mathbf{Y} = \frac{1}{Z\angle \pm\theta} = Y\angle \mp\theta$$

For the basic parallel *RL* circuit shown in Figure 16–21(a), the total admittance is the phasor sum of the conductance and the inductive susceptance, as shown in part (b).

Equation 16–10

$$\mathbf{Y} = G - jB_L$$

As with the *RC* circuit, the unit for conductance (*G*), inductive susceptance (B_L), and admittance (*Y*) is the siemens (S).
▲ FIGURE 16–21

Admittance in a parallel *RL* circuit.

EXAMPLE 16–9

Determine the total admittance and then convert it to total impedance in Figure 16–22. Draw the admittance phasor diagram.

◆ FIGURE 16–22
Solution   First, determine the conductance magnitude. $R = 330 \ \Omega$; thus,

$$G = \frac{1}{R} = \frac{1}{330 \ \Omega} = 3.03 \ \text{mS}$$

Then, determine the inductive reactance.

$$X_L = 2\pi fL = 2\pi(1000 \ \text{Hz})(100 \ \text{mH}) = 628 \ \Omega$$

The inductive susceptance magnitude is

$$B_L = \frac{1}{X_L} = \frac{1}{628 \ \Omega} = 1.59 \ \text{mS}$$

The total admittance is

$$\mathbf{Y}_{tot} = G - jB_L = 3.03 \ \text{mS} - j1.59 \ \text{mS}$$

which can be expressed in polar form as

$$\mathbf{Y}_{tot} = \sqrt{G^2 + B_L^2} \angle -\tan^{-1}\left(\frac{B_L}{G}\right)$$

$$= \sqrt{(3.03 \ \text{mS})^2 + (1.59 \ \text{mS})^2} \angle -\tan^{-1}\left(\frac{1.59 \ \text{mS}}{3.03 \ \text{mS}}\right) = \mathbf{3.42 \angle -27.7° \ mS}$$

The admittance phasor diagram is shown in Figure 16–23.

◆ FIGURE 16–23
Convert total admittance to total impedance as follows:

$$\mathbf{Z}_{tot} = \frac{1}{\mathbf{Y}_{tot}} = \frac{1}{3.42\angle -27.7° \text{ mS}} = 292\angle 27.7° \ \Omega$$

The positive phase angle indicates that the voltage leads the current.

1. If *Z* = 500 Ω, what is the value of the magnitude of the admittance *Y*?
2. In a certain parallel *RL* circuit, *R* = 470 Ω and X_L = 750 Ω. Determine *Y*.
3. In the circuit of Question 2, does the total current lead or lag the applied voltage? By what phase angle?

16–5   ANALYSIS OF PARALLEL *RL* CIRCUITS

Ohm's law and Kirchhoff's current law are used in the analysis of *RL* circuits. Current and voltage relationships in a parallel *RL* circuit are examined.

After completing this section, you should be able to

◆ **Analyze a parallel *RL* circuit**

   ◆ Apply Ohm's law and Kirchhoff's current law to parallel *RL* circuits

   ◆ Express the voltages and currents as phasor quantities

The following example applies Ohm's law to the analysis of a parallel *RL* circuit.

EXAMPLE 16–10

Determine the total current and the phase angle in the circuit of Figure 16–24. Draw a phasor diagram showing the relationship of $\mathbf{V}_s$ and $\mathbf{I}_{tot}$.

◆ FIGURE 16–24
Solution   The inductive reactance is

$$X_L = 2\pi f L = 2\pi(1.5\text{ kHz})(150\text{ mH}) = 1.41\text{ k}\Omega$$

The inductive susceptance magnitude is

$$B_L = \frac{1}{X_L} = \frac{1}{1.41\text{ k}\Omega} = 709\ \mu\text{S}$$

The conductance magnitude is

$$G = \frac{1}{R} = \frac{1}{2.2\text{ k}\Omega} = 455\ \mu\text{S}$$

The total admittance is

$$\mathbf{Y}_{tot} = G - jB_L = 455\ \mu\text{S} - j709\ \mu\text{S}$$

Converting to polar form yields

$$\mathbf{Y}_{tot} = \sqrt{G^2 + B_L^2}\angle -\tan^{-1}\left(\frac{B_L}{G}\right)$$

$$= \sqrt{(455\ \mu\text{S})^2 + (709\ \mu\text{S})^2}\angle -\tan^{-1}\left(\frac{709\ \mu\text{S}}{455\ \mu\text{S}}\right) = 842\angle -57.3°\ \mu\text{S}$$

The phase angle is −57.3°.
Use Ohm's law to determine the total current.

$$\mathbf{I}_{tot} = \mathbf{V}_s\mathbf{Y}_{tot} = (10\angle 0°\text{ V})(842\angle -57.3°\ \mu\text{S}) = \mathbf{8.42\angle -57.3°\text{ mA}}$$

The magnitude of the total current is 8.42 mA, and it lags the applied voltage by **57.3°**, as indicated by the negative angle associated with it. The phasor diagram in Figure 16–25 shows these relationships.

▶ **FIGURE 16–25**
Related Problem   Determine the current in polar form if *f* is reduced to 800 Hz in Figure 16–24.

Phase Relationships of Currents and Voltages

Figure 16–26(a) shows all the currents in a basic parallel *RL* circuit. The total current, I_{tot}, divides at the junction into the two branch currents, I_R and I_L. The applied voltage, V_s, appears across both the resistive and the inductive branches, so V_s, V_R, and V_L are all in phase and of the same magnitude.

The current through the resistor is in phase with the voltage. The current through the inductor lags the voltage and the resistor current by 90°. By Kirchhoff's current law, the total current is the phasor sum of the two branch currents, as shown by the phasor diagram in Figure 16–26(b). The total current is expressed as

$$\mathbf{I}_{tot} = I_R - jI_L$$ **Equation 16–11**

(a)　　　　　　　　　　　　　(b)
▲ FIGURE 16–26

Currents in a parallel *RL* circuit. The current directions shown in part (a) are instantaneous and, of course, reverse when the source voltage reverses during each cycle.

This equation can be expressed in polar form as

Equation 16–12

$$\mathbf{I}_{tot} = \sqrt{I_R^2 + I_L^2} \angle -\tan^{-1}\left(\frac{I_L}{I_R}\right)$$

where the magnitude of the total current is

$$I_{tot} = \sqrt{I_R^2 + I_L^2}$$

and the phase angle between the resistor current and the total current is

$$\theta = -\tan^{-1}\left(\frac{I_L}{I_R}\right)$$

　　Since the resistor current and the applied voltage are in phase, θ also represents the phase angle between the total current and the applied voltage. Figure 16–27 shows a complete current and voltage phasor diagram.

EXAMPLE 16–11

Determine the value of each current in Figure 16–28, and describe the phase relationship of each with the applied voltage. Draw the current phasor diagram.

▶ FIGURE 16–28
Solution   The resistor current, the inductor current, and the total current are expressed as follows:

$$\mathbf{I}_R = \frac{\mathbf{V}_s}{\mathbf{R}} = \frac{12\angle 0°\ \text{V}}{220\angle 0°\ \Omega} = \mathbf{54.5\angle 0°\ mA}$$

$$\mathbf{I}_L = \frac{\mathbf{V}_s}{\mathbf{X}_L} = \frac{12\angle 0°\ \text{V}}{150\angle 90°\ \Omega} = \mathbf{80\angle -90°\ mA}$$

$$\mathbf{I}_{tot} = I_R - jI_L = 54.5\ \text{mA} - j80\ \text{mA}$$

Converting $\mathbf{I}_{tot}$ to polar form yields

$$\mathbf{I}_{tot} = \sqrt{I_R^2 + I_L^2}\angle -\tan^{-1}\!\left(\frac{I_L}{I_R}\right)$$

$$= \sqrt{(54.5\ \text{mA})^2 + (80\ \text{mA})^2}\angle -\tan^{-1}\!\left(\frac{80\ \text{mA}}{54.5\ \text{mA}}\right) = \mathbf{96.8\angle -55.7°\ mA}$$

As the results show, the resistor current is 54.5 mA and is in phase with the applied voltage. The inductor current is 80 mA and lags the applied voltage by 90°. The total current is 96.8 mA and lags the voltage by 55.7°. The phasor diagram in Figure 16–29 shows these relationships.

SERIES-PARALLEL CIRCUITS

🌐 **16–6   ANALYSIS OF SERIES-PARALLEL _RL_ CIRCUITS**

The concepts studied with respect to series and parallel circuits are used to analyze circuits with combinations of both series and parallel R and L components.

After completing this section, you should be able to

- ◆ **Analyze series-parallel _RL_ circuits**
  - ◆ Determine total impedance
  - ◆ Calculate currents and voltages

Recall from Section 15–1 that the impedance of series components is most easily expressed in rectangular form and that the impedance of parallel components is best found by using polar form. The steps for analyzing a circuit with a series and a parallel component are illustrated in Example 16–12. First express the impedance of the series part of the circuit in rectangular form and the impedance of the parallel part in polar form. Next, convert the impedance of the parallel part to rectangular form and add it to the impedance of the series part. Once you determine the rectangular form of the total impedance, you can convert it to polar form in order to see the magnitude and phase angle and to calculate the current.

EXAMPLE 16–12

In the circuit of Figure 16–30, determine the following values:

(a) $\mathbf{Z}_{tot}$ **(b)** $\mathbf{I}_{tot}$ **(c)** θ

▸ **FIGURE 16–30**
Solution   **(a)** First, calculate the magnitudes of inductive reactance.

$$X_{L1} = 2\pi f L_1 = 2\pi(500 \text{ kHz})(2.5 \text{ mH}) = 7.85 \text{ k}\Omega$$
$$X_{L2} = 2\pi f L_2 = 2\pi(500 \text{ kHz})(1\text{mH}) = 3.14 \text{ k}\Omega$$

One approach is to find the impedance of the series portion and the impedance of the parallel portion and combine them to get the total impedance. The impedance of the series combination of R_1 and L_1 is

$$\mathbf{Z}_1 = R_1 + jX_{L1} = 4.7\,\text{k}\Omega + j7.85\,\text{k}\Omega$$

To determine the impedance of the parallel portion, first determine the admittance of the parallel combination of R_2 and L_2.

$$G_2 = \frac{1}{R_2} = \frac{1}{3.3\,\text{k}\Omega} = 303\,\mu\text{S}$$

$$B_{L2} = \frac{1}{X_{L2}} = \frac{1}{3.14\,\text{k}\Omega} = 318\,\mu\text{S}$$

$$\mathbf{Y}_2 = G_2 - jB_L = 303\,\mu\text{S} - j318\,\mu\text{S}$$

Converting to polar form yields

$$\mathbf{Y}_2 = \sqrt{G_2^2 + B_{L2}^2}\angle -\tan^{-1}\left(\frac{B_{L2}}{G_2}\right)$$

$$= \sqrt{(303\,\mu\text{S})^2 + (318\,\mu\text{S})^2}\angle -\tan^{-1}\left(\frac{318\,\mu\text{S}}{303\,\mu\text{S}}\right) = 439\angle -46.4°\,\mu\text{S}$$

Then, the impedance of the parallel portion is

$$\mathbf{Z}_2 = \frac{1}{\mathbf{Y}_2} = \frac{1}{439\angle -46.4°\,\mu\text{S}} = 2.28\angle 46.4°\,\text{k}\Omega$$

Converting to rectangular form yields

$$\mathbf{Z}_2 = Z_2\cos\theta + jZ_2\sin\theta$$

$$= (2.28\,\text{k}\Omega)\cos(46.4°) + j(2.28\,\text{k}\Omega)\sin(46.4°) = 1.57\,\text{k}\Omega + j1.65\,\text{k}\Omega$$

The series portion and the parallel portion are in series with each other. Combine $\mathbf{Z}_1$ and $\mathbf{Z}_2$ to get the total impedance.

$$\mathbf{Z}_{tot} = \mathbf{Z}_1 + \mathbf{Z}_2$$

$$= (4.7\,\text{k}\Omega + j7.85\,\text{k}\Omega) + (1.57\,\text{k}\Omega + j1.65\,\text{k}\Omega) = 6.27\,\text{k}\Omega + j9.50\,\text{k}\Omega$$

Expressing $\mathbf{Z}_{tot}$ in polar form yields

$$\mathbf{Z}_{tot} = \sqrt{Z_1^2 + Z_2^2}\angle \tan^{-1}\left(\frac{Z_2}{Z_1}\right)$$

$$= \sqrt{(6.27\,\text{k}\Omega)^2 + (9.50\,\text{k}\Omega)^2}\angle \tan^{-1}\left(\frac{9.50\,\text{k}\Omega}{6.27\,\text{k}\Omega}\right) = \mathbf{11.4\angle 56.6°\,\text{k}\Omega}$$

(b) Use Ohm's law to find the total current.

$$\mathbf{I}_{tot} = \frac{\mathbf{V}_s}{\mathbf{Z}_{tot}} = \frac{10\angle 0°\,\text{V}}{11.4\angle 56.6°\,\text{k}\Omega} = \mathbf{877\angle -56.6°\,\mu\text{A}}$$

(c) The total current lags the applied voltage by **56.6°**.

Related Problem **(a)** Determine the voltage across the series part of the circuit in Figure 16–30.

(b) Determine the voltage across the parallel part of the circuit in Figure 16–30.

Use Multisim files E16-12A and E16-12B to verify the calculated results in the (b) part of this example and to confirm your calculation for the related problem, part (b).

Example 16–13 shows two sets of series components in parallel. The approach is to first express each branch impedance in rectangular form and then convert each of these impedances to polar form. Next, calculate each branch current using polar notation. Once you know the branch currents, you can find the total current by adding the two branch currents in rectangular form. In this particular case, the total impedance is not required.

EXAMPLE 16–13

Determine the voltage across each component in Figure 16–31. Draw a voltage phasor diagram and a current phasor diagram.

▶ **FIGURE 16–31**
Solution First, calculate X_{L1} and X_{L2}.

$$X_{L1} = 2\pi fL_1 = 2\pi(2\,\text{MHz})(50\,\mu\text{H}) = 628\,\Omega$$
$$X_{L2} = 2\pi fL_2 = 2\pi(2\,\text{MHz})(100\,\mu\text{H}) = 1.26\,\text{k}\Omega$$

Next, determine the impedance of each branch.

$$\mathbf{Z}_1 = R_1 + jX_{L1} = 330\,\Omega + j628\,\Omega$$
$$\mathbf{Z}_2 = R_2 + jX_{L2} = 1.0\,\text{k}\Omega + j1.26\,\text{k}\Omega$$

Convert these impedances to polar form.

$$\mathbf{Z}_1 = \sqrt{R_1^2 + X_{L1}^2}\,\angle\tan^{-1}\!\left(\frac{X_{L1}}{R_1}\right)$$

$$= \sqrt{(330\,\Omega)^2 + (628\,\Omega)^2}\,\angle\tan^{-1}\!\left(\frac{628\,\Omega}{330\,\Omega}\right) = 709\angle62.3°\,\Omega$$

$$\mathbf{Z}_2 = \sqrt{R_2^2 + X_{L2}^2}\,\angle\tan^{-1}\!\left(\frac{X_{L2}}{R_2}\right)$$

$$= \sqrt{(1.0\,\text{k}\Omega)^2 + (1.26\,\text{k}\Omega)^2}\,\angle\tan^{-1}\!\left(\frac{1.26\,\text{k}\Omega}{1.0\,\text{k}\Omega}\right) = 1.61\angle51.6°\,\text{k}\Omega$$

Calculate each branch current.

$$\mathbf{I}_1 = \frac{\mathbf{V}_s}{\mathbf{Z}_1} = \frac{10\angle0°\,\text{V}}{709\angle62.3°\,\Omega} = 14.1\angle-62.3°\,\text{mA}$$

$$\mathbf{I}_2 = \frac{\mathbf{V}_s}{\mathbf{Z}_2} = \frac{10\angle0°\,\text{V}}{1.61\angle51.6°\,\text{k}\Omega} = 6.21\angle-51.6°\,\text{mA}$$

Now, use Ohm's law to get the voltage across each element.

$$\mathbf{V}_{R1} = \mathbf{I}_1\mathbf{R}_1 = (14.1\angle-62.3°\,\text{mA})(330\angle0°\,\Omega) = \mathbf{4.65\angle-62.3°\,V}$$
$$\mathbf{V}_{L1} = \mathbf{I}_1\mathbf{X}_{L1} = (14.1\angle-62.3°\,\text{mA})(628\angle90°\,\Omega) = \mathbf{8.85\angle27.7°\,V}$$
$$\mathbf{V}_{R2} = \mathbf{I}_1\mathbf{R}_2 = (6.21\angle-51.6°\,\text{mA})(1\angle0°\,\text{k}\Omega) = \mathbf{6.21\angle-51.6°\,V}$$
$$\mathbf{V}_{L2} = \mathbf{I}_2\mathbf{X}_{L2} = (6.21\angle-51.6°\,\text{mA})(1.26\angle90°\,\text{k}\Omega) = \mathbf{7.82\angle38.4°\,V}$$

The voltage phasor diagram is shown in Figure 16–32, and the current phasor diagram is shown in Figure 16–33.

SPECIAL TOPICS

16–7 POWER IN *RL* CIRCUITS

In a purely resistive ac circuit, all of the energy delivered by the source is dissipated in the form of heat by the resistance. In a purely inductive ac circuit, all of the energy delivered by the source is stored by the inductor in its magnetic field during a portion of the voltage cycle and then returned to the source during another portion of the cycle so that there is no net energy conversion to heat. When there is both resistance and inductance, some of the energy is alternately stored and returned by the inductance and some is dissipated by the resistance. The amount of energy converted to heat is determined by the relative values of the resistance and the inductive reactance.

After completing this section, you should be able to

 • **Determine power in *RL* circuits**

   • Explain true and reactive power

   • Draw the power triangle

   • Explain power factor correction

When the resistance in a series *RL* circuit is greater than the inductive reactance, more of the total energy delivered by the source is converted to heat by the resistance than is stored by the inductor. Likewise, when the reactance is greater than the resistance, more of the total energy is stored and returned than is converted to heat.

As you know, the power dissipation in a resistance is called the *true power*. The power in an inductor is reactive power and is expressed as

Equation 16–13

$$P_r = I^2 X_L$$

The Power Triangle for *RL* Circuits

The generalized power triangle for a series *RL* circuit is shown in Figure 16–34. The **apparent power, P_a,** is the resultant of the average power, P_{true}, and the reactive power, P_r.

▶ **FIGURE 16–34**

Power triangle for an *RL* circuit.
Recall that the **power factor** equals the cosine of θ ($PF = \cos\theta$). As the phase angle between the applied voltage and the total current increases, the power factor decreases, indicating an increasingly reactive circuit. A smaller power factor indicates less true power and more reactive power.

EXAMPLE 16–14

Determine the power factor, the true power, the reactive power, and the apparent power in the circuit in Figure 16–35.

► **FIGURE 16–35**
Solution   The total impedance of the circuit in rectangular form is

$$\mathbf{Z} = R + jX_L = 1.0\,\text{k}\Omega + j2\,\text{k}\Omega$$

Converting to polar form yields

$$\mathbf{Z} = \sqrt{R_2^2 + X_L^2}\angle\tan^{-1}\left(\frac{X_L}{R}\right)$$

$$= \sqrt{(1.0\,\text{k}\Omega)^2 + (2\,\text{k}\Omega)^2}\angle\tan^{-1}\left(\frac{2\,\text{k}\Omega}{1.0\,\text{k}\Omega}\right) = 2.24\angle 63.4°\,\text{k}\Omega$$

The current magnitude is

$$I = \frac{V_s}{Z} = \frac{10\,\text{V}}{2.24\,\text{k}\Omega} = 4.46\,\text{mA}$$

The phase angle, indicated in the expression for **Z**, is

$$\theta = 63.4°$$

The power factor is, therefore,

$$PF = \cos\theta = \cos(63.4°) = \mathbf{0.448}$$

The true power is

$$P_{\text{true}} = V_s I\cos\theta = (10\,\text{V})(4.46\,\text{mA})(0.448) = \mathbf{20\,mW}$$

The reactive power is

$$P_r = I^2 X_L = (4.46\,\text{mA})^2(2\,\text{k}\Omega) = \mathbf{39.8\,mVAR}$$

The apparent power is

$$P_a = I^2 Z = (4.46\,\text{mA})^2(2.24\,\text{k}\Omega) = \mathbf{44.6\,mVA}$$

Related Problem   If the frequency in Figure 16–35 is increased, what happens to P_{true}, P_r, and P_a?

Significance of the Power Factor

As you learned in Chapter 15, the power factor (PF) is important in determining how much useful power (true power) is transferred to a load. The highest power factor is 1, which

indicates that all of the current to a load is in phase with the voltage (resistive). When the power factor is 0, all of the current to a load is 90° out of phase with the voltage (reactive).

Generally, a power factor as close to 1 as possible is desirable because then most of the power transferred from the source to the load is the useful or true power. True power goes only one way—from source to load—and performs work on the load in terms of energy dissipation. Reactive power simply goes back and forth between the source and the load with no net work being done. Energy must be used in order for work to be done.

Many practical loads have inductance as a result of their particular function, and it is essential for their proper operation. Examples are transformers, electric motors, and speakers, to name a few. Therefore, inductive (and capacitive) loads are important considerations.

To see the effect of the power factor on system requirements, refer to Figure 16–36. This figure shows a representation of a typical inductive load consisting effectively of inductance and resistance in parallel. Part (a) shows a load with a relatively low power factor (0.75), and part (b) shows a load with a relatively high power factor (0.95). Both loads dissipate equal amounts of power as indicated by the wattmeters. Thus, an equal amount of work is done on both loads.

(a) A lower power factor means more total current for a given power dissipation (watts). A larger source VA rating is required to deliver the true power (watts).

(b) A higher power factor means less total current for a given power dissipation. A smaller source can deliver the same true power (watts).
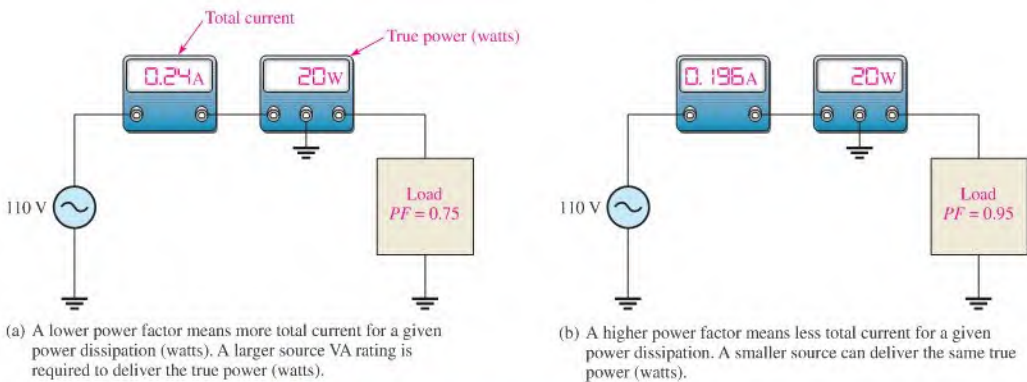

▲ **FIGURE 16–36**

Illustration of the effect of the power factor on system requirements such as source rating (VA) and conductor size.

Although both loads are equivalent in terms of the amount of work done (true power), the low power factor load in Figure 16–36(a) draws more current from the source than does the high power factor load in Figure 16–36(b), as indicated by the ammeters. Therefore, the source in part (a) must have a higher VA rating than the one in part (b). Also, the lines connecting the source to the load in part (a) must be a larger wire gauge than those in part (b), a condition that becomes significant when very long transmission lines are required, such as in power distribution.

Figure 16–36 has demonstrated that a higher power factor is an advantage in delivering power more efficiently to a load.

Power Factor Correction

The power factor of an inductive load can be increased by the addition of a capacitor in parallel, as shown in Figure 16–37. The capacitor compensates for the phase lag of the total current by creating a capacitive component of current that is 180° out of phase with the inductive component. This has a canceling effect and reduces the phase angle and the total current and increases the power factor, as illustrated in the figure.

(a) Total current is the resultant of I_R and I_L.

(b) I_C subtracts from I_L, leaving only a small reactive current, thus decreasing I_{tot} and the phase angle.
▲ FIGURE 16–37

Example of how the power factor can be increased by the addition of a compensating capacitor (C_c).

16–8 BASIC APPLICATIONS

Two applications of *RL* circuits are covered in this section. The first application is a basic frequency selective (filter) circuit. The second application is the switching regulator, a widely used circuit in power supplies because of its high efficiency. The switching regulator uses other components, but the *RL* circuit is emphasized.

After completing this section, you should be able to

♦ **Describe two examples of *RL* circuit applications**

   ♦ Discuss how the *RL* circuit operates as a filter

   ♦ Discuss the advantage of an inductor in a switching regulator

---

The *RL* Circuit as a Filter

As with *RC* circuits, series *RL* circuits also exhibit a frequency-selective characteristic and therefore act as basic filters.

Low-Pass Filter   You have seen what happens to the output magnitude and phase angle in a lag circuit. In terms of the filtering action, the variation of the magnitude of the output voltage as a function of frequency is important.

Figure 16–38 shows the filtering action of a series *RL* circuit using specific values for purposes of illustration. In part (a) of the figure, the input is zero frequency (dc). Since the inductor ideally acts as a short to constant direct current, the output voltage equals the full value of the input voltage (neglecting the winding resistance). Therefore, the circuit passes all of the input voltage to the output (10 V in, 10 V out).

In Figure 16–38(b), the frequency of the input voltage has been increased to 1 kHz, causing the inductive reactance to increase to 62.83 Ω. For an input voltage of 10 V rms, the output voltage is approximately 8.47 V rms, which can be calculated using the voltage-divider approach or Ohm's law.
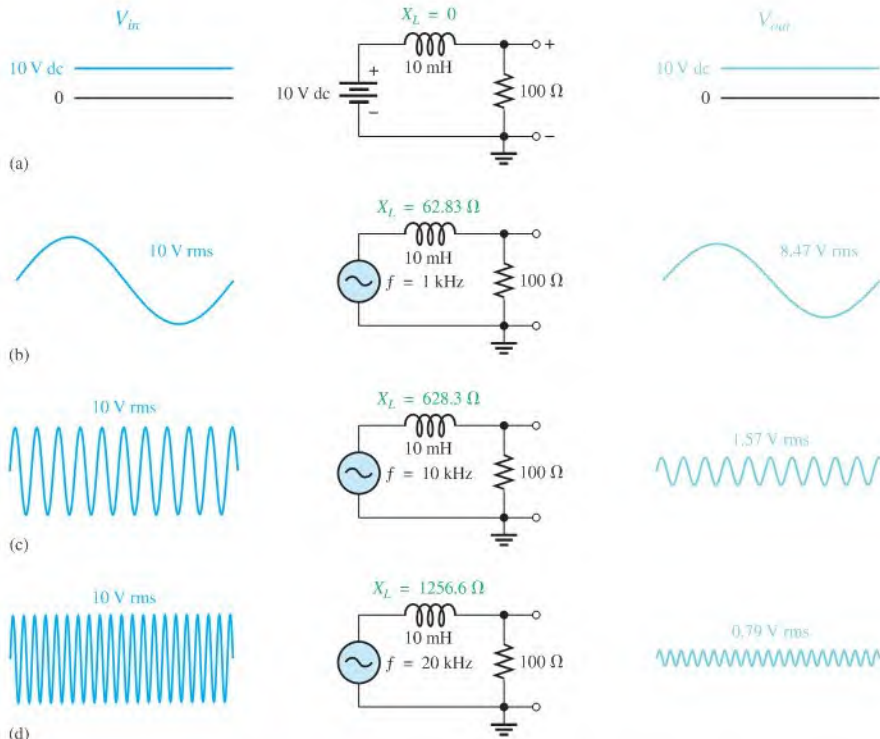

▲ **FIGURE 16–38**

Low-pass filtering action of an *RL* circuit (phase shift from input to output is not indicated).

In Figure 16–38(c), the input frequency has been increased to 10 kHz, causing the inductive reactance to increase further to 628.3 Ω. For a constant input voltage of 10 V rms, the output voltage is now 1.57 V rms.

As the input frequency is increased further, the output voltage continues to decrease and approaches zero as the frequency becomes very high, as shown in Figure 16–38(d) for $f = 20$ kHz.

A description of the circuit action is as follows: As the frequency of the input increases, the inductive reactance increases. Because the resistance is constant and the inductive reactance increases, the voltage across the inductor increases and that across the resistor (output voltage) decreases. The input frequency can be increased until it reaches a value at which the reactance is so large compared to the resistance that the output voltage can be neglected because it becomes very small compared to the input voltage.

As shown in Figure 16–38, the circuit passes dc (zero frequency) completely. As the frequency of the input increases, less of the input voltage is passed through to the output. That is, the output voltage decreases as the frequency increases. It is apparent that the lower frequencies pass through the circuit much better than the higher frequencies. This *RL* circuit is therefore a basic form of low-pass filter.

Figure 16–39 shows a response curve for a low-pass filter.

High-Pass Filter   Figure 16–40 illustrates high-pass filtering action, where the output is taken across the inductor. When the input voltage is dc (zero frequency) in part (a), the output is zero volts because the inductor ideally appears as a short across the output.
Low-pass filter response curve.

In Figure 16–40(b), the frequency of the input signal has been increased to 100 Hz with an rms value of 10 V. The output voltage is 0.63 V rms. Thus, only a small percentage of the input voltage appears at the output at this frequency.

In Figure 16–40(c), the input frequency is increased further to 1 kHz, causing more voltage to be developed as a result of the increase in the inductive reactance. The output voltage at this frequency is 5.32 V rms. As you can see, the output voltage increases as the frequency increases. A value of frequency is reached at which the reactance is very large compared to the resistance and most of the input voltage appears across the inductor, as shown in Figure 16–40(d).

This circuit tends to prevent lower frequency signals from appearing on the output but permits higher frequency signals to pass through from input to output; thus, it is a basic form of high-pass filter.
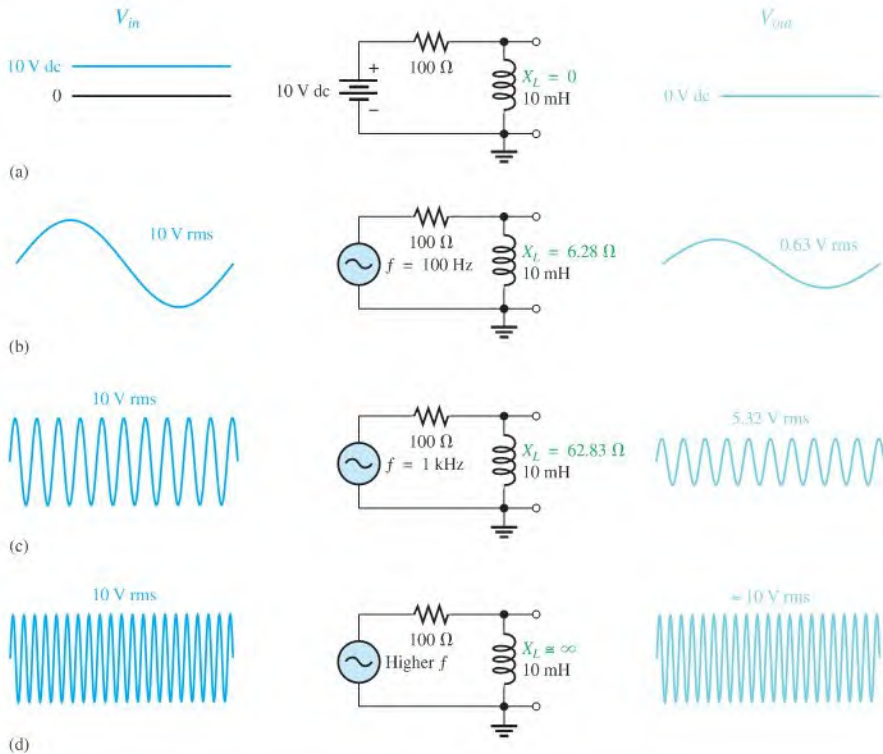

▲ FIGURE 16–40

High-pass filtering action of an *RL* circuit (phase shift from input to output is not indicated).

The response curve in Figure 16–41 shows that the output voltage increases and then levels off as it approaches the value of the input voltage as the frequency increases.

▶ **FIGURE 16–41**

High-pass filter response curve.
The Switching Regulator

In high-frequency switching power supplies, small inductors are used as an essential part of the filter section. A switching power supply is much more efficient at converting ac to dc than any other type of supply. For this reason it is widely used in computers and other electronic systems. A switching regulator precisely controls the dc voltage. One type of switching regulator is shown in Figure 16–42. It uses an electronic switch to change unregulated dc to high-frequency pulses. The output is the average value of the pulses. The pulse width is controlled by the pulse width modulator, which rapidly turns on and off a transistor switch and then is filtered by the filter section to produce regulated dc. (Ripple in the figure is exaggerated to show the cycle.) The pulse width modulator can increase pulse width if the output drops, or decrease it if the output rises, thus maintaining a constant average output for varying conditions.

▶ **FIGURE 16–42**

Diagram showing an inductor in a switching regulator.
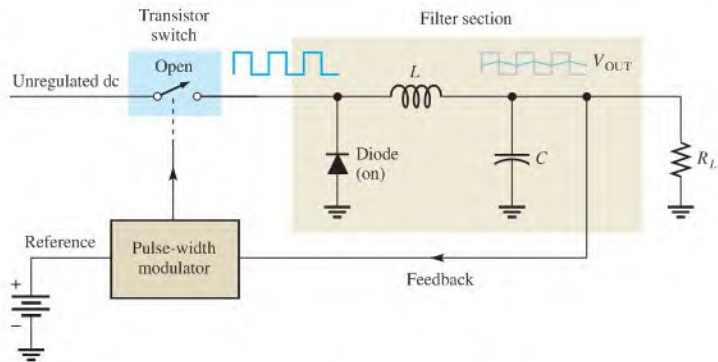

Figure 16–43 illustrates the basic filtering action. The filter consists of a diode, an inductor, and a capacitor. The diode is a one-way device for current that you will study in a devices course. In this application the diode acts as an on-off switch that allows current in only one direction.

An important component of the filter section is the inductor, which in this type of regulator will always have current in it. The average voltage and the load resistor determine the amount of current. Recall that Lenz's law states that an induced voltage is created across a coil that opposes a *change* in current. When the transistor switch is closed, the pulse is high and current is passed through the inductor and the load, as shown in Figure 16–43(a). The diode is off at this time. Notice that the inductor has an induced voltage across it that opposes a change in current. When the pulse goes low, as in Figure 16–43(b), the transistor is off and the inductor develops a voltage in the opposite direction than before. The diode acts as a closed switch, which provides a path for current. This action tends to keep the load current constant. The capacitor adds to this smoothing action by charging and discharging a small amount during the process.

16–9 TROUBLESHOOTING

Typical component failures have an effect on the frequency response of basic *RL* circuits.

After completing this section, you should be able to

- ◆ **Troubleshoot *RL* circuits**
  - ◆ Find an open inductor
  - ◆ Find an open resistor
  - ◆ Find an open in a parallel circuit

Effect of an Open Inductor   The most common failure mode for inductors occurs when the winding opens as a result of excessive current or a mechanical contact failure. It is easy to see how an open coil affects the operation of a basic series *RL* circuit, as shown in Figure 16–44. Obviously, there is no current path; therefore, the resistor voltage is zero, and the total applied voltage appears across the inductor. If you suspect an open coil, remove one or both leads from the circuit and check continuity with an ohmmeter.

▶ **FIGURE 16–44**

Effect of an open coil.
Effect of an Open Resistor   When the resistor is open, there is no current and the inductor voltage is zero. The total input voltage is across the open resistor, as shown in Figure 16–45.

▶ **FIGURE 16–45**

Effect of an open resistor.
Open Components in Parallel Circuits   In a parallel *RL* circuit, an open resistor or inductor will cause the total current to decrease because the total impedance will increase. Obviously, the branch with the open component will have zero current. Figure 16–46 illustrates these conditions.

(a) Before failure   (b) After *L* opens
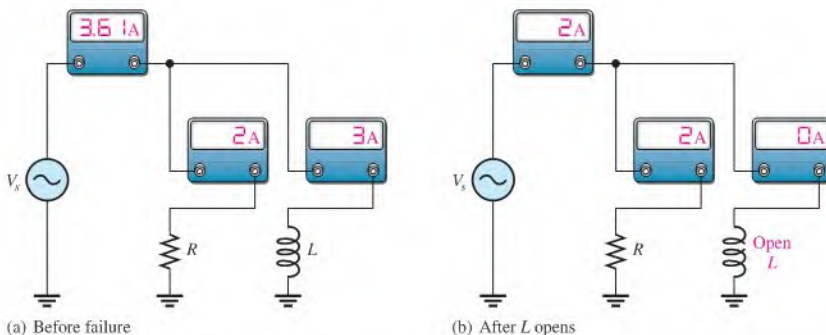

▲ **FIGURE 16–46**

Effect of an open component in a parallel circuit with V_s constant.

Effect of an Inductor with Shorted Windings   Although a rare occurrence, it is possible for some of the windings of coils to short together as a result of damaged insulation. This failure mode is much less likely than the open coil and is difficult to detect. Shorted windings may result in a reduction in inductance because the inductance of a coil is proportional to the square of the number of turns. A short between windings effectively reduces the number of turns, which may or may not have an adverse effect on the circuit depending on the number of turns that are shorted.

Other Troubleshooting Considerations

The failure of a circuit to work properly is not always the result of a faulty component. A loose wire, a bad contact, or a poor solder joint can cause an open circuit. A short can be caused by a wire clipping or solder splash. Things as simple as not plugging in a power supply or a function generator happen more often than you might think. Wrong values in a circuit (such as an incorrect resistor value), the function generator set at the wrong frequency, or the wrong output connected to the circuit can cause improper operation.

Always check to make sure that the instruments are properly connected to the circuits and to a power outlet. Also, look for obvious things such as a broken or loose contact, a connector that is not completely plugged in, or a piece of wire or a solder bridge that could be shorting something out.

The following example illustrates a troubleshooting approach to a circuit containing inductors and resistors using the APM (analysis, planning, and measurement) method and half-splitting.

EXAMPLE 16–15

The circuit represented by the schematic in Figure 16–47 has no output voltage. The circuit is physically constructed on a protoboard. Use your trouble-shooting skills to find the problem.

▶ **FIGURE 16–47**
Solution   Apply the APM method to this troubleshooting problem.

Analysis: First think of the possible causes for the circuit to have no output voltage.

1. There is no source voltage or the frequency is so high that the inductors appear to be open because their reactances are extremely high compared to the resistance values.

2. There is a short between one of the resistors and ground. Either a resistor could be shorted, or there could be some physical short. A shorted resistor is not a common fault.

3. There is an open between the source and the output. This would prevent current and thus cause the output voltage to be zero. An inductor could be open, or the conductive path could be open due to a broken or loose connecting wire or a bad protoboard contact.

4. There is an incorrect component value. A resistor could be so small that the voltage across it is negligible. An inductor could be so large that its reactance at the input frequency is extremely high.
(a) Scope shows the correct voltage at the input.
(b) A zero voltage at point ③ indicates the fault is between point ③ and the source. A reading of 8.31 V at point ② shows that L_2 is open.

▲ FIGURE 16–48

Planning: You decide to make some visual checks for problems such as the function generator power cord not plugged in or the frequency set at an incorrect value. Also, broken leads, shorted leads, as well as an incorrect resistor color code or inductor value often can be found visually. If nothing is discovered after a visual check, then you will make voltage measurements to track down the cause of the problem. You decide to use a digital oscilloscope and a DMM to make the measurements using the half-splitting technique to more quickly isolate the fault.

Measurement: Assume that you find that the function generator is plugged in and the frequency setting appears to be correct. Also, you find no visible opens or shorts during your visual check, and the component values are correct.

The first step in the measurement process is to check the voltage from the source with the scope. Assume a 10 V rms sine wave with a frequency of 5 kHz is observed at the circuit input as shown in Figure 16–48(a). The correct ac voltage is present, so *the first possible cause has been eliminated.*

Next, check for a short by disconnecting the source and placing the DMM (set on the ohmmeter function) across each resistor. If any resistor is shorted (unlikely), the meter will read zero or a very small resistance. Assuming the meter readings are okay, *the second possible cause has been eliminated.*

Since the voltage has been "lost" somewhere between the input and the output, you must now look for the voltage. You reconnect the source and, using the half-splitting approach, measure the voltage at point ③ (the middle of the circuit) with respect to ground. The DMM test lead is placed on the right lead of inductor L_2, as indicated in Figure 16–48(b). Assume the voltage at this point is zero. This tells you that the part of the circuit to the right of point ③ is probably okay and the fault is in the circuit between point ③ and the source.

Now, you begin tracing the circuit back toward the source looking for the voltage (you could also start from the source and work forward). Placing the meter test lead on point ②, at the left lead of inductor L_2, results in a reading of 8.31 V as shown in Figure 16–48(b). This, of course, indicates that L_2 is open. Fortunately, in this case, a component, and not a contact on the board, is faulty. It is usually easier to replace a component than to repair a bad contact.

Related Problem Suppose you had measured 0 V at the left lead of L_2 and 10 V at the right lead of L_1. What would this have indicated?

INTRODUCTION

In this chapter, the analysis methods learned in Chapters 15 and 16 are extended to the coverage of circuits with combinations of resistive, inductive, and capacitive components. Series and parallel *RLC* circuits, plus series-parallel combinations, are studied.

Circuits with both inductance and capacitance can exhibit the property of resonance, which is important in many types of applications. Resonance is the basis for frequency selectivity in communication systems. For example, the ability of a radio or television receiver to select a certain frequency that is transmitted by a particular station and, at the same time, to eliminate frequencies from other stations is based on the principle of resonance. The conditions in *RLC* circuits that produce resonance and the characteristics of resonant circuits are covered in this chapter.

COVERAGE OPTIONS

If you chose Option 1 to cover all of Chapter 15 and all of Chapter 16, then all of this chapter should be covered next.

If you chose Option 2 to cover reactive circuits in Chapters 15 and 16 on the basis of the four major parts, then the appropriate part of this chapter should be covered next, followed by the next part in Chapter 15, if applicable.

SERIES CIRCUITS

17–1 IMPEDANCE OF SERIES *RLC* CIRCUITS

A series *RLC* circuit contains resistance, inductance, and capacitance. Since inductive reactance and capacitive reactance have opposite effects on the circuit phase angle, the total reactance is less than either individual reactance.

After completing this section, you should be able to

- **Determine the impedance of a series *RLC* circuit**
  - Calculate total reactance
  - Determine whether a circuit is predominately inductive or capacitive

A series *RLC* circuit is shown in Figure 17–1. It contains resistance, inductance, and capacitance.

▶ **FIGURE 17–1**

Series *RLC* circuit.
As you know, inductive reactance ($\mathbf{X}_L$) causes the total current to lag the applied voltage. Capacitive reactance ($\mathbf{X}_C$) has the opposite effect: It causes the current to lead the voltage. Thus $\mathbf{X}_L$ and $\mathbf{X}_C$ tend to offset each other. When they are equal, they cancel, and the total reactance is zero. In any case, the magnitude of the total reactance in the series circuit is

Equation 17–1

$$X_{tot} = |X_L - X_C|$$

The term $|X_L - X_C|$ means the absolute value of the difference of the two reactances. That is, the sign of the result is considered positive no matter which reactance is greater. For example, $3 - 7 = -4$, but the absolute value is

$$|3 - 7| = 4$$

When $X_L > X_C$, the circuit is predominantly inductive, and when $X_C > X_L$, the circuit is predominantly capacitive.

The total impedance for the series *RLC* circuit is stated in rectangular form in Equation 17–2 and in polar form in Equation 17–3.

$$\mathbf{Z} = R + jX_L - jX_C$$

$$\mathbf{Z} = \sqrt{R^2 + (X_L - X_C)^2} \angle \pm \tan^{-1}\left(\frac{X_{tot}}{R}\right)$$

In Equation 17–3, $\sqrt{R^2 + (X_L - X_C)^2}$ is the magnitude and $\tan^{-1}(X_{tot}/R)$ is the phase angle between the total current and the applied voltage. If the circuit is predominately inductive, the phase angle is positive; and if predominately capacitive, the phase angle is negative.

EXAMPLE 17–1

For the series *RLC* circuit in Figure 17–2, determine the total impedance. Express it in both rectangular and polar forms.
▲ **FIGURE 17–2**

Solution   First, find X_C and X_L.

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(100\,\text{kHz})(470\,\text{pF})} = 3.39\,\text{k}\Omega$$

$$X_L = 2\pi fL = 2\pi(100\,\text{kHz})(10\,\text{mH}) = 6.28\,\text{k}\Omega$$

In this case, X_L is greater than X_C, and thus the circuit is more inductive than capacitive. The magnitude of the total reactance is

$$X_{tot} = |X_L - X_C| = |6.28\,\text{k}\Omega - 3.39\,\text{k}\Omega| = 2.89\,\text{k}\Omega \qquad \text{inductive}$$

The impedance in rectangular form is

$$\mathbf{Z} = R + (jX_L - jX_C) = 5.6\,\text{k}\Omega + (j6.28\,\text{k}\Omega - j3.39\,\text{k}\Omega) = \mathbf{5.6\,k\Omega + j2.89\,k\Omega}$$

The impedance in polar form is

$$\mathbf{Z} = \sqrt{R^2 + X_{tot}^2} \angle \tan^{-1}\left(\frac{X_{tot}}{R}\right)$$

$$= \sqrt{(5.6\,\text{k}\Omega)^2 + (2.89\,\text{k}\Omega)^2} \angle \tan^{-1}\left(\frac{2.89\,\text{k}\Omega}{5.6\,\text{k}\Omega}\right) = \mathbf{6.30 \angle 27.3° \,k\Omega}$$

The positive angle shows that the circuit is inductive.

Related Problem*   Determine **Z** in polar form if *f* is increased to 200 kHz.

*Answers are at the end of the chapter.

As you have seen, when the inductive reactance is greater than the capacitive reactance, the circuit appears inductive; so the current lags the applied voltage. When the capacitive reactance is greater, the circuit appears capacitive, and the current leads the applied voltage.

1. In a given series *RLC* circuit, X_C is 150 Ω and X_L is 80 Ω. What is the total reactance in ohms? Is it inductive or capacitive?

2. Determine the impedance in polar form for the circuit in Question 1 when $R = 47\,\Omega$. What is the magnitude of the impedance? What is the phase angle? Is the current leading or lagging the applied voltage?

17–2 ANALYSIS OF SERIES *RLC* CIRCUITS

Recall that capacitive reactance varies inversely with frequency and that inductive reactance varies directly with frequency. In this section, the combined effects of the reactances as a function of frequency are examined.

After completing this section, you should be able to

◆ **Analyze series *RLC* circuits**

  ◆ Determine current in a series *RLC* circuit

  ◆ Determine the voltages in a series *RLC* circuit

  ◆ Determine the phase angle

Figure 17–3 shows that for a typical series *RLC* circuit the total reactance behaves as follows: Starting at a very low frequency, X_C is high, and X_L is low, and the circuit is predominantly capacitive. As the frequency is increased, X_C decreases and X_L increases until a value is reached where $X_C = X_L$ and the two reactances cancel, making the circuit purely resistive. This condition is **series resonance** and will be studied in Section 17–3. As the frequency is increased further, X_L becomes greater than X_C, and the circuit is predominantly inductive. Example 17–2 illustrates how the impedance and phase angle change as the source frequency is varied.

▶ **FIGURE 17–3**

How X_C and X_L vary with frequency.
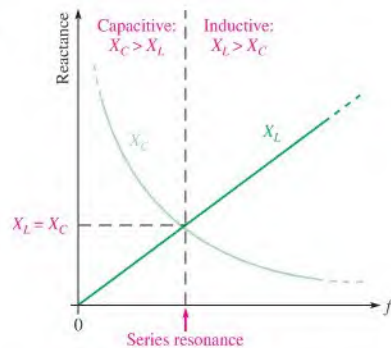

The graph of X_L is a straight line, and the graph of X_C is curved, as shown in Figure 17–3. The general equation for a straight line is $y = mx + b$, where m is the slope of the line and b is the y-axis intercept point. The formula $X_L = 2\pi fL$ fits this general straight-line formula, where $y = X_L$ (a variable), $m = 2\pi L$ (a constant), $x = f$ (a variable), and $b = 0$ as follows: $X_L = 2\pi Lf + 0$.

The X_C curve is called a *hyperbola*, and the general equation of a hyperbola is $xy = k$. The equation for capacitive reactance, $X_C = 1/2\pi fC$, can be rearranged as $X_C f = 1/2\pi C$ where $x = X_C$ (a variable), $y = f$ (a variable), and $k = 1/2\pi C$ (a constant).

EXAMPLE 17–2

For each of the following input frequencies, find the impedance in polar form for the circuit in Figure 17–4. Note the change in magnitude and phase angle with frequency.

(a) $f = 1\,\text{kHz}$ **(b)** $f = 2\,\text{kHz}$ **(c)** $f = 3.5\,\text{kHz}$ **(d)** $f = 5\,\text{kHz}$

▶ **FIGURE 17–4**
Solution   **(a)** At $f = 1\,\text{kHz}$,

$$X_C = \frac{1}{2\pi f C} = \frac{1}{2\pi(1\,\text{kHz})(0.022\,\mu\text{F})} = 7.23\,\text{k}\Omega$$

$$X_L = 2\pi f L = 2\pi(1\,\text{kHz})(100\,\text{mH}) = 628\,\Omega$$

The circuit is clearly capacitive, and the impedance is

$$\mathbf{Z} = \sqrt{R^2 + (X_L - X_C)^2} \angle -\tan^{-1}\left(\frac{X_{tot}}{R}\right)$$

$$= \sqrt{(3.3\,\text{k}\Omega)^2 + (628\,\Omega - 7.23\,\text{k}\Omega)^2} \angle -\tan^{-1}\left(\frac{6.60\,\text{k}\Omega}{3.3\,\text{k}\Omega}\right) = \mathbf{7.38 \angle -63.4°\,k\Omega}$$

The negative sign for the angle is used to indicate that the circuit is capacitive.

(b) At $f = 2\,\text{kHz}$,

$$X_C = \frac{1}{2\pi(2\,\text{kHz})(0.022\,\mu\text{F})} = 3.62\,\text{k}\Omega$$

$$X_L = 2\pi(2\,\text{kHz})(100\,\text{mH}) = 1.26\,\text{k}\Omega$$

The circuit is still capacitive, and the impedance is

$$\mathbf{Z} = \sqrt{(3.3\,\text{k}\Omega)^2 + (1.26\,\text{k}\Omega - 3.62\,\text{k}\Omega)^2} \angle -\tan^{-1}\left(\frac{2.36\,\text{k}\Omega}{3.3\,\text{k}\Omega}\right)$$

$$= \mathbf{4.06 \angle -35.6°\,k\Omega}$$

(c) At $f = 3.5\,\text{kHz}$,

$$X_C = \frac{1}{2\pi(3.5\,\text{kHz})(0.022\,\mu\text{F})} = 2.07\,\text{k}\Omega$$

$$X_L = 2\pi(3.5\,\text{kHz})(100\,\text{mH}) = 2.20\,\text{k}\Omega$$

The circuit is very close to being purely resistive because X_C and X_L are nearly equal, but it is slightly inductive. The impedance is

$$\mathbf{Z} = \sqrt{(3.3\,\text{k}\Omega)^2 + (2.20\,\text{k}\Omega - 2.07\,\text{k}\Omega)^2} \angle \tan^{-1}\left(\frac{0.13\,\text{k}\Omega}{3.3\,\text{k}\Omega}\right)$$

$$= \mathbf{3.3 \angle 2.26°\,k\Omega}$$

(d) At $f = 5\,\text{kHz}$,

$$X_C = \frac{1}{2\pi(5\,\text{kHz})(0.022\,\mu\text{F})} = 1.45\,\text{k}\Omega$$

$$X_L = 2\pi(5\,\text{kHz})(100\,\text{mH}) = 3.14\,\text{k}\Omega$$

The circuit is now predominantly inductive. The impedance is

$$Z = \sqrt{(3.3\text{ k}\Omega)^2 + (3.14\text{ k}\Omega - 1.45\text{ k}\Omega)^2}\angle\tan^{-1}\left(\frac{1.69\text{ k}\Omega}{3.3\text{ k}\Omega}\right)$$

$$= 3.71\angle27.1°\text{ k}\Omega$$

Notice how the circuit changed from capacitive to inductive as the frequency increased. The phase condition changed from the current leading to the current lagging as indicated by the sign of the angle. Note that the impedance magnitude decreased to a minimum equal to the resistance and then began increasing again. Also, notice that the negative phase angle decreased as the frequency increased and the angle became positive when the circuit became inductive and then increased with increasing frequency.

Related Problem   Determine **Z** in polar form for $f = 7$ kHz and draw a graph of impedance vs. frequency using the values in this example.

In a series *RLC* circuit, the capacitor voltage and the inductor voltage are always 180° out of phase with each other. For this reason, V_C and V_L subtract from each other, and thus the voltage across L and C combined is always less than the larger individual voltage across either element, as illustrated in Figure 17–5 and in the waveform diagram of Figure 17–6.

▶ **FIGURE 17–5**

The voltage across the series combination of C and L is always less than the larger individual voltage across either C or L.
▶ **FIGURE 17–6**

V_{CL} is the algebraic sum of V_L and V_C. Because of the phase relationship, V_L and V_C effectively subtract.
In the next example, Ohm's law is used to find the current and voltages in a series *RLC* circuit.

EXAMPLE 17–3   Find the current and the voltages across each component in Figure 17–7. Express each quantity in polar form, and draw a complete voltage phasor diagram.
Solution   First, find the total impedance.

$$\mathbf{Z} = R + jX_L - jX_C = 75\,k\Omega + j25\,k\Omega - j60\,k\Omega = 75\,k\Omega - j35\,k\Omega$$

Convert to polar form for convenience in applying Ohm's law.

$$\mathbf{Z} = \sqrt{R^2 + X_{tot}^2} \angle -\tan^{-1}\left(\frac{X_{tot}}{R}\right)$$

$$= \sqrt{(75\,k\Omega)^2 + (35\,k\Omega)^2} \angle -\tan^{-1}\left(\frac{35\,k\Omega}{75\,k\Omega}\right) = 82.8\angle -25°\,k\Omega$$

where $X_{tot} = |X_L - X_C|$.
Apply Ohm's law to find the current.

$$\mathbf{I} = \frac{\mathbf{V}_s}{\mathbf{Z}} = \frac{10\angle 0°\,V}{82.8\angle -25°\,k\Omega} = \mathbf{121\angle 25.0°\,\mu A}$$

Now, apply Ohm's law to find the voltages across *R*, *L*, and *C*.

$$\mathbf{V}_R = \mathbf{I}R = (121\angle 25.0°\,\mu A)(75\angle 0°\,k\Omega) = \mathbf{9.08\angle 25.0°\,V}$$

$$\mathbf{V}_L = \mathbf{I}X_L = (121\angle 25.0°\,\mu A)(25\angle 90°\,k\Omega) = \mathbf{3.03\angle 115°\,V}$$

$$\mathbf{V}_C = \mathbf{I}X_C = (121\angle 25.0°\,\mu A)(60\angle -90°\,k\Omega) = \mathbf{7.26\angle -65.0°\,V}$$

The phasor diagram is shown in Figure 17–8. The magnitudes represent rms values. Notice that V_L is leading V_R by 90°, and V_C is lagging V_R by 90°. Also, there is a 180° phase difference between V_L and V_C. If the current phasor were shown, it would be at

▶ FIGURE 17–8
the same angle as V_R. The current is leading V_s, the source voltage, by 25°, indicating a capacitive circuit ($X_C > X_L$). The phasor diagram is rotated 25° from its usual position because the reference is the source voltage, V_s, which is shown oriented along the x-axis.

Related Problem   What will happen to the current as the frequency of the source voltage in Figure 17–7 is increased?

SECTION 17–2 CHECKUP

1. The following voltages occur in a certain series *RLC* circuit. Determine the source voltage: $V_R = 24\angle30°$ V, $V_L = 15\angle120°$ V, and $V_C = 45\angle-60°$ V.

3. Determine the total reactance in Question 2.

17–3 SERIES RESONANCE

In a series *RLC* circuit, series resonance occurs when $X_C = X_L$. The frequency at which resonance occurs is called the **resonant frequency** and is designated f_r.

After completing this section, you should be able to

- ◆ **Analyze a circuit for series resonance**
  - ◆ Define *series resonance*
  - ◆ Determine the impedance at resonance
  - ◆ Explain why the reactances cancel at resonance
  - ◆ Determine the series resonant frequency
  - ◆ Calculate the current, voltages, and phase angle at resonance

Figure 17–9 illustrates the series resonant condition.

▶ **FIGURE 17–9**

Series resonance. X_C and X_L cancel each other resulting in a purely resistive circuit.
Resonance is a condition in a series *RLC* circuit in which the capacitive and inductive reactances are equal in magnitude; thus, they cancel each other and result in a purely resistive impedance. In a series *RLC* circuit, the total impedance was given in Equation 17–2 as

$$\mathbf{Z} = R + jX_L - jX_C$$

⊕*This icon indicates selected websites for further information on topics in this section. See the Companion Website provided with this text.*

At resonance, $X_L = X_C$ and the j terms cancel; thus, the impedance is purely resistive. These resonant conditions are stated in the following equations:

$$X_L = X_C$$
$$Z_r = R$$

EXAMPLE 17–4

For the series *RLC* circuit in Figure 17–10, determine X_C and **Z** at resonance.

▶ **FIGURE 17–10**
Solution $X_L = X_C$ at the resonant frequency. Thus, $X_C = X_L = \mathbf{500\ \Omega}$. The impedance at resonance is

$$\mathbf{Z}_r = R + jX_L - jX_C = 100\ \Omega + j500\ \Omega - j500\ \Omega = \mathbf{100\angle0°\ \Omega}$$

This shows that the impedance at resonance is equal to the resistance because the reactances are equal in magnitude and therefore cancel.

Related Problem   Just below the resonant frequency, is the circuit more inductive or more capacitive?

X_L and X_C Cancel at Resonance

At the series resonant frequency (f_r), the voltages across C and L are equal in magnitude because the reactances are equal. The same current is through both since they are in series ($IX_C = IX_L$). Also, V_L and V_C are always 180° out of phase with each other.

During any given cycle, the polarities of the voltages across C and L are opposite, as shown in parts (a) and (b) of Figure 17–11. The equal and opposite voltages across C and L cancel, leaving zero volts from point A to point B as shown. Since there is no voltage drop from A to B but there is still current, the total reactance must be zero, as indicated in part (c). Also, the voltage phasor diagram in part (d) shows that V_C and V_L are equal in magnitude and 180° out of phase with each other.

(a)   (b)   (c)   (d)
▲ **FIGURE 17–11**

At the resonant frequency, f_r, the voltages across C and L are equal in magnitude. Since they are 180° out of phase with each other, they cancel, leaving 0 V across the *LC* combination (point A to point B). The section of the circuit from A to B effectively looks like a short at resonance.

Series Resonant Frequency

For a given series *RLC* circuit, resonance occurs at only one specific frequency. A formula for this resonant frequency is developed as follows:

$$X_L = X_C$$

Substitute the reactance formulas.

$$2\pi f_r L = \frac{1}{2\pi f_r C}$$

Then, multiplying both sides by $f_r/2\pi L$,

$$f_r^2 = \frac{1}{4\pi^2 LC}$$

Take the square root of both sides. The formula for series resonant frequency is

Equation 17–4
$$f_r = \frac{1}{2\pi\sqrt{LC}}$$

EXAMPLE 17–5

Find the series resonant frequency for the circuit in Figure 17–12.

▶ **FIGURE 17–12**
Solution The resonant frequency is

$$f_r = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(5\text{ mH})(47\text{ pF})}} = \textbf{328 kHz}$$

Related Problem If $C = 0.01\ \mu\text{F}$ in Figure 17–12, what is the resonant frequency?

Use Multisim files E17-05A and E17-05B to verify the calculated results in this example and to confirm your calculation for the related problem.

Current and Voltages in a Series *RLC* Circuit

At the series resonant frequency, the current is maximum ($I_{max} = V_s/R$). Above and below resonance, the current decreases because the impedance increases. A response curve showing the plot of current versus frequency is shown in Figure 17–13(a). The resistor voltage, V_R, follows the current and is maximum (equal to V_s) at resonance and zero at $f = 0$ and at $f = \infty$, as shown in Figure 17–13(b). The general shapes of the V_C and V_L curves are indicated in Figure 17–13(c) and (d). Notice that $V_C = V_s$ when $f = 0$, because the capacitor appears open. Also notice that V_L approaches V_s as f approaches infinity, because the inductor appears open. The voltage across the C and L combination decreases as the frequency increases below resonance, reaching a minimum of zero at the resonant frequency; then it increases above resonance, as shown in Figure 17–13(e).
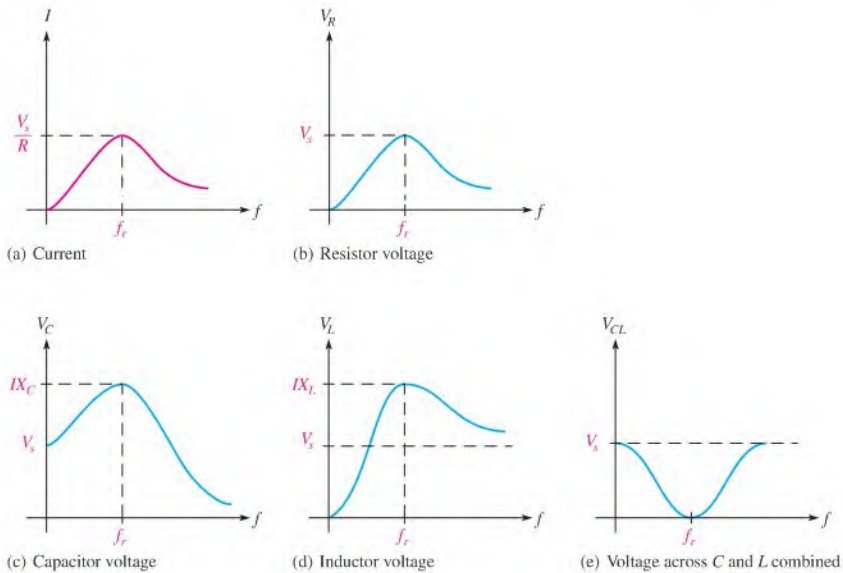

▲ FIGURE 17–13

Generalized current and voltage magnitudes as a function of frequency in a series *RLC* circuit. V_C and V_L can be much larger than the source voltage. The shapes of the graphs depend on specific circuit values.

The voltages are maximum at resonance but drop off above and below f_r. The voltages across *L* and *C* at resonance are exactly equal in magnitude but 180° out of phase; so they cancel. Thus, the total voltage across both *L* and *C* is zero, and $V_R = V_s$ at resonance, as indicated in Figure 17–14. Individually, V_L and V_C can be much greater than the source voltage, as you will see later. Keep in mind that V_L and V_C are always opposite in polarity regardless of the frequency, but only at resonance are their magnitudes equal.

EXAMPLE 17–6

Find *I*, V_R, V_L, and V_C at resonance for the circuit in Figure 17–15. The resonant values of X_L and X_C are shown.

► FIGURE 17–15
Solution   At resonance, I is maximum and equal to V_s/R.

$$I = \frac{V_s}{R} = \frac{5\,\text{V}}{1.5\,\text{k}\Omega} = \textbf{3.33 mA}$$

Apply Ohm's law to obtain the voltage magnitudes.

$$V_R = IR = (3.33\,\text{mA})(2.2\,\text{k}\Omega) = \textbf{7.33 V}$$
$$V_L = IX_L = (3.33\,\text{mA})(1\,\text{k}\Omega) = \textbf{3.33 V}$$
$$V_C = IX_C = (3.33\,\text{mA})(1\,\text{k}\Omega) = \textbf{3.33 V}$$

Notice that all of the source voltage is dropped across the resistor. Also, of course, V_L and V_C are equal in magnitude but opposite in phase. This causes these voltages to cancel, making the total reactive voltage zero.

Series *RLC* Impedance

At frequencies below f_r, $X_C > X_L$; thus, the circuit is capacitive. At the resonant frequency, $X_C = X_L$, so the circuit is purely resistive. At frequencies above f_r, $X_L > X_C$; thus, the circuit is inductive.

The impedance magnitude is minimum at resonance ($Z = R$) and increases in value above and below the resonant point. The graph in Figure 17–16 illustrates how impedance changes with frequency. At zero frequency, both X_C and Z are infinitely large and X_L is zero because the capacitor looks like an open at 0 Hz and the inductor looks like a short. As the frequency increases, X_C decreases and X_L increases. Since X_C is larger than X_L at frequencies below f_r, Z decreases along with X_C. At f_r, $X_C = X_L$ and $Z = R$. At frequencies above f_r, X_L becomes increasingly larger than X_C, causing Z to increase.

▶ **FIGURE 17–16**

Series *RLC* impedance as a function of frequency.
EXAMPLE 17–7

For the circuit in Figure 17–17, determine the impedance magnitude at the following frequencies:

(a) f_r **(b)** 1000 Hz below f_r **(c)** 1000 Hz above f_r

◆ **FIGURE 17–17**
Solution **(a)** At f_r, the impedance is equal to R.

$$Z = R = \mathbf{100\ \Omega}$$

To determine the impedance above and below f_r, first calculate the resonant frequency.

$$f_r = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(100\ \text{mH})(0.01\ \mu\text{F})}} = 5.03\ \text{kHz}$$

(b) At 1000 Hz below f_r, the frequency and reactances are as follows:

$$f = f_r - 1\ \text{kHz} = 5.03\ \text{kHz} - 1\ \text{kHz} = 4.03\ \text{kHz}$$

$$X_C = \frac{1}{2\pi f C} = \frac{1}{2\pi(4.03\ \text{kHz})(0.01\ \mu\text{F})} = 3.95\ \text{k}\Omega$$

$$X_L = 2\pi f L = 2\pi(4.03\ \text{kHz})(100\ \text{mH}) = 2.53\ \text{k}\Omega$$

Therefore, the impedance at $f_r - 1\ \text{kHz}$ is

$$Z = \sqrt{R^2 + (X_L - X_C)^2} = \sqrt{(100\ \Omega)^2 + (2.53\ \text{k}\Omega - 3.95\ \text{k}\Omega)^2} = \mathbf{1.42\ k\Omega}$$

(c) At 1000 Hz above f_r,

$$f = 5.03\ \text{kHz} + 1\ \text{kHz} = 6.03\ \text{kHz}$$

$$X_C = \frac{1}{2\pi(6.03\ \text{kHz})(0.01\ \mu\text{F})} = 2.64\ \text{k}\Omega$$

$$X_L = 2\pi(6.03\ \text{kHz})(100\ \text{mH}) = 3.79\ \text{k}\Omega$$

Therefore, the impedance at $f_r + 1\ \text{kHz}$ is

$$Z = \sqrt{(100\ \Omega)^2 + (3.79\ \text{k}\Omega - 2.64\ \text{k}\Omega)^2} = \mathbf{1.15\ k\Omega}$$

In part (b) Z is capacitive, and in part (c) Z is inductive.

Related Problem What happens to the impedance magnitude if f is decreased below 4.03 kHz? Above 6.03 kHz?

The Phase Angle of a Series *RLC* Circuit

At frequencies below resonance, $X_C > X_L$, and the current leads the source voltage, as indicated in Figure 17–18(a). The phase angle decreases as the frequency approaches the resonant value and is 0° at resonance, as indicated in part (b). At frequencies above resonance, $X_L > X_C$, and the current lags the source voltage, as indicated in part (c). As the frequency goes higher, the phase angle approaches 90°. A plot of phase angle versus frequency is shown in part (d) of the figure.

(a) Below f_r, I leads V_s.

(b) At f_r, I is in phase with V_s.

(c) Above f_r, I lags V_s.

PARALLEL CIRCUITS

17–4 IMPEDANCE OF PARALLEL *RLC* CIRCUITS

In this section, you will study the impedance and phase angle of a parallel *RLC* circuit. Also, conductance, susceptance, and admittance of a parallel *RLC* circuit are covered.

After completing this section, you should be able to

♦ **Determine the impedance of a parallel *RLC* circuit**

   ♦ Calculate the conductance, susceptance, and admittance

   ♦ Determine whether a circuit is predominately inductive or capacitive

Figure 17–19 shows a parallel *RLC* circuit. The total impedance can be calculated using the reciprocal of the sum-of-reciprocals method, just as was done for circuits with resistors in parallel.

$$\frac{1}{\mathbf{Z}} = \frac{1}{R\angle 0°} + \frac{1}{X_L\angle 90°} + \frac{1}{X_C\angle -90°}$$

or

$$\mathbf{Z} = \frac{1}{\dfrac{1}{R\angle 0°} + \dfrac{1}{X_L\angle 90°} + \dfrac{1}{X_C\angle -90°}}$$

Equation 17–5
◄ **FIGURE 17–19**

EXAMPLE 17–8

Find **Z** in polar form for the parallel *RLC* circuit in Figure 17–20.

► **FIGURE 17–20**
Solution   Use the sum-of-reciprocals formula.

$$\frac{1}{\mathbf{Z}} = \frac{1}{R\angle 0°} + \frac{1}{X_L\angle 90°} + \frac{1}{X_C\angle -90°} = \frac{1}{100\angle 0° \, \Omega} + \frac{1}{100\angle 90° \Omega} + \frac{1}{50\angle -90° \, \Omega}$$

Apply the rule for division of polar numbers.

$$\frac{1}{\mathbf{Z}} = 10\angle 0° \, \text{mS} + 10\angle -90° \, \text{mS} + 20\angle 90° \, \text{mS}$$

Recall that the sign of the denominator angle changes when dividing.
   Next, convert each term to its rectangular equivalent and combine.

$$\frac{1}{\mathbf{Z}} = 10 \, \text{mS} - j10 \, \text{mS} + j20 \, \text{mS} = 10 \, \text{mS} + j10 \, \text{mS}$$

Take the reciprocal to obtain **Z** and then convert to polar form.

$$\mathbf{Z} = \frac{1}{10 \, \text{mS} + j10 \, \text{mS}} = \frac{1}{\sqrt{(10 \, \text{mS})^2 + (10 \, \text{mS})^2}\angle \tan^{-1}\left(\dfrac{10 \, \text{mS}}{10 \, \text{mS}}\right)}$$

$$= \frac{1}{14.14\angle 45° \, \text{mS}} = \mathbf{70.7\angle -45° \, \Omega}$$

The negative angle shows that the circuit is capacitive. This may surprise you because $X_L > X_C$. However, in a parallel circuit, the smaller quantity has the greater effect on the total current because its current is the greatest. Similar to the case of resistances in parallel, the smaller reactance draws more current and has the greater effect on the total *Z*.
   In this circuit, the total current leads the total voltage by a phase angle of 45°.

Related Problem   If the frequency in Figure 17–20 increases, does the impedance increase or decrease?

Conductance, Susceptance, and Admittance

The concepts of conductance (*G*), capacitive susceptance (B_C), inductive susceptance (B_L) and admittance (*Y*) were discussed in Chapters 15 and 16. The phasor formulas are restated here.

Equation 17–6
$$\mathbf{G} = \frac{1}{R\angle 0°} = G\angle 0°$$

Equation 17–7
$$\mathbf{B}_C = \frac{1}{X_C\angle -90°} = B_C\angle 90° = jB_C$$

Equation 17–8
$$\mathbf{B}_L = \frac{1}{X_L\angle 90°} = B_L\angle -90° = -jB_L$$

Equation 17–9
$$\mathbf{Y} = \frac{1}{Z\angle \pm\theta} = Y\angle \pm\theta = G + jB_C - jB_L$$

As you know, the unit of each of these quantities is the siemens (S).

EXAMPLE 17–9

For the *RLC* circuit in Figure 17–21 determine the conductance, capacitive susceptance, inductive susceptance, and total admittance. Also, determine the impedance.
Solution

$$\mathbf{G} = \frac{1}{R\angle 0°} = \frac{1}{10\angle 0° \text{ k}\Omega} = 100\angle 0° \text{ }\mu\text{S}$$

$$\mathbf{B}_C = \frac{1}{X_C\angle -90°} = \frac{1}{10\angle -90° \text{ k}\Omega} = 100\angle 90° \text{ }\mu\text{S}$$

$$\mathbf{B}_L = \frac{1}{X_L\angle 90°} = \frac{1}{5\angle 90° \text{ k}\Omega} = 200\angle -90° \text{ }\mu\text{S}$$

$$\mathbf{Y}_{tot} = G + jB_C - jB_L = 100 \text{ }\mu\text{S} + j100 \text{ }\mu\text{S} - j200 \text{ }\mu\text{S}$$
$$= 100 \text{ }\mu\text{S} - j100 \text{ }\mu\text{S} = 141.4\angle -45° \text{ }\mu\text{S}$$

From $\mathbf{Y}_{tot}$, you can determine $\mathbf{Z}_{tot}$.

$$\mathbf{Z}_{tot} = \frac{1}{\mathbf{Y}_{tot}} = \frac{1}{141.4\angle -45° \text{ }\mu\text{S}} = 7.07\angle 45° \text{ k}\Omega$$

17–5 ANALYSIS OF PARALLEL *RLC* CIRCUITS

As you have learned, the smaller reactance in a parallel circuit dominates because it results in the larger branch current.

After completing this section, you should be able to

◆ **Analyze parallel *RLC* circuits**

   ◆ Explain how the currents are related in terms of phase

   ◆ Calculate impedance, currents, and voltages

Recall that capacitive reactance varies inversely with frequency and that inductive reactance varies directly with frequency. In a parallel *RLC* circuit at low frequencies, the inductive reactance is less than the capacitive reactance; therefore, the circuit is inductive. As the frequency is increased, X_L increases and X_C decreases until a value is reached where

$X_L = X_C$. This is the point of **parallel resonance**. As the frequency is increased further, X_C becomes smaller than X_L, and the circuit becomes capacitive.

Current Relationships

In a parallel *RLC* circuit, the current in the capacitive branch and the current in the inductive branch are *always* 180° out of phase with each other (neglecting any coil resistance). Because I_C and I_L add algebraically, the total current is actually the difference in their magnitudes. Thus, the total current into the parallel branches of *L* and *C* is always less than the largest individual branch current, as illustrated in Figure 17–22 and in the waveform diagram of Figure 17–23. Of course, the current in the resistive branch is always 90° out of phase with both reactive currents, as shown in the current phasor diagram of Figure 17–24. Notice that I_C is plotted on the positive *y*-axis and I_L is plotted on the negative *y*-axis.
▲ FIGURE 17–22

The total current into the parallel combination of *C* and *L* is the difference of the two branch currents.

▶ FIGURE 17–23

I_C and I_L effectively subtract.
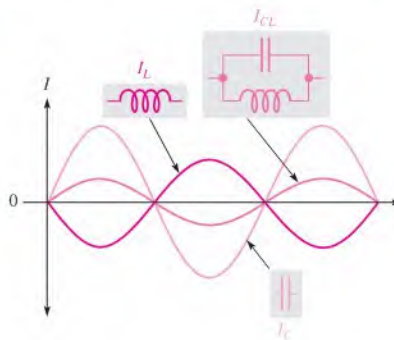

▶ FIGURE 17–24

Typical current phasor diagram for a parallel *RLC* circuit.
The total current can be expressed as

$$\mathbf{I}_{tot} = \sqrt{I_R^2 + (I_C - I_L)^2} \angle \tan^{-1}\left(\frac{I_{CL}}{I_R}\right)$$

where I_{CL} is $I_C - I_L$, the total current into the L and C branches.

EXAMPLE 17–10

For the circuit in Figure 17–25 find each branch current and the total current. Draw a diagram of their relationship.

▶ **FIGURE 17–25**
Solution Use Ohm's law to find each branch current in phasor form.

$$\mathbf{I}_R = \frac{\mathbf{V}_s}{\mathbf{R}} = \frac{5\angle 0°\text{ V}}{2.2\angle 0°\text{ k}\Omega} = \mathbf{2.27\angle 0°\text{ mA}}$$

$$\mathbf{I}_C = \frac{\mathbf{V}_s}{\mathbf{X}_C} = \frac{5\angle 0°\text{ V}}{5\angle -90°\text{ k}\Omega} = \mathbf{1\angle 90°\text{ mA}}$$

$$\mathbf{I}_L = \frac{\mathbf{V}_s}{\mathbf{X}_L} = \frac{5\angle 0°\text{ V}}{10\angle 90°\text{ k}\Omega} = \mathbf{0.5\angle -90°\text{ mA}}$$

The total current is the phasor sum of the branch currents. By Kirchhoff's law,

$$\mathbf{I}_{tot} = \mathbf{I}_R + \mathbf{I}_C + \mathbf{I}_L$$
$$= 2.27\angle 0°\text{ mA} + 1\angle 90°\text{ mA} + 0.5\angle -90°\text{ mA}$$
$$= 2.27\text{ mA} + j1\text{ mA} - j0.5\text{ mA} = 2.27\text{ mA} + j0.5\text{ mA}$$

Converting to polar form yields

$$\mathbf{I}_{tot} = \sqrt{I_R^2 + (I_C - I_L)^2} \angle \tan^{-1}\left(\frac{I_{CL}}{I_R}\right)$$
$$= \sqrt{(2.27\text{ mA})^2 + (0.5\text{ mA})^2} \angle \tan^{-1}\left(\frac{0.5\text{ mA}}{2.27\text{ mA}}\right) = \mathbf{2.32\angle 12.4°\text{ mA}}$$

The total current is 2.32 mA leading V_s by 12.4°. Figure 17–26 is the current phasor diagram for the circuit.

17–6   Parallel Resonance

In this section, we will first look at the resonant condition in an ideal parallel *LC* circuit (no winding resistance). Then, we will examine the more realistic case where the resistance of the coil is taken into account.

After completing this section, you should be able to

◆ **Analyze a circuit for parallel resonance**

   ◆ Describe parallel resonance in an ideal circuit

   ◆ Describe parallel resonance in a nonideal circuit

   ◆ Explain how impedance varies with frequency

   ◆ Determine current and phase angle at resonance

   ◆ Determine parallel resonant frequency

Condition for Ideal Parallel Resonance

Ideally, parallel resonance occurs when $X_C = X_L$. The frequency at which resonance occurs is called the *resonant frequency,* just as in the series case. When $X_C = X_L$, the two branch currents, I_C and I_L, are equal in magnitude, and, of course, they are always 180° out of phase with each other. Thus, the two currents cancel and the total current is zero, as shown in Figure 17–27.

(a) Parallel circuit at resonance ($X_C = X_L$, $Z = \infty$)   (b) Current phasors   (c) Current waveforms
▲ **FIGURE 17–27**

An ideal parallel *LC* circuit at resonance.

Since the total current is zero, the impedance of the parallel *LC* circuit is infinitely large (∞). These ideal resonant conditions are stated as follows:

$$X_L = X_C$$
$$Z_r = \infty$$

Parallel Resonant Frequency

For an ideal (no resistance) parallel resonant circuit, the frequency at which resonance occurs is determined by the same formula as in series resonant circuits; that is,

$$f_r = \frac{1}{2\pi\sqrt{LC}}$$

Tank Circuit

The parallel resonant LC circuit is often called a **tank circuit**. The term *tank circuit* refers to the fact that the parallel resonant circuit stores energy in the magnetic field of the coil and in the electric field of the capacitor. The stored energy is transferred back and forth between the capacitor and the coil on alternate half-cycles as the current goes first one way and then the other when the inductor deenergizes and the capacitor charges, and vice versa. This concept is illustrated in Figure 17–28.

(a) The coil deenergizes as the capacitor charges.   (b) The capacitor discharges as the coil energizes.
▲ **FIGURE 17–28**

Energy storage in an ideal parallel resonant tank circuit.

Variation of the Impedance with Frequency

Ideally, the impedance of a parallel resonant circuit is infinite. In practice, the impedance is maximum at the resonant frequency and decreases at lower and higher frequencies, as indicated by the curve in Figure 17–29.
▲ **FIGURE 17–29**

Generalized impedance curve for a parallel resonant circuit. The circuit is inductive below f_r, resistive at f_r, and capacitive above f_r.

At very low frequencies, X_L is very small and X_C is very high, so the total impedance is essentially equal to that of the inductive branch. As the frequency goes up, the impedance also increases, and the inductive reactance dominates (because it is less than X_C) until the resonant frequency is reached. At this point, of course, $X_L \cong X_C$ (for $Q > 10$) and the

impedance is at its maximum. As the frequency goes above resonance, the capacitive reactance dominates (because it is less than X_L) and the impedance decreases.

Current and Phase Angle at Resonance

In the ideal tank circuit, the total current from the source at resonance is zero because the impedance is infinite. In the nonideal case when the winding resistance is considered, there is some total current at the resonant frequency, and it is determined by the impedance at resonance.

Equation 17–11

$$I_{tot} = \frac{V_s}{Z_r}$$

The phase angle of the parallel resonant circuit is 0° because the impedance is purely resistive at the resonant frequency.

Effect of Winding Resistance on the Parallel Resonant Frequency

When the winding resistance is considered, the resonant condition can be expressed as

$$2\pi f_r L\left(\frac{Q^2 + 1}{Q^2}\right) = \frac{1}{2\pi f_r C}$$

where Q is the **quality factor** of the coil, X_L/R_W. Solving for f_r in terms of Q yields

Equation 17–12

$$f_r = \frac{1}{2\pi\sqrt{LC}}\sqrt{\frac{Q^2}{Q^2 + 1}}$$

When $Q \geq 10$, the term with the Q factors is approximately 1.

$$\sqrt{\frac{Q^2}{Q^2 + 1}} = \sqrt{\frac{100}{101}} = 0.995 \cong 1$$

Therefore, the parallel resonant frequency is approximately the same as the series resonant frequency as long as Q is equal to or greater than 10.

$$f_r \cong \frac{1}{2\pi\sqrt{LC}} \qquad \text{for } Q \geq 10$$

A precise expression for f_r in terms of the circuit component values is

Equation 17–13

$$f_r = \frac{\sqrt{1 - (R_W^2 C/L)}}{2\pi\sqrt{LC}}$$

This precise formula is seldom necessary and the simpler equation $f_r = 1/(2\pi\sqrt{LC})$ is sufficient for most practical situations. A derivation of Equation 17–13 is given in Appendix B.

EXAMPLE 17–11

Find the precise frequency and the value of Q at resonance for the circuit in Figure 17–30.

▶ **FIGURE 17–30**

V_s 10 V, $R_W = 100\ \Omega$, L 0.1 H, C 0.047 μF
Solution   Use Equation 17–13 to find the resonant frequency.

$$f_r = \frac{\sqrt{1 - (R_W^2 C/L)}}{2\pi\sqrt{LC}} = \frac{\sqrt{1 - [(100\ \Omega)^2(0.047\ \mu F)/0.1\ H]}}{2\pi\sqrt{(0.047\ \mu F)(0.1\ H)}} = \textbf{2.32 kHz}$$

To calculate the quality factor, Q, first find X_L.

$$X_L = 2\pi f_r L = 2\pi(2.32\ \text{kHz})(0.1\ \text{H}) = 1.46\ \text{k}\Omega$$

$$Q = \frac{X_L}{R_W} = \frac{1.46\ \text{k}\Omega}{100\ \Omega} = \textbf{14.6}$$

Note that since $Q > 10$, the approximate formula, $f_r \cong 1/(2\pi\sqrt{LC})$, can be used.

Related Problem   For a smaller R_W, will f_r be less than or greater than 2.32 kHz?

SERIES-PARALLEL CIRCUITS

17–7 ANALYSIS OF SERIES-PARALLEL *RLC* CIRCUITS

In this section, series and parallel combinations of R, L, and C components are analyzed in specific examples. Also, conversion of a series-parallel circuit to an equivalent parallel circuit is covered and resonance in a nonideal parallel circuit is considered.

After completing this section, you should be able to

♦ **Analyze series-parallel *RLC* circuits**

♦ Determine currents and voltages

♦ Convert a series-parallel circuit to an equivalent parallel form

♦ Analyze nonideal (with coil resistance) parallel circuits for parallel resonance

♦ Examine the effect of a resistive load on a tank circuit

The following two examples illustrate an approach to the analysis of circuits with both series and parallel combinations of resistance, inductance, and capacitance.

EXAMPLE 17–12   In Figure 17–31, find the voltage across the capacitor in polar form. Is this circuit predominantly inductive or capacitive?
▲ **FIGURE 17–31**

Solution   Use the voltage-divider formula in this analysis. The impedance of the series combination of R_1 and X_L is called $\mathbf{Z}_1$. In rectangular form,

$$\mathbf{Z}_1 = R_1 + jX_L = 1000\ \Omega + j500\ \Omega$$

Converting to polar form yields

$$\mathbf{Z}_1 = \sqrt{R_1^2 + X_L^2} \angle \tan^{-1}\left(\frac{X_L}{R_1}\right)$$

$$= \sqrt{(1000\ \Omega)^2 + (500\ \Omega)^2} \angle \tan^{-1}\left(\frac{500\ \Omega}{1000\ \Omega}\right) = 1118\angle 26.6°\ \Omega$$

The impedance of the parallel combination of R_2 and X_C is called $\mathbf{Z}_2$. In polar form,

$$\mathbf{Z}_2 = \left(\frac{R_2 X_C}{\sqrt{R_2^2 + X_C^2}}\right) \angle -\tan^{-1}\left(\frac{R_2}{X_C}\right)$$

$$= \left[\frac{(1000\ \Omega)(500\ \Omega)}{\sqrt{(1000\ \Omega)^2 + (500\ \Omega)^2}}\right] \angle -\tan^{-1}\left(\frac{1000\ \Omega}{500\ \Omega}\right) = 447\angle -63.4°\ \Omega$$

Converting to rectangular form yields

$$\mathbf{Z}_2 = Z_2\cos\theta + jZ_2\sin\theta$$

$$= (447\ \Omega)\cos(-63.4°) + j447\sin(-63.4°) = 200\ \Omega - j400\ \Omega$$

The total impedance $\mathbf{Z}_{tot}$ in rectangular form is

$$\mathbf{Z}_{tot} = \mathbf{Z}_1 + \mathbf{Z}_2 = (1000\ \Omega + j500\ \Omega) + (200\ \Omega - j400\ \Omega) = 1200\ \Omega + j100\ \Omega$$

Converting to polar form yields

$$\mathbf{Z}_{tot} = \sqrt{(1200\ \Omega)^2 + (100\ \Omega)^2} \angle \tan^{-1}\left(\frac{100\ \Omega}{1200\ \Omega}\right) = 1204\angle 4.76°\ \Omega$$

Now apply the voltage-divider formula to get $\mathbf{V}_C$.

$$\mathbf{V}_C = \left(\frac{\mathbf{Z}_2}{\mathbf{Z}_{tot}}\right)\mathbf{V}_s = \left(\frac{447\angle -63.4°\ \Omega}{1204\angle 4.76°\ \Omega}\right)5\angle 0°\ \text{V} = \mathbf{1.86}\angle -\mathbf{68.2°\ V}$$

Therefore, V_C is 1.86 V and lags V_s by 68.2°.

The $+j$ term in $\mathbf{Z}_{tot}$, or the positive angle in its polar form, indicates that the circuit is more inductive than capacitive. However, it is just slightly more inductive because the angle is small. This result may surprise you, because $X_C = X_L = 500\ \Omega$. However, the capacitor is in parallel with a resistor, so the capacitor actually has less effect on the total impedance than does the inductor. Figure 17–32 shows the phasor relationship of V_C and V_s. Although $X_C = X_L$, this circuit is not at resonance because the j term of the total impedance is not zero due to the parallel combination of R_2 and X_C. You can see this by noting that the phase angle associated with $\mathbf{Z}_{tot}$ is 4.76° and not zero.

EXAMPLE 17–13

For the reactive circuit in Figure 17–33, find the voltage at point B with respect to ground.

▶ **FIGURE 17–33**
Solution The voltage ($\mathbf{V}_B$) at point B is the voltage across the open output terminals. Use the voltage-divider approach. To do so, you must know the voltage ($\mathbf{V}_A$) at point A first; so you need to find the impedance from point A to ground as a starting point.

The parallel combination of X_L and R_2 is in series with X_{C2}. This combination is in parallel with R_1. Call this impedance from point A to ground, $\mathbf{Z}_A$. To find $\mathbf{Z}_A$, take the following steps. The impedance of the parallel combination of R_2 and X_L is called $\mathbf{Z}_1$.

$$\mathbf{Z}_1 = \left(\frac{R_2 X_L}{\sqrt{R_2^2 + X_L^2}}\right)\angle\tan^{-1}\left(\frac{R_2}{X_L}\right)$$

$$= \left(\frac{(8\text{ k}\Omega)(5\text{ k}\Omega)}{\sqrt{(8\text{ k}\Omega)^2 + (5\text{ k}\Omega)^2}}\right)\angle\tan^{-1}\left(\frac{8\text{ k}\Omega}{5\text{ k}\Omega}\right) = 4.24\angle58.0°\text{ k}\Omega$$

Next, combine $\mathbf{Z}_1$ in series with $\mathbf{X}_{C2}$ to get an impedance $\mathbf{Z}_2$.

$$\mathbf{Z}_2 = \mathbf{X}_{C2} + \mathbf{Z}_1$$
$$= 1\angle-90°\text{ k}\Omega + 4.24\angle58°\text{ k}\Omega = -j1\text{ k}\Omega + 2.25\text{ k}\Omega + j3.6\text{ k}\Omega$$
$$= 2.25\text{ k}\Omega + j2.6\text{ k}\Omega$$

Converting to polar form yields

$$\mathbf{Z}_2 = \sqrt{(2.25\text{ k}\Omega)^2 + (2.6\text{ k}\Omega)^2}\angle\tan^{-1}\left(\frac{2.6\text{ k}\Omega}{2.25\text{ k}\Omega}\right) = 3.44\angle49.1°\text{ k}\Omega$$

Finally, combine $\mathbf{Z}_2$ and $\mathbf{R}_1$ in parallel to get $\mathbf{Z}_A$.

$$\mathbf{Z}_A = \frac{\mathbf{R}_1\mathbf{Z}_2}{\mathbf{R}_1 + \mathbf{Z}_2} = \frac{(10\angle0°\text{ k}\Omega)(3.44\angle49.1°\text{ k}\Omega)}{10\text{ k}\Omega + 2.25\text{ k}\Omega + j2.6\text{ k}\Omega}$$

$$= \frac{34.4\angle49.1°\text{ k}\Omega}{12.25\text{ k}\Omega + j2.6\text{ k}\Omega} = \frac{34.4\angle49.1°\text{ k}\Omega}{12.5\angle12.0°\text{ k}\Omega} = 2.75\angle37.1°\text{ k}\Omega$$

The simplified circuit is shown in Figure 17–34.

▶ **FIGURE 17–34**
Next, use the voltage-divider principle to find the voltage (V_A) at point A in Figure 17–33. The total impedance is

$$\mathbf{Z}_{tot} = \mathbf{X}_{C1} + \mathbf{Z}_A$$
$$= 2\angle -90° \text{ k}\Omega + 2.75\angle 37.1° \text{ k}\Omega = -j2 \text{ k}\Omega + 2.19 \text{ k}\Omega + j1.66 \text{ k}\Omega$$
$$= 2.19 \text{ k}\Omega - j0.340 \text{ k}\Omega$$

Converting to polar form yields

$$\mathbf{Z}_{tot} = \sqrt{(2.19 \text{ k}\Omega)^2 + (0.340 \text{ k}\Omega)^2} \angle -\tan^{-1}\left(\frac{0.340 \text{ k}\Omega}{2.19 \text{ k}\Omega}\right) = 2.22\angle -8.82° \text{ k}\Omega$$

The voltage at point A is

$$\mathbf{V}_A = \left(\frac{\mathbf{Z}_A}{\mathbf{Z}_{tot}}\right)\mathbf{V}_s = \left(\frac{2.75\angle 37.1° \text{ k}\Omega}{2.22\angle -8.82° \text{ k}\Omega}\right)30\angle 0° \text{ V} = 37.2\angle 45.9° \text{ V}$$

Next, find the voltage (V_B) at point B by dividing V_A down, as indicated in Figure 17–35. V_B is the open terminal output voltage.

$$\mathbf{V}_B = \left(\frac{\mathbf{Z}_1}{\mathbf{Z}_2}\right)\mathbf{V}_A = \left(\frac{4.24\angle 58° \text{ k}\Omega}{3.44\angle 49.1° \text{ k}\Omega}\right)37.2\angle 45.9° \text{ V} = \mathbf{45.9\angle 54.8° \text{ V}}$$

Surprisingly, V_A is greater than V_s, and V_B is greater than V_A! This result is possible because of the out-of-phase relationship of the reactive voltages. Remember that X_C and X_L tend to cancel each other.

Conversion of Series-Parallel to Parallel

The particular series-parallel configuration shown in Figure 17–36 is important because it represents a circuit having parallel L and C branches, with the winding resistance of the coil taken into account as a series resistance in the L branch.
◀ **FIGURE 17–36**

A series-parallel *RLC* circuit
($Q = X_L/R_W$).

It is helpful to view the series-parallel circuit in Figure 17–36 in an equivalent parallel form, as indicated in Figure 17–37.

Parallel equivalent form of the circuit in Figure 17–36.
The equivalent inductance, L_{eq}, and the equivalent parallel resistance, $R_{p(eq)}$, are given by the following formulas:

Equation 17–14

$$L_{eq} = L\left(\frac{Q^2 + 1}{Q^2}\right)$$

Equation 17–15

$$R_{p(eq)} = R_W(Q^2 + 1)$$

where Q is the quality factor of the coil, X_L/R_W. Derivations of these formulas are quite involved and thus are not given here. Notice in the equations that for a $Q \geq 10$, the value of L_{eq} is approximately the same as the original value of L. For example, if $L = 10$ mH and $Q = 10$, then

$$L_{eq} = 10\,\text{mH}\left(\frac{10^2 + 1}{10^2}\right) = 10\,\text{mH}(1.01) = 10.1\,\text{mH}$$

The equivalency of the two circuits means that at a given frequency, when the same value of voltage is applied to both circuits, the same total current is in both circuits and the phase angles are the same. Basically, an equivalent circuit simply makes circuit analysis more convenient.

Solution   Determine the inductive reactance.

$$X_L = 2\pi fL = 2\pi(15.9\,\text{kHz})(5\,\text{mH}) = 500\,\Omega$$

The Q of the coil is

$$Q = \frac{X_L}{R_W} = \frac{500\,\Omega}{25\,\Omega} = 20$$

Since $Q > 10$, then $L_{eq} \cong L = 5$ mH.

The equivalent parallel resistance is

$$R_{p(eq)} = R_W(Q^2 + 1) = (25\ \Omega)(20^2 + 1) = 10\ \text{k}\Omega$$

This equivalent resistance appears in parallel with R_1 as shown in Figure 17–39(a). When combined, they give a total parallel resistance ($R_{p(tot)}$) of 3.2 kΩ, as indicated in Figure 17–39(b).

Parallel Resonant Conditions in a Nonideal Circuit

The resonance of an ideal parallel *LC* circuit was examined in Section 17–6. Now, let's consider resonance in a tank circuit with the resistance of the coil taken into account. Figure 17–40 shows a nonideal tank circuit and its parallel *RLC* equivalent.

Recall that the quality factor, *Q*, of the circuit at resonance is simply the *Q* of the coil if no other resistance is in the circuit.

$$Q = \frac{X_L}{R_W}$$

The expressions for the equivalent inductance and the equivalent parallel resistance were given in Equations 17–14 and 17–15 as

$$L_{eq} = L\left(\frac{Q^2 + 1}{Q^2}\right)$$

$$R_{p(eq)} = R_W(Q^2 + 1)$$

For $Q \geq 10, L_{eq} \cong L$.

(b) Parallel *RLC* equivalent
◄ **FIGURE 17–40**

A practical treatment of parallel resonant circuits must include the coil resistance.

At parallel resonance,

$$X_{L(eq)} = X_C$$

In the parallel equivalent circuit, $R_{p(eq)}$ is in parallel with an ideal coil and a capacitor, so the L and C branches act as an ideal tank circuit which has an infinite impedance at resonance as shown in Figure 17–41. Therefore, the total impedance of the nonideal tank circuit at resonance can be expressed as simply the equivalent parallel resistance.

$$Z_r = R_W(Q^2 + 1)$$

A derivation of Equation 17–16 is given in Appendix B.

▶ **FIGURE 17–42**
Solution Before you can calculate the impedance using Equation 17–16, you must find the quality factor. To get Q, first find the inductive reactance.

$$X_L = 2\pi f_r L = 2\pi(17{,}794 \text{ Hz})(8 \text{ mH}) = 894 \text{ } \Omega$$

$$Q = \frac{X_L}{R_W} = \frac{894 \text{ } \Omega}{50 \text{ } \Omega} = 17.9$$

$$Z_r = R_W(Q^2 + 1) = 50 \text{ } \Omega(17.9^2 + 1) = \mathbf{16.1 \text{ k}\Omega}$$

Related Problem Determine Z_r for $R_W = 10 \text{ } \Omega$.

An External Load Resistance Affects a Tank Circuit

In most practical situations, an external load resistance appears in parallel with a nonideal tank circuit, as shown in Figure 17–43(a). Obviously, the external resistor (R_L) will dissipate more of the energy delivered by the source and thus will lower the overall Q of the
▲ **FIGURE 17–43**

circuit. The external resistor effectively appears in parallel with the equivalent parallel re-sistance of the coil, $R_{p(eq)}$, and both are combined to determine a total parallel resistance, $R_{p(tot)}$, as indicated in Figure 17–43(b).

$$R_{p(tot)} = R_L \parallel R_{p(eq)}$$

The overall Q, designated Q_O, for a parallel RLC circuit is expressed differently from the Q of a series circuit.

$$Q_O = \frac{R_{p(tot)}}{X_{L(eq)}}$$

Equation 17–17

As you can see, the effect of loading the tank circuit is to reduce its overall Q (which is equal to the coil Q when unloaded).

SPECIAL TOPICS

17–8 BANDWIDTH OF RESONANT CIRCUITS

The current in a series *RLC* is maximum at the resonant frequency because the reactances cancel. The current in a parallel *RLC* is minimum at the resonant frequency because the inductive and capacitive currents cancel. This circuit behavior relates to a characteristic called bandwidth.

After completing this section, you should be able to

- ◆ **Determine the bandwidth of resonant circuits**
  - ◆ Discuss the bandwidth of series and parallel resonant circuits
  - ◆ State the formula for bandwidth
  - ◆ Define *half-power frequency*
  - ◆ Define *selectivity*
  - ◆ Explain how the *Q* affects the bandwidth

Series Resonant Circuits

The current in a series *RLC* circuit is maximum at the resonant frequency (also known as *center frequency*) and drops off on either side of this frequency. Bandwidth, sometimes abbreviated *BW*, is an important characteristic of a resonant circuit. The bandwidth is the range of frequencies for which the current is equal to or greater than 70.7% of its resonant value.

Figure 17–44 illustrates bandwidth on the response curve of a series *RLC* circuit. Notice that the frequency f_1 below f_r is the point at which the current is $0.707I_{max}$ and is commonly called the *lower critical frequency*. The frequency f_2 above f_r, where the current is again $0.707I_{max}$, is the *upper critical frequency*. Other names for f_1 and f_2 are *−3 dB frequencies, cutoff frequencies,* and *half-power frequencies.* The significance of the latter term is discussed later in the chapter.

▶ **FIGURE 17–44**

Bandwidth on series resonant response curve for *I*.
EXAMPLE 17–16	A certain series resonant circuit has a maximum current of 100 mA at the resonant frequency. What is the value of the current at the critical frequencies?
Solution	Current at the critical frequencies is 70.7% of maximum.

$$I_{f1} = I_{f2} = 0.707I_{max} = 0.707(100\,\text{mA}) = \mathbf{70.7\,mA}$$

Related Problem	A certain series resonant circuit has a current of 25 mA at the critical frequencies. What is the current at resonance?

Parallel Resonant Circuits

For a parallel resonant circuit, the impedance is maximum at the resonant frequency; so the total current is minimum. The bandwidth can be defined in relation to the impedance curve in the same manner that the current curve was used in the series circuit. Of course, f_r is the frequency at which Z is maximum; f_1 is the lower critical frequency at which $Z = 0.707Z_{max}$; and f_2 is the upper critical frequency at which again $Z = 0.707Z_{max}$. The bandwidth is the range of frequencies between f_1 and f_2, as shown in Figure 17–45.
◀ **FIGURE 17–45**

Bandwidth of the parallel resonant response curve for Z_{tot}.

Formula for Bandwidth

The bandwidth for either series or parallel resonant circuits is the range of frequencies between the critical frequencies for which the response curve (I or Z) is 0.707 of the maximum value. Thus, the bandwidth is actually the difference between f_2 and f_1.

$$BW = f_2 - f_1 \qquad\qquad \textbf{Equation 17–18}$$

Ideally, f_r is the center frequency and can be calculated as follows:

$$f_r = \frac{f_1 + f_2}{2} \qquad\qquad \textbf{Equation 17–19}$$

EXAMPLE 17–17	A resonant circuit has a lower critical frequency of 8 kHz and an upper critical frequency of 12 kHz. Determine the bandwidth and center (resonant) frequency.
Solution	

$$BW = f_2 - f_1 = 12\,\text{kHz} - 8\,\text{kHz} = \mathbf{4\,kHz}$$
$$f_r = \frac{f_1 + f_2}{2} = \frac{12\,\text{kHz} + 8\,\text{kHz}}{2} = \mathbf{10\,kHz}$$

Related Problem	If the bandwidth of a resonant circuit is 2.5 kHz and its center frequency is 8 kHz, what are the lower and upper critical frequencies?

Half-Power Frequencies

As previously mentioned, the upper and lower critical frequencies are sometimes called the **half-power frequencies**. This term is derived from the fact that the power from the source at these frequencies is one-half the power delivered at the resonant frequency. The following shows that this is true for a series circuit. The same end result also applies to a parallel circuit. At resonance,

$$P_{max} = I_{max}^2 R$$

The power at f_1 or f_2 is

$$P_{f1} = I_{f1}^2 R = (0.707I_{max})^2 R = (0.707)^2 I_{max}^2 R = 0.5 I_{max}^2 R = 0.5 P_{max}$$

Selectivity

The response curves in Figures 17–44 and 17-45 are also called *selectivity curves*. **Selectivity** defines how well a resonant circuit responds to a certain frequency and discriminates against all others. *The narrower the bandwidth, the greater the selectivity.*

Ideally, we assume that a resonant circuit accepts frequencies within its bandwidth and completely eliminates frequencies outside the bandwidth. Such is not actually the case, however, because signals with frequencies outside the bandwidth are not completely eliminated. Their magnitudes, however, are greatly reduced. The further the frequencies are from the critical frequencies, the greater the reduction, as illustrated in Figure 17–46(a). An ideal selectivity curve is shown in Figure 17–46(b).

(a) Actual

(b) Ideal
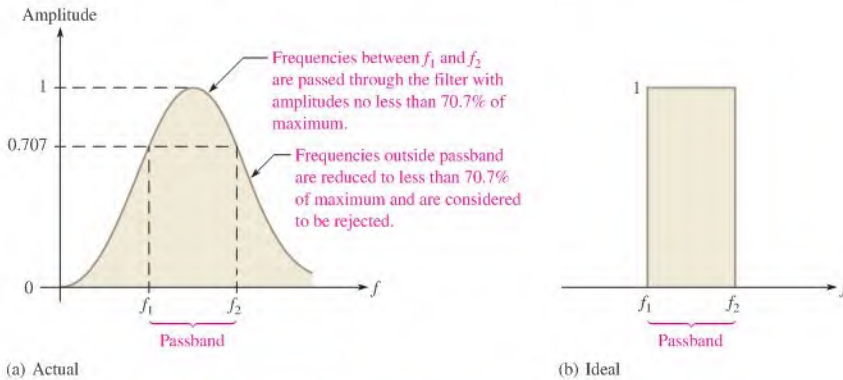

▲ **FIGURE 17–46**

Generalized selectivity curve.

Another factor that influences selectivity is the steepness of the slopes of the response curve. The faster the curve drops off at the critical frequencies, the more selective the circuit is because it tends to respond only to the frequencies within the bandwidth. Figure 17–47 shows a general comparison of three response curves with varying degrees of selectivity.

Q Affects Bandwidth

A higher value of circuit Q results in a narrower bandwidth. A lower value of Q causes a wider bandwidth. A formula for the bandwidth of a resonant circuit in terms of Q is stated in the following equation:

Equation 17–20

$$BW = \frac{f_r}{Q}$$

EXAMPLE 17–18

What is the bandwidth of each circuit in Figure 17–48?
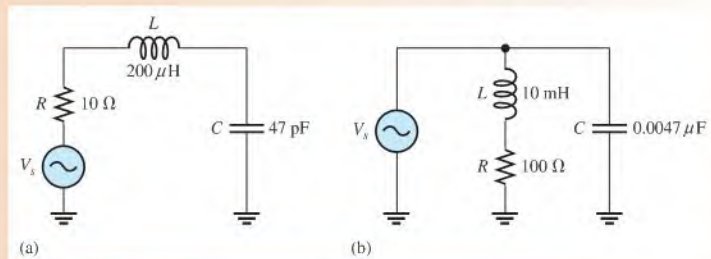

▲ FIGURE 17–48

Solution   For the circuit in Figure 17–48(a), determine the bandwidth as follows:

$$f_r = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(200\ \mu H)(47\ pF)}} = 1.64\ MHz$$

$$X_L = 2\pi f_r L = 2\pi(1.64\ MHz)(200\ \mu H) = 2.06\ k\Omega$$

$$Q = \frac{X_L}{R} = \frac{2.06\ k\Omega}{10\ \Omega} = 206$$

$$BW = \frac{f_r}{Q} = \frac{1.64\ MHz}{206} = \textbf{7.96 kHz}$$

For the circuit in Figure 17–48(b),

$$f_r = \frac{\sqrt{1-(R_W^2\,C/L)}}{2\pi\sqrt{LC}} \cong \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(10\ mH)(0.0047\ \mu F)}} = 23.2\ kHz$$

$$X_L = 2\pi f_r L = 2\pi(23.2\ kHz)(10\ mH) = 1.46\ k\Omega$$

$$Q = \frac{X_L}{R} = \frac{1.46\ k\Omega}{100\ \Omega} = 14.6$$

$$BW = \frac{f_r}{Q} = \frac{23.2\ kHz}{14.6} = \textbf{1.59 kHz}$$

17–9 Applications

Resonant circuits are used in a wide variety of applications, particularly in communication systems. In this section, we will look briefly at a few common communication systems applications to illustrate the importance of resonant circuits in electronic communication.

After completing this section, you should be able to

◆ **Discuss some applications of resonant circuits**

◆ Describe a tuned amplifier application

◆ Describe antenna coupling

◆ Describe tuned amplifiers

◆ Describe audio crossover networks

◆ Describe a radio receiver

Tuned Amplifiers

A *tuned amplifier* is a circuit that amplifies signals within a specified band. Typically, a parallel resonant circuit is used in conjunction with an amplifier to achieve the selectivity. In terms of the general operation, input signals with frequencies that range over a wide band are accepted on the amplifier's input and are amplified. The resonant circuit allows only a relatively narrow band of those frequencies to be passed on. The variable capacitor allows tuning over the range of input frequencies so that a desired frequency can be selected, as indicated in Figure 17–49.

Antenna Input to a Receiver

Radio signals are sent out from a transmitter via electromagnetic waves that propagate through the atmosphere. When the electromagnetic waves cut across the receiving antenna, small voltages are induced. Out of all the wide range of electromagnetic frequencies, only

Resonant coupling from an antenna.

one frequency or a limited band of frequencies must be extracted. Figure 17–50 shows a typical arrangement of an antenna coupled to the receiver input by a transformer. A variable capacitor is connected across the transformer secondary to form a parallel resonant circuit.

Double-Tuned Transformer Coupling in a Receiver

In some types of communication receivers, tuned amplifiers are transformer-coupled together to increase the amplification. Capacitors can be placed in parallel with the primary and secondary windings of the transformer, effectively creating two parallel resonant band-pass filters that are coupled together. This technique, illustrated in Figure 17–51, can result
▲ FIGURE 17–51

Double-tuned amplifiers.

in a wider bandwidth and steeper slopes on the response curve, thus increasing the selectivity for a desired band of frequencies.

Audio Crossover Networks

Most quality stereo systems have speakers designed for specific parts of the audio frequency spectrum. Audio crossover networks are filter networks that separate the audio signal into different frequency bands for the speakers while maintaining an overall flat response. Crossover networks can be passive (meaning only inductors, capacitors, and resistors are used) or active (meaning transistor and operational amplifiers are used).

A three-way passive network includes a band-pass filter that is essentially a low-Q resonant filter designed to have a broad flat response. The design of passive crossover networks is complicated because of various factors that affect the overall response (such as variations of the speaker's impedance as a function of frequency), but the basic concept is simple. The network separates the audio spectrum into three parts and passes each part to the appropriate speaker, as indicated in Figure 17–52. The network has three filters: a high-pass filter that passes high frequencies to the tweeter (or high-frequency speaker), a band-pass filter that passes middle frequencies to the mid-range speaker, and a low-pass filter that passes low frequencies to the woofer (or low-frequency speaker).
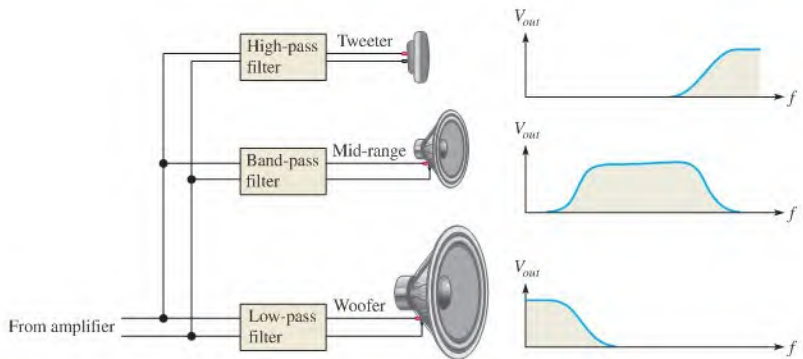

▲ **FIGURE 17–52**

A crossover network uses filters to separate the audio frequency bands.

Superheterodyne Receiver

Another example of resonant circuit (filter) applications is in the common AM (amplitude modulation) receiver. The AM broadcast band ranges from 535 kHz to 1605 kHz. Each AM station is assigned a 10 kHz bandwidth within that range. The tuned circuits are designed to pass only the signals from the desired radio station, rejecting all others. To reject stations outside the one that is tuned, the tuned circuits must be selective, passing on only the signals in the 10 kHz band and rejecting all others. Too much selectivity is not desirable either however. If the bandwidth is too narrow, some of the higher frequency modulated signals will be rejected, resulting in a loss of fidelity. Ideally, the
▲ **FIGURE 17–53**

A simplified diagram of a superheterodyne AM radio broadcast receiver showing an example of the application of tuned resonant circuits.

resonant circuit must reject signals that are not in the desired passband. A simplified block diagram of a superheterodyne AM receiver is shown in Figure 17–53.

There are basically three parallel resonant circuits in the front end of the receiver. Each of these resonant circuits is gang-tuned by capacitors; that is, the capacitors are mechanically or electronically linked together so that they change together as the tuning knob is turned. The front end is tuned to receive a desired station, for example, one that transmits at 600 kHz. The input resonant circuit from the antenna and the RF (radio frequency) amplifier resonant circuit select only a frequency of 600 kHz out of all the frequencies crossing the antenna.

The actual audio (sound) signal is carried by the 600 kHz carrier frequency by modulating the amplitude of the carrier so that it follows the audio signal as indicated. The variation in the amplitude of the carrier corresponding to the audio signal is called the *envelope*. The 600 kHz is then applied to a circuit called the *mixer*.

The *local oscillator* (LO) is tuned to a frequency that is 455 kHz above the selected frequency (1055 kHz, in this case). By a process called *heterodyning* or *beating*, the AM signal and the local oscillator signal are mixed together, and the 600 kHz AM signal is converted by the mixer to a 455 kHz AM signal (1055 kHz − 600 kHz = 455 kHz).

The 455 kHz is the intermediate frequency (IF) for standard AM receivers. No matter which station within the broadcast band is selected, its frequency is always converted to the 455 kHz IF. The amplitude-modulated IF is amplified by the IF amplifier which is tuned to 455 kHz. The output of the IF amplifier is applied to an *audio detector* which removes the IF, leaving only the envelope which is the audio signal. The audio signal is then amplified and applied to the speaker.

Application Activity

In the Chapter 11 application activity, you worked with a receiver system to learn basic ac measurements. In this chapter, the receiver is again used to illustrate one application of resonant circuits. We will focus on a part of the "front end" of the receiver system that contains resonant circuits. Generally, the front end includes the RF amplifier, the local oscillator, and the mixer. In this application activity, the RF amplifier is the focus. A knowledge of amplifier circuits is not necessary at this time.

A basic block diagram of an AM radio receiver is shown in Figure 17–54. In this particular system, the "front end" includes the circuitry used for tuning in a desired broadcasting station by frequency selection and then converting that selected frequency to a standard intermediate frequency (IF). AM radio stations transmit in the frequency range from 535 kHz to 1605 kHz. The purpose of the RF amplifier is to take the signals picked up by the antenna, reject all but the signal from the desired station, and amplify it to a higher level.

A schematic of the RF amplifier is shown in Figure 17–55. The parallel resonant tuning circuit consists of L, C_1 and C_2.

This particular RF amplifier does not have a resonant circuit on the output. C_1 is a varactor, which is a semiconductor device that you will learn more about in a later course. All that you need to know at this point is that the varactor is basically a variable capacitor whose capacitance is varied by changing the dc voltage across it. In this circuit, the dc voltage comes from the wiper of the potentiometer used for tuning the receiver.

The voltage from the potentiometer can be varied from +1 V to +9 V. The particular varactor used in this circuit can be varied from 200 pF at 1 V to 5 pF at 9 V. The capacitor C_2 is a trimmer capacitor that is used for initially adjusting the resonant circuit. Once it is preset, it is left at that value. C_1 and C_2 are in parallel and their capacitances add to produce the total capacitance for the resonant circuit. C_3 has a minimal effect on the resonant circuit and can be ignored. The purpose of C_3 is to allow the dc voltage to be applied to the varactor while providing an ac ground.

In this application activity, you will focus on the RF amplifier circuit board in Figure 17–56. Although all of the amplifier components are on the board, the part that you are to focus on is the resonant circuit indicated by the highlighted area.

Capacitance in the Resonant Circuit

1. Calculate a capacitance setting for C_2 that will ensure a complete coverage of the AM frequency band as the varactor is varied over its capacitance range. C_3 can be ignored. The full range of resonant frequencies for the tuning circuit should more than cover the AM band, so that at the maximum varactor capacitance, the resonant frequency will be less than 535 kHz and at the minimum varactor capacitance, the resonant frequency will be greater than 1605 kHz.

2. Using the value of C_2 that you have calculated, determine the values of the varactor capacitance that will produce a resonant frequency of 535 kHz and 1605 kHz, respectively.

Testing the Resonant Circuit

3. Suggest a procedure for testing the resonant circuit using the instruments in the test bench setup of Figure 17–57.

Develop a test setup by creating a point-to-point hook-up of the board and the instruments.

4. Using the graph in Figure 17–58 that shows the variation in varactor capacitance versus varactor voltage, determine the resonant frequency for each indicated setting from the B outputs of the dc power supply (rightmost output terminals). The A output of the power supply is used to provide 9 V to the amplifier. The B output of the power supply is used to simulate the potentiometer voltage.

SUMMARY

◆ X_L and X_C have opposing effects in an *RLC* circuit.

◆ In a series *RLC* circuit, the larger reactance determines the net reactance of the circuit.

◆ At series resonance, the inductive and capacitive reactances are equal.

◆ The impedance of a series *RLC* circuit is purely resistive at resonance.

◆ In a series *RLC* circuit, the current is maximum at resonance.

◆ The reactive voltages V_L and V_C cancel at resonance in a series *RLC* circuit because they are equal in magnitude and 180° out of phase.

◆ In a parallel *RLC* circuit, the smaller reactance determines the net reactance of the circuit.

◆ In a parallel resonant circuit, the impedance is maximum at the resonant frequency.

◆ A parallel resonant circuit is commonly called a *tank circuit*.

◆ The impedance of a parallel *RLC* circuit is purely resistive at resonance.

◆ The bandwidth of a series resonant circuit is the range of frequencies for which the current is $0.707I_{max}$ or greater.

◆ The bandwidth of a parallel resonant circuit is the range of frequencies for which the impedance is $0.707Z_{max}$ or greater.

◆ The critical frequencies are the frequencies above and below resonance where the circuit response is 70.7% of the maximum response.

◆ A higher Q produces a narrower bandwidth.

KEY TERMS

Key terms and other bold terms in the chapter are defined in the end-of-book glossary.

Half-power frequency The frequency at which the output power of a resonant circuit is 50% of the maximum (the output voltage is 70.7% of maximum); another name for *critical* or *cutoff frequency*.

Parallel resonance A condition in a parallel *RLC* circuit in which the reactances ideally are equal and the impedance is maximum.

Resonant frequency The frequency at which resonance occurs; also known as the *center frequency*.

Selectivity A measure of how effectively a resonant circuit passes certain desired frequencies and rejects all others. Generally, the narrower the bandwidth, the greater the selectivity.

Series resonance A condition in a series *RLC* circuit in which the reactances ideally cancel and the impedance is minimum.

Tank circuit A parallel resonant circuit.

INTRODUCTION

The concept of filters was introduced in Chapters 15, 16, and 17 to illustrate applications of *RC*, *RL*, and *RLC* circuits. This chapter is essentially an extension of the earlier material and provides additional coverage of the important topic of filters.

  Passive filters are discussed in this chapter. Passive filters use various combinations of resistors, capacitors, and inductors. In a later course, you will study active filters that use passive components combined with amplifiers. You have already seen how basic *RC*, *RL*, and *RLC* circuits can be used as filters. Now, you will learn that passive filters can be placed in four general categories according to their response characteristics: low-pass, high-pass, band-pass, and band-stop. Within each category, there are several common types that will be examined.

18–1 LOW-PASS FILTERS

A **low-pass filter** allows signals with lower frequencies to pass from input to output while rejecting higher frequencies.

After completing this section, you should be able to

◆ **Analyze the operation of *RC* and *RL* low-pass filters**

   ◆ Express the voltage and power ratios of a filter in decibels

   ◆ Determine the critical frequency of a low-pass filter

   ◆ Explain the difference between actual and ideal low-pass response curves

   ◆ Define *roll-off*

   ◆ Generate a Bode plot for a low-pass filter

   ◆ Discuss phase shift in a low-pass filter

Figure 18–1 shows a block diagram and a general response curve for a low-pass filter. The range of frequencies passed by a filter within specified limits is called the **passband** of the filter. The point considered to be the upper end of the passband is at the critical frequency, f_c, as illustrated in Figure 18–1(b). The **critical frequency (f_c)** is the frequency at which the filter's output voltage is 70.7% of the maximum. The filter's critical frequency is also called the *cutoff frequency, break frequency,* or *−3 dB frequency* because the output voltage is down 3 dB from its maximum at this frequency. The term *dB (decibel)* is a commonly used unit in filter measurements.

◆ **FIGURE 18–1**

Decibels

The basis for the decibel unit stems from the logarithmic response of the human ear to the intensity of sound. The **decibel** is a logarithmic measurement of the ratio of one power to another or one voltage to another, which can be used to express the input-to-output relationship of a filter. The following equation expresses a power ratio in decibels:

Equation 18–1

$$dB = 10 \log\left(\frac{P_{out}}{P_{in}}\right)$$

🌐 *This icon indicates selected websites for further information on topics in this section. See the Companion Website provided with this text.*

From the properties of logarithms, the following decibel formula for a voltage ratio is derived.

$$dB = 20 \log\left(\frac{V_{out}}{V_{in}}\right)$$

EXAMPLE 18–1   At a certain frequency, the output voltage of a filter is 5 V and the input is 10 V. Express the voltage ratio in decibels.

Solution $$20 \log\left(\frac{V_{out}}{V_{in}}\right) = 20 \log\left(\frac{5\text{ V}}{10\text{ V}}\right) = 20 \log(0.5) = \mathbf{-6.02\text{ dB}}$$

Related Problem*   Express the ratio $V_{out}/V_{in} = 0.85$ in decibels.

*Answers are at the end of the chapter.

RC Low-Pass Filter

A basic *RC* low-pass filter is shown in Figure 18–2. Notice that the output voltage is taken across the capacitor.

When the input is dc (0 Hz), the output voltage equals the input voltage because X_C is infinitely large. As the input frequency is increased, X_C decreases and, as a result, V_{out} gradually decreases until a frequency is reached where $X_C = R$. This is the critical frequency, f_c, of the filter.

▲ **FIGURE 18–2**

$$X_C = \frac{1}{2\pi f_c C} = R$$

Solving for f_c,

$$f_c = \frac{1}{2\pi RC}$$

At any frequency, by application of the voltage-divider formula, the output voltage magnitude is

$$V_{out} = \left(\frac{X_C}{\sqrt{R^2 + X_C^2}}\right) V_{in}$$

Since $X_C = R$ at f_c, the output voltage at the critical frequency can be expressed as

$$V_{out} = \left(\frac{R}{\sqrt{R^2 + R^2}}\right) V_{in} = \left(\frac{R}{\sqrt{2R^2}}\right) V_{in} = \left(\frac{R}{R\sqrt{2}}\right) V_{in} = \left(\frac{1}{\sqrt{2}}\right) V_{in} = 0.707 V_{in}$$

These calculations show that the output is 70.7% of the input when $X_C = R$. The frequency at which this occurs is, by definition, the critical frequency.

The ratio of output voltage to input voltage at the critical frequency can be expressed in decibels as follows:

$$V_{out} = 0.707 V_{in}$$
$$\frac{V_{out}}{V_{in}} = 0.707$$
$$20 \log\left(\frac{V_{out}}{V_{in}}\right) = 20 \log(0.707) = -3\text{ dB}$$
EXAMPLE 18–2

Determine the critical frequency and V_{out} at f_c for an input of 10 V for the RC low-pass filter in Figure 18–2.

Solution

$$f_c = \frac{1}{2\pi RC} = \frac{1}{2\pi (100\,\Omega)(0.0047\,\mu F)} = \mathbf{339\,kHz}$$

The output voltage is 3 dB below V_{in} at this frequency (V_{out} has a maximum value of V_{in}).

$$V_{out} = 0.707 V_{in} = \mathbf{7.07\,V}$$

Related Problem

A certain RC low-pass filter has $R = 1.0\,k\Omega$ and $C = 0.022\,\mu F$. Determine its critical frequency.

Roll-Off of the Response Curve

The blue line in Figure 18–3 shows an actual response curve for a low-pass filter. The maximum output is defined to be 0 dB as a reference. Zero decibels corresponds to $V_{out} = V_{in}$ because $20 \log(V_{out}/V_{in}) = 20 \log 1 = 0$ dB. The output drops from 0 dB to -3 dB at the critical frequency and then continues to decrease at a fixed rate. This pattern of decrease is called the **roll-off** of the frequency response. The red line shows an ideal output response that is considered to be "flat" out to the critical frequency. The output then decreases at the fixed rate.

◢ **FIGURE 18–3**

Actual and ideal response curves for a low-pass filter.
As you have seen, the output voltage of a low-pass filter decreases by 3 dB when the frequency is increased to the critical value f_c. As the frequency continues to increase above f_c, the output voltage continues to decrease. In fact, for each tenfold increase in frequency above f_c, there is a 20 dB reduction in the output, as shown in the following steps.

Let's take a frequency that is ten times the critical frequency ($f = 10f_c$). Since $R = X_C$ at f_c, then $R = 10X_C$ at $10f_c$ because of the inverse relationship of X_C and f.

The **attenuation** is the reduction in voltage expressed as the ratio V_{out}/V_{in} and is developed as follows:

$$\frac{V_{out}}{V_{in}} = \frac{X_C}{\sqrt{R^2 + X_C^2}} = \frac{X_C}{\sqrt{(10X_C)^2 + X_C^2}}$$

$$= \frac{X_C}{\sqrt{100X_C^2 + X_C^2}} = \frac{X_C}{\sqrt{X_C^2(100 + 1)}} = \frac{X_C}{X_C\sqrt{101}} = \frac{1}{\sqrt{101}} \cong \frac{1}{10} = 0.1$$

The dB attenuation is

$$20 \log\left(\frac{V_{out}}{V_{in}}\right) = 20 \log(0.1) = -20\,dB$$

A tenfold change in frequency is called a **decade**. So, for an *RC* circuit, the output voltage is reduced by 20 dB for each decade increase in frequency. A similar result can be derived for a high-pass circuit. The roll-off is a constant −20 dB/decade for a basic *RC* or *RL* filter. Figure 18–4 shows the ideal frequency response plot on a semilog scale, where each interval on the horizontal axis represents a tenfold increase in frequency. This response curve is called a **Bode plot**.

▲ FIGURE 18–5

Solution   The critical frequency for this low-pass filter is

$$f_c = \frac{1}{2\pi RC} = \frac{1}{2\pi(1.0\ k\Omega)(0.0047\ \mu F)} = 33.9\ kHz$$

The idealized Bode plot is shown with the red line on the semilog graph in Figure 18–6. The approximate actual response curve is shown with the blue line. Notice first that the horizontal scale is logarithmic and the vertical scale is linear. The frequency is on the logarithmic scale, and the filter output in decibels is on the linear scale.

The output is flat below f_c (33.9 kHz). As the frequency is increased above f_c, the output drops at a −20 dB/decade rate. Thus, for the ideal curve, every time the frequency is increased by ten, the output is reduced by 20 dB. A slight variation from this occurs in actual practice. The output is actually at −3 dB rather than 0 dB at the critical frequency.

RL Low-Pass Filter

▲ FIGURE 18–7

RL low-pass filter.

A basic *RL* low-pass filter is shown in Figure 18–7. Notice that the output voltage is taken across the resistor.

When the input is dc (0 Hz), the output voltage ideally equals the input voltage because X_L is a short (if R_W is neglected). As the input frequency is increased, X_L increases and, as a result, V_{out} gradually decreases until the critical frequency is reached. At this point, $X_L = R$ and the frequency is

$$2\pi f_c L = R$$

$$f_c = \frac{R}{2\pi L}$$

Equation 18–4

$$f_c = \frac{1}{2\pi(L/R)}$$

Just as in the *RC* low-pass filter, $V_{out} = 0.707V_{in}$ and, thus, the output voltage is −3 dB below the input voltage at the critical frequency.

$$f_c = \frac{1}{2\pi(L/R)} = \frac{1}{2\pi(4.7\ \text{mH}/2.2\ \text{k}\Omega)} = 74.5\ \text{kHz}$$

The idealized Bode plot is shown with the red line on the semilog graph in Figure 18–9. The approximate actual response curve is shown with the blue line. Notice first that the horizontal scale is logarithmic and the vertical scale is linear. The frequency is on the logarithmic scale, and the filter output in decibels is on the linear scale.

Phase Shift in a Low-Pass Filter

The RC low-pass filter acts as a lag circuit. Recall from Chapter 15 that the phase shift from input to output is expressed as

$$\phi = -\tan^{-1}\left(\frac{R}{X_C}\right)$$

At the critical frequency, $X_C = R$ and, therefore, $\phi = -45°$. As the input frequency is reduced, ϕ decreases and approaches $0°$ when the frequency approaches zero. Figure 18–10, illustrates this phase characteristic.

▶ **FIGURE 18–10**

Phase characteristic of a low-pass filter.
The RL low-pass filter also acts as a lag circuit. Recall from Chapter 16 that the phase shift is expressed as

$$\phi = -\tan^{-1}\left(\frac{X_L}{R}\right)$$

As in the RC filter, the phase shift from input to output is $-45°$ at the critical frequency and decreases for frequencies below f_c.

voltage increases until it equals V_{in}. The expression for the critical frequency of the high-pass filter is the same as for the low-pass filter.

$$f_c = \frac{1}{2\pi(L/R)}$$

Phase Shift in a High-Pass Filter

Both the RC and the RL high-pass filters act as lead circuits. Recall from Chapters 15 and 16 that the phase shift from input to output for the RC lead circuit is

$$\phi = \tan^{-1}\left(\frac{X_C}{R}\right)$$

and the phase shift for the RL lead circuit is

$$\phi = \tan^{-1}\left(\frac{R}{X_L}\right)$$

EXAMPLE 18–6

(a) In Figure 18–18, find the value of C so that X_C is approximately ten times less than R at an input frequency of 10 kHz.

(b) If a 5 V sine wave with a dc level of 10 V is applied, what are the output voltage magnitude and the phase shift?

▶ FIGURE 18–18
Solution   (a) Determine the value of C as follows:

$$X_C = 0.1R = 0.1(680\,\Omega) = 68\,\Omega$$

$$C = \frac{1}{2\pi f X_C} = \frac{1}{2\pi(10\,\text{kHz})(68\,\Omega)} = \mathbf{0.234\,\mu F}$$

Using the nearest standard value of $C = 0.22\,\mu F$,

$$X_C = \frac{1}{2\pi f C} = \frac{1}{2\pi(10\,\text{kHz})(0.22\,\mu F)} = 72\,\Omega$$

(b) Determine the magnitude of the sinusoidal output using the voltage-divider formula.

$$V_{out} = \left(\frac{R}{\sqrt{R^2 + X_C^2}} \right) V_{in} = \left(\frac{680 \ \Omega}{\sqrt{(680 \ \Omega)^2 + (72 \ \Omega)^2}} \right) 5 \ \text{V} = \mathbf{4.97 \ V}$$

The phase shift is

$$\phi = \tan^{-1} \left(\frac{X_C}{R} \right) = \tan^{-1} \left(\frac{72 \ \Omega}{680 \ \Omega} \right) = \mathbf{6.04°}$$

At $f = 10$ kHz, which is a decade above the critical frequency, the sinusoidal output is almost equal to the input in magnitude, and the phase shift is very small. The 10 V dc level has been filtered out and does not appear at the output.

18–3   BAND-PASS FILTERS

A **band-pass filter** allows a certain band of frequencies to pass and attenuates or rejects all frequencies below and above the passband.

- ◆ Explain the series-resonant band-pass filter
- ◆ Explain the parallel-resonant band-pass filter
- ◆ Calculate the bandwidth and output voltage of a band-pass filter

---

The bandwidth of a band-pass filter is the range of frequencies for which the current, and therefore the output voltage, is equal to or greater than 70.7% of its value at the resonant frequency.

As you know, bandwidth is often abbreviated *BW* and can be calculated as

$$BW = f_{c2} - f_{c1}$$

where f_{c1} is the lower cutoff frequency and f_{c2} is the upper cutoff frequency.

Figure 18–19 shows a typical band-pass response curve.

Low-Pass/High-Pass Filter

A combination of a low-pass and a high-pass filter can be used to form a band-pass filter, as illustrated in Figure 18–20. The loading effect of the second filter on the first must be taken into account.

▶ FIGURE 18–20

$$BW = f_{c(l)} - f_{c(h)} = 2.5 \text{ kHz} - 2 \text{ kHz} = \textbf{500 Hz}$$

Related Problem If $f_{c(l)} = 9$ kHz and the bandwidth is 1.5 kHz, what is $f_{c(h)}$?

Series Resonant Band-Pass Filter

A type of series resonant band-pass filter is shown in Figure 18–22. As you learned in Chapter 17, a series resonant circuit has minimum impedance and maximum current at the resonant frequency, f_r. Thus, most of the input voltage is dropped across the resistor at the resonant frequency. Therefore, the output across R has a band-pass characteristic with a maximum output at the frequency of resonance. The resonant frequency is called the **center frequency, f_0.** The bandwidth is determined by the quality factor, Q, of the circuit and the resonant frequency, as was discussed in Chapter 17. Recall that $Q = X_L/R$, where R is the resistance in the circuit.
▲ **FIGURE 18–22**

Series resonant band-pass filter.

A higher value of Q results in a smaller bandwidth. A lower value of Q causes a larger bandwidth. A formula for the bandwidth of a resonant circuit in terms of Q is stated in the following equation:

$$BW = \frac{f_0}{Q}$$

Equation 18–5

EXAMPLE 18–8

Determine the output voltage magnitude at the center frequency (f_0) and the bandwidth for the filter in Figure 18–23.

▶ **FIGURE 18–23**
Solution   At f_0, X_C and X_L cancel and the impedance of the resonant circuit is equal to the winding resistance, R_W. The total circuit resistance is $R_L + R_W$. By the voltage-divider formula,

$$V_{out} = \left(\frac{R_L}{R_L + R_W}\right)V_{in} = \left(\frac{100\ \Omega}{110\ \Omega}\right)10\ V = \mathbf{9.09\ V}$$

The center frequency is

$$f_0 = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(1\ \text{mH})(0.0022\ \mu F)}} = 107\ \text{kHz}$$

At f_0, the inductive reactance is

$$X_L = 2\pi fL = 2\pi(107\text{ kHz})(1\text{ mH}) = 672\,\Omega$$

and the total resistance is

$$R_{tot} = R_L + R_W = 100\,\Omega + 10\,\Omega = 110\,\Omega$$

Therefore, the circuit Q is

$$Q = \frac{X_L}{R_{tot}} = \frac{672\,\Omega}{110\,\Omega} = 6.11$$

The bandwidth is

$$BW = \frac{f_0}{Q} = \frac{107\text{ kHz}}{6.11} = \mathbf{17.5\text{ kHz}}$$

Related Problem   If a 1 mH coil with a winding resistance of 18 Ω replaces the existing coil in Figure 18–23, how is the bandwidth affected?

Use Multisim files E18-08A and E18-08B to verify the calculated results in this example and to confirm your answer for the related problem.

Parallel Resonant Band-Pass Filter

A type of band-pass filter using a parallel resonant circuit is shown in Figure 18–24. Recall that a parallel resonant circuit has maximum impedance at resonance. The circuit in Figure 18–24 acts as a voltage divider. At resonance, the impedance of the tank circuit is much greater than the resistance. Thus, most of the input voltage is across the tank circuit, producing a maximum output voltage at the resonant (center) frequency.

▶ **FIGURE 18–24**

Parallel resonant band-pass filter.
For frequencies above or below resonance, the tank circuit impedance drops off, and more of the input voltage is across R. As a result, the output voltage across the tank circuit drops off, creating a band-pass characteristic.

EXAMPLE 18–9

What is the center frequency of the filter in Figure 18–25? Assume $R_W = 0\,\Omega$.

▶ **FIGURE 18–25**
Solution   The center frequency of the filter is its resonant frequency.

EXAMPLE 18–10   Determine the center frequency and bandwidth for the band-pass filter in Figure 18–26 if the inductor has a winding resistance of 15 Ω.

▶ **FIGURE 18–26**
Solution   Recall from Chapter 17 (Eq. 17–13) that the resonant (center) frequency of a nonideal tank circuit is

$$f_0 = \frac{\sqrt{1 - (R_W^2 C/L)}}{2\pi\sqrt{LC}} = \frac{\sqrt{1 - (15\,\Omega)^2(0.01\,\mu F)/50\,\text{mH}}}{2\pi\sqrt{(50\,\text{mH})(0.01\,\mu F)}} = 7.12\,\text{kHz}$$

The Q of the coil at resonance is

$$Q = \frac{X_L}{R_W} = \frac{2\pi f_0 L}{R_W} = \frac{2\pi(7.12\,\text{kHz})(50\,\text{mH})}{15\,\Omega} = 149$$

The bandwidth of the filter is

$$BW = \frac{f_0}{Q} = \frac{7.12\,\text{kHz}}{149} = 47.8\,\text{Hz}$$

Note that since $Q > 10$, the simpler formula, $f_0 = 1/(2\pi\sqrt{LC})$, could have been used to calculate f_0.

Related Problem   Knowing the value of Q, recalculate f_0 using the simpler formula.

$$Q = \frac{X_L}{R_{(tot)}} = \frac{2\pi fL}{R + R_W} = \frac{2\pi(5.03\text{ kHz})(100\text{ mH})}{58\ \Omega} = \frac{3.16\text{ k}\Omega}{58\ \Omega} = 54.5$$

$$BW = \frac{f_0}{Q} = \frac{5.03\text{ kHz}}{54.5} = \textbf{92.3 Hz}$$

Related Problem   Assume $R_W = 10\ \Omega$ in Figure 18–31. Determine V_{out} and the bandwidth.

Parallel Resonant Band-Stop Filter

A parallel resonant circuit used in a band-stop configuration is shown in Figure 18–32. At the resonant frequency, the tank impedance is maximum, and so most of the input voltage appears across it. Very little voltage is across R at resonance. As the tank impedance decreases above and below resonance, the output voltage increases.

▶ **FIGURE 18–32**

Parallel resonant band-stop filter.
EXAMPLE 18–12

Find the center frequency of the filter in Figure 18–33. Draw the output response curve showing the minimum and maximum voltages.
▲ **FIGURE 18–33**

Solution The center frequency is

$$f_0 = \frac{\sqrt{1 - R_W^2 C/L}}{2\pi\sqrt{LC}} = \frac{\sqrt{1 - (8\,\Omega)^2(150\,\text{pF})/5\,\mu\text{H}}}{2\pi\sqrt{(5\,\mu\text{H})(150\,\text{pF})}} = \textbf{5.79 MHz}$$

At the center (resonant) frequency,

$$X_L = 2\pi f_0 L = 2\pi(5.79\,\text{MHz})(5\,\mu\text{H}) = 182\,\Omega$$

$$Q = \frac{X_L}{R_W} = \frac{182\,\Omega}{8\,\Omega} = 22.8$$

$$Z_r = R_W(Q^2 + 1) = 8\,\Omega(22.8^2 + 1) = 4.17\,\text{k}\Omega \quad \text{(purely resistive)}$$

Next, use the voltage-divider formula to find the minimum output voltage magnitude.

$$V_{out(min)} = \left(\frac{R_L}{R_L + Z_r}\right)V_{in} = \left(\frac{560\,\Omega}{4.73\,\text{k}\Omega}\right)10\,\text{V} = 1.18\,\text{V}$$

At zero frequency, the impedance of the tank circuit is R_W because $X_C = \infty$ and $X_L = 0\,\Omega$. Therefore, the maximum output voltage below resonance is

$$V_{out(max)} = \left(\frac{R_L}{R_L + R_W}\right)V_{in} = \left(\frac{560\,\Omega}{568\,\Omega}\right)10\,\text{V} = 9.86\,\text{V}$$

As the frequency increases much higher than f_0, X_C approaches $0\,\Omega$, and V_{out} approaches V_{in} (10 V). Figure 18–34 shows the response curve.

INTRODUCTION

Four important theorems were covered in Chapter 8 with emphasis on their applications in the analysis of dc circuits. This chapter is a continuation of that coverage with emphasis on applications in the analysis of ac circuits with reactive components.

The theorems in this chapter make analysis easier for certain types of circuits. These methods do not replace Ohm's law and Kirchhoff's laws, but they are normally used in conjunction with those laws in certain situations.

The superposition theorem helps you to deal with circuits that have multiple sources. Thevenin's and Norton's theorems provide methods for reducing a circuit to a simple equivalent form for easier analysis. The maximum power transfer theorem is used in applications where it is important for a given circuit to provide maximum power to a load.

19–1 THE SUPERPOSITION THEOREM

The superposition theorem was introduced in Chapter 8 for use in dc circuit analysis. In this section, the superposition theorem is applied to circuits with ac sources and reactive components.

After completing this section, you should be able to

◆ **Apply the superposition theorem to ac circuit analysis**

  ◆ State the superposition theorem

  ◆ List the steps in applying the theorem

The **superposition theorem** can be stated as follows:

The current in any given branch of a multiple-source circuit can be found by determining the currents in that particular branch produced by each source acting alone, with all other sources replaced by their internal impedances. The total current in the given branch is the phasor sum of the individual currents in that branch.

The procedure for the application of the superposition theorem is as follows:

Step 1: Leave one of the voltage (current) sources in the circuit, and replace all others with their internal impedance. For ideal voltage sources, the internal impedance is zero. For ideal current sources, the internal impedance is infinite. We will call this procedure *zeroing* the source.

Step 2: Find the current in the branch of interest produced by the one remaining source.

Step 3: Repeat Steps 1 and 2 for each source in turn. When complete, you will have a number of current values equal to the number of sources in the circuit.

Step 4: Add the individual current values as phasor quantities.

Example 19–1 illustrates this procedure for a circuit containing two ideal voltage sources, V_{s1} and V_{s2}.

EXAMPLE 19–1

Find the current in R of Figure 19–1 using the superposition theorem. Assume the internal source impedances are zero.
▲ **FIGURE 19–1**

Solution **Step 1:** Replace V_{s2} with its internal impedance (zero in this case), and find the current in R due to V_{s1}, as indicated in Figure 19–2.

$$X_{C1} = \frac{1}{2\pi f C_1} = \frac{1}{2\pi (10 \text{ kHz})(0.01 \text{ } \mu\text{F})} = 1.59 \text{ k}\Omega$$

$$X_{C2} = \frac{1}{2\pi f C_2} = \frac{1}{2\pi (10 \text{ kHz})(0.022 \text{ } \mu\text{F})} = 723 \text{ }\Omega$$
▲ FIGURE 19–2

Looking from V_{s1}, the impedance is

$$\mathbf{Z} = \mathbf{X}_{C1} + \frac{\mathbf{R}\mathbf{X}_{C2}}{\mathbf{R} + \mathbf{X}_{C2}} = 1.59\angle -90° \text{ k}\Omega + \frac{(1.0\angle 0° \text{ k}\Omega)(723\angle -90° \text{ }\Omega)}{1.0 \text{ k}\Omega - j723 \text{ }\Omega}$$

$$= 1.59\angle -90° \text{ k}\Omega + 588\angle -54.1° \text{ }\Omega$$

$$= -j1.59 \text{ k}\Omega + 345 \text{ }\Omega - j476 \text{ }\Omega = 345 \text{ }\Omega - j2.07 \text{ k}\Omega$$

Converting to polar form yields

$$\mathbf{Z} = 2.10\angle -80.5° \text{ k}\Omega$$

The total current from V_{s1} is

$$\mathbf{I}_{s1} = \frac{\mathbf{V}_{s1}}{\mathbf{Z}} = \frac{10\angle 0° \text{ V}}{2.10\angle -80.5° \text{ k}\Omega} = 4.76\angle 80.5° \text{ mA}$$

Use the current-divider formula. The current through R due to V_{s1} is

$$\mathbf{I}_{R1} = \left(\frac{X_{C2}\angle -90°}{R - jX_{C2}}\right)\mathbf{I}_{s1} = \left(\frac{723\angle -90° \text{ }\Omega}{1.0 \text{ k}\Omega - j723 \text{ }\Omega}\right)4.76\angle 80.5° \text{ mA}$$

$$= (0.588\angle -54.9° \text{ }\Omega)(4.76\angle 80.5° \text{ mA}) = 2.80\angle 25.6° \text{ mA}$$

Step 2: Find the current in R due to source V_{s2} by replacing V_{s1} with its internal impedance (zero), as shown in Figure 19–3.
▲ FIGURE 19–3

Looking from V_{s2}, the impedance is

$$\mathbf{Z} = \mathbf{X}_{C2} + \frac{\mathbf{RX}_{C1}}{\mathbf{R} + \mathbf{X}_{C1}} = 723\angle-90°\,\Omega + \frac{(1.0\angle0°\,k\Omega)(1.59\angle-90°\,k\Omega)}{1.0\,k\Omega - j1.59\,k\Omega}$$

$$= 723\angle-90°\,\Omega + 847\angle-32.2°\,\Omega$$

$$= -j723\,\Omega + 717\,\Omega - j451\,\Omega = 717\,\Omega - j1174\,\Omega$$

Converting to polar form yields

$$\mathbf{Z} = 1376\angle-58.6°\,\Omega$$

The total current from V_{s2} is

$$\mathbf{I}_{s2} = \frac{\mathbf{V}_{s2}}{\mathbf{Z}} = \frac{8\angle0°\,V}{1376\angle-58.6°\,\Omega} = 5.81\angle58.6°\,mA$$

Use the current-divider formula. The current through R due to V_{s2} is

$$\mathbf{I}_{R2} = \left(\frac{X_{C1}\angle-90°}{R - jX_{C1}}\right)\mathbf{I}_{s2}$$

$$= \left(\frac{1.59\angle-90°\,k\Omega}{1.0\,k\Omega - j1.59\,k\Omega}\right)5.81\angle58.6°\,mA = 4.91\angle26.4°\,mA$$

Step 3: Convert the two individual resistor currents to rectangular form and add to get the total current through R.

$$\mathbf{I}_{R1} = 2.80\angle25.6°\,mA = 2.53\,mA + j1.21\,mA$$

$$\mathbf{I}_{R2} = 4.91\angle26.4°\,mA = 4.40\,mA + j2.18\,mA$$

$$\mathbf{I}_R = \mathbf{I}_{R1} + \mathbf{I}_{R2} = 6.93\,mA + j3.39\,mA = \mathbf{7.71\angle26.1°\,mA}$$

19–2 THEVENIN'S THEOREM

Thevenin's theorem, as applied to ac circuits, provides a method for reducing any circuit to an equivalent form that consists of an equivalent ac voltage source in series with an equivalent impedance.

After completing this section, you should be able to

◆ **Apply Thevenin's theorem to simplify reactive ac circuits for analysis**

 ◆ Describe the form of a Thevenin equivalent circuit

 ◆ Obtain the Thevenin equivalent ac voltage source

 ◆ Obtain the Thevenin equivalent impedance

 ◆ List the steps in applying Thevenin's theorem to an ac circuit

Equivalency

The form of Thevenin's **equivalent circuit** is shown in Figure 19–12. Regardless of how complex the original circuit is, it can always be reduced to this equivalent form. The equivalent voltage source is designated $\mathbf{V}_{th}$; the equivalent impedance is designated $\mathbf{Z}_{th}$ (lowercase italic subscript denotes ac quantity). Notice that the impedance is represented by a block in the circuit diagram. This is because the equivalent impedance can be of several forms: purely resistive, purely capacitive, purely inductive, or a combination of a resistance and a reactance.

Figure 19–13(a) shows a block diagram that represents an ac circuit of any given complexity. This circuit has two output terminals, A and B. A load impedance, $\mathbf{Z}_L$, is connected to the terminals. The circuit produces a certain voltage, $\mathbf{V}_L$, and a certain current, $\mathbf{I}_L$, as illustrated.

▲ **FIGURE 19–12**

Thevenin's equivalent circuit.

(a)   (b)

▲ **FIGURE 19–13**

An ac circuit of any complexity can be reduced to a Thevenin equivalent for analysis purposes.

By Thevenin's theorem, the circuit in the block can be reduced to an equivalent form, as indicated in the beige area of Figure 19–13(b). The term *equivalent* means that when the same value of load is connected to both the original circuit and Thevenin's equivalent circuit, the load voltages and currents are equal for both. Therefore, as far as the load is concerned, there is no difference between the original circuit and Thevenin's equivalent circuit. The load "sees" the same current and voltage regardless of whether it is connected to the original circuit or to the Thevenin equivalent. For ac circuits, the equivalent circuit is for one particular frequency. When the frequency is changed, the equivalent circuit must be recalculated.

Thevenin's Equivalent Voltage (V_{th})

As you have seen, the equivalent voltage, $\mathbf{V}_{th}$, is one part of the complete Thevenin equivalent circuit.

Thevenin's equivalent voltage is defined as the open circuit voltage between two specified terminals in a circuit.

(a) Circuit   (b) With *R* removed

▲ FIGURE 19–14

How $\mathbf{V}_{th}$ is determined.

To illustrate, let's assume that an ac circuit of some type has a resistor connected be-tween two specified terminals, *A* and *B*, as shown in Figure 19–14(a). We wish to find the Thevenin equivalent circuit for the circuit as "seen" by *R*. $\mathbf{V}_{th}$ is the voltage across termi-nals *A* and *B*, with *R* removed, as shown in part (b) of the figure. The circuit is viewed from the open terminals *A* and *B*, and *R* is considered external to the circuit for which the Thevenin equivalent is to be found.

The following three examples show how to find $\mathbf{V}_{th}$.

EXAMPLE 19–4

Refer to Figure 19–15. Determine $\mathbf{V}_{th}$ for the circuit within the beige box as viewed from terminals *A* and *B*.
▲ FIGURE 19–15

Solution   Remove R_L and determine the voltage from *A* to *B* ($\mathbf{V}_{th}$). In this case, the voltage from *A* to *B* is the same as the voltage across X_L. This is determined using the voltage-divider method.

$$\mathbf{V}_L = \left(\frac{X_L \angle 90°}{R_1 + jX_L}\right)\mathbf{V}_s = \left(\frac{50 \angle 90° \ \Omega}{100 \ \Omega + j50 \ \Omega}\right)\mathbf{V}_s$$

$$= \left(\frac{50 \angle 90° \ \Omega}{112 \angle 26.6° \ \Omega}\right)25 \angle 0° \ \text{V} = 11.2 \angle 63.4° \ \text{V}$$

$$\mathbf{V}_{th} = \mathbf{V}_{AB} = \mathbf{V}_L = \mathbf{11.2} \angle \mathbf{63.4°} \ \textbf{V}$$

EXAMPLE 19–5

Refer to Figure 19–16. Determine the Thevenin voltage for the circuit within the beige box as viewed from terminals *A* and *B*.
Solution   Thevenin's voltage for the circuit between terminals *A* and *B* is the voltage that appears across *A* and *B* with R_L removed from the circuit.

There is no voltage drop across R_2 because the open between terminals *A* and *B* prevents current through it. Thus, $\mathbf{V}_{AB}$ is the same as $\mathbf{V}_{C2}$ and can be found by the voltage-divider formula.

$$\mathbf{V}_{AB} = \mathbf{V}_{C2} = \left(\frac{X_{C2}\angle -90°}{R_1 - jX_{C1} - jX_{C2}} \right)\mathbf{V}_s = \left(\frac{1.5\angle -90° \text{ k}\Omega}{1.0 \text{ k}\Omega - j3 \text{ k}\Omega} \right)10\angle 0° \text{ V}$$

$$= \left(\frac{1.5\angle -90° \text{ k}\Omega}{3.16\angle -71.6° \text{ k}\Omega} \right)10\angle 0° \text{ V} = 4.75\angle -18.4° \text{ V}$$

Solution   First remove R_L and determine the voltage across the resulting open terminals, which is $\mathbf{V}_{th}$. Find $\mathbf{V}_{th}$ by applying the voltage-divider formula to X_C and R.

$$\mathbf{V}_{th} = \mathbf{V}_R = \left(\frac{R\angle 0°}{R - jX_C}\right)\mathbf{V}_s = \left(\frac{10\angle 0°\ \text{k}\Omega}{10\ \text{k}\Omega - j10\ \text{k}\Omega}\right)5\angle 0°\ \text{V}$$

Notice X_L has no effect on the result, since the 5 V source appears across X_C and R in combination.

Thevenin's Equivalent Impedance ($\mathbf{Z}_{th}$)

The previous examples illustrated how to find $\mathbf{V}_{th}$. Now, let's determine the Thevenin equivalent impedance, $\mathbf{Z}_{th}$, the second part of a Thevenin equivalent circuit. As defined by Thevenin's theorem,

> Thevenin's equivalent impedance is the total impedance appearing between two specified terminals in a given circuit with all sources replaced by their internal impedances.

To find $\mathbf{Z}_{th}$ between any two terminals in a circuit, replace all the voltage sources by a short (any internal impedance remains in series). Replace all the current sources by an open (any internal impedance remains in parallel). Then determine the total impedance between the two terminals. The following three examples illustrate how to find $\mathbf{Z}_{th}$.

EXAMPLE 19–7   Find $\mathbf{Z}_{th}$ for the part of the circuit in Figure 19–18 that is within the beige box as viewed from terminals A and B. This is the same circuit used in Example 19–4.

▶ **FIGURE 19–18**
Solution   First, replace $\mathbf{V}_s$ with its internal impedance (zero in this case), as shown in Figure 19–19. Looking in between terminals A and B, R_1 and X_L are in parallel. Thus,

$$\mathbf{Z}_{th} = \frac{(R_1\angle 0°)(X_L\angle 90°)}{R_1 + jX_L} = \frac{(100\angle 0°\ \Omega)(50\angle 90°\ \Omega)}{100\ \Omega + j50\ \Omega}$$

$$= \frac{(100\angle 0°\ \Omega)(50\angle 90°\ \Omega)}{112\angle 26.6°\ \Omega} = \mathbf{44.6\angle 63.4°\ \Omega}$$

▲ FIGURE 19–21

Looking from terminals A and B, C_2 appears in parallel with the series combination of R_1 and C_1. This entire combination is in series with R_2. The calculation for $\mathbf{Z}_{th}$ is as follows:

$$\mathbf{Z}_{th} = R_2\angle 0° + \frac{(X_{C2}\angle -90°)(R_1 - jX_{C1})}{R_1 - jX_{C1} - jX_{C2}}$$

$$= 560\angle 0° \,\Omega + \frac{(1.5\angle -90°\,\text{k}\Omega)(1.0\,\text{k}\Omega - j1.5\,\text{k}\Omega)}{1.0\,\text{k}\Omega - j3\,\text{k}\Omega}$$

$$= 560\angle 0° \,\Omega + \frac{(1.5\angle -90°\,\text{k}\Omega)(1.8\angle -56.3°\,\text{k}\Omega)}{3.16\angle -71.6°\,\text{k}\Omega}$$

$$= 560\angle 0° \,\Omega + 854\angle -74.7° \,\Omega = 560\,\Omega + 225\,\Omega - j824\,\Omega$$

Thevenin's Equivalent Circuit

The previous six examples have shown how to find the two equivalent components of a Thevenin circuit, $\mathbf{V}_{th}$ and $\mathbf{Z}_{th}$. Keep in mind that you can find $\mathbf{V}_{th}$ and $\mathbf{Z}_{th}$ for any circuit. Once you have determined these equivalent values, you must connect them in series to form the Thevenin equivalent circuit. The following three examples use the previous examples to illustrate this final step.

EXAMPLE 19–10

$$\mathbf{Z}_{th} = 20 \ \Omega + j40 \ \Omega$$

This form indicates that the impedance is a 20 Ω resistor in series with a 40 Ω inductive reactance. The Thevenin equivalent circuit is shown in Figure 19–25.

Summary of Thevenin's Theorem

Remember that the Thevenin equivalent circuit is always a voltage source in series with an impedance regardless of the original circuit that it replaces. The significance of Thevenin's theorem is that the equivalent circuit can replace the original circuit as far as any external load is concerned. Any load connected between the terminals of a Thevenin equivalent circuit experiences the same current and voltage as if it were connected to the terminals of the original circuit.

A summary of steps for applying Thevenin's theorem follows.

Step 1: Open the two terminals between which you want to find the Thevenin circuit. This is done by removing the component from which the circuit is to be viewed.

Step 2: Determine the voltage across the two open terminals.

Step 3: Determine the impedance viewed from the two open terminals with ideal voltage sources replaced with shorts and ideal current sources replaced with opens (zeroed).

Step 4: Connect $\mathbf{V}_{th}$ and $\mathbf{Z}_{th}$ in series to produce the complete Thevenin equivalent circuit.

1. What are the two basic components of a Thevenin equivalent ac circuit?

2. For a certain circuit, $Z_{th} = 25\ \Omega - j50\ \Omega$, and $V_{th} = 5\angle 0°$ V. Draw the Thevenin equivalent circuit.

19–3 NORTON'S THEOREM

Like Thevenin's theorem, Norton's theorem provides a method of reducing a more complex circuit to a simpler, more manageable form for analysis. The basic difference is that **Norton's theorem** gives an equivalent current source (rather than a voltage source) in parallel (rather than in series) with an equivalent impedance.

After completing this section, you should be able to

- ◆ **Apply Norton's theorem to simplify reactive ac circuits**
  - ◆ Describe the form of a Norton equivalent circuit
  - ◆ Obtain the Norton equivalent ac current source
  - ◆ Obtain the Norton equivalent impedance
▲ **FIGURE 19–31**

Norton equivalent circuit.

The form of Norton's equivalent circuit is shown in Figure 19–31. Regardless of how complex the original circuit is, it can be reduced to this equivalent form. The equivalent current source is designated I_n, and the equivalent impedance is Z_n (lowercase italic subscript denotes ac quantity).

Norton's theorem shows you how to find I_n and Z_n. Once they are known, simply connect them in parallel to get the complete Norton equivalent circuit.

Norton's Equivalent Current Source (I_n)

I_n is one part of the Norton equivalent circuit; Z_n is the other part.

Norton's equivalent current is defined as the short-circuit current between two specified terminals in a given circuit.

Any load connected between these two terminals effectively "sees" a current source I_n in parallel with Z_n.

To illustrate, let's suppose that the circuit shown in Figure 19–32 has a load resistor connected to terminals A and B, as indicated in part (a), and we wish to find the Norton equivalent

(a) Circuit with load resistor   (b) Load is replaced by a short, resulting in a short circuit current, $\mathbf{I}_n$.

How $\mathbf{I}_n$ is determined.

for the circuit as viewed from terminals A and B. To find $\mathbf{I}_n$, calculate the current between terminals A and B with those terminals shorted, as shown in part (b). Example 19–13 shows how to find $\mathbf{I}_n$.

EXAMPLE 19–13

In Figure 19–33, determine $\mathbf{I}_n$ for the circuit as "seen" by the load resistor. The beige area identifies the portion of the circuit to be nortonized.
▶ FIGURE 19–33

Solution Short the terminals A and B, as shown in Figure 19–34.

▶ FIGURE 19–34
$\mathbf{I}_n$ is the current through the short and is calculated as follows. First, the total impedance viewed from the source is

$$\mathbf{Z} = \mathbf{X}_{C1} + \frac{\mathbf{R}\mathbf{X}_{C2}}{\mathbf{R} + \mathbf{X}_{C2}} = 50\angle -90°\,\Omega + \frac{(56\angle 0°\,\Omega)(100\angle -90°\,\Omega)}{56\,\Omega - j100\,\Omega}$$

$$= 50\angle -90°\,\Omega + 48.9\angle -29.3°\,\Omega$$

$$= -j50\,\Omega + 42.6\,\Omega - j23.9\,\Omega = 42.6\,\Omega - j73.9\,\Omega$$

Converting to polar form yields

$$\mathbf{Z} = 85.3\angle -60.0°\,\Omega$$

Next, the total current from the source is

$$\mathbf{I}_s = \frac{\mathbf{V}_s}{\mathbf{Z}} = \frac{6\angle 0° \text{ V}}{85.3 \angle -60.0° \ \Omega} = 70.3 \angle 60.0° \text{ mA}$$

Finally, apply the current-divider formula to get $\mathbf{I}_n$ (the current through the short between terminals A and B).

$$\mathbf{I}_n = \left(\frac{\mathbf{R}}{\mathbf{R} + \mathbf{X}_{C2}} \right)\mathbf{I}_s = \left(\frac{56\angle 0° \ \Omega}{56 \ \Omega - j100 \ \Omega} \right)70.3 \angle 60.0° \text{ mA} = \mathbf{34.4 \angle 121° \text{ mA}}$$

This is the value for the equivalent Norton current source.

Related Problem   Determine $\mathbf{I}_n$ if $\mathbf{V}_s$ is changed to $2.5\angle 0°$ V and R is changed to $33 \ \Omega$ in Figure 19–33.

Norton's Equivalent Impedance ($\mathbf{Z}_n$)

$\mathbf{Z}_n$ is defined the same as $\mathbf{Z}_{th}$: It is the total impedance appearing between two specified terminals of a given circuit viewed from the open terminals with all sources replaced by their internal impedances.

EXAMPLE 19–14   Find $\mathbf{Z}_n$ for the circuit in Figure 19–33 (Example 19–13) viewed from the open across terminals A and B.

Solution   First, replace $\mathbf{V}_s$ with its internal impedance (zero), as indicated in Figure 19–35.

▶ **FIGURE 19–35**
Looking in between terminals A and B, C_2 is in series with the parallel combination of R and C_1. Thus,

$$\mathbf{Z}_n = \mathbf{X}_{C2} + \frac{\mathbf{R}\mathbf{X}_{C1}}{\mathbf{R} + \mathbf{X}_{C1}} = 100\angle -90° \ \Omega + \frac{(56\angle 0° \ \Omega)(50\angle -90° \ \Omega)}{56 \ \Omega - j50 \ \Omega}$$

$$= 100\angle -90° \ \Omega + 37.3 \angle -48.2° \ \Omega$$

$$= -j100 \ \Omega + 24.8 \ \Omega - j27.8 \ \Omega = \mathbf{24.8 \ \Omega - j128 \ \Omega}$$

The Norton equivalent impedance is a $24.8 \ \Omega$ resistance in series with a $128 \ \Omega$ capacitive reactance.

Related Problem   Find $\mathbf{Z}_n$ in Figure 19–33 if $R = 33 \ \Omega$.

Examples 19–13 and 19–14 showed how to find the two equivalent components of a Norton equivalent circuit. Keep in mind that you can find these values for any given ac circuit. Once you know $\mathbf{I}_n$ and $\mathbf{Z}_n$, connect them in parallel to form the Norton equivalent circuit, as Example 19–15 illustrates.

Solution   From Examples 19–13 and 19–14, respectively, $\mathbf{I}_n = 34.4\angle 121°$ mA and $\mathbf{Z}_n = 24.8\ \Omega - j128\ \Omega$. The Norton equivalent circuit is shown in Figure 19–36.

Summary of Norton's Theorem

Any load connected between the terminals of a Norton equivalent circuit will have the same current through it and the same voltage across it as it would when connected to the terminals of the original circuit. A summary of steps for theoretically applying Norton's theorem is as follows:

Step 1:   Replace the load connected to the two terminals between which the Norton circuit is to be determined with a short.

Step 2:   Determine the current through the short. This is $\mathbf{I}_n$.

Step 3:   Open the terminals and determine the impedance between the two open terminals with all sources replaced with their internal impedances. This is $\mathbf{Z}_n$.

Step 4:   Connect $\mathbf{I}_n$ and $\mathbf{Z}_n$ in parallel.

19–4   MAXIMUM POWER TRANSFER THEOREM

> Maximum power is transferred to a load connected to a circuit when the load imped-
> ance is the complex conjugate of the circuit's output impedance.
>
> After completing this section, you should be able to
>
> ◆ **Apply the maximum power transfer theorem**
>
>   ◆ Explain the maximum power transfer theorem
>
>   ◆ Determine the value of load impedance for which maximum power is transferred
>   from a given circuit

The **complex conjugate** of $R - jX_C$ is $R + jX_L$ and vice versa, where the resistances
are equal in magnitude and the reactances are equal in magnitude but opposite in sign. The
output impedance is effectively Thevenin's equivalent impedance viewed from the output
terminals. When $\mathbf{Z}_L$ is the complex conjugate of $\mathbf{Z}_{out}$, maximum power is transferred from
the circuit to the load with a power factor of 1. An equivalent circuit with its output im-
pedance and load is shown in Figure 19–38.

▶ FIGURE 19–38

Equivalent circuit with load.
Example 19–16 shows that maximum power occurs when the impedances are conju-
gately matched.

EXAMPLE 19–16

The circuit to the left of terminals A and B in Figure 19–39 provides power to the load
$\mathbf{Z}_L$. This can be viewed as simulating a power amplifier delivering power to a complex
load. It is the Thevenin equivalent of a more complex circuit. Calculate and plot a
▲ FIGURE 19–39

graph of the power delivered to the load for each of the following frequencies: 10 kHz, 30 kHz, 50 kHz, 80 kHz, and 100 kHz.

Solution   For $f = 10\,\text{kHz}$,

$$X_C = \frac{1}{2\pi fC} = \frac{1}{2\pi(10\,\text{kHz})(0.01\,\mu\text{F})} = 1.59\,\text{k}\Omega$$

$$X_L = 2\pi fL = 2\pi(10\,\text{kHz})(1\,\text{mH}) = 62.8\,\Omega$$

The magnitude of the total impedance is

$$Z_{tot} = \sqrt{(R_s + R_L)^2 + (X_L - X_C)^2} = \sqrt{(20\,\Omega)^2 + (1.53\,\text{k}\Omega)^2} = 1.53\,\text{k}\Omega$$

The current is

$$I = \frac{V_s}{Z_{tot}} = \frac{10\,\text{V}}{1.53\,\text{k}\Omega} = 6.54\,\text{mA}$$

The load power is

$$P_L = I^2 R_L = (6.54\,\text{mA})^2(10\,\Omega) = \textbf{428}\,\boldsymbol{\mu}\textbf{W}$$

For $f = 30\,\text{kHz}$,

$$X_C = \frac{1}{2\pi(30\,\text{kHz})(0.01\,\mu\text{F})} = 531\,\Omega$$

$$X_L = 2\pi(30\,\text{kHz})(1\,\text{mH}) = 189\,\Omega$$

$$Z_{tot} = \sqrt{(20\,\Omega)^2 + (342\,\Omega)^2} = 343\,\Omega$$

$$I = \frac{V_s}{Z_{tot}} = \frac{10\,\text{V}}{343\,\Omega} = 29.2\,\text{mA}$$

$$P_L = I^2 R_L = (29.2\,\text{mA})^2(10\,\Omega) = \textbf{8.53\,mW}$$

For $f = 50\,\text{kHz}$,

$$X_C = \frac{1}{2\pi(50\,\text{kHz})(0.01\,\mu\text{F})} = 318\,\Omega$$

$$X_L = 2\pi(50\,\text{kHz})(1\,\text{mH}) = 314\,\Omega$$

Note that X_C and X_L are very close to being equal which makes the impedances approximately complex conjugates. The exact frequency at which $X_L = X_C$ is 50.3 kHz.

$$Z_{tot} = \sqrt{(20\,\Omega)^2 + (4\,\Omega)^2} = 20.4\,\Omega$$

$$I = \frac{V_s}{Z_{tot}} = \frac{10\,\text{V}}{20.4\,\Omega} = 490\,\text{mA}$$

$$P_L = I^2 R_L = (490\,\text{mA})^2(10\,\Omega) = \textbf{2.40\,W}$$

For $f = 80\,\text{kHz}$,

$$X_C = \frac{1}{2\pi(80\,\text{kHz})(0.01\,\mu\text{F})} = 199\,\Omega$$

$$X_L = 2\pi(80\,\text{kHz})(1\,\text{mH}) = 503\,\Omega$$

$$Z_{tot} = \sqrt{(20\,\Omega)^2 + (304\,\Omega)^2} = 305\,\Omega$$

$$I = \frac{V_s}{Z_{tot}} = \frac{10\,\text{V}}{305\,\Omega} = 32.8\,\text{mA}$$

$$P_L = I^2 R_L = (32.8\,\text{mA})^2(10\,\Omega) = \textbf{10.8\,mW}$$

For $f = 100\,\text{kHz}$,

$$X_C = \frac{1}{2\pi(100\,\text{kHz})(0.01\,\mu\text{F})} = 159\,\Omega$$

$$X_L = 2\pi(100\,\text{kHz})(1\,\text{mH}) = 628\,\Omega$$

$$Z_{tot} = \sqrt{(20\,\Omega)^2 + (469\,\Omega)^2} = 469\,\Omega$$

$$I = \frac{V_s}{Z_{tot}} = \frac{10\,\text{V}}{469\,\Omega} = 21.3\,\text{mA}$$

$$P_L = I^2 R_L = (21.3\,\text{mA})^2(10\,\Omega) = \textbf{4.54\,mW}$$

As you can see from the results, the power to the load peaks at the frequency (50 kHz) for which the load impedance is the complex conjugate of the output impedance (when the reactances are equal in magnitude). A graph of the load power versus frequency is shown in Figure 19–40. Since the maximum power is so much larger than the other values, an accurate plot is difficult to achieve without intermediate values.

▶ **FIGURE 19–40**
Related Problem   If $R = 47\,\Omega$ and $C = 0.022\,\mu\text{F}$ in a series RC circuit, what is the complex conjugate of the impedance at 100 kHz?

Use Multisim files E19-16A and E19-16B to verify the calculated results in this example.

Example 19–17 illustrates that the frequency at which maximum load power occurs is the value that makes the source and load impedances complex conjugates.

EXAMPLE 19–17

(a) Determine the frequency at which maximum power is transferred from the amplifier to the speaker in Figure 19–41(a). The amplifier and coupling capacitor are the source, and the speaker is the load, as shown in the equivalent circuit of Figure 19–41(b).

(b) How many watts of power are delivered to the speaker at this frequency if $V_s = 3.8\,\text{V}$ rms?
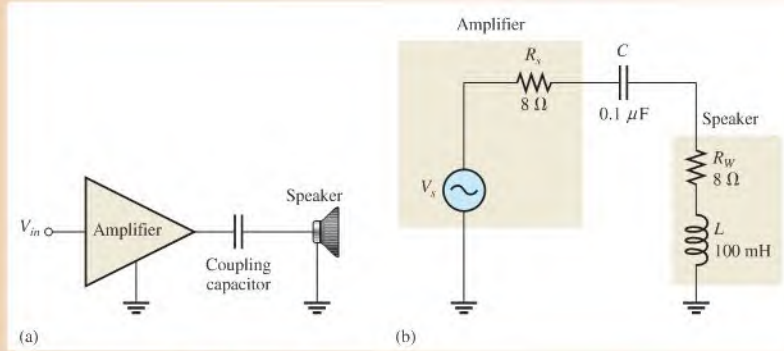

▲ **FIGURE 19–41**

Solution   **(a)** When the power to the speaker is maximum, the source impedance $(R_s - jX_C)$ and the load impedance $(R_W + jX_L)$ are complex conjugates, so

$$X_C = X_L$$

$$\frac{1}{2\pi f C} = 2\pi f L$$

Solving for f,

$$f^2 = \frac{1}{4\pi^2 LC}$$

$$f = \frac{1}{2\pi\sqrt{LC}} = \frac{1}{2\pi\sqrt{(100\ \text{mH})(0.1\ \mu\text{F})}} \cong \mathbf{1.59\ kHz}$$

(b) Calculate the power to the speaker as follows:

$$Z_{tot} = R_s + R_W = 8\ \Omega + 8\ \Omega = 16\ \Omega$$

$$I = \frac{V_s}{Z_{tot}} = \frac{3.8\ \text{V}}{16\ \Omega} = 238\ \text{mA}$$

$$P_{max} = I^2 R_W = (238\ \text{mA})^2 (8\ \Omega) = \mathbf{453\ mW}$$

Related Problem   Determine the frequency at which maximum power is transferred from the amplifier to the speaker in Figure 19–41 if the coupling capacitor is 1 μF.

1. If the output impedance of a certain driving circuit is 50 Ω − j10Ω, what value of load impedance will result in the maximum power to the load?

2. For the circuit in Question 1, how much power is delivered to the load when the load impedance is the complex conjugate of the output impedance and when the load current is 2 A?

Application Activity

In this application activity, you have a sealed band-pass filter module that has been removed from a system and two schematics. Both schematics indicate that the band-pass filter is implemented with a low-pass/high-pass combination. It is uncertain which schematic corresponds to the filter module, but one of them does. By certain measurements, you will determine which schematic represents the filter so that the filter circuit can be reproduced. Also, you will determine the proper load for maximum power transfer. The filter circuit contained in a sealed module and two schematics, one of which corresponds to the filter circuit, are shown in Figure 19–42.

Filter Measurement and Analysis

1. Based on the oscilloscope measurement of the filter output shown in Figure 19–43, determine which schematic in Figure 19–42 represents the component values of the filter

circuit in the module. A 10 V peak-to-peak voltage is applied to the input.

2. Based on the oscilloscope measurement in Figure 19–43, determine if the filter is operating at its approximate center frequency.

3. Using Thevenin's theorem, determine the load impedance that will provide for maximum power transfer at the center frequency when connected to the output of the filter. Assume the source impedance is zero.

INTRODUCTION

In Chapters 15 and 16, the frequency response of *RC* and *RL* circuits was covered. In this chapter, the time response of *RC* and *RL* circuits with pulse inputs is examined. Before starting this chapter, you should review the material in Sections 12–5 and 13–4. Understanding exponential changes of voltages and currents in capacitors and inductors is crucial to the study of time response. Throughout this chapter, exponential formulas that were given in Chapters 12 and 13 are used.

With pulse inputs, the time responses of circuits are important. In the areas of pulse and digital circuits, technicians are often concerned with how a circuit responds over an interval of time to rapid changes in voltages or current. The relationship of the circuit time constant to the input pulse characteristics, such as pulse width and period, determines the wave shapes of voltages in the circuit.

Integrator and *differentiator*, terms used throughout this chapter, refer to mathematical functions that are approximated by these circuits under certain conditions. Mathematical integration is a summation process, and mathematical differentiation is a process for establishing an instantaneous rate of change of a quantity.

20–1 THE *RC* INTEGRATOR

In terms of time response, a series *RC* circuit in which the output voltage is taken across the capacitor is known as an **integrator**. Recall that in terms of frequency response, it is a low-pass filter. The term *integrator* is derived from the mathematical process of integration, which this type of circuit approximates under certain conditions.

After completing this section, you should be able to

◆ **Explain the operation of an *RC* integrator**

◆ Describe how a capacitor charges and discharges

◆ Explain how a capacitor reacts to an instantaneous change in voltage or current

◆ Describe the basic output voltage waveform

Charging and Discharging of a Capacitor

When a pulse generator is connected to the input of an *RC* integrator, as shown in Figure 20–1, the capacitor will charge and discharge in response to the pulses. When the input goes from its low level to its high level, the capacitor charges toward the high level of the pulse through the resistor. This charging action is analogous to connecting a battery through a closed switch to the *RC* circuit, as illustrated in Figure 20–2(a). When the pulse goes from its high level back to its low level, the capacitor discharges back through the source. Compared to the resistance of the resistor, the resistance of the source is assumed to be negligible. This discharging action is analogous to replacing the source with a closed switch, as illustrated in Figure 20–2(b).

▶ **FIGURE 20–1**

An *RC* integrator with a pulse generator connected.

(a) When the input pulse goes HIGH, the source effectively acts as a battery in series with a closed switch, thereby charging the capacitor.

(b) When the input pulse goes back LOW, the source effectively acts as a closed switch, providing a discharge path for the capacitor.
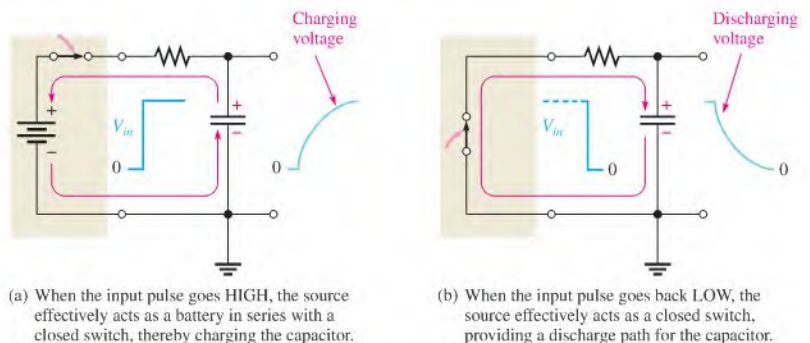

▲ **FIGURE 20–2**

The equivalent action when a pulse source charges and discharges the capacitor.

As you learned in Chapter 12, a capacitor will charge and discharge following an exponential curve. Its rate of charging and discharging, of course, depends on the *RC* **time constant**, a fixed time interval determined by *R* and *C* ($\tau = RC$).

For an ideal pulse, both edges are considered to be instantaneous. Two basic rules of capacitor behavior help in understanding the response of *RC* circuits to pulse inputs.

1. The capacitor appears as a short to an instantaneous change in current and as an open to dc.

2. The voltage across the capacitor cannot change instantaneously—it can change only exponentially.

Capacitor Voltage

In an *RC* integrator, the output is the capacitor voltage. The capacitor charges during the time that the pulse is high. If the pulse is at its high level long enough, the capacitor will fully charge to the voltage amplitude of the pulse, as illustrated in Figure 20–3. The capacitor discharges during the time that the pulse is low. If the low time between pulses is long enough, the capacitor will fully discharge to zero, as shown in the figure. Then when the next pulse occurs, it will charge again.

20–2 RESPONSE OF AN *RC* INTEGRATOR TO A SINGLE PULSE

From the previous section, you have a general idea of how an *RC* integrator responds to an input pulse. In this section, the response to a single pulse is examined in detail.

After completing this section, you should be able to

◆ **Analyze an *RC* integrator with a single input pulse**

   ◆ Discuss the importance of the circuit time constant

   ◆ Define *transient time*

   ◆ Determine the response when the pulse width is equal to or greater than five time constants

   ◆ Determine the response when the pulse width is less than five time constants

Two conditions of pulse response must be considered:

1. When the input pulse width (t_W) is equal to or greater than five time constants ($t_W \geq 5\tau$)

2. When the input pulse width is less than five time constants ($t_W < 5\tau$)

Recall that five time constants is accepted as the time for a capacitor to fully charge or fully discharge; this time is often called the **transient time**. A capacitor will fully charge if the pulse width is equal to or greater than five time constants (5τ). This condition is expressed as $t_W \geq 5\tau$. At the end of the pulse, the capacitor fully discharges back through the source.

Figure 20–4 illustrates the output waveforms for various RC transient times and a fixed input pulse width. Notice that as the transient time becomes shorter, compared to the pulse width, the shape of the output pulse approaches that of the input. In each case, the output reaches the full amplitude of the input.
▲ **FIGURE 20–4**

Variation of an RC integrator's output pulse shape with time constant. The shaded areas indicate when the capacitor is charging or discharging.

Figure 20–5 shows how a fixed time constant and a variable input pulse width affect the integrator output. Notice that as the pulse width is increased, the shape of the output pulse approaches that of the input. Again, this means that the transient time is short compared to the pulse width.

▶ **FIGURE 20–5**

Variation of an RC integrator's output pulse shape with input pulse width (the time constant is fixed). Dark blue is input and light blue is output.

(a) $t_W = 5\tau$

(b) $t_W = 10\tau$

(c) $t_W = 20\tau$

(d) $t_W = 40\tau$
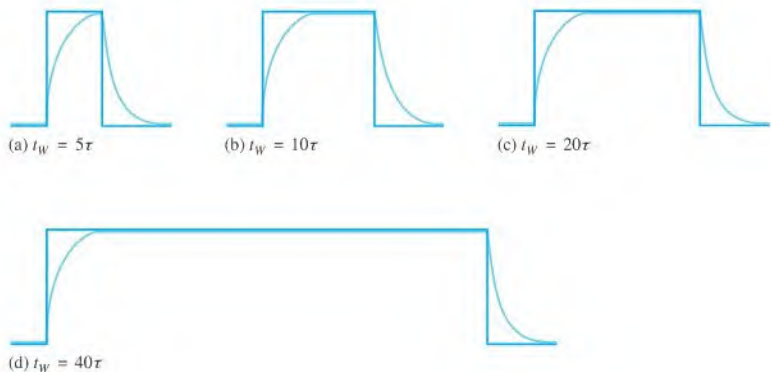

Now let's examine the case in which the width of the input pulse is less than five time constants of the *RC* integrator. This condition is expressed as $t_W < 5\tau$. As you know, the capacitor charges for the duration of the pulse. However, because the pulse width is less than the time it takes the capacitor to fully charge (5τ), the output voltage will *not* reach the full input voltage before the end of the pulse. The capacitor only partially charges, as illustrated in Figure 20–6 for several values of *RC* time constants. Notice that for longer time constants, the output reaches a lower voltage because the capacitor cannot charge as much. Of course, in the examples with a single pulse input, the capacitor fully discharges after the pulse ends.
▲ **FIGURE 20–6**

Capacitor voltage for various time constants that are longer than the input pulse width. Dark blue is input and light blue is output.

When the time constant is much greater than the input pulse width, the capacitor charges very little, and, as a result, the output voltage becomes almost negligible, as indicated in Figure 20–6.

Figure 20–7 illustrates the effect of reducing the input pulse width for a fixed time constant value. As the input pulse width is reduced, the output voltage decreases because the capacitor has less time to charge. However, it takes the capacitor approximately the same length of time (5τ) to discharge back to zero for each condition after the pulse is removed.
▲ **FIGURE 20–7**

The capacitor charges less and less as the input pulse width is reduced. The time constant is fixed.

EXAMPLE 20–1

A single 10 V pulse with a width of 100 μs is applied to the *RC* integrator in Figure 20–8.

(a) To what voltage will the capacitor charge?

(b) How long will it take the capacitor to discharge if the internal resistance of the pulse source is 50 Ω?

(c) Draw the output voltage waveform.

▶ **FIGURE 20–8**
Solution (a) The circuit time constant is

$$\tau = RC = (100\,\text{k}\Omega)(0.001\,\mu\text{F}) = 100\,\mu\text{s}$$

Notice that the pulse width is exactly equal to the time constant. Thus, the capacitor will charge approximately 63% of the full input amplitude in one time constant, so the output will reach a maximum voltage of

$$V_{out} = (0.63)10\,\text{V} = \textbf{6.3 V}$$

(b) The capacitor discharges back through the source when the pulse ends. You can neglect the 50 Ω source resistance in series with 100 kΩ. The total approximate discharge time, therefore, is

$$5\tau = 5(100\,\mu\text{s}) = \textbf{500}\,\boldsymbol{\mu}\textbf{s}$$

(c) The output charging and discharging curve is shown in Figure 20–9.

*Answers are at the end of the chapter.

EXAMPLE 20–2

Determine how much the capacitor in Figure 20–10 will charge when the single pulse is applied to the input.

▶ **FIGURE 20–10**
Solution Calculate the time constant.

$$\tau = RC = (2.2 \text{ k}\Omega)(1 \text{ }\mu\text{F}) = 2.2 \text{ ms}$$

Because the pulse width is 5 ms, the capacitor charges for 2.27 time constants (5 ms/2.2 ms = 2.27). Use the exponential formula from Chapter 12 (Eq. 12–19) to find the voltage to which the capacitor will charge. With $V_F = 25$ V and $t = 5$ ms, the calculation is as follows:

$$v = V_F(1 - e^{-t/RC})$$
$$= (25 \text{ V})(1 - e^{-5\text{ms}/2.2\text{ms}}) = (25 \text{ V})(1 - e^{-2.27})$$
$$= (25 \text{ V})(1 - 0.103) = (25 \text{ V})(0.897) = \mathbf{22.4 \text{ V}}$$

These calculations show that the capacitor charges to 22.4 V during the 5 ms duration of the input pulse. It will discharge back to zero when the pulse goes back to zero.

Related Problem Determine how much *C* will charge if the pulse width is increased to 10 ms.

20–3 RESPONSE OF *RC* INTEGRATORS TO REPETITIVE PULSES

In electronic systems, you will encounter waveforms with repetitive pulses much more often than single pulses. However, an understanding of the integrator's response to single pulses is necessary in order to understand how these circuits respond to repeated pulses.

After completing this section, you should be able to

◆ **Analyze an *RC* integrator with repetitive input pulses**

   ◆ Determine the response when the capacitor does not fully charge or discharge

   ◆ Define *steady state*

   ◆ Describe the effect of an increase in time constant on circuit response

If a **periodic** pulse waveform is applied to an *RC* integrator, as shown in Figure 20–12, the output waveshape depends on the relationship of the circuit time constant and the frequency (period) of the input pulses. The capacitor, of course, charges and discharges in response to a pulse input. The amount of charge and discharge of the capacitor depends both on the circuit time constant and on the input frequency, as mentioned.
▲ **FIGURE 20–12**

RC integrator with a repetitive pulse waveform input ($T = 10\tau$).

If the pulse width and the time between pulses are each equal to or greater than five time constants, the capacitor will fully charge and fully discharge during each period (*T*) of the input waveform. This case is shown in Figure 20–12.

When the pulse width and the time between pulses are shorter than five time constants, as illustrated in Figure 20–13 for a square wave, the capacitor will *not* completely charge or discharge. We will now examine the effects of this situation on the output voltage of the *RC* integrator.

For illustration, let's use an *RC* integrator with a charging and discharging time constant equal to the pulse width of a 10 V square wave input, as shown in Figure 20–14. This choice will simplify the analysis and will demonstrate the basic action of the integrator under these conditions. At this point, we do not care what the exact time constant value is because we know that an *RC* circuit charges approximately 63% during one time constant interval.
RC integrator with a square wave input having a period equal to two time constants ($T = 2\tau$).

Let's assume that the capacitor in Figure 20–14 begins initially uncharged and examine the output voltage on a pulse-by-pulse basis. Figure 20–15 shows the charging and discharging shapes of five pulses.
Input and output for the initially uncharged integrator in Figure 20–14.

First pulse   During the first pulse, the capacitor charges. The output voltage reaches 6.32 V (63.2% of 10 V), as shown in Figure 20–15.

Between first and second pulses   The capacitor discharges, and the voltage decreases to 36.8% of the voltage at the beginning of this interval: 0.368(6.32 V) = 2.33 V.

Second pulse   The capacitor voltage begins at 2.33 V and increases 63.2% of the way to 10 V. This calculation is as follows: The total charging range is 10 V − 2.33 V = 7.67 V. The capacitor voltage will increase an additional 63.2% of 7.67 V, which is 4.85 V. Thus, at the end of the second pulse, the output voltage is 2.33 V + 4.85 V = 7.18 V, as shown in Figure 20–15. Notice that the average is building up.

Between second and third pulses   The capacitor discharges during this time, and therefore the voltage decreases to 36.8% of the initial voltage by the end of the second pulse: 0.368(7.18 V) = 2.64 V.

Third pulse   At the start of the third pulse, the capacitor voltage begins at 2.64 V. The capacitor charges 63.2% of the way from 2.64 V to 10 V: 0.632(10 V − 2.64 V) = 4.65 V. Therefore, the voltage at the end of the third pulse is 2.64 V + 4.65 V = 7.29 V.

Between third and fourth pulses   The voltage during this interval decreases due to capacitor discharge. It will decrease to 36.8% of its value by the end of the third pulse. The final voltage in this interval is 0.368(7.29 V) = 2.68 V.

Fourth pulse   At the start of the fourth pulse, the capacitor voltage is 2.68 V. The voltage increases by $0.632(10 \text{ V} - 2.68 \text{ V}) = 4.63 \text{ V}$. Therefore, at the end of the fourth pulse, the capacitor voltage is $2.68 \text{ V} + 4.63 \text{ V} = 7.31 \text{ V}$. Notice that the values are leveling off as the pulses continue.

Between fourth and fifth pulses   Between these pulses, the capacitor voltage drops to $0.368(7.31 \text{ V}) = 2.69 \text{ V}$.

Fifth pulse   During the fifth pulse, the capacitor charges $0.632(10 \text{ V} - 2.69 \text{ V}) = 4.62 \text{ V}$. Since it started at 2.69 V, the voltage at the end of the pulse is $2.69 \text{ V} + 4.62 \text{ V} = 7.31 \text{ V}$.

Steady-State Time Response

In the preceding discussion, the output voltage gradually built up and then began leveling off. It takes approximately 5τ for the output voltage to build up to a constant average value. This interval is the transient time of the circuit. Once the output voltage reaches the average value of the input voltage, a **steady-state** condition is reached that continues as long as the periodic input continues. This condition is illustrated in Figure 20–16 based on the values obtained in the preceding discussion.
▲ **FIGURE 20–16**

Output reaches steady state after 5τ.

The transient time for our example circuit is the time from the beginning of the first pulse to the end of the third pulse. The reason for this interval is that the capacitor voltage at the end of the third pulse is 7.29 V, which is about 99% of the final voltage.

The Effect of an Increase in Time Constant

What happens to the output voltage if the *RC* time constant of the integrator is increased with a variable resistor, as indicated in Figure 20–17? As the time constant is increased, the capacitor charges less during a pulse and discharges less between pulses. The result is a

▶ **FIGURE 20–17**

Integrator with a variable *RC* time constant.
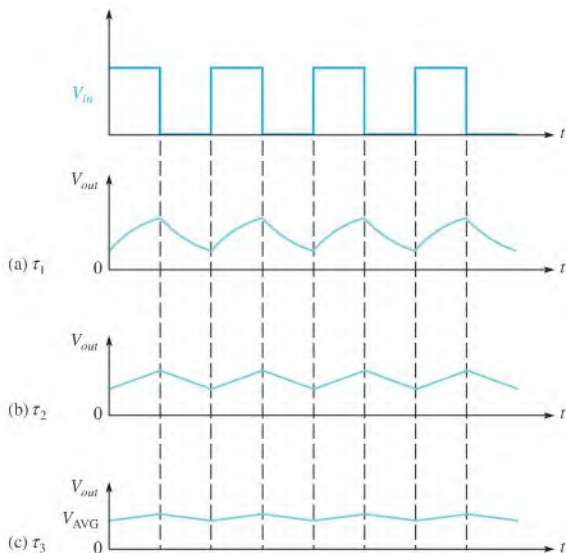

▲ FIGURE 20–18

Effect of longer time constants on the output of an *RC* integrator ($\tau_3 > \tau_2 > \tau_1$).

smaller fluctuation in the output voltage for increasing values of time constant, as shown in Figure 20–18.

As the time constant becomes extremely long compared to the pulse width, the output voltage approaches a constant dc voltage, as shown in Figure 20–18(c). This value is the average value of the input. For a square wave, it is one-half the amplitude.

EXAMPLE 20–3

Determine the output voltage waveform for the first two pulses applied to the *RC* integrator in Figure 20–19. Assume that the capacitor is initially uncharged and the rheostat is set to 5 kΩ.
▲ FIGURE 20–19

Solution First, calculate the circuit time constant.

$$\tau = RC = (5\,k\Omega)(0.01\,\mu F) = 50\,\mu s$$

Obviously, the time constant is much longer than the input pulse width or the interval between pulses (notice that the input is not a square wave). In this case, the exponential formulas must be applied, and the analysis is relatively difficult. Follow the solution carefully.

1. *Calculation for first pulse:* Use the equation for an increasing exponential because C is charging. Note that V_F is 5 V, and t equals the pulse width of 10 μs. Therefore,

$$v_C = V_F(1 - e^{-t/RC}) = (5\text{ V})(1 - e^{-10\mu s/50\mu s})$$
$$= (5\text{ V})(1 - 0.819) = \textbf{906 mV}$$

This result is plotted in Figure 20–20(a).

2. *Calculation for interval between first and second pulse:* Use the equation for a decreasing exponential because C is discharging. Note that V_i is 906 mV because C begins to discharge from this value at the end of the first pulse. The discharge time is 15 μs. Therefore,

$$v_C = V_i e^{-t/RC} = (906\text{ mV})e^{-15\mu s/50\mu s}$$
$$= (906\text{ mV})(0.741) = \textbf{671 mV}$$

This result is shown in Figure 20–20(b).

3. *Calculation for second pulse:* At the beginning of the second pulse, the output voltage is 671 mV. During the second pulse, the capacitor will again charge. In this case, it does not begin at zero volts. It already has 671 mV from the previous charge and discharge. To handle this situation, you must use the general exponential formula.

$$v = V_F + (V_i - V_F)e^{-t/\tau}$$

(a)

(b)

(c)
▲ **FIGURE 20–20**

Using this equation, you can calculate the voltage across the capacitor at the end of the second pulse as follows:

$$v_C = V_F + (V_i - V_F)e^{-t/RC}$$
$$= 5\,\text{V} + (671\,\text{mV} - 5\,\text{V})e^{-10\mu s/50\mu s}$$
$$= 5\,\text{V} + (-4.33\,\text{V})(0.819) = 5\,\text{V} - 3.55\,\text{V} = \mathbf{1.45\,V}$$

This result is shown in Figure 20–20(c).

Notice that the output waveform builds up on successive input pulses. After approximately 5τ, it will reach its steady state and will fluctuate between a constant maximum and a constant minimum, with an average equal to the average value of the input. You can see this pattern by carrying the analysis in this example further.

20–4 RESPONSE OF AN *RC* DIFFERENTIATOR TO A SINGLE PULSE

In terms of time response, a series *RC* circuit in which the output voltage is taken across the resistor is known as a **differentiator**. Recall that in terms of frequency response, it is a high-pass filter. The term *differentiator* is derived from the mathematical process of differentiation, which this type of circuit approximates under certain conditions.

After completing this section, you should be able to

♦ **Analyze an *RC* differentiator with a single input pulse**

   ♦ Describe the response at the rising edge of the input pulse

   ♦ Determine the response during and at the end of a pulse for various pulse width–time constant relationships

Figure 20–21 shows an *RC* differentiator with a pulse input. The same action occurs in a differentiator as in an integrator, except the output voltage is taken across the resistor rather than across the capacitor. The capacitor charges exponentially at a rate depending on the *RC* time constant. The shape of the differentiator's resistor voltage is determined by the charging and discharging action of the capacitor.

An *RC* differentiator with a pulse generator connected.
Pulse Response

To understand how the output voltage is shaped by a differentiator, you must consider the following:

1. The response to the rising pulse edge

2. The response between the rising and falling edges

3. The response to the falling pulse edge

Let's assume that the capacitor is initially uncharged prior to the rising pulse edge. Prior to the pulse, the input is zero volts. Thus, there are zero volts across the capacitor and also zero volts across the resistor, as indicated in Figure 20–22(a).

(a) Before pulse is applied

(e) During level part of pulse when $t_W < 5\tau$

(f) At falling edge of pulse when $t_W < 5\tau$
▲ FIGURE 20–22

Examples of the response of an *RC* differentiator to a single input pulse under two conditions: $t_W \geq 5\tau$ and $t_W < 5\tau$.

Response to the Rising Edge of the Input Pulse   Let's also assume that a 10 V pulse is applied to the input. When the rising edge occurs, point *A* goes to +10 V. Recall that the voltage across a capacitor cannot change instantaneously, and thus the capacitor appears

instantaneously as a short. Therefore, if point *A* goes instantly to +10 V, then point *B must* also go instantly to +10 V, keeping the capacitor voltage zero for the instant of the rising edge. The capacitor voltage is the voltage from point *A* to point *B*.

The voltage at point *B* with respect to ground is the voltage across the resistor (and the output voltage). Thus, the output voltage suddenly goes to +10 V in response to the rising pulse edge, as indicated in Figure 20–22(b).

Response During Pulse When $t_W \geq 5\tau$ While the pulse is at its high level between the rising edge and the falling edge, the capacitor is charging. When the pulse width is equal to or greater than five time constants ($t_W \geq 5\tau$), the capacitor has time to fully charge.

As the voltage across the capacitor builds up exponentially, the voltage across the resistor decreases exponentially until it reaches zero volts at the time the capacitor reaches full charge (+10 V in this case). This decrease in the resistor voltage occurs because the sum of the capacitor voltage and the resistor voltage at any instant must be equal to the applied voltage, in compliance with Kirchhoff's voltage law ($v_C + v_R = v_{in}$). This part of the response is illustrated in Figure 20–22(c).

Response to Falling Edge When $t_W \geq 5\tau$ Let's examine the case in which the capacitor is fully charged at the end of the pulse ($t_W \geq 5\tau$). Refer to Figure 20–22(d). On the falling edge, the input pulse suddenly goes from +10 V back to zero. An instant before the falling edge, the capacitor is charged to 10 V, so point *A* is +10 V and point *B* is 0 V. The voltage across a capacitor cannot change instantaneously, so when point *A* makes a transition from +10 V to zero on the falling edge, point *B must* also make a 10 V transition from zero to −10 V. This keeps the voltage across the capacitor at 10 V for the instant of the falling edge.

The capacitor now begins to discharge exponentially. As a result, the resistor voltage goes from −10 V to zero in an exponential curve, as indicated in red in Figure 20–22(d).

Response During Pulse When $t_W < 5\tau$ When the pulse width is less than five time constants ($t_W < 5\tau$), the capacitor does not have time to fully charge. Its partial charge depends on the relation of the time constant and the pulse width.

Because the capacitor does not reach the full +10 V, the resistor voltage will not reach zero volts by the end of the pulse. For example, if the capacitor charges to +5 V during the pulse interval, the resistor voltage will decrease to +5 V, as illustrated in Figure 20–22(e).

Response to Falling Edge When $t_W < 5\tau$ Now, let's examine the case in which the capacitor is only partially charged at the end of the pulse ($t_W < 5\tau$). For example, if the capacitor charges to +5 V, the resistor voltage at the instant before the falling edge is also +5 V because the capacitor voltage plus the resistor voltage must add up to +10 V, as illustrated in Figure 20–22(e).

When the falling edge occurs, point *A* goes from +10 V to zero. As a result, point *B* goes from +5 V to −5 V, as illustrated in Figure 20–22(f). This decrease occurs, of course, because the capacitor voltage cannot change at the instant of the falling edge. Immediately after the falling edge, the capacitor begins to discharge to zero. As a result, the resistor voltage goes from −5 V to zero, as shown.

Summary of *RC* Differentiator Response to a Single Pulse

A good way to summarize this section is to look at the general output waveforms of a differentiator as the time constant is varied from one extreme, when 5τ is much less than the pulse width, to the other extreme, when 5τ is much greater than the pulse width. These situations are illustrated in Figure 20–23. In part (a) of the figure, the output consists of narrow positive and negative "spikes." In part (e), the output approaches the shape of the input. Various conditions between these extremes are illustrated in parts (b), (c), and (d).

You may have observed a pulse that looks similar to Figure 20–23(e) when you ac couple a pulse to an oscilloscope. In this case the capacitor in the oscilloscope coupling circuit can act as an unwanted differentiating circuit, causing the pulse to droop. To avoid this, you can dc couple the scope and check the probe compensation.

   On the rising edge, the resistor voltage jumps to +5 V and then decreases exponentially to zero by the end of the pulse. On the falling edge, the resistor voltage jumps to −5 V and then goes back to zero exponentially. The resistor voltage is, of course, the output, and its shape is shown in Figure 20–25.

$$\tau = R_{tot}C = (2 \text{ k}\Omega)(1 \text{ μF}) = 2 \text{ ms}$$

On the rising edge, the resistor voltage immediately jumps to +25 V. Because the pulse width is 5 ms, the capacitor charges for 2.5 time constants and therefore does not reach full charge. Thus, you must use the formula for a decreasing exponential in order to calculate to what voltage the output decreases by the end of the pulse.

$$v_{out} = V_i e^{-t/RC} = 25e^{-5ms/2ms} = 25(0.082) = 2.05 \text{ V}$$

where $V_i = 25$ V and $t = 5$ ms. This calculation gives the resistor voltage (v_{out}) at the end of the 5 ms pulse width interval.

On the falling edge, the resistor voltage immediately jumps from +2.05 V down to −22.95 V (a 25 V transition). The resulting waveform of the output voltage is shown in Figure 20–27.

SECTION 20–4 CHECKUP

1. Draw the output of a differentiator for a 10 V input pulse when $5\tau = 0.5t_W$.
2. Under what condition does the output pulse shape most closely resemble the input pulse for a differentiator?
3. What does the differentiator output look like when 5τ is much less than the pulse width of the input?
4. If the resistor voltage in a differentiating circuit is down to $+5\,V$ at the end of a 15 V input pulse, to what negative value will the resistor voltage go in response to the falling edge of the input?

20–5 RESPONSE OF *RC* DIFFERENTIATORS TO REPETITIVE PULSES

The *RC* differentiator response to a single pulse, covered in the last section, is extended in this section to repetitive pulses.

After completing this section, you should be able to

◆ **Analyze an *RC* differentiator with repetitive input pulses**

   ◆ Determine the response when the pulse width is less than five time constants

If a periodic pulse waveform is applied to an *RC* differentiating circuit, two conditions again are possible: $t_W \geq 5\tau$ or $t_W < 5\tau$. Figure 20–28 shows the output when $t_W = 5\tau$. As the time constant is reduced, both the positive and the negative portions of the output become narrower. Notice that the average value of the output is zero. An average value of zero means that the waveform has equal positive and negative portions. The average value of a waveform is its **dc component**. Because a capacitor blocks dc, the dc component of the input is prevented from passing through to the output, resulting in an average value of zero.
▲ FIGURE 20–28

Example of differentiator response when $t_W = 5\tau$.

Figure 20–29 shows the steady-state output when $t_W < 5\tau$. As the time constant is increased, the positively and negatively sloping portions become flatter. For a very long time constant, the output approaches the shape of the input, but with an average value of zero.
▲ FIGURE 20–29

Example of differentiator response when $t_W < 5\tau$.

Analysis of a Repetitive Waveform

Like the integrator, the differentiator output takes time (5τ) to reach steady state. To illustrate the response, let's take an example in which the time constant equals the input pulse width. At this point, we do not care what the circuit time constant is because we know that the resistor voltage will decrease to approximately 37% of its maximum value during one pulse (1τ).

Let's assume that the capacitor in Figure 20–30 begins initially uncharged and then examine the output voltage on a pulse-by-pulse basis. The results of the analysis that follows are shown in Figure 20–31.
◀ FIGURE 20–30

RC differentiator with $\tau = t_W$.
◀ FIGURE 20–31

Differentiator output waveform during transient time for the circuit in Figure 20–30.

First pulse   On the rising edge, the output instantaneously jumps to $+10$ V. Then the capacitor partially charges to 63.2% of 10 V, which is 6.32 V. Thus, the output voltage must decrease to 3.68 V, as shown in Figure 20–31. On the falling edge, the output instantaneously makes a negative-going 10 V transition to -6.32 V (-10 V $+ 3.68$ V $= -6.32$ V).

Between first and second pulses   The capacitor discharges to 36.8% of 6.32 V, which is 2.33 V. Thus, the resistor voltage, which starts at -6.32 V, must increase to -2.33 V. Why? Because at the instant prior to the next pulse, the input voltage is zero. Therefore, the sum of v_C and v_R must be zero (2.33 V $- 2.33$ V $= 0$). Remember that $v_C + v_R = v_{in}$ at all times, in accordance with Kirchhoff's voltage law.

Second pulse   On the rising edge, the output makes an instantaneous, positive-going, 10 V transition from -2.33 V to 7.67 V. Then by the end of the pulse the capacitor charges $0.632 \times (10$ V $- 2.33$ V$) = 4.85$ V. Thus, the capacitor voltage increases from 2.33 V to 2.33 V $+ 4.85$ V $= 7.18$ V. The output voltage drops to 0.368×7.67 V $= 2.82$ V.

On the falling edge, the output instantaneously makes a negative-going transition from 2.82 V to -7.18 V, as shown in Figure 20–31.

Between second and third pulses   The capacitor discharges to 36.8% of 7.18 V, which is 2.64 V. Thus, the output voltage starts at -7.18 V and increases to -2.64 V because the capacitor voltage and the resistor voltage must add up to zero at the instant prior to the third pulse (the input is zero).

Third pulse   On the rising edge, the output makes an instantaneous 10 V transition from -2.64 V to $+7.36$ V. Then the capacitor charges $0.632 \times (10$ V $- 2.64$ V$) = 4.65$ V to 2.64 V $+ 4.65$ V $= 7.29$ V. As a result, the output voltage drops to 0.368×7.36 V $= 2.71$ V. On the falling edge, the output instantly goes from $+2.71$ V down to -7.29 V.

After the third pulse, five time constants have elapsed, and the output voltage is close to its steady state. Thus, it will continue to vary from a positive maximum of about $+7.3$ V to a negative maximum of about -7.3 V, with an average value of zero.

CHECKUP**

1. What conditions allow an *RC* differentiator to fully charge and discharge when a periodic pulse waveform is applied to the input?

2. What will the output waveform look like if the circuit time constant is extremely short compared to the pulse width of a square wave input?

20–6 RESPONSE OF *RL* INTEGRATORS TO PULSE INPUTS

A series *RL* circuit in which the output voltage is taken across the resistor is known as an integrator in terms of time response. Although only the response to a single pulse is discussed, it can be extended to repetitive pulses, as described for the *RC* integrator.

After completing this section, you should be able to

◆ **Analyze the operation of an *RL* integrator**

   ◆ Determine the response to a single input pulse

Figure 20–32 shows an *RL* integrator. The output waveform is taken across the resistor and, under equivalent conditions, is the same shape as that for the *RC* integrator. Recall that in the *RC* case, the output was across the capacitor.
◄ **FIGURE 20–32**

An *RL* integrator with a pulse genera-
tor connected.

As you know, each edge of an ideal pulse is considered to be instantaneous. Two basic
rules for inductor behavior will aid in analyzing *RL* circuit responses to pulse inputs:

1. The inductor appears as an open to an instantaneous change in current and as a
short (ideally) to dc.

2. The current in an inductor cannot change instantaneously—it can change only ex-
ponentially.

Response of the *RL* Integrator to a Single Pulse

When a pulse generator is connected to the input of the integrator and the voltage pulse
goes from its low level to its high level, the inductor prevents a sudden change in current.
As a result, the inductor acts as an open, and all of the input voltage is across it at the in-
stant of the rising pulse edge. This situation is indicated in Figure 20–33(a).

(b) During flat portion of pulse

(c) At falling edge of pulse and after
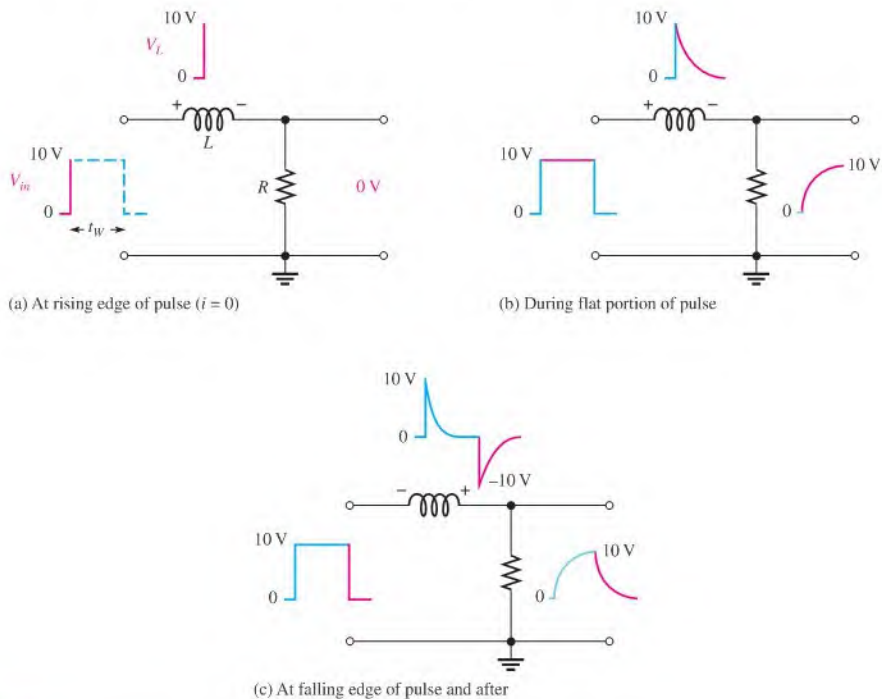

▲ **FIGURE 20–33**

Illustration of the pulse response of an *RL* integrator ($t_w > 5\tau$).

After the rising edge, the current builds up, and the output voltage follows the current as it increases exponentially, as shown in Figure 20–33(b). The current can reach a maximum of V_p/R if the transient time is shorter than the pulse width ($V_p = 10$ V in this example).

When the pulse goes from its high level to its low level, an induced voltage with reversed polarity is created across the coil in an effort to keep the current equal to V_p/R. The output voltage begins to decrease exponentially, as shown in Figure 20–33(c).

The exact shape of the output depends on the L/R time constant as summarized in Figure 20–34 for various relationships between the time constant and the pulse width. You should note that the response of this RL circuit in terms of the shape of the output is identical to that of the RC integrator. The relationship of the L/R time constant to the input pulse width has the same effect as the RC time constant that was shown in Figure 20–4. For example, when $t_W < 5\tau$, the output voltage will not reach its maximum possible value.

EXAMPLE 20–6

Determine the maximum output voltage for the *RL* integrator in Figure 20–35 when a single pulse is applied as shown. The rheostat is set so that the total resistance is 50 Ω.

▶ **FIGURE 20–35**
Solution   Calculate the time constant.

$$\tau = \frac{L}{R} = \frac{100 \text{ mH}}{50 \text{ }\Omega} = 2 \text{ ms}$$

Because the pulse width is 5 ms, the inductor charges for 2.5τ. Use the exponential formula derived from Equation 13–8 with $V_i = 0$ and $\tau = L/R$ to calculate the voltage.

$$v_{out(max)} = V_F(1 - e^{-t/\tau}) = 25(1 - e^{-5\text{ms}/2\text{ms}})$$
$$= 25(1 - e^{-2.5}) = 25(1 - 0.082) = 25(0.918) = \textbf{22.9 V}$$

To what resistance must the rheostat, R_2, be set for the output voltage to reach 25 V by the end of the pulse in Figure 20–35?

EXAMPLE 20–7

A pulse is applied to the *RL* integrator in Figure 20–36. Determine the complete wave-shapes and the values for *I*, V_R, and V_L.
▲ **FIGURE 20–36**

Solution   The circuit time constant is

$$\tau = \frac{L}{R} = \frac{5\,\text{mH}}{1.5\,\text{k}\Omega} = 3.33\,\mu\text{s}$$

Since $5\tau = 16.7\,\mu\text{s}$ is less than t_W, the current will reach its maximum value and remain there until the end of the pulse.

At the rising edge of the pulse,

$$i = 0\,\text{A}$$
$$v_R = 0\,\text{V}$$
$$v_L = 10\,\text{V}$$

The inductor initially appears as an open, so all of the input voltage appears across *L*.

During the pulse,

$$i \text{ increases exponentially to } \frac{V_p}{R} = \frac{10\,\text{V}}{1.5\,\text{k}\Omega} = 6.67\,\text{mA in } 16.7\,\mu\text{s}$$

v_R increases exponentially to 10 V in 16.7 μs

v_L decreases exponentially to zero in 16.7 μs

At the falling edge of the pulse,

$$i = 6.67\,\text{mA}$$
$$v_R = 10\,\text{V}$$
$$v_L = -10\,\text{V}$$

After the pulse,

i decreases exponentially to zero in 16.7 μs

v_R decreases exponentially to zero in 16.7 μs

v_L increases exponentially to zero in 16.7 μs

The waveforms are shown in Figure 20–37.

Use Multisim files E20-07A and E20-07B to verify the calculated results in this example and to confirm your calculation for the related problem. To simulate a single pulse, specify a waveform with the given pulse width but a small duty cycle.

EXAMPLE 20–8

A 10 V pulse with a width of 1 ms is applied to the *RL* integrator in Figure 20–38. Determine the voltage level that the output will reach during the pulse. If the source has an internal resistance of 30 Ω, how long will it take the output to decay to zero? Draw the output voltage waveform.
▲ FIGURE 20–38

Solution   The inductor charges through the 30 Ω source resistance plus the 470 Ω external resistor. The time constant is

$$\tau = \frac{L}{R_{tot}} = \frac{500 \text{ mH}}{470 \, \Omega + 30 \, \Omega} = \frac{500 \text{ mH}}{500 \, \Omega} = 1 \text{ ms}$$

Notice that in this case the pulse width is exactly equal to τ. Thus, the output V_R will reach approximately 63% of the full input amplitude in 1τ. Therefore, the output voltage gets to **6.3 V** at the end of the pulse.

After the pulse is gone, the inductor discharges back through the 30 Ω source resistance and the 470 Ω resistor. The output voltage takes **5τ** to completely decay to zero.

$$5\tau = 5(1 \text{ ms}) = 5 \text{ ms}$$

The output voltage is shown in Figure 20–39.

20–7   RESPONSE OF *RL* DIFFERENTIATORS TO PULSE INPUTS

A series *RL* circuit in which the output voltage is taken across the inductor is known as a differentiator in terms of time response. Although only the response to a single pulse is discussed, it can be extended to repetitive pulses, as was described for the *RC* differentiator.

After completing this section, you should be able to

◆ **Analyze the operation of an *RL* differentiator**

   ◆ Determine the response to a single input pulse

Response of the *RL* Differentiator to a Single Pulse

Figure 20–40 shows an *RL* differentiator with a pulse generator connected to the input.

▶ **FIGURE 20–40**

An *RL* differentiator with a pulse generator connected.
Initially, before the pulse, there is no current in the circuit. When the input pulse goes from its low level to its high level, the inductor prevents a sudden change in current. It does so, as you know, with an induced voltage equal and opposite to the input. As a result, *L* looks like an open, and all of the input voltage appears across it at the instant of the rising edge, as shown in Figure 20–41(a) with a 10 V pulse.

(a) At rising edge of pulse

(b) During flat portion of pulse

(c) At falling edge when $t_W < 5\tau$

(d) At falling edge when $t_W \geq 5\tau$
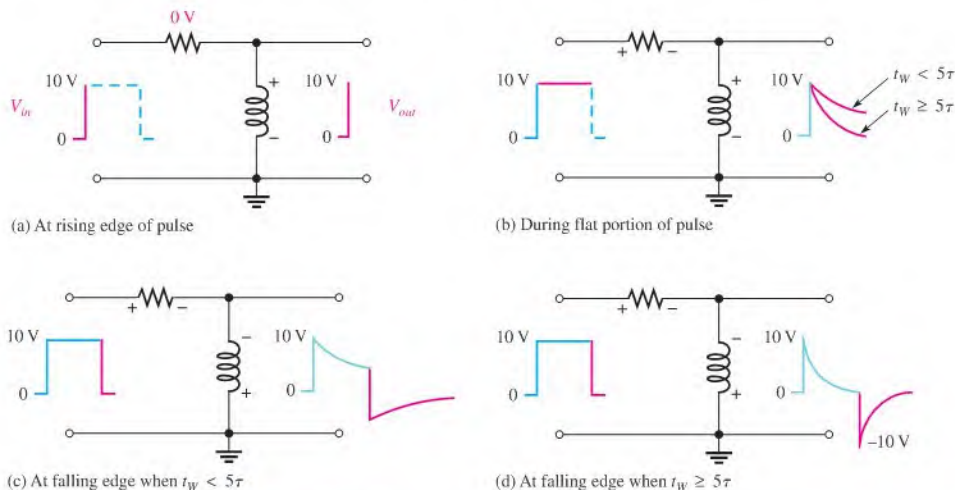

▲ **FIGURE 20–41**

Illustration of the response of an *RL* differentiator for both time constant conditions.

During the pulse, the current exponentially builds up. As a result, the inductor voltage decreases, as shown in Figure 20–41(b). The rate of decrease, as you know, depends on the *L*/*R* time constant. When the falling edge of the input occurs, the inductor reacts to keep the current as is, by creating an induced voltage in a direction as indicated in Figure 20–41(c). This reaction is seen as a sudden negative-going transition of the inductor voltage, as indicated in Figure 20–41(c) and (d).

Two conditions are possible, as indicated in Figure 20–41(c) and (d). In part (c), 5τ is greater than the input pulse width, and the output voltage does not have time to decay to zero. In part (d), 5τ is less than or equal to the pulse width, and so the output decays to zero before the end of the pulse. In this case a −10 V transition occurs at the trailing edge.

Keep in mind that as far as the input and output waveforms are concerned, the *RL* integrator and differentiator perform the same as their *RC* counterparts.

A summary of the *RL* differentiator response for relationships of various time constants and pulse widths is shown in Figure 20–42.
▲ **FIGURE 20–42**

Illustration of the variation in output pulse shape with the *RL* time constant.

EXAMPLE 20–9

Draw the output voltage for the *RL* differentiator in Figure 20–43.

▶ **FIGURE 20–43**
Solution First, calculate the time constant.

$$\tau = \frac{L}{R} = \frac{200\,\mu\text{H}}{100\,\Omega} = 2\,\mu\text{s}$$

In this case, $t_W = 5\tau$, so the output will decay to zero at the end of the pulse.

On the rising edge, the inductor voltage jumps to +5 V and then decays exponentially to zero. It reaches approximately zero at the instant of the falling edge. On the falling edge of the input, the inductor voltage jumps to −5 V and then goes back to zero. The output waveform is shown in Figure 20–44.

▶ FIGURE 20–44
Related Problem   Draw the output voltage if the pulse width is reduced to 5 μs in Figure 20–43.

EXAMPLE 20–10   Determine the output voltage waveform for the RL differentiator in Figure 20–45.
▲ FIGURE 20–45

Solution   First, calculate the time constant.

$$\tau = \frac{L}{R} = \frac{20\,\text{mH}}{10\,\text{k}\Omega} = 2\,\mu s$$

On the rising edge, the inductor voltage immediately jumps to +25 V. Because the pulse width is 5 μs, the inductor charges for only 2.5τ, so you must use the formula for a decreasing exponential derived from Equation 13–8 with $V_F = 0$ and $\tau = L/R$.

$$v_L = V_i e^{-t/\tau} = 25 e^{-5\mu s/2\mu s} = 25 e^{-2.5} = 25(0.082) = 2.05\,\text{V}$$

This result is the inductor voltage at the end of the 5 μs input pulse.
   On the falling edge, the output immediately jumps from +2.05 V down to −22.95 V (a 25 V negative-going transition). The complete output waveform is shown in Figure 20–46.

20–8 RELATIONSHIP OF TIME RESPONSE TO FREQUENCY RESPONSE

A definite relationship exists between time (pulse) response and frequency response. The fast rising and falling edges of a pulse waveform contain the higher frequency components. The flatter portions of the pulse waveform, which are the tops and the baseline of the pulses, represent slow changes or lower frequency components. The average value of the pulse waveform is its dc component.

After completing this section, you should be able to

♦ **Explain the relationship of time response to frequency response**

♦ Describe a pulse waveform in terms of its frequency components

♦ Explain how *RC* and *RL* integrators act as filters

♦ Explain how *RC* and *RL* differentiators act as filters

♦ State the formulas that relate rise and fall times to frequency

The relationships of pulse characteristics and frequency content of pulse waveforms are indicated in Figure 20–47.

"Flat" portions contain low-frequency components.

dc component (Average value)

Rising and falling edges contain high-frequency components.
▲ **FIGURE 20–47**

Frequency content of a pulse waveform.

The Integrator

RC Integrator In terms of frequency response, the *RC* integrator acts as a low-pass filter. As you learned, the *RC* integrator tends to exponentially "round off" the edges of the applied pulses. This rounding off occurs to varying degrees, depending on the relationship of the time constant to the pulse width and period. The rounding off of the edges indicates that the integrator tends to reduce the higher frequency components of the pulse waveform, as illustrated in Figure 20–48.
▲ **FIGURE 20–48**

Time and frequency response relationship in an *RC* integrator (one pulse in a repetitive waveform shown).

RL Integrator Like the *RC* integrator, the *RL* integrator also acts as a basic low-pass filter because *L* is in series between the input and output. The inductive reactance, X_L, is small for low frequencies and offers little opposition. It increases with frequency, so at higher frequencies most of the total voltage is dropped across *L* and very little across *R*, the output. If the input is dc, *L* is like a short ($X_L = 0$). At high frequencies, *L* becomes like an open, as illustrated in Figure 20–49.
▲ **FIGURE 20–49**

Low-pass filtering action.

The Differentiator

RC Differentiator In terms of frequency response, the *RC* differentiator acts as a high-pass filter. As you know, the differentiator tends to introduce tilt to the flat portion of a pulse. That is, it tends to reduce the lower frequency components of a pulse waveform. Also, it completely eliminates the dc component of the input and produces a zero average-value output. This action is illustrated in Figure 20–50.

RL Differentiator Again like the *RC* differentiator, the *RL* differentiator also acts as a basic high-pass filter. Because *L* is connected across the output, less voltage is developed
Time and frequency response relationship in an *RC* differentiator (one pulse in a repetitive waveform shown).

across it at lower frequencies than at higher ones. There are zero volts across the output for dc (ignoring winding resistance). For high frequencies, most of the input voltage is dropped across the output coil ($X_L = 0$ for dc; $X_L \cong$ open for high frequencies). Figure 20–51 shows high-pass filter action.
▲ FIGURE 20–51

High-pass filtering action.

Formulas Relating Time Response to Frequency Response

The fast transitions of a pulse (rise time, t_r, and fall time, t_f) are related to the highest frequency component, f_h, in that pulse by the following formula:

$$t_r = \frac{0.35}{f_h}$$

Equation 20–1

This formula also applies to fall time, and the fastest transition determines the highest frequency in the pulse waveform.

Equation 20–1 can be rearranged to give the highest frequency as follows:

$$f_h = \frac{0.35}{t_r}$$

Equation 20–2

also,

$$f_h = \frac{0.35}{t_f}$$

Equation 20–3

EXAMPLE 20–11

What is the highest frequency contained in a pulse that has rise and fall times equal to 10 nanoseconds (10 ns)?

20–9 TROUBLESHOOTING

In this section, *RC* circuits with pulse inputs are used to demonstrate the effects of common component failures in selected cases. The concepts can then be easily related to *RL* circuits.

After completing this section, you should be able to

◆ **Troubleshoot *RC* integrators and *RC* differentiators**

  ◆ Recognize the effect of an open capacitor

  ◆ Recognize the effect of a leaky capacitor

  ◆ Recognize the effect of a shorted capacitor

  ◆ Recognize the effect of an open resistor

Open Capacitor

If the capacitor in an *RC* integrator opens, the output has the same waveshape as the input, as shown in Figure 20–52(a). If the capacitor in a differentiator opens, the output is zero because it is held at ground through the resistor, as illustrated in part (b).

(a) Integrator

(b) Differentiator
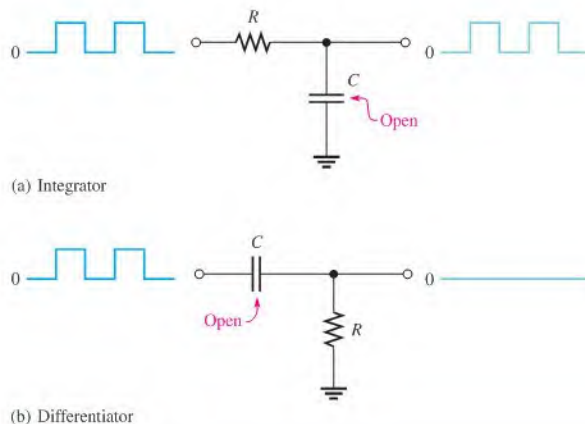

▲ FIGURE 20–52

Examples of the effect of an open capacitor.

Leaky Capacitor

If the capacitor in an RC integrator becomes leaky, three things happen: (a) the time constant will be effectively reduced by the leakage resistance (when thevenized, looking from C it appears in parallel with R); (b) the waveshape of the output voltage (across C) is altered from normal by a shorter charging time; and (c) the amplitude of the output is reduced because R and R_{leak} effectively act as a voltage divider. These effects are illustrated in Figure 20–53(a).
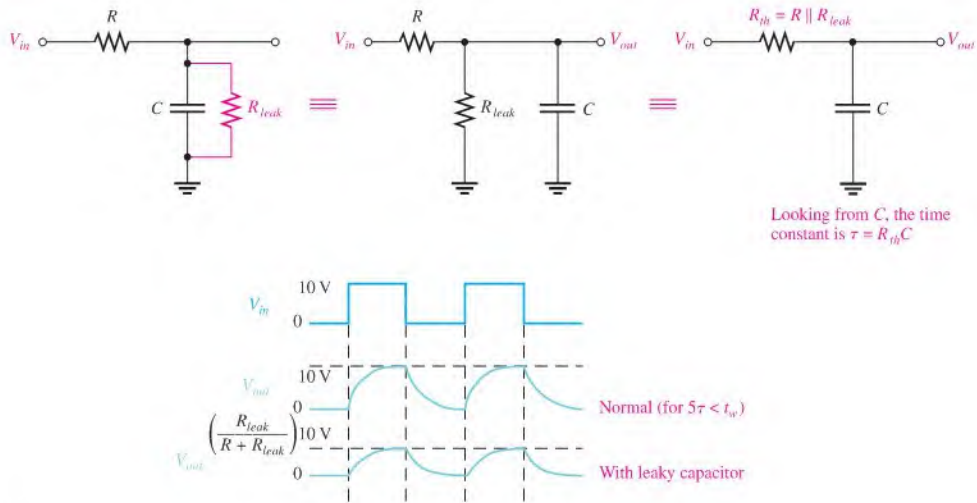

▲ FIGURE 20–53

Examples of the effect of a leaky capacitor.

If the capacitor in a differentiator becomes leaky, the time constant is reduced, just as in the integrator (they are both simply series RC circuits). When the capacitor reaches full charge, the output voltage (across R) is set by the effective voltage-divider action of R and R_{leak}, as shown in Figure 20–53(b).

Shorted Capacitor

If the capacitor in an *RC* integrator shorts, the output is at ground, as shown in Figure 20–54(a). If the capacitor in a *RC* differentiator shorts, the output is the same as the input, as shown in part (b).

(a)

(b)
▲ FIGURE 20–54

Examples of the effect of a shorted capacitor.

Open Resistor

If the resistor in an *RC* integrator opens, the capacitor has no discharge path, and, ideally, it will hold its charge. In an actual situation, the charge will gradually leak off or the capacitor will discharge slowly through a measuring instrument connected to the output. This is illustrated in Figure 20–55(a).

(a)

(b)
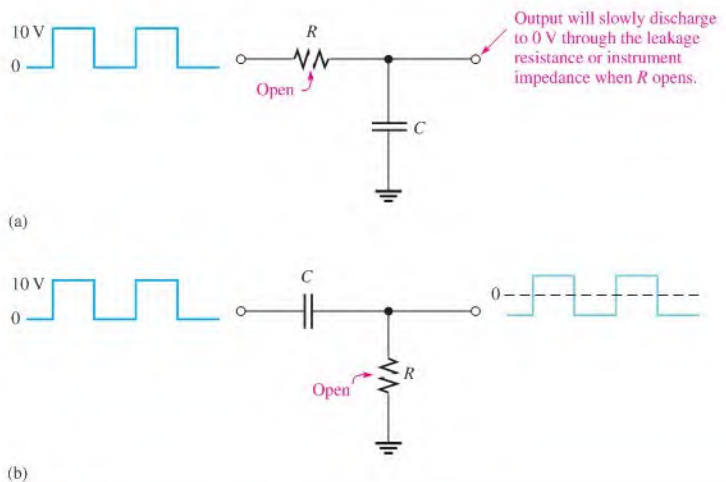

▲ FIGURE 20–55

Examples of the effects of an open resistor.

If the resistor in a differentiator opens, the output looks like the input except for the dc level because the capacitor now must charge and discharge through the extremely high resistance of the oscilloscope, as shown in Figure 20–55(b).

Application Activity

In this application activity, you are asked to build and test a time-delay circuit that will provide five switch-selectable delay times. An RC integrator is selected for this application. The input is a 5 V pulse of long duration, and the output goes to a threshold trigger circuit that is used to turn the power on to a portion of a system at any of the five selected time intervals after the occurrence of the original pulse.

A schematic of the selectable time-delay integrating circuit is shown in Figure 20–56. The RC integrator is driven by a pulse input; and the output is an exponentially increasing voltage that is used to trigger a threshold circuit at the 3.5 V level, which then turns power on to part of a system. The basic concept is shown in Figure 20–57. In this application, the delay time of the integrator is specified to be the time from the rising edge of the input pulse to the point where the output voltage reaches 3.5 V. The specified delay times are as listed in Table 20–1.

INTRODUCTION

In Chapter 11, the basic concepts of three-phase ac generators were introduced. In this chapter, the basic generation of three-phase sinusoidal waveforms is examined further. The advantages of three-phase systems in power applications are covered, and various types of three-phase connections and power measurement are introduced.

21–1 GENERATORS IN POWER APPLICATIONS

Three-phase generators (alternators) were introduced in Chapter 11. The advantages of using three-phase generators to deliver power to a load over using a single-phase machine are discussed in this section.

After completing this section, you should be able to

◆ **Discuss the advantages of three-phase generators in power applications**

　◆ Compare single-phase and three-phase systems in terms of the copper advantage

　◆ Explain the advantage of constant power

　◆ Explain the advantage of a constant rotating magnetic field
▲ **FIGURE 21–1**

Simplified representation of a single-phase generator connected to a resistive load.

The size of the copper wire required to carry current from a generator to a load can be reduced when a three-phase rather than a single-phase generator is used.

Figure 21–1 is a simplified representation of a single-phase generator connected to a resistive load. The coil symbol represents the generator winding.

For example, a single-phase sinusoidal voltage is induced in the winding and applied to a 60 Ω load, as indicated in Figure 21–2. The resulting load current is

$$\mathbf{I}_{RL} = \frac{120\angle 0° \text{ V}}{60\angle 0° \text{ Ω}} = 2\angle 0° \text{ A}$$

▶ **FIGURE 21–2**

Single-phase example.
The total current that must be delivered by the generator to the load is $2\angle 0°$ A. This means that the two conductors carrying current to and from the load must each be capable of handling 2 A; thus, the total copper cross section must handle 4 A. (The copper cross section is a measure of the total amount of wire required based on its physical size as related to its diameter.) The total load power is

$$P_{L(tot)} = I_{RL}^2 R_L = 240 \text{ W}$$

Figure 21–3 shows a simplified representation of a three-phase generator connected to three 180 Ω resistive loads. An equivalent single-phase system would be required to feed

▶ **FIGURE 21–3**

A simplified representation of a three-phase generator with each phase connected to a 180 Ω load.
three $180 \, \Omega$ resistors in parallel, thus creating an effective load resistance of $60 \, \Omega$. The coils represent the generator windings separated by $120°$.

The voltage across R_{L1} is $120 \angle 0° \, \text{V}$, the voltage across R_{L2} is $120 \angle 120° \, \text{V}$, and the voltage across R_{L3} is $120 \angle -120° \, \text{V}$, as indicated in Figure 21–4(a). The current from each winding to its respective load is as follows:

$$\mathbf{I}_{RL1} = \frac{120 \angle 0° \, \text{V}}{180 \angle 0° \, \Omega} = 667 \angle 0° \, \text{mA}$$

$$\mathbf{I}_{RL2} = \frac{120 \angle 120° \, \text{V}}{180 \angle 0° \, \Omega} = 667 \angle 120° \, \text{mA}$$

$$\mathbf{I}_{RL3} = \frac{120 \angle -120° \, \text{V}}{180 \angle 0° \, \Omega} = 667 \angle -120° \, \text{mA}$$

(a)   (b)
▲ **FIGURE 21–4**

Three-phase example.

The total load power is

$$P_{L(tot)} = I_{RL1}^2 R_{L1} + I_{RL2}^2 R_{L2} + I_{RL3}^2 R_{L3} = 240 \, \text{W}$$

This is the same total load power as delivered by the single-phase system previously discussed.

Notice that four conductors, including the neutral, are required to carry the currents to and from the loads. The current in each of the three conductors is 667 mA, as indicated in Figure 21–4(a). The current in the neutral conductor is the phasor sum of the three load currents and is equal to zero, as shown in the following equation, with reference to the phasor diagram in Figure 21–4(b).

$$\mathbf{I}_{RL1} + \mathbf{I}_{RL2} + \mathbf{I}_{RL3} = 667 \angle 0° \, \text{mA} + 667 \angle 120° \, \text{mA} + 667 \angle -120° \, \text{mA}$$
$$= 667 \, \text{mA} - 333.5 \, \text{mA} + j578 \, \text{mA} - 333.5 \, \text{mA} - j578 \, \text{mA}$$
$$= 667 \, \text{mA} - 667 \, \text{mA} = 0 \, \text{A}$$

This condition, where all load currents are equal and the neutral current is zero, is called a **balanced load** condition.

The total copper cross section must handle $667 \, \text{mA} + 667 \, \text{mA} + 667 \, \text{mA} + 0 \, \text{mA} = 2 \, \text{A}$. This result shows that considerably less copper is required to deliver the same load power with a three-phase system than is required for the single-phase system. The amount of copper is an important consideration in power distribution systems.

EXAMPLE 21–1

Compare the total copper cross sections in terms of current-carrying capacity for single-phase and three-phase 120 V systems with effective load resistances of 12 Ω.

Solution   *Single-phase system:*   The load current is

$$I_{RL} = \frac{120 \text{ V}}{12 \text{ Ω}} = 10 \text{ A}$$

The conductor to the load must carry 10 A, and the conductor from the load must also carry 10 A.

The total copper cross section, therefore, must be sufficient to handle $2 \times 10 \text{ A} = 20 \text{ A}$. *Three-phase system:*   For an effective load resistance of 12 Ω, the three-phase generator feeds three load resistors of 36 Ω each. The current in each load resistor is

$$I_{RL} = \frac{120 \text{ V}}{36 \text{ Ω}} = 3.33 \text{ A}$$

Each of the three conductors feeding the balanced load must carry 3.33 A, and the neutral current is zero.

Therefore, the total copper cross section must be sufficient to handle $3 \times 3.33 \text{ A} \cong 10 \text{ A}$. This is significantly less than for the single-phase system with an equivalent load.

*Related Problem**   Compare the total copper cross sections in terms of current-carrying capacity for single-phase and three-phase 240 V systems with effective load resistances of 100 Ω.

*Answers are at the end of the chapter.

A second advantage of three-phase systems over a single-phase system is that three-phase systems produce a constant amount of power in the load. As shown in Figure 21–5, the load power fluctuates as the square of the sinusoidal voltage divided by the resistance. It changes from a maximum of $V_{RL(max)}^2/R_L$ to a minimum of zero at a frequency equal to twice that of the voltage.

▶ **FIGURE 21–5**

Single-phase load power (sin² curve).
The power waveform across one of the load resistors in a three-phase system is 120° out of phase with the power waveforms across the other loads, as shown in Figure 21–6. Examination of the power waveforms shows that when three instantaneous values are added, the sum is always constant and equal to $V_{RL(max)}^2/R_L$. A constant load power means

▶ **FIGURE 21–6**

Three-phase power ($P_L = V_{RL(max)}^2/R_L$).
a uniform conversion of mechanical to electrical energy, which is an important consideration in many power applications.

In many applications, ac generators are used to drive ac motors for conversion of electrical energy to mechanical energy in the form of shaft rotation in the motor. The original energy for operation of the generator can come from any of several sources, such as hydroelectric or steam. Figure 21–7 illustrates the basic concept.

When a three-phase generator is connected to the motor windings, a magnetic field is created within the motor that has a constant flux density and that rotates at the frequency of the three-phase sine wave. The motor's rotor is pulled around at a constant rotational velocity by the rotating magnetic field, producing a constant shaft rotation, which is an advantage of three-phase systems.

A single-phase system is unsuitable for many applications because it produces a magnetic field that fluctuates in flux density and reverses direction during each cycle without providing the advantage of constant rotation.

SECTION 21–1 CHECKUP Answers are at the end of the chapter.	1. List three advantages of three-phase systems over single-phase systems. 2. Which advantage is most important in mechanical-to-electrical energy conversions? 3. Which advantage is most important in electrical-to-mechanical energy conversions?

21–2 TYPES OF THREE-PHASE GENERATORS

In the previous sections, the Y-connection was used for illustration. In this section, the Y-connection is examined further and a second type, the Δ-connection, is introduced.

After completing this section, you should be able to

◆ **Analyze three-phase generator connections**

  ◆ Analyze the Y-connected generator

  ◆ Analyze the Δ-connected generator

The Y-Connected Generator

A Y-connected system can be either a three-wire or, when the neutral is used, a four-wire system, as shown in Figure 21–8, connected to a generalized load, which is indicated by the green block. Recall that when the loads are perfectly balanced, the neutral current is zero; therefore, the neutral conductor is unnecessary. However, in cases where the loads are not equal (unbalanced), a neutral wire is essential to provide a return current path because the neutral current has a nonzero value.

Y-connected generator.
The voltages across the generator windings are called **phase voltages (V_θ)**, and the currents through the windings are called **phase currents (I_θ)**. Also, the currents in the lines connecting the generator windings to the load are called **line currents (I_L)**, and the voltages across the lines are called the **line voltages (V_L)**. Note that the magnitude of each line current is equal to the corresponding phase current in the Y-connected circuit.

Equation 21–1
$$I_L = I_\theta$$

In Figure 21–9, the line terminations of the windings are designated a, b, and c, and the neutral point is designated n. These letters are added as subscripts to the phase and line currents to indicate the phase with which each is associated. The phase voltages are also designated in the same manner. Notice that the phase voltages are always positive at the terminal end of the winding and are negative at the neutral point. The line voltages are from one winding terminal to another, as indicated by the double-letter subscripts. For example, $\mathbf{V}_{L(ba)}$ is the line voltage from b to a.

Phase voltages and line voltages in a Y-connected system.
Figure 21–10(a) shows a phasor diagram for the phase voltages. By rotation of the phasors, as shown in part (b), $V_{\theta a}$ is given a reference angle of zero, and the polar expressions for the phasor voltages are as follows:

$$\mathbf{V}_{\theta a} = V_{\theta a}\angle 0°$$
$$\mathbf{V}_{\theta b} = V_{\theta b}\angle 120°$$
$$\mathbf{V}_{\theta c} = V_{\theta c}\angle -120°$$

There are three line voltages: one between a and b, one between a and c, and another between b and c. It can be shown that the magnitude of each line voltage is equal to $\sqrt{3}$ times the magnitude of the phase voltage and that there is a phase angle of 30° between each line voltage and the nearest phase voltage.

Equation 21–2

Since all phase voltages are equal in magnitude,

$$\mathbf{V}_{L(ba)} = \sqrt{3}V_\theta \angle 150°$$
$$\mathbf{V}_{L(ac)} = \sqrt{3}V_\theta \angle 30°$$
$$\mathbf{V}_{L(cb)} = \sqrt{3}V_\theta \angle -90°$$

The line voltage phasor diagram is shown in Figure 21–11 superimposed on the phasor diagram for the phase voltages. Notice that there is a phase angle of 30° between each line voltage and the nearest phase voltage and that the line voltages are 120° apart.

Related Problem Determine the line voltage magnitude if the generator position indicated in Figure 21–13 is rotated another 45° clockwise.

The Δ-Connected Generator

In the Y-connected generator, two voltage magnitudes are available at the terminals in the four-wire system: the phase voltage and the line voltage. Also, in the Y-connected generator, the line current is equal to the phase current. Keep these characteristics in mind as you examine the Δ-connected generator.

The windings of a three-phase generator can be rearranged to form a Δ-connected generator, as shown in Figure 21–14. By examination of this diagram, you can see that the magnitudes of the line voltages and phase voltages are equal, but the line currents do not equal the phase currents.

▶ FIGURE 21–14

Δ-connected generator.
Since this is a three-wire system, only a single voltage magnitude is available, expressed as

Equation 21–3

$$V_L = V_\theta$$

All of the phase voltages are equal in magnitude; thus, the line voltages are expressed in polar form as follows:

$$\mathbf{V}_{L(ac)} = V_\theta \angle 0°$$
$$\mathbf{V}_{L(ba)} = V_\theta \angle 120°$$
$$\mathbf{V}_{L(cb)} = V_\theta \angle -120°$$

The phasor diagram for the phase currents is shown in Figure 21–15, and the polar expressions for each current are as follows:

$$\mathbf{I}_{\theta a} = I_{\theta a}\angle 0°$$
$$\mathbf{I}_{\theta b} = I_{\theta b}\angle 120°$$
$$\mathbf{I}_{\theta c} = I_{\theta c}\angle -120°$$

It can be shown that the magnitude of each line current is equal to $\sqrt{3}$ times the magnitude of the phase current and that there is a phase angle of 30° between each line current and the nearest phase current.

$$I_L = \sqrt{3}I_\theta \qquad\qquad \text{Equation 21–4}$$

Since all phase currents are equal in magnitude,

$$\mathbf{I}_{L1} = \sqrt{3}I_\theta \angle -30°$$
$$\mathbf{I}_{L2} = \sqrt{3}I_\theta \angle 90°$$
$$\mathbf{I}_{L3} = \sqrt{3}I_\theta \angle -150°$$

(a) The polar expressions for the other phase currents

(b) The polar expressions for each of the line currents

(c) The complete current phasor diagram

► FIGURE 21–17

$$\mathbf{I}_{\theta c} = 10\angle(30° - 120°) = \mathbf{10\angle -90°}\ \text{A}$$

(b) The line currents are separated from the nearest phase current by 30°; therefore,

$$\mathbf{I}_{L1} = \sqrt{3}I_{\theta a}\angle(30° - 30°) = \mathbf{17.3}\angle \mathbf{0°}\,\mathbf{A}$$
$$\mathbf{I}_{L2} = \sqrt{3}I_{\theta b}\angle(150° - 30°) = \mathbf{17.3}\angle \mathbf{120°}\,\mathbf{A}$$

21–3 THREE-PHASE SOURCE/LOAD ANALYSIS

In this section, we look at four basic types of source/load configurations. As with the generator connections, a load can be either a Y or a Δ configuration.

After completing this section, you should be able to

◆ **Analyze three-phase generators with three-phase loads**

  ◆ Analyze the Y-Y source/load configuration

  ◆ Analyze the Y-Δ source/load configuration

  ◆ Analyze the Δ-Y source/load configuration

  ◆ Analyze the Δ-Δ source/load configuration

A Y-connected load is shown in Figure 21–19(a), and a Δ-connected load is shown in part (b). The blocks $\mathbf{Z}_a$, $\mathbf{Z}_b$, and $\mathbf{Z}_c$ represent the load impedances, which can be resistive, reactive, or both.

The four source/load configurations are:

1. Y-connected source driving a Y-connected load (Y-Y system)

2. Y-connected source driving a Δ-connected load (Y-Δ system)

3. Δ-connected source driving a Y-connected load (Δ-Y system)

4. Δ-connected source driving a Δ-connected load (Δ-Δ system)
◀ **FIGURE 21–19**

Three-phase loads.

(a) Y-connected load   (b) Δ-connected load

The Y-Y System

Figure 21–20 shows a Y-connected source driving a Y-connected load. The load can be a balanced load, such as a three-phase motor where $\mathbf{Z}_a = \mathbf{Z}_b = \mathbf{Z}_c$, or it can be three independent single-phase loads where, for example, $\mathbf{Z}_a$ is a lighting circuit, $\mathbf{Z}_b$ is a heater, and $\mathbf{Z}_c$ is an air-conditioning compressor.
◀ **FIGURE 21–20**

A Y-connected source driving a Y-connected load.

An important feature of a Y-connected source is that two different values of three-phase voltage are available: the phase voltage and the line voltage. For example, in the standard power distribution system, a three-phase transformer can be considered a source of three-phase voltage supplying 120 V and 208 V. In order to utilize a phase voltage of 120 V, the loads are connected in the Y configuration. A Δ-connected load is used for the 208 V line voltages.

Notice in the Y-Y system in Figure 21–20 that the phase current, the line current, and the load current are all equal in each phase. Also, each load voltage equals the corresponding phase voltage. These relationships are expressed as follows and are true for either a balanced or an unbalanced load.

$$I_\theta = I_L = I_Z$$

$$V_\theta = V_Z$$

Equation 21–5

Equation 21–6

where V_Z and I_Z are the load voltage and current, respectively.

For a balanced load, all the phase currents are equal, and the neutral current is zero. For an unbalanced load, each phase current is different, and the neutral current is, therefore, nonzero.

EXAMPLE 21–4

(a) Each load current   (b) Each line current   (c) Each phase current

(d) Neutral current   (e) Each load voltage

$$\mathbf{I}_{\theta b} = \mathbf{5.36\angle 93.4°\ A}$$
$$\mathbf{I}_{\theta c} = \mathbf{5.36\angle -147°\ A}$$

(d) $\mathbf{I}_{neut} = \mathbf{I}_{Za} + \mathbf{I}_{Zb} + \mathbf{I}_{Zc}$

$= 5.36\angle -26.6°\ \mathrm{A} + 5.36\angle 93.4°\ \mathrm{A} + 5.36\angle -147°\ \mathrm{A}$

If the load impedances were not equal (unbalanced load), the neutral current would have a nonzero value.

(e) The load voltages are equal to the corresponding source phase voltages.

$$V_{Za} = 120 \angle 0° \text{ V}$$
$$V_{Zb} = 120 \angle 120° \text{ V}$$

The Δ-Y System

Figure 21–25 shows a Δ-connected source driving a Y-connected balanced load. By examination of the figure, you can see that the line voltages are equal to the corresponding phase voltages of the source. Also, each phase voltage equals the difference of the corresponding load voltages, as you can see by the polarities.

Each load current equals the corresponding line current. The sum of the load currents is zero because the load is balanced; thus, there is no need for a neutral return.

21–4 THREE-PHASE POWER

In this section, power in three-phase systems is studied and methods of power measurement are introduced.

After completing this section, you should be able to

◆ **Discuss power measurements in three-phase systems**

  ◆ Describe the three-wattmeter method

  ◆ Describe the two-wattmeter method

Each phase of a balanced three-phase load has an equal amount of power. Therefore, the total true load power is three times the power in each phase of the load.

$$P_{L(tot)} = 3V_Z I_Z \cos\theta$$

Equation 21–13

where V_Z and I_Z are the voltage and current associated with each phase of the load, and $\cos\theta$ is the power factor.

Recall that in a balanced Y-connected system, the line voltage and line current were

$$V_L = \sqrt{3}V_Z \qquad \text{and} \qquad I_L = I_Z$$

and in a balanced Δ-connected system, the line voltage and line current were

$$V_L = V_Z \qquad \text{and} \qquad I_L = \sqrt{3}I_Z$$

When either of these relationships is substituted into Equation 21–13, the total true power for both Y- and Δ-connected systems is

$$P_{L(tot)} = \sqrt{3}V_L I_L \cos\theta$$

Equation 21–14

EXAMPLE 21–8

In a certain Δ-connected balanced load, the line voltages are 250 V and the impedances are $50\angle 30°$ Ω. Determine the total load power.

Solution In a Δ-connected system, $V_Z = V_L$ and $I_L = \sqrt{3}I_Z$. The load current magnitudes are

$$I_Z = \frac{V_Z}{Z} = \frac{250\text{ V}}{50\text{ }\Omega} = 5\text{ A}$$

and

$$I_L = \sqrt{3}I_Z = \sqrt{3}(5\text{ A}) = 8.66\text{ A}$$

The power factor is

$$\cos \theta = \cos 30° = 0.866$$

The total load power is

$$P_{L(tot)} = \sqrt{3} V_L I_L \cos \theta = \sqrt{3}(250 \text{ V})(8.66 \text{ A})(0.866) = \textbf{3.25 kW}$$

Related Problem Determine the total load power if $V_L = 120$ V and $\mathbf{Z} = 100 \angle 30° \ \Omega$.

Power Measurement

Power is measured in three-phase systems using wattmeters. The wattmeter uses a basic electrodynamometer-type movement consisting of two coils. One coil is used to measure the current, and the other is used to measure the voltage. Figure 21–29 shows a basic wattmeter schematic and the connections for measuring power in a load. The resistor in series with the voltage coil limits the current through the coil to a small amount proportional to the voltage across the coil.

▲ FIGURE 21–29

Three-Wattmeter Method Power can be measured easily in a balanced or unbalanced three-phase load of either the Y or the Δ type by using three wattmeters connected as shown in Figure 21–30. This is sometimes known as the *three-wattmeter method*.

(a) Y-connected load

(b) Δ-connected load
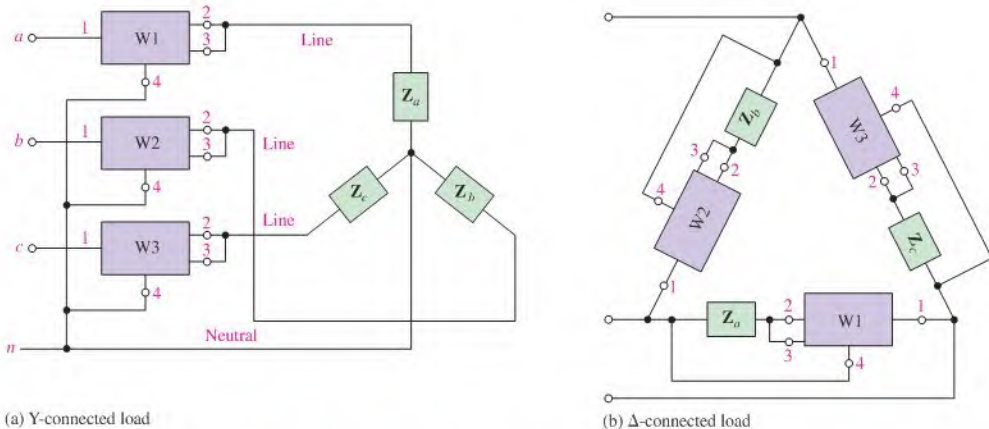

▲ FIGURE 21–30

Three-wattmeter method of power measurement.

The total power is determined by summing the three wattmeter readings.

$$P_{tot} = P_1 + P_2 + P_3$$

If the load is balanced, the total power is simply three times the reading on any one wattmeter.

In many three-phase loads, particularly the Δ configuration, it is difficult to connect a wattmeter such that the voltage coil is across the load or such that the current coil is in series with the load because of inaccessibility of points within the load.

Two-Wattmeter Method   Another method of three-phase power measurement uses only two wattmeters. The connections for this two-wattmeter method are shown in Figure 21–31. Notice that the voltage coil of each wattmeter is connected across a line voltage and that the current coil has a line current through it. It can be shown that the algebraic sum of the two wattmeter readings equals the total power in the Y- or Δ-connected load.

$$P_{tot} = P_1 \pm P_2$$

Equation 7–3   Output Voltage of Temperature Measuring Bridge

At balance $V_{OUT} = 0$ and all resistances have the value R. For a small imbalance:

$$V_B = \frac{V_S}{2} \text{ and } V_A = \left(\frac{R}{2R + \Delta R_{THERM}}\right)V_S$$

$$\Delta V_{OUT} = V_B - V_A = \frac{V_S}{2} - \left(\frac{R}{2R + \Delta R_{THERM}}\right)V_S$$

$$= \left(\frac{1}{2} - \frac{R}{2R + \Delta R_{THERM}}\right)V_S$$

$$= \left(\frac{2R + \Delta R_{THERM} - 2R}{2(2R + \Delta R_{THERM})}\right)V_S$$

$$= \left(\frac{\Delta R_{THERM}}{4R + 2\Delta R_{THERM}}\right)V_S$$

Assume $2\Delta R_{THERM} << 4R$, then

$$\Delta V_{OUT} \cong \left(\frac{\Delta R_{THERM}}{4R}\right)V_S = \Delta R_{THERM}\left(\frac{V_S}{4R}\right)$$

Equation 11–5   RMS (Effective) Value of a Sine Wave

The abbreviation "rms" stands for the root mean square process by which this value is derived. In the process, we first square the equation of a sine wave.

$$v^2 = V_p^2 \sin^2\theta$$

Next, we obtain the mean or average value of v^2 by dividing the area under a half-cycle of the curve by π (see Figure B–1). The area is found by integration and trigonometric identities.

▲ FIGURE B–1

$$V_{avg}^2 = \frac{area}{\pi} = \frac{1}{\pi}\int_0^\pi V_p^2 \sin^2\theta\, d\theta$$

$$= \frac{V_p^2}{2\pi}\int_0^\pi (1 - \cos 2\theta)d\theta = \frac{V_p^2}{2\pi}\int_0^\pi 1\, d\theta - \frac{V_p^2}{2\pi}\int_0^\pi (-\cos 2\theta)\, d\theta$$

$$= \frac{V_p^2}{2\pi}(\theta - \tfrac{1}{2}\sin 2\theta)_0^\pi = \frac{V_p^2}{2\pi}(\pi - 0) = \frac{V_p^2}{2}$$

Finally, the square root of V_{avg}^2 is V_{rms}.

$$V_{rms} = \sqrt{V_{avg}^2} = \sqrt{V_p^2/2} = \frac{V_p}{\sqrt{2}} = 0.707V_p$$
Equation 11–11   Average Value of a Half-Cycle Sine Wave

The average value of a sine wave is determined for a half-cycle because the average over a full cycle is zero.

The equation for a sine wave is

$$v = V_p \sin \theta$$

The average value of the half-cycle is the area under the curve divided by the distance of the curve along the horizontal axis (see Figure B–2).

$$V_{\text{avg}} = \frac{\text{area}}{\pi}$$
▲ FIGURE B–2

To find the area, we use integral calculus.

$$V_{\text{avg}} = \frac{1}{\pi} \int_0^\pi V_p \sin \theta \, d\theta = \frac{V_p}{\pi}(-\cos \theta)\Big|_0^\pi$$

$$= \frac{V_p}{\pi}[-\cos \pi - (-\cos 0)] = \frac{V_p}{\pi}[-(-1) - (-1)]$$

$$= \frac{V_p}{\pi}(2) = \frac{2}{\pi}V_p = 0.637V_p$$

Equations 12–25 and 13–12   Reactance Derivations

Derivation of Capacitive Reactance

$$\theta = 2\pi ft = \omega t$$

$$i = C\frac{dv}{dt} = C\frac{d(V_p \sin \theta)}{dt} = C\frac{d(V_p \sin \omega t)}{dt} = \omega C(V_p \cos \omega t)$$

$$I_{\text{rms}} = \omega C V_{\text{rms}}$$

$$X_C = \frac{V_{\text{rms}}}{I_{\text{rms}}} = \frac{V_{\text{rms}}}{\omega C V_{\text{rms}}} = \frac{1}{\omega C} = \frac{1}{2\pi fC}$$

Derivation of Inductive Reactance

$$v = L\frac{di}{dt} = L\frac{d(I_p \sin \omega t)}{dt} = \omega L(I_p \cos \omega t)$$

$$V_{\text{rms}} = \omega L I_{\text{rms}}$$

$$X_L = \frac{V_{\text{rms}}}{I_{\text{rms}}} = \frac{\omega L I_{\text{rms}}}{I_{\text{rms}}} = \omega L = 2\pi fL$$

Equation 15–33

The feedback circuit in the phase-shift oscillator consists of three RC stages, as shown in Figure B–3. An expression for the attenuation is derived using the loop analysis method for the loop assignment shown. All Rs are equal in value, and all Cs are equal in value.

$$(R - j1/2\pi fC)I_1 - RI_2 + 0I_3 = V_{in}$$
$$-RI_1 + (2R - j1/2\pi fC)I_2 - RI_3 = 0$$
$$0I_1 - RI_2 + (2R - j1/2\pi fC)I_3 = 0$$
▲ FIGURE B–3

In order to get V_{out}, we must solve for I_3 using determinants:

$$I_3 = \frac{\begin{vmatrix} (R - j1/2\pi fC) & -R & V_{in} \\ -R & (2R - j1/2\pi fC) & 0 \\ 0 & -R & 0 \end{vmatrix}}{\begin{vmatrix} (R - j1/2\pi fC) & -R & 0 \\ -R & (2R - j1/2\pi fC) & -R \\ 0 & -R & (2R - j1/2\pi fC) \end{vmatrix}}$$

$$I_3 = \frac{R^2 V_{in}}{(R - j1/2\pi fC)(2R - j1/2\pi fC)^2 - R^2(2R - j1/2\pi fC) - R^2(R - 1/2\pi fC)}$$

$$\frac{V_{out}}{V_{in}} = \frac{RI_3}{V_{in}}$$

$$= \frac{R^3}{(R - j1/2\pi fC)(2R - j1/2\pi fC)^2 - R^3(2 - j1/2\pi fRC) - R^3(1 - 1/2\pi fRC)}$$

$$= \frac{R^3}{R^3(1 - j1/2\pi fRC)(2 - j1/2\pi fRC)^2 - R^3[(2 - j1/2\pi fRC) - (1 - j1/2\pi fRC)]}$$

$$= \frac{R^3}{R^3(1 - j1/2\pi fRC)(2 - j1/2\pi fRC)^2 - R^3(3 - j1/2\pi fRC)}$$

$$\frac{V_{out}}{V_{in}} = \frac{1}{(1 - j1/2\pi fRC)(2 - j1/2\pi fRC)^2 - (3 - j1/2\pi fRC)}$$

Expanding and combining the real terms and the j terms separately,

$$\frac{V_{out}}{V_{in}} = \frac{1}{\left(1 - \dfrac{5}{4\pi^2 f^2 R^2 C^2}\right) - j\left(\dfrac{6}{2\pi fRC} - \dfrac{1}{(2\pi f)^3 R^3 C^3}\right)}$$

For oscillation in the phase-shift amplifier, the phase shift through the RC circuit must equal 180°. For this condition to exist, the j term must be 0 at the frequency of oscillation f_r.

$$\frac{6}{2\pi f_r RC} - \frac{1}{(2\pi f_r)^3 R^3 C^3} = 0$$

$$\frac{6(2\pi)^2 f_r^2 R^2 C^2 - 1}{(2\pi)^3 f_r^3 R^3 C^3} = 0$$

$$6(2\pi)^2 f_r^2 R^2 C^2 - 1 = 0$$

$$f_r^2 = \frac{1}{6(2\pi)^2 R^2 C^2}$$

$$f_r = \frac{1}{2\pi\sqrt{6}RC}$$

Equation 17–13   Resonant Frequency for a Nonideal Parallel Resonant Circuit

$$\frac{1}{\mathbf{Z}} = \frac{1}{-jX_C} + \frac{1}{R_W + jX_L}$$

$$= j\left(\frac{1}{X_C}\right) + \frac{R_W - jX_L}{(R_W + jX_L)(R_W - jX_L)} = j\left(\frac{1}{X_C}\right) + \frac{R_W - jX_L}{R_W^2 + X_L^2}$$

The first term plus splitting the numerator of the second term yields

$$\frac{1}{\mathbf{Z}} = j\left(\frac{1}{X_C}\right) - j\left(\frac{X_L}{R_W^2 + X_L^2}\right) + \frac{R_W}{R_W^2 + X_L^2}$$

The j terms are equal.

$$\frac{1}{X_C} = \frac{X_L}{R_W^2 + X_L^2}$$

Thus,

$$R_W^2 = X_L^2 = X_L X_C$$

$$R_W^2 + (2\pi f_r L)^2 = \frac{2\pi f_r L}{2\pi f_r C}$$

$$R_W^2 + 4\pi^2 f_r^2 L^2 = \frac{L}{C}$$

$$4\pi^2 f_r^2 L^2 = \frac{L}{C} - R_W^2$$

Solving for f_r^2,

$$f_r^2 = \frac{\left(\dfrac{L}{C}\right) - R_W^2}{4\pi^2 L^2}$$

Multiplying both numerator and denominator by C,

$$f_r^2 = \frac{L - R_W^2 C}{4\pi^2 L^2 C} = \frac{L - R_W^2 C}{L(4\pi^2 LC)}$$

Factoring an L out of the numerator and canceling gives

$$f_r^2 = \frac{1 - (R_W^2 C/L)}{4\pi^2 LC}$$

Taking the square root of both sides yields

$$f_r = \frac{\sqrt{1 - (R_W^2 C/L)}}{2\pi\sqrt{LC}}$$

Equation 17–16   Impedance of Nonideal Tank Circuit at Resonance

Begin with the following expression for $1/\mathbf{Z}$ that was developed in the derivation for Equation 17–13.

$$\frac{1}{\mathbf{Z}} = j\left(\frac{1}{X_C}\right) - j\left(\frac{X_L}{R_W^2 + X_L^2}\right) + \frac{R_W}{R_W^2 + X_L^2}$$

At resonance, $\mathbf{Z}$ is purely resistive; so it has no j part (the j terms in the last expression cancel). Thus, only the real part is left, as stated in the following equation for Z at resonance:

$$Z_r = \frac{R_W^2 + X_L^2}{R_W}$$

Splitting the denominator, we get

$$Z_r = \frac{R_W^2}{R_W} + \frac{X_L^2}{R_W} = R_W + \frac{X_L^2}{R_W}$$

Factoring out R_W gives

$$Z_r = R_W\left(1 + \frac{X_L^2}{R_W^2}\right)$$

Since $X_L^2/R_W^2 = Q^2$, then

$$Z_R = R_W(Q^2 + 1)$$

Some capacitors have color-coded designations. The color code used for capacitors is basically the same as that used for resistors. Some variations occur in tolerance designation. The basic color codes are shown in Table C–1, and some typical color-coded capacitors are illustrated in Figure C–1.

NI MULTISIM FOR CIRCUIT SIMULATION

Simulate, Prototype, and Test Circuits

Theory, Design, and Prototype

As electronic circuits and systems become more advanced, circuit designers rely on computers in the design process. It is essential for engineers and technicians to systematically design, simulate, prototype, and lay out the circuit. Students can also use the engineering and design process to reinforce concepts and theory in the classroom. The three stages of the student design process are illustrated in Figure D–1.

Notice: This appendix was written for use with the Multisim Version 10.0 software. Some or all of the information in this Appendix may not apply to other versions of the software.

The National Instruments Electronics Education Platform is an end-to-end tool-chain designed to meet student and educator needs. The platform consists of NI Multisim simulation software, the NI Educational Laboratory Virtual Instrumentation Suite (NI ELVIS) prototyping workstation, and the NI LabVIEW graphical programming environment. NI Multisim provides intuitive schematic capture, SPICE simulation, and integration with the NI ELVIS to help students explore circuit theory and design circuits to investigate behavior. NI ELVIS is a prototyping platform that allows students to quickly and easily create their circuits. With NI LabVIEW, students can measure real-world signals and compare simulation results.

1. Investigate Theory   Learn the fundamental theory of circuit design through the *Principles of Electric Circuits* textbook and course lectures. Reinforce important concepts in the easy-to-use Multisim environment by downloading the Multisim circuit files for the textbook. The Multisim circuit files help build the foundation for an in-depth understanding of circuit behavior. Using the prebuilt circuit files, simulate and analyze the circuit behavior of examples and problems in each chapter.

2. Design and Simulate   Circuit simulation provides an interactive view into a circuit. Build a circuit from scratch and learn about the design performance using built-in circuit instruments and probes in an ideal pre-laboratory environment. With the 3D breadboard in Multisim, take the leap from circuit diagram to real-world physical implementation.

3. Prototype, Measure, and Compare   Hands-on experience building physical circuitry is essential. Move from the 3D breadboard in Multisim to a real-world breadboard on NI ELVIS to seamlessly complete the entire design process by prototyping the circuit. Within the LabVIEW environment, compare real-world measurements to the simulation values to reinforce theory, fully understand circuit behavior, and build the foundations of professional engineering analysis.

NI Multisim

Multisim software integrates powerful SPICE simulation and schematic capture into a highly intuitive electronics lab on the computer. Use the Multisim Student Edition to enhance learning by:

> Building circuits in a simple, easy-to-learn environment
> Simulating and analyzing circuits for homework and prelab assignments
> Breadboarding in 3D at home before lab sessions
> Creating designs of up to 50 components using a library of nearly 4,000 devices
> Integrating with the NI ELVIS prototyping workstation

While using industry-standard SPICE in the background, you can take advantage of the Multisim drag-and-drop interface to make circuit drawing, wiring, and analysis simple and easy to use. You can build circuits from scratch and learn about design performances using built-in virtual instruments and probes in an ideal environment for experimentation. With the 3D breadboard, you can easily take the leap from circuit diagram to real-world implementation.

Using Multisim with Principles of Electric Circuits   Create an example from the textbook to get familiar with the Multisim environment. First, launch Multisim and open a new schematic window (**File >> New >> Schematic Capture**). Design circuits in the circuit window by placing components from the component toolbar. Clicking on the component toolbar opens the component browser. Choose the family of components and select an individual component to place on the circuit window by double-clicking on it.

Once you have selected a component, it attaches itself and "ghosts" the mouse cursor. Place the component by clicking again on the desired location in the schematic. If you are
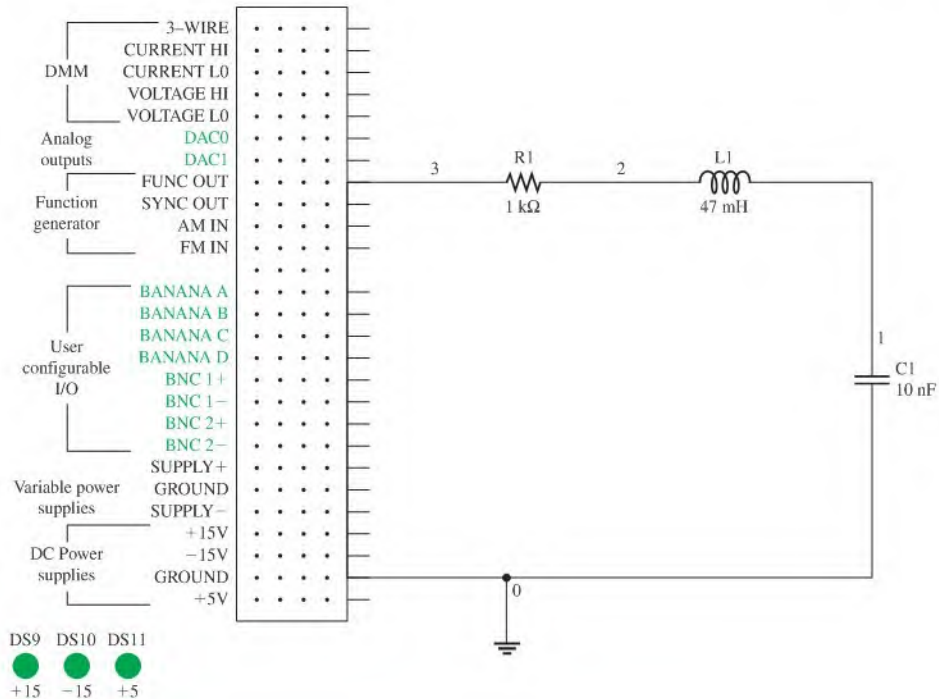

▲ **FIGURE D–2**

Multisim schematic of *RLC* circuit.

new to Multisim, you should use the **BASIC_VIRTUAL** family of components, which you can assign any arbitrary value. As an example of a simple Multisim circuit, an *RLC* circuit is shown in Figure D–2. The circuit connects a 1 kΩ resistor, a 47 mH inductor, and a 10 nF capacitor. All these components are found in the Basic Group of the Component Database.

The next step is to wire the components together. Simply left-click on the source terminal and left-click on the destination terminal. Multisim automatically chooses the best path for the virtual wire between the two terminals. Always be sure you have fully captured your circuit; then you can simulate it. You can use your simulation results as a comparison with the physical circuit.

To analyze the circuit, use a measurement probe to measure the voltages and other characteristics from the circuit while the simulation is running. Use the virtual oscilloscope to analyze the output signal from our sample *RLC* circuit.

NI ELVIS

NI ELVIS is a LabVIEW-based design and prototyping environment based on LabVIEW for university science and engineering laboratories. NI ELVIS consists of virtual instruments, or functions, based on LabVIEW; a multifunction data acquisition device; and a custom-designed benchtop workstation and prototyping board. This combination provides a ready-to-use suite of instruments for educational laboratories. The NI ELVIS workstation is shown in Figure D–3.

NI ELVIS is an ideal companion to any electronics lab that uses Multisim. It features USB connectivity for easy setup, maintenance, and portability, as well as a portable breadboard for real-world circuit prototyping.

The NI ELVIS workstation.

NI ELVIS features a breadboard prototyping environment with built-in instruments including a function generator, digital multimeter (DMM), oscilloscope, and variable power supplies. The breadboard is detachable, so you can work on your projects and labs independently of the NI ELVIS unit. NI ELVIS provides software based on LabVIEW for interacting with virtual instruments.

Using NI ELVIS with Principles of Electric Circuits   Returning to the *RLC* circuit introduced with Multisim as an example, you can continue the prototyping step. With prototyping hardware, you can quickly construct a circuit on a standard protoboard and test it with the laboratory instruments to complete the design.

Alternatively, you can repeat the simulation step but this time as a prototype using the Virtual 3D NI ELVIS from within Multisim. To construct a 3D NI ELVIS prototype, open the 3D breadboard by clicking **Tools >> Show Breadboard**. Place components and wires to build up your circuit. The corresponding connection points and symbols on the NI ELVIS schematic turn green, indicating the 3D connections are correct. If you create a traditional schematic, you see a standard breadboard. Figure D–4 shows the circuit on 3D Virtual

Multisim simulated signal.
▲ FIGURE D–6

NI ELVIS measured signal.

NI ELVIS prototyped in Multisim and ready for construction. Once you have verified the layout of your circuit using the 3D virtual environment, you can physically build it on NI ELVIS.

After constructing the circuit, you can use the NI ELVIS instrument launcher to measure the output signal of this circuit. Figure D–5 shows the simulated signal of the *RLC* circuit on the Multisim oscilloscope. Figure D–6 shows the measured signal using the ELVIS II Oscilloscope. The most important step in the process is to compare the measurement of the prototyped circuit to the simulation. This helps you determine where potential errors exist in the design. After comparing the measurement with the theoretical values, you can revisit your design to improve it or prepare it for layout on a PCB board, using software such as NI Ultiboard.
