The military, military contractors, and their families have felt the war costs most directly. The federal budget deficit grew significantly due to the Iraq war. This reality excludes the fact that the budget was already in a deficit at the start of the war. When the budget deficit increases, all citizens ultimately have to pay for those increases, usually through higher future taxes. Additionally, when foreigners buy U.S. Treasury bonds, they are in effect funding the U.S. government, putting United States in debt to international debt buyers.

Economically, war always diverts production away from domestic goods and toward war-related products. More military weapons means less domestic production and investment in technologies and new corporate capital projects. This creates a chain reaction that diminishes the investment in our country, leading to lower domestic growth, less development, and lower living standards in the future.

The costs of war not only impact the current generation, but also have long-term effects on future generations: Future generations will pay the bills incurred by the war today. Since money is borrowed for war through the issuance of Treasury securities, that money will be paid back by taxes assessed on future workers.

Stiglitz and Bilmes (2008), authors of *The Three Trillion Dollar War: The True Cost of the Iraq Conflict*, allege that the war in Iraq influenced higher oil prices. The authors present a direct correlation between the start of the war and an increase in oil prices. During the war, Iraqi oil production was halted. Additionally, the military used substantial amounts of oil. This does not mean oil prices would have remained stable if the United States had not gone to war with Iraq, but only that the war furthered the increase in oil prices by curtailing of the supply that the war created.

Costs to the Military and Related Population

The costs to the military and their families are immeasurable. A military class of citizens is returning to this country with severe physical and mental problems. These soldiers return to an economy with high unemployment, leading to underemployment or no employment for many them. While the social costs of war cannot be measured in dollars and cents, these costs have a tremendous impact on our financial and social economies. Returning veterans who do not have employment create financial expenses for our social service systems, as well as immeasurable emotional costs to a valuable segment of the population.

It is reported that almost 4,500 U.S. troops were killed and more than 32,000 were wounded. No dollar amount can be allocated to those losses.

Regardless of whether one believes the war was just or successful, there are both tangible and intangible economic costs from the 10-year long war in Iraq. The costs to the U.S. economy for this war span the current generation and future generations. There are individual financial costs to the soldiers and their families as well as broad economic costs to the United States.

JUILLIARD V. GREENMAN

The Legal Tender cases were a series of cases filed during and after the Civil War, culminating in *Juilliard v. Greenman*, 110 U.S. 421 (1884). The Civil War brought an economic urgency to the United States. In 1862, Congress passed the Legal Tender Act, allowing U.S. notes to be printed to help finance the war debt. Paper money depreciates in terms of gold and silver, which were used prior to its issuance. Cheap money chases out expensive money, and old debts were soon paid with controversial paper. During Reconstruction, the Legal Tender cases challenged the authority of Congress to print paper money—beginning with *Hepburn v. Griswold* in 1870, where the Supreme Court said paper currency was unconstitutional, and ending in 1884, with the *Juilliard v. Greenman* case stating the opposite interpretation. Article I, Section 8, of the Constitution grants Congress the power to coin money, but gold and silver are the metals mentioned. Whether the framers of the Constitution could have fathomed "plastic" as a method of payment is open to speculation; however, some argue that if their prohibition on paper money had been implemented, the American economy would have been sent into disarray at best, and at worst, would have ceased to exist. This case settled once and for all the constitutional disputes between paper money and a currency limited to gold and silver.

Case Summary

Augustus D. Juilliard was a Frenchman who made his wealth in New York textiles. His skills as a businessman proved beneficial to the arts, as upon his death in 1919, he bequeathed a large amount of money to establish the Juilliard School of Music. In all these endeavors he was a winner, but in the Supreme Court he was a loser. This is not to say that the United States did not benefit from his loss.

Juilliard v. Greenman was a case that grew out of fear and hard times. There was a fear of cheap money (money without intrinsic value or backed by gold or silver) combined with insecurities about government. American political stability had been tested by the Civil War, the assassination of the president, and a financial panic in 1873 (which was referred to as the "great depression" until the depression of the 1930s took the title). This sad constellation of events did very little to encourage trust in the federal government's greenbacks (the first noninterest-bearing notes printed by the government to pay for the war debt).

In 1879, Juilliard sued Thomas S. Greenman of Connecticut to secure payment of a private debt. Greenman had purchased 100 bales of cotton from Juilliard, who expected a payment of $5,122.90 upon delivery. Greenman paid $22.90 in gold and silver coin and offered U.S. paper notes (paper money issued by the U.S. government without intrinsic value or backed by gold or silver), also known as greenbacks (because the back is printed in green), for the remainder of the bill. Juilliard refused the paper currency. Greenman took the $5,000 note and the $100 note into court to prove his intent to pay, whereupon the plaintiff demurred (made an objection or delay) on the grounds that the defendant's response to being sued was to produce the same evidence that had caused the action and therefore was without legal significance. The Circuit Court of the United States for the Southern District of New York disagreed, and ruled in favor of the defendant.

Juilliard filed a writ of error (a directive to a trial court to send the records of a case to the appellate court to be examined for potential procedure errors) to the Supreme Court with two assertions. First, the act passed by Congress on May 31, 1878, allowing U.S. bank notes to be paid out and reissued did not make those notes legal tender (a currency that is recognized by law as legal and must be accepted in payment of debts). Second, to construe that this act did make the notes legal tender is unconstitutional because Congress does not have the power to make such a law. The case was submitted to the Supreme Court in January 1884.

Juilliard's legal representative argued that the Constitution had intended for gold and silver to be the monetary base of the new country. James Madison and other framers remembered the debacle of the continentals (bills of credit that states had issued that depreciated and lost their value) during the Revolutionary War under the Articles of Confederation and had every intention of correcting that mistake in the new Constitution. The plaintiff claimed that Article I, Section 8, of the Constitution established the federal government as sole possessor of the power to coin money. However, wartime measures revisited the U.S. Treasury in 1861, bringing back a reliance on greenbacks, which were very similar to continentals. The legal tender clauses of the acts passed in 1861, 1862, and 1863 were wartime measures enacted to preserve the Union. They were police powers that could not be justified as constitutional without the context of an extreme emergency, which did not exist in 1879, and therefore were void in peacetime. Furthermore, they concluded, printing paper money and declaring it legal tender by statute gave the Congress the ability to change the Constitution without abiding by Article V (the constitutional requirement that amendments have a two-thirds vote of both houses of Congress to propose an amendment and three-fourths of the states to ratify such proposals).

The defense stated that the defendant had followed the full faith and credit of the government. It argued forcibly that Congress had the power to make notes issued by legislative statute into legal tender without contradicting the Constitution; Article I, Section 8, Clause 18, grants Congress the power to do what is necessary and proper to ensure the functioning of the government. The defense found no error of procedure and viewed the Court's decision as necessary to establish the constitutionality of the acts in question. The responsibility of the Supreme Court in *Juilliard v. Greenman* was to determine whether or not acts of Congress issuing paper currency considered legal tender for private and public use during wartime could be considered legal tender during peacetime as well.

The Supreme Court decided this case on March 3, 1884. Justice Gray wrote the majority opinion. All the judges agreed that this case could not be separated in principle from the previous legal tender cases of *Dooley v. Smith* (1871), *Railroad Co. v. Johnson*, and *Maryland v. Railroad Co.*, which established the power of Congress to make notes of the U.S. legal tender in payment of private debts. However, Justice Field dissented for the same reasons that he had in the previous cases. Justice Gray revisited John Marshall's opinion in *McCulloch v. Maryland*, where the powers of the government are limited but not to the point where the government cannot execute its duties set forth in the Constitution. Therefore, Congress has the power to make all necessary and proper laws that are conducive toward those legitimate ends. The rule of interpretation thus laid down is what is deferred to in this case. There are no enumerated powers granting the establishment of banks or creating corporations, as these are among the powers implied in the Constitution. The Court affirmed the ruling and upheld once and for all the constitutionality of paper currency as legal tender.

When the framers left out the phrase "and emit bills" from the prohibited powers of Congress, they left it up to future generations to determine whether the power to issue paper money was best for the nation. If they found it important enough to eliminate titles of nobility, certainly they did not overlook a prohibition on printing paper currency. The men at the Philadelphia convention may not have foreseen plastic money, but they included flexibility into the Constitution to provide for a means of exchange that can adapt to it whatever the future may bring.

K

KAHN, ALFRED

Born: October 17, 1917, in Paterson, New Jersey; Died: December 27, 2010, in Ithaca, New York; Nationality: American; Professional Interests: regulation and deregulation; Major Works: *The Economics of Regulation: Principles and Institutions* (1970), *Lessons from Deregulation: Telecommunications and Airlines after the Crunch* (2004).

Alfred Kahn led the U.S. economy of the late 20th century into the era of deregulation. Kahn's career was highlighted by his efforts to deregulate what he considered the anticonsumer regulated industries of the U.S. economy. Appointed by President Jimmy Carter to head the Civil Aeronautics Board, Kahn was instrumental in deregulating the airline industry. Kahn's deregulation of the airline industry transformed air travel into a form of mass transportation with discount prices affordable to most everyone. Kahn was known for continually extolling the virtues of simpler wording to explain the law or economics. Kahn died in 2010.

Alfred Edward Kahn was born on October 17, 1917, in Paterson, New Jersey. The son of Russian Jewish immigrants, Kahn graduated from New York University when most people his age (18) were graduating from high school. He continued his graduate studies in economics, beginning at New York University and ending at Yale, where he earned his doctorate in 1942. Kahn began his career in public service in the U.S. Justice Department, Antitrust Division. He served in the army during World War II.

Following World War II, he served as chair of the Economics department at Ripon College, before moving on to Cornell in 1947. At Cornell he returned to the department chair role for the Economics department. He eventually became dean of the College of Arts and Sciences and a member of the Cornell board of trustees.

Kahn authored many books and articles in his academic career. His classic work was *The Economics of Regulation: Principles and Institutions*—a two-volume set in which he brought economics to the forefront of exploring the costs and benefits or regulation. Many of his works focused on the deregulation of industries.

Kahn reentered public service in 1974 when he chaired the New York Public Service Commission. Alfred Kahn was responsible for utility companies charging different rates for different times or seasons. Using marginal analysis theory, utility companies changed their rate charge practices in order to charge higher rates during peak times when costs were higher. This created incentives for customers to pursue alternatives and to use power during off-peak times when rates were lower. As a result, the utility companies earned revenues based on costs and consumers saved by using utilities during lower-cost, and consequently lower-priced, periods. Kahn is also credited with the telephone industry eliminating free telephone directory assistance. He also served the private sector as an expert on regulations and deregulation in the electricity, transportation, telecommunications, and utility industries.

His notoriety as a public servant reached national status when he joined the Carter administration as President Carter's economic adviser on inflation in 1978. With inflation rates as high as ever in the United States, President Carter appointed Kahn to head his Council on Wage and Price Stability. Tabbed the "inflation czar," Kahn called the job thankless and in 1980 he resigned after only 15 months in the position. He had even lamented that the only reason he was not fired was that no one else would take the job.

President Carter appointed Kahn as head of the Civil Aeronautics Board (CAB) in 1977. At the time of his appointment, the airlines industry was regulated from prices and routes down to the meals that would be served on a flight. This structure of the airline industry was viewed as very much to benefit the airlines at a cost to the consumers. Kahn put his experience in economics and deregulation to work on the industry. During 1977 and 1978, Kahn and the CAB deregulated the airline industry, freeing up routes, carriers, and prices.

Under Kahn's leadership, the CAB did such a good job in deregulating the airline industry that in 1978 the board ceased to exist. Kahn has been labeled the "father of the airline deregulation," a label he did not cherish.

While Kahn took his work very seriously, he was noted for the quick quip or quote. He once used the word "depression" when describing a potential scenario for the U.S. economy. Being ever the economist and not the politician, he was admonished for using the "d" word. So when the same topic came up again, he changed the "d" word to "banana." However, after objections from the banana industry, addressing the same issue a third time he changed "banana" to "kumquat." He was also known for sarcastically asking if an economic or law statement could be made more complicated. This attitude played directly into his continual efforts to have legal and economic policies explained in simple, understandable language.

In 1980, Kahn returned to Cornell, continuing his role as dean of Cornell's College of Arts and Sciences. He was also the Robert Julius Thorne Professor Emeritus of Political Economy. In 1997, he received the L. Welch Pogue Award for Lifetime Achievement in Aviation.

Alfred Kahn died on December 27, 2010, in Ithaca, New York.

KALDOR, NICHOLAS

Born: May 12, 1908, in Budapest, Hungary; Died: September 30, 1986, in Papworth Everard, Cambridgeshire, England; Nationality: Hungarian, naturalized English citizen; Professional Interests: political economy, Keynesian economic theory, development economics; Major Work: *An Expenditure Tax* (1955).

Nicholas Kaldor was one of the leading economists of the Cambridge School, a school of thought that promoted the Keynesian economic philosophy. He was also one of the few economists who changed views at the height of his career. Once an Austrian at the London School of Economics, he converted to Keynesian economic theory once the general theory emerged. While a proponent of the Austrian School he was a contributor to equilibrium theory and capital, but focused on welfare economics. Once a Keynesian, he altered his efforts to rates of interest and dynamics of speculation and the business cycle. Kaldor was known for his debate with Friedrich von Hayek. Kaldor died in 1986.

Nicholas Kaldor was born on May 12, 1908, in Budapest, Hungary, and attended the Model Gymnasium in Budapest. He began his study of economics at the University of Berlin. He graduated from the London School of Economics in 1930. In 1934, Kaldor became a naturalized citizen of England. He began his career as a lecturer at the London School of Economics in 1938. Kaldor moved his family to Cambridge during World War II and began a tenure with the National Institute of Economic and Social Research. In 1947 he moved once again, this time to Geneva, Switzerland, to direct research and planning at the Commission of Europe. In 1949, he returned to England to take a position of lecturer in the economics faculty at King's College of the University of Cambridge, where he remained until his retirement as professor in 1966.

Kaldor began his economics studies at the London School of Economics and the Austrian School. However, once John Maynard Keynes published his general theory, Kaldor became one of the theory's most ardent supporters, both in his development of economic theory and in his publications. He created the growth theory that became the main approach of the Cambridge School of economic thought. Kaldor's growth approach was the foundation of future economic philosophy for the neo-Ricardian and neo-Keynesian economic philosophies. As a leading voice for the new economic philosophy, Kaldor's focus shifted to the areas of growth theory and Thorstein Veblen's theory of accumulation, and he was an unwavering critic of neoclassical economics.

Kaldor developed or was very influential in the development of several postwar economic theories. Following World War II, Kaldor shifted his professional focus once again to the development of developing countries and postwar reconstruction. As a consultant to several developing countries, Kaldor concentrated on growth, monetarism, equilibrium theory, and taxation. In 1955 Kaldor wrote *Expenditure Tax,* the early efforts proposing a value-added tax. His tax structure was implemented by two of his clients: India and Sri Lanka. Kaldor's tax plan was the basis for a value-added tax. In England, Harold Wilson's Labour government implemented such a tax under the term "selective employment tax." This tax was designed to tax service-sector employment to subsidize the manufacturing sector. While the tax did not survive political scrutiny, it set the stage for future efforts to create a value-added tax base. Kaldor was also an economic policy adviser to the United Nations.

He was well known for the Kaldor-Hicks efficiency theory he developed with John Hicks in 1939, comparing the welfare of other countries. He was credited with the term "convenience yield" relative to commodity markets. In 1964, he addressed the issue of reserve currency with "commodity reserve currency" with Hart and Tinbergen. While his contributions to economics were in several different fields, his legacy is in his contributions to developing the Cambridge School and the later post-Keynesian and neo-Ricardian schools of economic thought.

In 1974, Kaldor was awarded a peerage as the City of Cambridge's Lord Kaldor of Newham. Kaldor retired in 1975, although he continued to lecture and provide advice on economic matters.

Nicholas Kaldor died on September 30, 1986, in Papworth Everard, Cambridgeshire, England.

KALECKI, MICHAL

Born: June 22, 1899, in Lodz, Poland; Died: April 18, 1970, in Warsaw, Poland; Nationality: Polish; Professional Interests: macroeconomics, political economy; Major Work: *Proba teorii koniunktury* [An essay on the theory of the business cycle] (1937).

Michal Kalecki is referred to as one of the unsung heroes of macroeconomics. He predated Keynes by three years in writing about the principles commonly known as the Keynesian theory. Both economists worked independently but came to the same conclusion—that the capitalist economy is demand determined—and both of them advocated government intervention to prevent down cycles in the economy. Kalecki did not receive earlier recognition, because his essay was published in Polish and not immediately translated to English. Consequently, the English-speaking world was unaware of his writings. Kalecki died in 1970.

Michal Kalecki was born June 22, 1899, in Lodz, Poland. Kalecki was a self-taught economist. He finished a bachelor's degree in 1917 and entered the University of Warsaw to study civil engineering, completing only one year because of military duty from 1918 to 1921. Upon leaving the military, he entered the Polytechnic of Gdansk and continued there until 1924. Negative family financial circumstances forced him to leave the Polytechnic before finishing his degree.

After five years of using his mathematical genius at private companies and writing for newspapers on topics in economics, in 1929 Kalecki began work as an economist with the Research Institute of Business Cycle and Prices (RIBCP). It was at the RIBCP in 1933 that Kalecki wrote his most famous paper concerning the theory of the business cycle. In 1937 he quit the RIBCP and left Poland.

From 1940 to 1945 during World War II, Kalecki was employed bythe Oxford Institute of Statistics (OIS) in England, writing reports for the British government. After leaving the OIS, he traveled and worked in Paris and Montreal. In July 1946, he returned to Poland to head the Central Planning Office of the Ministry of Economics but left after several months. He then was employed by the United Nations Secretariat in the economics department. He again returned to Poland in 1957, becoming the chairman of the Committee for Perspective Planning. His input was basically rejected, and he left the position in 1959.

After 1959, he focused on research and teaching, particularly on the economies of developing countries. His teaching career included appointments at the University of Oxford, the University of Cambridge, the London School of Economics, and the Warsaw School of Economics. Michal Kalecki was an adviser to the governments of Cuba, India, Israel, Mexico, and Poland.

In his 1933 work, *Proba teorii koniunktury* [An essay on the theory of the business cycle], Kalecki arrived at conclusions similar to those that John Maynard Keynes put forth in *The General Theory of Employment, Interest and Money* in 1936. Kalecki published three years before Keynes.

Much like Keynes, Kalecki was an advocate of full employment and a more equitable distribution of wealth. However, he disagreed with Keynes's view that capitalist economies are able to realize these goals. Kalecki held to a democratic, decentralized socialism. As a political economist, he developed a model of a "political business cycle." He favored central planning rather than laissez-faire capitalism. He was a reformer who favored socialism, including government involvement in economic planning.

Kalecki and Keynes came from different schools of economic thought but arrived at the same conclusion. Kalecki's theory was based on Marxism. Keynes's theory was based on Marshallian theory. Both economists began their investigations seeking the cause of massive unemployment during the Great Depression. Kalecki's contributions helped create American post-Keynesian theory.

Kalecki was not fully appreciated by his fellow economists during his lifetime. There has been a renewal of interest in his writings, with more of them being translated into English and published. By the time of his death in 1970, Kalecki's contributions to economic theory were enormous, although it appears that even Kalecki himself did not fully appreciate his contributions to macroeconomic theory. In fact, he once stated that his influence was limited only to Israel, which did exactly the opposite of what he recommended.

Michal Kalecki died on April 18, 1970, in Warsaw at the age of 70.

KELO V. CITY OF NEW LONDON, CONNECTICUT

In the United States, it is customary to think that home ownership is secure. Private property rights give good reason to trust in this assurance. In *Kelo v. New London*, 545 U.S. 469 (2005), however, the question of how secure individuals are in their right to ownership of private property was brought into question. In this case, the government's power to take private property through eminent domain was granted to a private corporation, which in turn condemned individuals' homes and leased the property to private businesses with the intended purpose of economic revitalization for the area at large.

The Supreme Court's responsibility in this case was to determine whether the reason private property was taken from individuals was within the meaning of the Fifth Amendment to the U.S. Constitution. In a close vote, the Court indicated that, indeed, New London did not violate the takings clause of the Fifth Amendment.

The majority opinion interpreted economic development as a traditional and accepted function of government. Quoting precedent cases, the majority of justices embraced acquiescence to local government—that is, the ability to have pragmatic knowledge of what was appropriate to area economies—rather that courts having such insight. However, much can be inferred from the minority opinion as well. Justice Sandra Day O'Connor foreshadowed why this case was destined to have such a lasting imprint on the American free enterprise system and its underlying premise of private property and rule of law. She warned that the ghost of condemnation would haunt all property, and that not much would prevent a government entity from replacing a single home, farm, or small business with a larger, more prosperous and tax-generating strip mall or manufacturing plant. It is one thing to give property to a railroad or utility that will be used by the public, but to give it to another private entity to create jobs and pay higher amounts of taxes is another thing altogether.

Case Summary

New London is a city in Connecticut midway between Boston and New York. It was once the second-largest whaling port in the world, and currently it is home of the United States Coast Guard Academy. New London experienced significant economic decline during the 1980s and 1990s. During this time, the government closed the Naval Undersea Warfare Center, a submarine industry that employed a large number of the area's working population. In 1990, a state agency declared New London a distressed municipality.

In 1998, a pharmaceutical company announced the development of a global waterfront research facility within the area of New London. In 2000, acting through a nonprofit private entity called the New London Development Corporation (NLDC), the city of New London adopted a wide-ranging redevelopment plan. The plan focused on a 90-acre development area adjacent to the new global waterfront research facility. The NLDC purchased the majority of the land from property owners. However, 15 property owners did not want to sell. Therefore, by means of the authority granted by the city of New London and state law, NLDC used the power of eminent domain (the ability to take private property for public use) to acquire the remaining property.

The NLDC began taking these properties through condemnation (the process of taking private property through the power of eminent domain), which is generally understood to be for public use, such as building a school, road, or a utility. The power of eminent domain allows governmental entities to take properties from homeowners as long as the homeowners are granted due process and just compensation. The Fifth Amendment to the U.S. Constitution, as well as the Connecticut State constitution, authorizes the power of eminent domain. Condemnation is not unusual where the property being taken is deteriorated or in poor condition. This was not the case in New London. Instead, these maintained homes were to be taken by the NLDC, a private entity, for the benefit of private developers in an effort to create jobs and increase tax revenue for the city of New London. The NLDC would own the land within the development area and would contract leases with private developers, which would be required to comply with the development plan that had been approved by city and state governments. In summary, the government's power to take private property was in the hands of a private corporation, which then leased this property to private businesses for them to carry out a plan with the intention of benefiting the public at large.

Susette Kelo was among the owners whose property was condemned by the NLDC. These property owners sued New London in state court to stop the city from seizing their property. The petitioners alleged that the taking of their properties violated the public use requirement of the Fifth Amendment. They argued that an economic redevelopment project does not qualify as public use, because private parties will own most of the condemned property. The Connecticut Supreme Court held that economic development was a valid "public use" because the local legislature, when granting the power of eminent domain, determined the "taking" was reasonably necessary to implement a plan that increased tax revenue and created jobs, and would improve the neighboring economy. The Connecticut Supreme Court upheld the legislature's rationale and ruled in favor of New London. The homeowner petitioners appealed to the U.S. Supreme Court and were granted *certiorari* (a request by the Supreme Court to the lower court for the files of the case to be sent up for review).

The petitioners claimed that the decision by the Connecticut Supreme Court to uphold the NLDC's use of eminent domain as public use could not include the development of land for private economic purposes. Furthermore, the petitioner argued that because the character of these takings would not produce immediate public benefit, the Court should establish a more inquiring test that entailed some degree of realistic assurance that the condemned properties would actually be put to public use. This could be demonstrated through contracts or state guarantees, among other things.

In 2004, *Kelo v. City of New London* was argued in the U.S. Supreme Court. In 2005, the Rehnquist Court returned a 5–4 opinion delivered by Justice John Paul Stevens in favor of New London. The majority held that the city's taking of private property to sell for private development qualified as a "public use" within the meaning of the takings clause of the Fifth Amendment. The Court held that New London was not taking the land to benefit a certain group of private individuals, but rather to benefit the community as a whole. As long as a clear economic development plan was followed, the process did not violate the Constitution. The majority opinion stated that this expansive interpretation of public use as public purpose was inferred in the Fifth Amendment and did not require a literal interpretation. The majority opinion explained that among other things, promoting economic development is a time-honored and accepted function of government.

In the minority opinion, Justice Sandra Day O'Connor stated that the Fifth Amendment's takings clause was violated in the New London case. She said there was no interpretation except the literal application of the words "public use." In addition, the minority opinion expressed the belief that taking a private citizen's property to sell to private investors was not for "public use" but rather for corporate profit. In Justice O'Connor's opinion, by the Court ruling in favor of New London, the citizen lost any effectual check on the power of eminent domain.

KYDLAND, FINN

Born: December 1, 1943, in Algard, Norway; Nationality: Norwegian; Professional Interests: business cycles, monetary policy, fiscal policy, labor economics, Nobel Prize (2004); Major Works: *Inflation Persistence and Flexible Prices* (2001), "Argentina's Recovery and 'Excess' Capital Shallowing of the 1990s" (2002), "Inflation Persistence and Flexible Prices" (with Robert D. Dittmar and William T. Gavin) (2005).

Finn Kydland is a notable economist whose primary interests are business cycles, monetary and fiscal policies, and labor economics. Kydland was awarded the 2004 Nobel Prize in Economics with his former adviser and fellow colleague, Edward C. Prescott. Their work in macroeconomics, particularly the time consistency of economic policy and the driving forces behind business cycles, has influenced the monetary and fiscal policies of several governments, including the United Kingdom and New Zealand, and has helped to encourage the independence of many central banks.

Finn Erling Kydland was born on a farm in Algard, Rogaland County, Norway, on December 1, 1943. He was the only pupil in his elementary school full of farm children to go past elementary school. At 15, he left for Bryne and rented a room to go to Rogaland, the closest high school. He received high grades, but originally the Norwegian School of Economics and Business Administration (NHH) rejected him. He taught mathematics to sixth and seventh graders while studying for a supplementary exam in economics, law, and business correspondence in English, German, and French. The following year, he attended NHH, receiving his BS in 1968.

He then attended Carnegie Mellon University in Pittsburgh, where he obtained his PhD in 1973. Kydland served as a professor of economics at NHH until 1978. In 1978, he taught at the Tepper School of Business of Carnegie Mellon University until 2004.

Kydland completed his earliest works, on economic fluctuations, while a student at the Graduate School of Industrial Administration (GSIA). There he studied under future Nobel laureate Robert Lucas Jr., who received the Nobel Prize for "Expectations and the Neutrality of Money," a paper he developed while teaching a class Kydland had taken. Kydland's first paper, "Duality in Fractional Programming," combined shipbuilding and mathematical programming and was published in *Naval Research Logistics Quarterly*. His second paper continued on with dual prices in conjunction with hierarchical linear programs and was published in *Management Science*. Kydland claimed that if the right instruments were assigned to the right targets, the economy would function quite well. If the target was incorrect, then problems would result and the economy would not function properly.

In Kydland's view, fiscal and monetary policymakers have different goals and as a consequence the target variables of the objectives function with different relative weights. Kydland saw fiscal policymakers as leaders and monetary policymakers as secondary. His theory was innovative because it was an alternative to the symmetric noncooperative solution developed earlier by John F. Nash. The theory laid the foundations for his future work with Prescott.

Together, Kydland and Edward C. Prescott shaped dynamic economics by explaining how supply shocks are leading reasons for economic fluctuations. They were also able to show why the best government economic policies are often not implemented consistently over time. This helped them to explain microeconomic, supply-side influences on the business cycle, integrating theories of business cycles and of long-term economic growth. Kydland and Prescott showed, for example, that political commitments to keep inflation low can lead investors to expect low inflation and unemployment rates. If policymakers decide, to the contrary, to reduce interest rates in order to take advantage of short-term gains in employment rates and general prosperity, they risk losing credibility. In fact, economic conditions may even worsen because of the discretionary policy.

Kydland's "Inflation Persistence and Flexible Prices" was published in 2005. His thesis is that when central banks follow an interest rate rule, then inflation will likely persist, even when prices are fully flexible. He argues that inflation persistence may result from any shock, whether persistent or not. Hence, in equilibrium, the real driver behind the dynamics of inflation is the evolution of the spread between the real interest rate and the central bank's target.

Finn Kydland has been a fellow in the Econometric Society since 1992. He received the John Stauffer National Fellowship from Hoover Institution in 1982–1983 and the Alexander Henderson Award of Carnegie Mellon in 1973. He is a member of the Norwegian Academy of Science and Letters, and he received the 2004 Nobel Prize in Economics. Since 2004, Kydland has served as a faculty member of the University of California, Santa Barbara, and has founded the Laboratory for Aggregate Economics and Finance. He is a senior research fellow at the IC2

Institute at the University of Texas, Austin, and is an adjunct professor at the NHH. Kydland also has served as a research associate for the Federal Reserve Banks of Dallas, Cleveland, and St. Louis.

LABOR FORCE

The *labor force* is made up of persons at least 16 years of age who are willing and able to work. It excludes those who are incapable of working and those not looking for work, as well as those in the armed forces or those who are institutionalized. The labor force is directly affected by the economy and economic conditions.

During the Great Depression, the unemployment rate was as high as 25 percent, as millions of people were out of work. Yet they continued to seek employment, and so they were counted as part of the labor force. Many workers had given up and stopped looking for work. They were labeled "discouraged workers," and because they stopped looking for employment they were not counted as part of the labor force. The involvement of the United States in World War II increased the demand for workers, stimulated the economy, and increased the size of the labor force, as many people began looking for employment again.

One significant impact on the U.S. labor force was the baby boom generation coming of age. In the 1970s, there was a marked increase in the labor force as the baby boomers reached working age and began to look for work. In the 2000s, the United States experienced a reversal and decline in the labor force with the aging of the baby boomer population. As the baby boomers retire, there will be significant effects on the labor force and a marked decrease in the growth of the labor force. It is estimated by the year 2020, people 55 years of age and older will account for less than 25 percent of the labor force (Toossi 2006).

The number of women in the labor force has also fluctuated over the years. In the 1950s, the percentage of women in the labor force was significantly low. Men had returned from World War II, and as a result, women went back into the home after working in factories producing war-related goods. Women's labor participation rates increased steadily in the 1970s and 1980s and led to a growth in gross domestic product (GDP). Women's labor force rates had leveled off by the end of the 1990s and fluctuated around 59 to 60 percent. It is anticipated that in the future, this rate will continue to decline and will be lower than that of men.

Those aged 24 to 54 have the highest labor participation rates (Toossi 2006), and are considered prime-aged workers. This group generally has labor force rates of 80 percent or higher, and it is expected that this trend will continue in the future. (Labor participation rate is a measure of the labor force as a percentage of the total population at least 16 years of age.)

The increasing ethnic and racial diversity of the United States is expected to account for increases of these groups within the labor force. In the future, Asians and Hispanics are expected to increase the population, as well as the labor force and labor participation rate. Both Asians and Hispanics have high labor participation rates that will add to the labor force in the coming years. Blacks will also continue to add to the labor force with higher birth rates and high participation rates among women.

The Bureau of Labor Statistics (BLS) publishes labor force projections every two years, assuming full employment at 5 percent unemployment (or 95 percent employment). These reports estimate labor force participation rates based on the age, race/ethnicity, and gender of the population. Demographics and changes within the population affect the labor force as well as the types of unemployment the economy is experiencing. It appears that changes within the labor force are a direct result of a changing population. The BLS also analyzes the growth rate of the civilian noninstitutional population, which seems to have maintained a steady growth rate of around 1 percent.

In the 1980s, the term *discouraged worker* was revised to mean someone who has stopped looking for work because the person believes no jobs are available. Discouraged workers are not counted in the nation's unemployment rate; if they were, unemployment rates would be slightly higher than the published rates provided by the BLS. Age, gender, and race play a factor in how long a person remains a discouraged worker before trying to reenter the workforce.

The business cycle and cyclical changes within the economy also impact the labor force. As the economy expands, the labor force increases, and as the economy declines, the labor force decreases.

Today, the labor force is still an indicator of economic health and growth. In the future, the labor force participation rate is expected to decrease due to the retirement of the baby boomers, lower fertility rates, and a decrease in immigrants.

LABOR FORCE PARTICIPATION RATE

The *labor force participation rate* (LFPR) measures the active portion of people in an economy's labor force. The *participation rate* refers to the group of individuals who are of working age and are either currently employed or actively seeking work. This is the civilian noninstitutional population that is ages 16 and over and is working or looking for work. This element is critical to the calculation of the unemployment rate, as it captures those workers who are steadily trying to obtain employment but are unable to secure a job. The *unemployment rate* is the ratio of the number of unemployed people to the sum of the number of employed and unemployed people, according to the Bureau of Labor Statistics survey.

The *labor force* is the compilation of both employed and unemployed persons. *Employed* persons are people who work for pay or profit, people who did at least 15 hours of unpaid work in a family-operated enterprise, and people who were temporarily absent from their regular jobs due to illness or vacation, or for other personal reasons. People are considered *unemployed* if they do not have a job, have actively looked for work in the prior four weeks, and are currently available for work. Unemployed workers also include those who may have been temporarily laid off from a job and are waiting to be recalled to that job. Just because someone receives Unemployment Insurance (UI) does not necessarily mean that person a part of the Unemployed classification.

Individuals not in the labor force include retirees, students, those who are the primary caregivers of children or other family members, and everyone else who is not working or not seeking work. An important category of Unemployed to consider when determining the LFPR is *discouraged workers*. These individuals are not in the labor force although they are available for work but they may or may not want to do so. These workers have looked for a job sometime within the past 12 months but were not counted as unemployed because they had not searched for work in the 4 weeks leading up to the survey responsible for reporting this data. This group of individuals is growing, as many college graduates finish college but spend quite some time looking for a job that uses their newly acquired skills.

Since the Great Recession of 2008, and the slow recovery afterward, there has been a sharp decline in the labor force. Some of the decrease may be a result of long-term demographic trends and other factors that had an impact on the LFPR prior to 2007. There has been a significant withdrawal of prime-age workers from the labor market that is unprecedented and may indicate a cyclical component that could reverse as the labor market recovery continues. If these workers return, it may offset some long-term effects and increase the participation rate. This could lead to an increase in the number of job-seekers and temporarily increase the of the unemployment rate. The LFPR had fallen to its lowest rate since 1978 at 62.7 percent.

The labor force decline was attributed mainly to the retirement rate of baby boomers and the expansion of social programs. Researchers believe the drop in the LFPR disguises exactly how many people are unemployed and are not accurately represented in the unemployment rate.

LABOR PRODUCTIVITY

Labor productivity is considered to be a major economic indicator and a key determinant in defining a business or economy's success. *Labor productivity* is the measurement of output in relation to labor hours used in the production of a given output. Labor productivity measures the amount of real gross domestic product (GDP) produced by an hour of work. In more simple terms, labor productivity measures how efficient workers are relative to their output. Labor productivity is viewed from both a business standpoint and in terms of macroeconomy. To determine labor productivity, total output is divided by total productive hours.

GDP is generally used as the measure of total output. Labor productivity has been an accurate measurement of the U.S. economy's performance, remaining low during depressions and recessions and high during periods of economic growth. Interestingly, during the Great Recession labor productivity actually rose while GDP dropped significantly.

The Bureau of Labor Statistics produces labor productivity and costs measures for sectors of the U.S. economy. The Major Sector Productivity publishes both quarterly and annual measures of output per hour and unit labor costs for these sectors: U.S. business, nonfarm business, manufacturing, durable manufacturing, nondurable manufacturing, and nonfinancial corporate. These measurements are commonly used and cited by national media.

Businesses use labor productivity to justify the amount of money workers are earning to perform a job in relation to their output. From a business perspective, these measurements are used to make sure the business is performing at a rate that is competitive relative to its competition. This measurement can be useful for pinpointing a company's weak areas in terms of revenue and profits. Labor productivity can sometimes be improved through better equipment and technology. Increasingly popular methods of raising worker productivity are for companies to offer ongoing training and education and better work environments to increase overall performance. These offerings increase employee morale and make employees more committed to the company. Increased human capital through education, technology advances, and improved physical equipment increase labor productivity.

Labor productivity data is a key measure of output efficiency and standard of living. It is also used by countries to measure economic growth and to determine the amount of goods and services that can be anticipated from one hour of labor. A country's labor productivity is a function of technological innovation, labor resources, and capital investment.

LABOR UPRISINGS, 1936–1939

The 1930s was a decade of economic turmoil in the United States on all fronts. The National Labor Relations Act, or Wagner Act, named after Senator Robert Wagner of New York, was the cornerstone of President Franklin D. Roosevelt's New Deal social legislation. This act changed the very landscape of labor in the United States in hopes of avoiding widespread social unrest during the Great Depression. Roosevelt also hoped that higher wages would improve the economy, which had slipped into recession in 1936. The Wagner Act would usher in a wave of unionization in the steel, automotive, rubber, mining, and electrical industries. At the start of the 1930s, less than 10 percent of America's labor force was unionized; after the 1935 passage of the Wagner Act, the decade ended with 35 percent of the labor force unionized. The act changed the role of government in labor policy. The act declared that democracy must apply in the workplace and that the means to this democracy was the right of workers to organize and bargain collectively through employee representatives. The act established a National Labor Relations Board (NLRB) to implement and oversee the Wagner Act.

The labor movement had been stalled by 1935 when the Committee for Industrial Organization (CIO) was formed to take on U.S. companies. The CIO was in its embryonic stages of bringing together eight international unions under the guidance of John Lewis. It was clear that unions would have to move from a crafts model to an industrial model. Skilled and unskilled laborers would have to unite under one union. Solidarity was needed, which required opening membership to all workers of all races. Unions had rallied under Roosevelt in 1933, but strikes proved unsuccessful except against the mining industry. After much blood and violence, the miners won recognition for their union by the mining companies. They came together in solidarity, offering the core model to expand the CIO.

The highly concentrated rubber industry in Akron, Ohio, offered the best hope for unionization under the new Wagner Act. By the end of January 1936, small sit-down strikes hit Firestone, Goodrich, and Goodyear. Small victories were won on a departmental basis. By February, the union was ready for a more traditional strike at the heart of the anti-union movement: Goodyear. If Goodyear fell, so would the whole industry. The strike this time blew up at Goodyear Plant No. 2, where hundreds of picketers blocked the gates and prevented management replacements and supporters from entering and continuing production.

The new union lacked structure and discipline, but the strike dragged on for five weeks. Akron police tried to avoid violence but could do little else in the face of thousands of workers. Shanties were set up and called "Fort Roosevelt." Fistfights were common as replacement workers tried to cross picket lines, and the local police were overwhelmed by the daily fights that broke out. Both sides seemed to use force when they felt it necessary. Food was brought in by U.S. Postal trucks sent by management to feed strikebreakers, as only government vehicles were allowed through the picket lines.

Eventually, government negotiators broke the standoff, and the union claimed victory but did not achieve real recognition of the union. The five-week struggle ended with mixed results. The union did win a six-hour day, which was cause for much celebration in the streets of Akron. The strike had also destroyed support for the Industrial Assembly company union. The union victory at Goodyear boosted the membership in the United Rubber Workers union throughout Akron, and the union strengthened its resources by joining the CIO that summer. The battle for unionization moved to the Gadsden, Alabama, Goodyear plant, which became the next focus of the union fight. The CIO was strengthened, however, and would gain recognition in the rubber industry by 1940.

Within a year of the rubber strike, the Steel Workers Organizing Committee (SWOC) of the CIO evolved. On January 1, 1937, United States Steel accepted a one-year contract with the SWOC that included union recognition, a 40-hour workweek, time-and-a-half pay for overtime, holiday pay, a week's vacation, and a $5-a-day wage. Other industrialists thought United States Steel was selling out, and a national strike against the other companies raged in 1937. The strike reached a peak at Republic Steel's South Chicago Plant, where in one day 10 workers were killed (seven shot in the back) and more than 50 wounded by police; overall, 16 people died in the strike, 10 workers and 6 police. Strikers also died at plants. This bloody strike (far bloodier than the 1937 Homestead strike had been) ended in acceptance of the United Steel Workers union throughout the steel industry. Thus, in 1937, the first industrial union was fully developed.

The key to the union's success was a secret ballot to decide whether to unionize under the auspices of the NLRB. Since the passage of the Wagner Act, there have been more than 360,000 secret ballot elections. Initially, the NLRB had five members appointed by the president with Senate oversight. Early on, employers and the American Federation of Labor, which argued that CIO unions were favored, questioned the neutrality of the NLRB. Neutrality has proved difficult over the years. The Wagner Act had many critics; but in the end, the Supreme Court upheld it as constitutional in 1937 in *NLRB v. Jones & Laughlin Steel*. The argument over individual choice on whether to join the union continued, and President Roosevelt attempted to counterbalance the actions of some of the extreme activist union supporters who wanted to expand the intent of the act.

LAFFER, ARTHUR

Born: August 14, 1940, in Youngstown, Ohio; Nationality: American; Professional Interests: fiscal policy, political economy; Major Works: *Foundations of Supply-Side Economics* (with Victor A. Canto, Douglas H. Joines, Paul Evans, Marc A. Miles, and Robert I. Webb) (1983), *End of Prosperity: How Higher Taxes Will Doom the Economy—If We Let It Happen* (with Stephen Moore and Peter J. Tanous) (2008), *Return to Prosperity* (with Stephen Moore) (2010).

Arthur Laffer is one of the few economists whose work became a namesake and foundation for a whole school of economic thought. The supply-side philosophy of economics laid the foundation for what was to become the Reaganomics of the 1980s. Supply-side economics underscored that lower tax rates would generate higher tax revenues. With this thesis, Laffer influenced business, government, and academic worlds. Laffer served the United States in several positions, including consultant to Treasury Secretaries William Simon and George Shultz, chief economist for the Office of Budget and Management for George Shultz, and consultant to President Reagan's Economic Policy Advisory Board. Laffer was a founding member of the Congressional Policy Advisory Board. Arthur Laffer held academic positions at Pepperdine University, University of Southern California, and the University of Chicago.

Arthur Betz Laffer was born on August 14, 1940, in Youngstown, Ohio. After receiving his BA with a major in economics from Yale in 1963, he earned an MBA from Stanford University in 1965 and a PhD from Stanford in 1972. In 1967, he began his academic career by joining the faculty at the University of Chicago. In

1976, Laffer left for the University of Southern California where he was the Charles B. Thornton Professor of Business Economics. In 1984, he joined the faculty of Pepperdine University where he remained till 1987.

Laffer's career in the political arena began in 1970 when he served as chief economist for the Office of Budget and Management under U.S. Secretary of the Treasury George Shultz, a colleague of his at the University of Chicago. From 1972 to 1977, he served as a consultant to Treasury Secretary George Shultz as well as to U.S. Secretary of Treasury William Simon and Defense Secretary Ronald Rumsfeld. In the 1980s, Arthur Laffer's economic-political influence heightened when he served on President Reagan's Economic Policy Advisory Board from 1981 to 1989. His association with President Reagan began in 1980 as a member of then presidential candidate Ronald Reagan's Executive Advisory Committee. During the 1980s, he was also a consultant to U.K. Prime Minister Margaret Thatcher.

Using the Laffer curve illustration as a teaching tool in his classes, he showed that at some level of tax rates, government would generate less revenue by creating disincentives to be productive through labor and more incentives to barter, participate in an underground economy, or just enjoy leisure. Consequently, these disincentives would then reduce tax revenues.

While this relationship between tax rates and tax revenues has become known as Laffer curve, Laffer himself never made any claim that the tax rates-tax revenues relationship was an original insight. He credited Ibn Khaldun and John Maynard Keynes as early architects. In the mid-1770s, both Adam Smith and David Ricardo made similar arguments.

Acceptance of the Laffer curve premise has not been universal. While there has been some research to identify tax rate ranges at which the tax rate-tax revenue relationship turns negative, there is also significant criticism of Laffer's illustration. Nobel laureates John Kenneth Galbraith and Paul Krugman both criticized Laffer's approach on the basis of equity and fairness. Others have criticized Arthur Laffer's description as too simplistic, while others attacked the theoretical, claiming the economy and consequently tax revenues would not totally be eliminated at a tax rate of 100 percent. Regardless of the criticisms, supply-side economics was the basis for the Kemp-Roth Tax Cut of 1981 and both the Economic Growth and Tax Relief Reconciliation Act of 2001 and Jobs and Growth Tax Relief Reconciliation Act of 2003 (the "Bush tax cuts").

Arthur Laffer has authored several books and many articles on business economics and the political economy. In 1971 Laffer authored *Private Short-Term Capital Flows*. In 1983 Laffer—with Victor Canto, Douglas Joines, Paul Evans, Marc Miles, and Robert Webb—laid the foundations for supply-side economics with *Foundations of Supply Side Economics: Theory and Evidence*.

As an author Laffer is noted more for his recent works: *End of Prosperity: How Higher Taxes Will Doom the Economy—If We Let It Happen* (2009) with Stephen Moore and *Return to Prosperity* (2010) with Stephen Moore and Peter Tanous.

Laffer received many awards and honors during his career. In 1999 he was recognized as one of "The Century's Greatest Minds" for the Laffer curve. He received several Graham and Dodd Awards from the Financial Analyst Federation, the National Association of Investment Clubs Distinguished Service Award, and the Adam Smith Award.

LAFFER CURVE

Supply-side economists often use the Laffer curve, named after the economist Arthur Laffer (b. 1940), to illustrate the effects of tax rates on tax revenue. The Laffer curve shows the relationship between the tax rate set by the government and the total tax revenue that the government collects. The total revenue depends on both the tax rate and the health of the economy. The Laffer curve illustrates that high tax rates may not bring in much revenue if these high tax rates cause economic activity to decrease.

Suppose the government imposes a tax on the wages of workers. If the tax rate is zero, the government will collect no revenue. However, with no taxation, the economy will prosper. As the government raises the tax rates, it starts to collect some revenue. According to Laffer, as the tax rate increases, government revenue will also increase to a certain point, known as the revenue maximizing point.

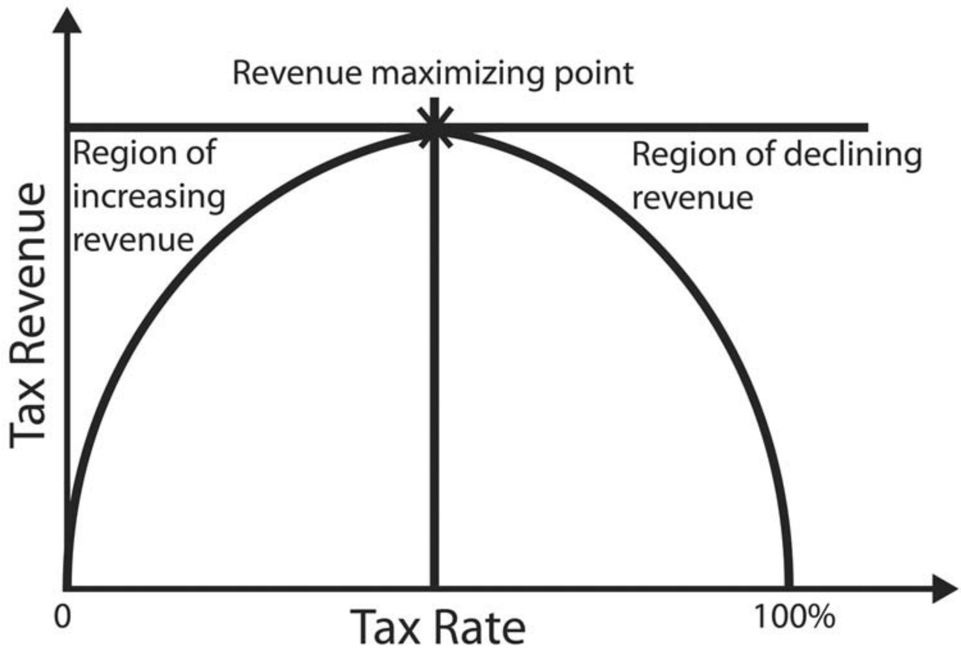

Figure 1. With the Laffer curve, Arthur Laffer proposed that high tax rates will result in lower government revenue

Even though higher tax rates do discourage some people from working as many hours as possible, the net effect of a higher tax rate and a slightly lower tax base is an increase in revenue to a certain point. However, any point along the curve to the right of the revenue-maximizing point illustrates the negative effects of increased taxation. Once the tax rate surpasses the revenue-maximizing point, the decrease in workers' efforts is so large that the higher tax rate actually decreases total tax revenue. Another effect of the higher tax rates is on companies and their unwillingness to invest and increase production due to more spending on taxation. In effect, the high rates of taxation will eventually discourage so many people from working and businesses from investing that the tax revenues will fall sharply. In the most extreme case, at a 100 percent tax rate, no one would want to work and the government would collect no revenue.

Laffer Curve in Practice

Arthur Laffer's theory has not been widely accepted by economists, even though the relationship between tax rates and tax revenues he proposed appeared logical in theory. One major issue that economists point to is the ability to actually find the extreme levels of tax rates Laffer suggests (i.e., the highest point on the curve in which tax revenues begin to decline as tax rates increase). From 1945 to 1960, the top marginal income tax rates were in the 90 percent range. From 1965 to 1980, they were lower, but still high—in the 70 percent range.

By 1980, Arthur Laffer's curve had caught the attention of presidential candidate Ronald Reagan. An integral component of candidate Reagan's platform was cutting tax rates, à la the Laffer curve. Candidate Reagan campaigned on the issue that the current high income tax rates discouraged employment. His remedy was to follow the ideas of Laffer and lower tax rates to provide incentives for employment, and by extension increase human dignity and government revenues. Between Laffer's economic focus and Reagan's political focus on increasing the incentives by which individuals would participate in the labor force and the supply side of the economy, the theory became the basis for what would become supply-side economics.

Even though debates continue over the economic theories of the 1980s and the Laffer curve, the general consensus is that the implementation of major income tax cuts is favorable overall. To evaluate Laffer's theory would be impossible, since one would need to rerun history without the tax cuts to see if tax revenues would have been higher or lower.

However, most economists agree that a relationship between tax rates and government revenues exists, and it's likely that additional government revenues are generated when tax rate cuts occur for those in the highest tax brackets. The Laffer curve also creates a standard measurement of tax rates throughout the world, and nations can use it to increase or decrease their income tax rates accordingly.

LEADING ECONOMIC INDICATORS

A business cycle occurs because of fluctuations in an economy, and it demonstrates periods of expansion and contraction. Understanding business cycles is essential to discerning where the economy is and where it is heading. When the economy is in an unfavorable position or heading toward one, fiscal or monetary policy tools are sometimes implemented to change its course. Economists are able to determine the health of the economy, or the future economy, by examining economic indicators.

There are three classifications of economic indicators: coincident indicators, lagging indicators, and leading indicators. Coincident indicators run in sync with the business cycle and include indicators such as gross domestic product (GDP), industrial production, and personal income. Lagging indicators follow changes in the business cycle and include indicators such as average duration of unemployment, ratio of consumer debt to personal income, changes in labor costs, and short-term interest rates. Leading indicators indicate or signal future changes in the economy and are therefore the most widely followed.

Leading economic indicators are statistics published by government agencies, nonprofit organizations, and private agencies that predict recessions and expansions in the business cycle. Statistics are used by investors, businesses, and government agencies in anticipating the future condition of the economy. Investors analyze indicators in creating investment strategies. Business leaders analyze indicators to make staffing decisions, plan inventories, evaluate new business opportunities, and forecast the price and availability of raw materials. Government officials use indicators to guide economic policy decisions. The main statistical reporting agencies in the United States are the Bureau of Economic Analysis, the United States Census Bureau, and the Bureau of Labor Statistics.

The Conference Board (a global, independent business membership and research association) publishes composite averages for 10 of the published indicators in The Conference Board Leading Economic Index (LEI), which is designed to signal future peaks and troughs in the business cycle. The index is constructed by averaging its individual components in order to smooth out the volatility found in the individual data. In theory, three consecutive months of declines of Leading Economic Indicators signals an upcoming recession.

The Conference Board LEI has 10 components:

1. average weekly hours of manufacturing workers,
2. average weekly initial claims for unemployment insurance,
3. manufacturers' new orders for consumer goods and materials,
4. vendor performance diffusion index,
5. manufacturer's new orders for nondefense capital goods,
6. building permits for new private housing units,
7. stock prices and S&P 500 common stocks,
8. the Leading Credit Index,
9. interest rate spread (10-year Treasury bonds less federal funds), and
10. the Index of Consumer Expectations.

Average weekly hours of manufacturing workers is a measure of labor demand and shows how employers respond to the business cycle. It measures time on the job, including straight and overtime hours, of all full and part-time workers. If demand is beginning to slow down, employers will reduce worker's hours before making layoffs. If the slowdown deepens, employers will be forced to lay off workers, which will show a more significant trend of reduced production and increased unemployment. If the economy is expanding, employers generally will increase hours of current workers prior to hiring new ones. This signals a trend toward increased output. Average weekly hours (manufacturing) data is published monthly by Bureau of Labor Statistics.

Average weekly initial claims for unemployment insurance is a measure of applications for state jobless benefits made by unemployed individuals, which signals a trend toward future layoffs. This indicator is considered highly sensitive to business conditions compared with other employment data. When using this indicator for the LEI, the Conference Board reverses the value from positive to negative because the relationship between initial claims and job loss is inverted. The data is a good indicator of the health of the U.S. labor market and is released weekly by the U.S. Department of Labor.

Manufacturers' new orders for consumer goods and materials measures changes in orders for consumer goods, which indicate changes in actual production. If orders decrease, then future production will decrease as well, which indicates future trends in output and unemployment. The Bureau of Economic Analysis uses this data to estimate future GDP. The Federal Reserve Board and the Department of the Treasury use the data to formulate monetary policy. The index is reported monthly by the U.S. Census Bureau and includes 4,300 reporting companies with $500 million or more in shipments and a sampling of smaller companies.

Vendor performance diffusion index measures the amount of time it takes vendors to deliver inputs to industrial companies. Deliveries taking longer indicate an increase of demand for production goods. When this index increases, it indicates that future production will also increase. The data is gathered through a survey from the National Association for Purchasing Managers and is reported monthly.

Manufacturers' new orders for nondefense capital goods is the counterpart to Manufacturers' new orders for consumer goods, and it includes orders for capital goods used by firms in production. This data is reported monthly by the U.S. Census Bureau.

Building permits for new private housing units provides data on the amount of new housing authorized, but not started. This data provides an indication of future construction activity. The Federal Reserve Board uses this indicator to analyze economic conditions, the Department of Housing and Urban Development uses it to evaluate housing needs and programs, and financial institutions use it to forecast future mortgage demand. The index is published monthly by the U.S. Census Bureau.

The *Standard & Poor's 500* is an index of publicly traded stocks that is designed to measure changes in stock prices. It measures the nation's stock of capital and it can indicate confidence levels of businesses and consumers. A growth of the index may indicate growth of business investment and consumer spending. A declining index may indicate reduced spending on the part of both business and consumer. Information on the index is available in real time from financial news organizations and is published by Standard and Poor.

The Leading Credit Index is compiled from six financial indicators:

1. The 2-year Swap Spread measures the creditworthiness of banks.
2. The LIBOR 3 month less 3 month Treasury-Bill spread measures liquidity and funding conditions of banks.
3. The Debit balances at margin account at broker dealer measures the willingness and ability of speculators to leverage their bets on financial markets.

4. The AAII Investors Sentiment Bullish (%) less Bearish (%) measures how much risk a retail investor is willing to take.
5. The Senior Loan Officers C&I loan survey-Bank tightening credit to large and medium firms indicates the availability of credit.
6. The Security Repurchases from the Total Finance-Liabilities section of the Federal Reserve's flow of fund report is an indicator of activity in the shadow-banking industries (institutions that carry out banking functions outside the traditional banking system).

The Leading Credit Index measures the availability and cost of credit and institutions' willingness to borrow or lend. As the availability of credit in the market decreases, so does growth and investment.

The *interest rate spread* is the difference of interest rates on long-term investments (10-year Treasury bonds) and short-term investments (federal funds rate). This index gives some indication of the stance of the monetary policy due to the fact that the Federal Reserve Board has some control of the federal funds rate and it rises when short-term rates are low and falls when short-term rates are high. A rise in this index indicates that the economy may be expanding, and a fall indicates when the economy will be contracting. This index is a strong indicator of future recession when it is negative.

The Index of Consumer Expectations is compiled from the Consumer Expectations for Business Conditions 6-months ahead survey of 5,000 households, conducted by the Conference Board, and Consumer Expectations for Economic Conditions 12-months ahead, conducted by Reuters/University of Michigan. This index measures consumers' confidence in the future of the economy, which demonstrates spending and saving activity.

LECHMERE, INC. V. NATIONAL LABOR RELATIONS BOARD

Private property is fundamental in a free enterprise economy. *Lechmere, Inc. v. National Labor Relations Board*, 502 U.S. 527 (1992) is about balancing the private property rights of employers with the rights of their employees in the process of deciding to join a union. In a capitalist system, when private property rights are secure, competition is defined by peaceful means and guided by the rule of law.

In 1935, to maintain this balance, Congress passed the National Labor Relations Act (NLRA). Section 7 of the act established an employee's right to join a union and take part in collective bargaining, as well as establishing an administrative board (the National Labor Relations Board, or NLRB) to enforce all requirements thereof. Congress deferred any ambiguity within the act to the NLRB for final resolve. In the *Lechmere* case, the Supreme Court changed this default setting from the rule of deference to Court-based adjudication favoring the protection of private property rights.

Case Summary

In the United States, property rights are considered human rights. In the Declaration of Independence, Thomas Jefferson referenced this thought as people's right to life and freedom and to be secure in their property. *Lechmere, Inc. v. National Labor Relations Board* (NLRB) was concerned with balancing the private property rights of employers with the rights of their employees in the process of deciding to join a labor union. This balancing act is key if there is to be equity on both sides of the bargaining table. Nonetheless, there remains inequality in a free market economy. In the view of Adam Smith, a few owners could combine much more easily to gain an advantage in bargaining power in the marketplace over the multitude of workers. The result is inequality of bargaining power. This delicate balance is critical in perpetuating a healthy marketplace for both owners and laborers.

The Cohen family started Lechmere, Inc., in 1913 in the Boston area. One of the first large discount stores, Lechmere grew rapidly in the 1950s and 1960s. In the late 1980s, it opened a retail store in a shopping mall in Newington, Connecticut. The company owned part of the parking lot and 4 feet of the 46-foot grassy barrier between the parking lot and the Berlin Turnpike. The store had more than 200 employees, most of whom parked in that lot. Lechmere maintained a no-soliciting policy that pertained to everyone from Salvation Army bell ringers to the Girl Scouts.

In June 1987, the United Food and Commercial Workers International Union (UFCW) began a campaign to organize the workers at Lechmere. While the history of the UFCW began in 1979, the history of the retail industry organizing in the United States began much earlier. In the late 19th century, retail employees earned perhaps $10 per week, and 80-plus-hour workweeks were not uncommon. Toward the turn of the century, the Retail Clerks National Protective Union joined with the American Federation of Labor, later to become the UFCW. The UFCW struggled for better working conditions with fair hours and equal pay. It was the first to establish the principle of overtime pay for anything over 63 hours worked in a week.

The UFCW's campaign to organize Lechmere's retail store in Newington included using strategies to communicate meeting times and union information to employees. The parking lot allowed the union organizers within 4 feet of the employees' vehicles. It also allowed nonemployee organizers to picket in the grassy area with signs indicating union meetings. Furthermore, union organizers recorded the license plates of workers' vehicles to obtain addresses for mailing information. The nonemployee organizers placed ads in *The Courant*, a local newspaper. From the union's point of view, all of these attempts were not enough.

Union organizers circulated handbills in the parking lot to reach employees more directly. Lechmere company representatives asked the organizers to leave; when they returned, Lechmere called the police to enforce the city's no-soliciting law. In response, the UFCW filed an unfair labor practice charge with the NLRB, claiming that Lechmere violated Section 7 of the NLRA, which establishes an employee's right to join a union and participate in collective bargaining activities. The NLRB joined the union as correspondent in an appeal to an administrative law judge, who held that the co-petitioners could not be banned from the parking lot. Lechmere appealed to the U.S. Court of Appeals for the First Circuit. When the appellate court affirmed the NLRB's ruling, Lechmere appealed to the Supreme Court and was granted a hearing on certiorari (a request by the Supreme Court to the lower court for the files of the case to be sent up for review).

The *Lechmere* case was argued before the Supreme Court in November 1991. The petitioner stated that the question was whether an employer could prohibit nonemployee union organizers from trespassing on its private property in an attempt to organize its employees when other reasonable ways to reach them were available. Stopping this trespass did not constitute unfair labor practice; rather, it was a consistent policy that applied to everyone. Furthermore, Lechmere argued that it was not access on which union organizers based their unfair plea, but instead on how effectively their persuasion was through the various means they had available to reach the employees. Robert Joy, attorney for Lechmere, cited *NLRB v. Babcock & Wilcox Co.* (1956) as the precedent that held that an employer may indeed exclude the union to preserve private property rights when reasonable means were available.

The NLRB countered that Congress had charged it with implementing the policy legislated in the NLRA, and as such, it would know the best interpretation. The respondents used the *Babcock* case as well. They claimed that *Babcock* established that some circumstances might warrant the right of the union to distribute literature on private property, and that although in *Babcock* those circumstances did not exist, in *Lechmere* they did. In addition, Michael Dreeben, attorney for the NLRB, argued that *Hudgens v. National Labor Relations Board* (1976) set an additional precedent. In the *Hudgens* case, the employer prohibited the trespass during a lawful strike by employees of a shoe company. There could be scores of circumstances to consider when determining whether or not the employer's property rights and the employee's rights under Section 7 of the NLRA were balanced. *Babcock* established that they should be considered; *Hudgens* established that it was the primary responsibility of the NLRB to make those interpretations. Furthermore, it was argued that in each case the NLRB had historically and consistently used the criterion whereby rights were balanced with the least amount of damage of one so as to maintain the other.

The Supreme Court decided the case on January 27, 1992, in a 6–3 decision in favor of Lechmere, Inc. Justice Clarence Thomas wrote for the majority. He reasoned that private property rights could not be denied the owners where there were alternatives short of trespass to communicate effectively. In this case, there were signs held in petition, mailings, phone calls, home visits, and newspaper ads. The majority opinion stated that because the union had failed to establish the existence of any special impediments that frustrated access to Lechmere's employees, the NLRB erred in concluding that Lechmere committed an unfair labor practice by barring the nonemployee organizers from its property. This defense of private property reversed the judgment of the First Circuit and denied enforcement of the NLRB's order.

The opposite view was expressed in the dissenting opinion. Justice White wrote the opinion and was joined by Justice Blackmun. They agreed that the Court should follow a policy of deferment, keeping the role of the judiciary narrow. It was their opinion that the NLRB had made its decision on reasonable information and rational logic. Justice Stevens wrote a separate dissent. The current interpretation of the *Babcock* decision, Stevens wrote, is open to question. The majority opinion errs in establishing inflexible judicial rules where Congress has delegated authority to the NLRB to deal with ambiguous matters such as the issue of Section 7 and private property rights. Again, Justice Stevens deferred to the judgment of the NLRB.

Between 1935 and 1992, much changed in the bargaining power between owners and employees. Government intervention in the affairs of the market weighed heavily on the side of labor unions and collective bargaining. In an effort to swing the pendulum back toward equilibrium, the *Lechmere* case placed a heavier burden on the NLRB to supply evidence that the employees' statutory rights supersede the owner's fundamental natural right to control access to its private property. It is also a reminder that Congress cannot defer to a bureaucratic agency something that is not clearly articulated, given the fact that the judiciary has the final word.

LENDER OF LAST RESORT

Lender of last resort is a macroeconomic tool used by central banks and in the international community for financial crises. It is the place where a nation can borrow funds after all other funding sources, such as commercial sources, have disappeared.

In a macroeconomy, this role is usually filled by a central bank. A central bank becomes the lender of last resort to commercial financial institutions during times of financial crisis. The financial crisis may be brought on by an economic downturn; by bad business decisions, which would lead to major macroeconomic consequences, or a by natural disaster, such as a hurricane or a flood, where the local financial institutions need financial support to provide all the necessary financial assistance to aid the effected region.

In the international community, the International Monetary Fund (IMF) fills this role with the support of high-income countries like Germany and the United States, among others. When nations reach their crisis point financially—meaning that they cannot convert their currency into another currency due to lack of international reserves, and they cannot make payments on their international loans—the lender of last resort is asked to intervene.

Financial crises bring about a dilemma for policymakers. There is a societal need to keep the financial sector functioning, even if that means using public funds to bail out the banks. This creates a moral hazard, or the incentive for those in the financial sector to withhold information, take on excessive risk that they otherwise wouldn't, and behave in a manner that generates costs to the society. The problem of moral hazard is unavoidable if there are policies that protect any financial system from collapse.

Moral hazard is the reason why the lender of last resort is worrisome to many observers, who believe that last resort lenders should cease to exist. The problems of moral hazard can expand when managers of failing firms use the certain prospect of a bailout as reasoning to gamble on high-risk ventures; the bailout will cover all of their losses if the high-risk gamble does not work.

To combat moral hazard, many who support the idea of a lender of last resort stress the importance of regulation in the financial sector. If financial firms risk a substantial loss as a result of their risks, they would be less likely to take excessive risks.

Another issue regarding the lender of last resort is the size of the loans distributed by the lender. Countries pay a quota to the IMF. The size of the quota depends on the strength and size of the economy. The quota determines multiple circumstances within the IMF. The size of the quota determines the amount of money a country can borrow during a normal crisis. The quota also determines how many votes the country has in setting the policies of the IMF. Generally, the countries are supposed to receive up to 300 percent of their quota. However, precedent has been set and history has shown that the IMF is willing to pay whatever amount the country needs at the time and not a predetermined number. Examples include the 1994 Mexican peso crisis as well as the 1997 Asian financial crisis. Some observers argue that borrowing limits need to be greatly increased, while others argue that circumstantial information regarding the size and scope of the crisis should be taken into consideration. For example, does the crisis have a high probability of spreading, or is it contained to a single country.

Before dispensing funds to nations in crisis, the lender of last resort, the IMF, sets a number of conditions related to the bailout. *Conditionality* refers to the changes in economic policy that nations are required to make if they wish to receive loaned funds from the lender of last resort. Deficits are the number one target of the conditions set by the lender. These conditions usually involve policies with the goal to reduce or eliminate trade deficits as well as budget deficits. The goal is to reduce expenditures by the government and raise revenue in order to set a plan in place to pay back the loans. The lender of last resort makes its loans to the country in installments. Each installment payment is contingent upon completion of the set conditionality. These conditions are often the subject of criticism due to their attack on national sovereignty and their macroeconomic contractionary policies.

The lender of last resort macroeconomic tool is subject to international debate. Many observers believe that the moral hazard tendency surrounding a lender of last resort is reason enough to disband the policy, while others believe that tighter restrictions are needed. However, there are already restrictions in place, called conditionality. These conditionalities are thought to impede national sovereignty. What's certain is that the lender of last resort is a highly debatable subject around the globe. Nations in the international community are almost certain to face some sort of financial crisis at some point in time.

LEONTIEF, WASSILY

Born: August 5, 1905, in Munich, Germany; Died: February 5, 1999, in New York; Nationality: Russian-American; Professional Interests: macroeconomics, input-output analysis, Nobel Prize (1973); Major Work: *Structure of American Industry, 1919–1929* (1941).

Wassily Leontief, a Russian-American economist, led the criticism of John Maynard Keynes's general theory during the 1930s. Leontief is associated with developing models of equilibrium and input-output analysis. Leontief's input-output model distinguished the many components of an economy and their interdependence on each other. His models broadened how the circular flow of economics was used to describe the relationships between inputs (land, labor, capital) and outputs (goods and services) in an economy. Wassily Leontief won the Nobel Prize in Economics in 1973 for his input-output modeling efforts. He was honored with awards from around the world. Leontief died in 1999.

Wassily Wassilyovich Leontief was born on August 5, 1905, in Munich, Germany. Wassily was a second-generation economist, following his father, Wassily Sr., in the profession. Wassily Jr. enrolled in the University of Leningrad at the age of 15, earned his master's degree at age 19, and completed his PhD at the University of Berlin in 1928. The topic of his PhD dissertation was the circular flow of economic activity.

Leontief began his professional career in the Soviet Union at the University of Kiel, working at the Institute of World Economics. In 1930, he moved on to serve as an adviser for the Chinese Ministry of Railroads for a year, before immigrating to the United States to join the National Bureau of Economic Research. He joined Harvard University in 1932. When World War II broke out, Leontief was a consultant to the U.S. Office of Strategic Services. In 1946, he began a new era of his career with his appointment as professor at Harvard University.

At Harvard, Leontief established the Harvard Economic Research Project and was its director till 1973. He then established the Institute of Economic Analysis at New York University in 1975. Continuing the work he began in his dissertation, Leontief was most noted for his study of input-output analysis. He was expanding on the work of François Quesnay (*Tableau Économique*) and Leon Walras (*Elements of Pure Economics*), both of whom had developed earlier versions of the circular flow. Leontief's contribution was his ability to simplify and quantify the components of the circular flow.

The circular flow in its more complex form is an input-output model of general equilibrium analysis. Leontief's input-output analysis models show how the components of an economy are interrelated. His models exhibit the dynamics of how a change in one sector of the economy will impact other sectors. This interdependence of economic sectors became a crucial component in understanding the consequences of policy decisions by governments. In 1941, continuing his efforts on the national accounting of an economy and input-output analysis, Leontief wrote his major work, *Structure of American Industry, 1919–1929*.

At the U.S. Bureau of Labor Statistics, Leontief was able to identify 500 different sectors of the economy. He created a quantitative measure for each one, thus creating a quantitative input-output analysis model for the entire economy. He is credited with being one of the first to use computers for mathematical modeling.

Wassily Leontief s contributions to economics go beyond his input-output models. In the area of international trade, in 1953 he founded what became known as the Leontief paradox. The Leontief paradox surmised that the United States was exporting labor-intensive goods rather than capital-intensive goods. The significance of this finding was that it was a reversal (a paradox) to a widely held international trade theory of the time: that countries should produce and trade based on the relative scarcity of their resources. Yet the United States as a capital-intensive economy was trading internationally those goods that were labor-intensive.

In 1973, Wassily Leontief was awarded the Nobel Prize in Economics for his novel work on the input-output tables. Given specific assumptions, the tables he created can be used to approximate the changes necessary in the resources (inputs) needed when there is a change in the production of a final good. As stated before, Leontief's input-output tables showed how changes in one sector of the economy will influence changes in another sector, making an economy's sectors interdependent to each other.

An ardent and vocal critic of John Maynard Keynes's general theory, in the 1930s Leontief participated in debates on Keynes's general theory. Leontief was particularly critical of Keynes's methodology and definitions, criticizing Keynes's definitions of *aggregate demand* and *aggregate supply curves*. Leontief's most serious criticism was that Keynes was proposing simplistic remedies for an interdependent, intricate, and complicated economy. Leontief also questioned Keynes's labor supply curve and "liquidity preference," arguing that it prevented expansionary monetary policy for attaining full employment. Leontief expressed his doubts about Keynes's ideas in an article titled "Implicit Theorising: A Methodological Criticism of the Neo-Cambridge School."

Along with the Nobel Prize in Economics in 1973, Wassily Leontief received many awards and honors, including many honorary doctorates from universities around the world. He was awarded the French Legion of Honor in 1968, the West German Bernhard-Harms Prize in Economics in 1970, and the Japanese Order of the Rising Sun in 1984. In 1980, Leontief was inducted into the Russian-American Hall of Fame, and in 1989 he was honored with the Society of the Optimate by the Italian Cultural Institute in New York. In 1995, the International House of New York honored Leontief with the Harry Edmonds Award for Life Achievement.

One particular award is named in his honor: Each year, Tufts University's Global Development and Environment Institute awards an individual Leontief Prize in Economics.

Wassily Leontief died in New York City on February 5, 1999, at the age of 93.

LONDON INTER-BANK OFFER RATE

Intercontinental Exchange London Inter-Bank Offer Rate (ICE LIBOR), previously known as British Bankers' Association LIBOR (BBA LIBOR), is a benchmark rate that is used by financial companies around the world. LIBOR is the average rate that LIBOR contributor banks, which are banks that are active in the London financial market, would charge each other to borrow unsecured funds for a given period in a particular currency.

LIBOR was designed to reflect the short-term funding costs of major banks that are active in London, considered one of the world's most important financial markets. LIBOR is a polled rate that is calculated by having a panel of representative banks—11 to 18 banks, depending upon the currency—submit the rate at which they would be able to borrow funds of a reasonable market size from another bank.

The rate is calculated by using the *trimmed arithmetic mean*, which is the average of the rates after the highest and lowest rates submitted by LIBOR contributor banks are removed from the calculation. ICE LIBOR rates are calculated for the U.S. dollar (USD), the euro (EUR), the British pound sterling (GBP), the Japanese yen (JPY), and the Swiss franc (CHF). For each currency, LIBOR quotes maturities for overnight, one week, and 1, 2, 3, 6, and 12 months. The rates are published with a one-day delay at 11:45 a.m. GMT, because this is the most active part of the business day in London. The rates are all quoted based on an annualized interest rate in keeping with market convention. The "reasonable market size" that is mentioned when banks report their rates is intentionally unquantified, due to the fact that it would need to be constantly monitored and changed frequently. ICE LIBOR quotes rates in five currencies and seven maturities, which could vary greatly and lead to considerable confusion.

The LIBOR index is widely used in the financial markets for a variety of different financial instruments, because the rate is used in multiple currencies that have a variety of maturities. This allows LIBOR to be used globally as an index, since it can be easily used for many financial markets. LIBOR is often used in private loan contracts such as mortgages, student loans, and car loans. These are usually set up so that the interest rate is LIBOR plus a set number of percentage points. Financial derivatives such as interest rate swaps compare fixed interest rates to LIBOR, because LIBOR can vary from day to day. Futures exchanges use LIBOR for contracts in the marketplace. The individual submissions of the representative banks are not published until three months after the submission date. This is one of the changes after LIBOR was moved from the British Bankers' Association (BBA) to the Intercontinental Exchange. It helped to preserve the integrity of the rate by making it more difficult for banks to set their rates in line with other banks rather than with their own funding costs. It also protects banks from negative signaling effects caused by the market's perceptions of a bank's financial stability. This helps to prevent banks from submitting a false rating to understate their true borrowing costs so that they appear more financially stable than they actually are. Keeping the rates confidential enables the banks to submit their rates with less concern that they will be affected negatively. The one-day delay of publishing rates and the delay of publishing the individual data of the contributing banks also help to prevent banks from profiting from changes in the interest rate.

The BBA was a private trade association that was responsible for administering LIBOR (the data was published by Thomson Reuters on a daily basis), until LIBOR was handed over to the ICE Benchmark Administration on February 1, 2014. Before that date, BBA LIBOR had quoted rates for the additional currencies of the Australian dollar (AUD), Canadian dollar (CAD), Danish krone (DKK), New Zealand dollar (NZD), and Swedish krona (SEK) in many other maturities than are currently offered; the practice was discontinued in 2013. The administration for the LIBOR index was moved from the BBA to ICE after a number of scandals related to multiple banks and other financial institutions attempting to fix the LIBOR index for their own benefit. Some of the banks involved in the scandal were reporting false rates to benefit their derivatives trading positions, or to protect their bank's reputation in the marketplace. Another issue that came to light with the LIBOR scandal is that some of the banks and financial institutions were colluding to have false rates submitted by banks so that the LIBOR index could be fixed to benefit both companies. The scandal led to multiple investigations in the United States and Europe, and the investigations led to many changes to protect the LIBOR index from being manipulated, with the first major change being the move to the Intercontinental Exchange.

LORENZ CURVE

Income distribution is the equality with which income is spread throughout society. Income distribution is perfectly equal if every member of society earns the same amount. If no one earns money except for one person, income distribution is perfectly unequal. Income equality is determined by breaking the population into segments (generally five segments of 20 percent each) and measuring how much income is earned by each segment. The data showing income distribution between the population segments is recorded on a graph called a Lorenz curve.

The Lorenz curve, developed by Max Lorenz in 1905, is a graphical representation of income distribution and shows what percentage of a nation's residents possess what percentage of that nation's wealth. The Lorenz curve describes income using a two-dimensional graph. The horizontal axis of the Lorenz curve is the cumulative percentage of people in a country. The vertical axis is the percent of total income in the economy. The curve always starts at (0, 0), as 0 percent of the population earn 0 percent of the income, and ends at (100, 100), as 100 percent of the population earns 100 percent of the income. The line of perfect equity is a 45-degree line, which acts as a point of reference where all people in the country have perfectly equal incomes. The Lorenz curve will always curve below the line of perfect equity. The points on the curve often represent the Pareto principle (also known as the 80/20 rule), which states that roughly 80 percent of the events come from 20 percent of

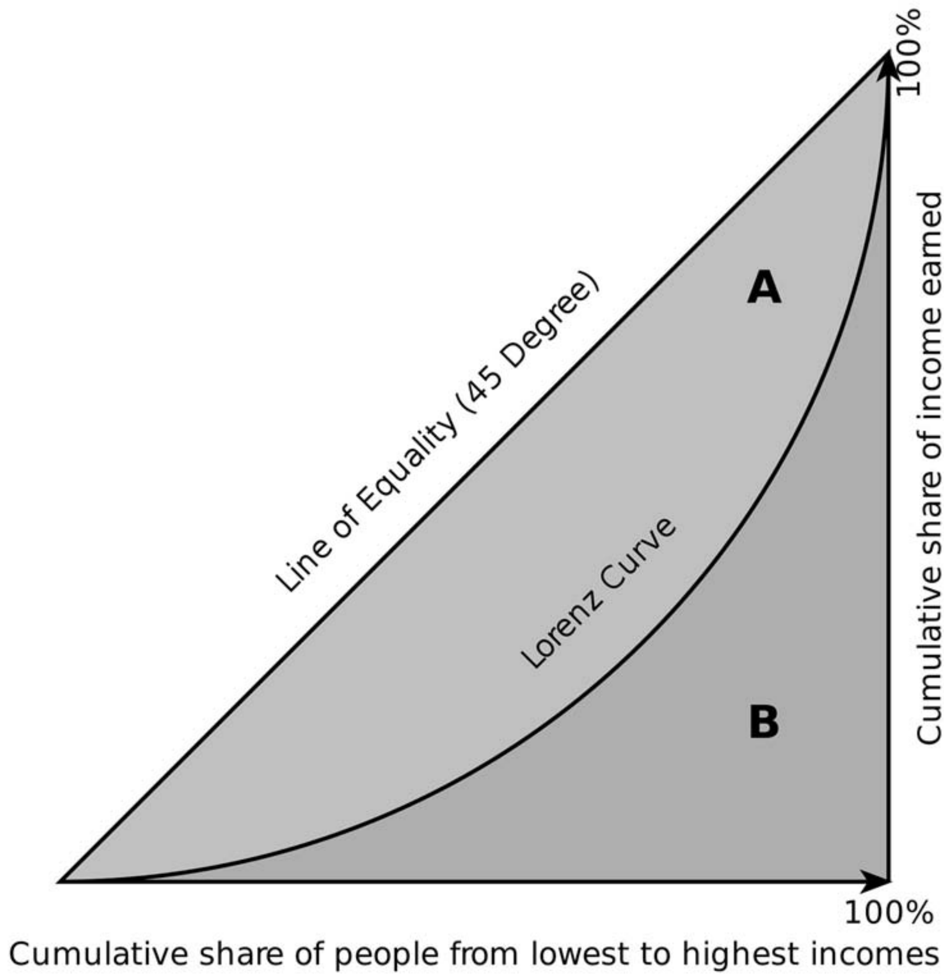

Figure 1. Lorenze curve

the causes—or in relation to income, roughly 80 percent of the income is earned by 20 percent of the population. The curve in constructed by marking the coordinates of percentages of population and its corresponding percentages of income.

The Lorenz curve is then evaluated to determine the Gini coefficient, which is generally used to measure the inequality values of income or wealth. Perfect equality is expressed in a Gini coefficient of zero, where all values are the same. Maximum inequality (one person having all the income) is expressed in a Gini coefficient of one (or 100 percent).

The Gini index is the measure of the area between the line of perfect equality and the Lorenz curve (A), as a percentage (ratio) of the area between the line of perfect equality and the line of perfect inequality (B).

LUCAS, ROBERT, JR.

Born: September 15, 1937, in Yakima, Washington; Nationality: American; Professional Interests: rational expectations, monetary theory, international trade, fiscal policy, and economic growth, Nobel Prize (1995); Major Works: "Expectations and the Neutrality of Money" (1972), *Lectures on Economic Growth* (2002).

Robert Lucas Jr. is an American economist who was awarded the Nobel Prize in Economics in 1995 for his pioneering work in econometrics and his contribution to the theory of rational expectations. Applying econometric hypothesis testing, Lucas correlated public policy decisions regarding fiscal and monetary policy at the macroeconomic level with the private microeconomic decisions made by individuals. Individuals, Lucas suggested, will use past experience and future predictions—that is, rational expectations—in their microeconomic decision-making process, thus offsetting the macroeconomic policies. Lucas's arguments, which became known as the "Lucas Critique," were debated as the antithesis of John Maynard Keynes's government interventionist programs, which were the dominant theories and practices of the 1970s.

Robert Emerson Lucas Jr. was born on September 15, 1937, in Yakima, Washington. Growing up in Seattle, Washington, young Lucas was expected to attend the University of Washington and study engineering. But his interest was in history, not math, and he attended the University of Chicago where he earned his BA in history in 1959. Lucas then began his graduate work in history at the University of California, Berkeley, on a Woodrow Wilson doctoral fellowship. While at Berkeley, however, his interest changed from history to economics. Due to financial considerations, he returned to the University of Chicago to pursue economics, earning his PhD in 1964. While at Chicago, Lucas was introduced to two of his mentors: Paul Samuelson through his textbook, and Milton Friedman through his classes. The ideas of Milton Friedman were foreign to Robert Lucas the graduate student, who had grown up in a family of New Deal political thinkers. But regardless of his early political leanings, Mr. Lucas's thinking began to be reshaped.

In 1963, Robert Lucas accepted a position in the Graduate School of Industrial Administration at Carnegie Mellon University. In 1974, he returned to the University of Chicago as a professor of economics, and in 1980, Lucas was named the John Dewey Distinguished Service Professor.

Lucas's time at Carnegie Mellon was one of intense research and rapid formation of his beliefs regarding economic dynamics. In particular, Lucas devoted great energy to understanding tax structure and the taxation of capital gains. During the early years of his career, in the 1960s, Lucas promoted proposals to tax capital gains as ordinary income. Later in his career, he advocated not taxing capital gains at all, in line with supply-side economics.

As much as Lucas enjoyed his time at Carnegie Mellon professionally, his return to the University of Chicago in 1974 was a homecoming. He found the University of Chicago environment exciting and conducive for teaching and research. Through his graduate teaching, he was able to address research issues in the areas of economic growth and international trade, along with fiscal and monetary policy.

Lucas researched and published in several areas of economics, including labor economics, business cycles, investment theory, and economic growth. With his Carnegie Mellon colleague Leonard Rapping, he researched labor economics (U.S. wages and employment from 1929 to 1958). With another Carnegie Mellon colleague, David Cass, he researched Samuelson's overlapping generations model. In his 1988 publication "On the Mechanics of Economic Development," Lucas blended two fields of economic study: economic growth and economic development. He submitted that the same economic framework can apply to both fields. Prior to Lucas's work, the field of economic growth focused on developed countries while economic development focused on developing countries.

Lucas also challenged the Phillips curve, an inverse relationship between inflation and employment made famous by A. W. H. Phillips. Using rational expectations, Lucas argued that workers will eventually understand that the higher wages resulting from higher inflation do not equate to real income growth. As a result, unemployment will not fall as the Phillips curve assumes. Lucas's argument became known as the "policy ineffectiveness proposition," since individuals' rational expectations will neutralize any policy decisions, preventing economic growth.

Based on the number of Nobel laureates or Nobel laureates-to-be who would influence Lucas and vice versa, his success in economics should come as no surprise. Milton Friedman (1976) served on his University of Chicago thesis committee and was one of his professors, he credits Paul Samuelson's (1970) textbook for preparing him for his economics studies, Thomas Sargent (2011) was a colleague at Carnegie Mellon, and Edward Prescott (2004) was one of his graduate students at Carnegie Mellon. He would later write "Investment under Uncertainty" with Edward Prescott, a work that altered the view of rational expectations.

Robert Lucas was awarded the Nobel Prize in Economics in 1995 for his work on rational expectations and macroeconomic analysis. His Nobel lecture came from his paper with Edward Prescott, "Expectations and the Neutrality of Money" (1972), which Lucas considers the most influential of all his writings. To celebrate the paper's importance in macroeconomic theory, the Federal Reserve Bank of Minneapolis conducted a 25th Anniversary Conference on the paper in 1995. Lucas edited or co-edited numerous economics journals. He also held the prestigious office of president for both the American Economic Association and the Econometric Society.

Robert Lucas is considered one of the economic revolutionaries of the second half of the 20th century. He is one of the top 10 economists as reported by the *Research Papers in Economics* rankings. His work has influenced many economists, including Nobel laureates.

M

MACHLUP, FRITZ

Born: December 15, 1902, in Wiener-Neustadt, Austria; Died: January 30, 1983, in Princeton, New Jersey; Nationality: Austria-Hungarian, naturalized U.S. citizen in 1940; Professional Interests: international monetary theory, information economics; Major Works: *Die Goldkernwahrung* [The gold bullion standard] (1925), The *Production and Distribution of Knowledge in the United States* (1962), *Knowledge: Its Creation, Distribution, and Economic Significance* (1980, 1982, 1983).

Fritz Machlup, an Austrian-American, is considered the father of the idea of the information economy. He was one of the first economists to explore the economics of invention, innovation, and knowledge. Born in Austria, and naturalized as a U.S. citizen after fleeing Nazi Germany, Machlup was a noted international economist specializing in monetary mechanisms, particularly the gold standard. Fritz Machlup's influence on the development of economics and economic theory was significant, as he made contributions in virtually every field of economics in areas of theory, policy, and methodology. Machlup died in 1983.

Fritz Machlup was born on December 15, 1902, in Wiener-Neustadt, Austria. Machlup studied under Friedrich von Weiser and Ludwig von Mises at the University of Vienna, earning his doctorate in 1923. He wrote his dissertation on the gold standard, and it was published in 1925 as *Die Goldkernwahrung*, translated as *The Gold Bullion Standard.* His dissertation adviser was the "father of the Austrian School," Ludwig von Mises.

Machlup followed his father into the cardboard-manufacturing business, forming a paperboard corporation in Hungary in 1923. Machlup continued his interest in economics as a member of the Austrian Economic Society, serving as its treasurer and secretary. He was a participant in the *Geistkreis*, a seminar led by Austrian School leader Ludwig von Mises. In 1927, Machlup published a book on Europe's adoption of the gold standard. He also wrote on German war reparations, and in 1931 he wrote a book on the stock market: *The Stock Market, Credit and Capital Formation.* Receiving a Rockefeller fellowship for the United States in 1933, Machlup spent time at several U.S. universities, including Chicago, Stanford, and Harvard.

In 1935, Machlup accepted a professorship at the University of Buffalo, never to return to Austria professionally. While at Buffalo, he accepted visiting professorships at American University, Columbia, Cornell, Northwestern, Stanford, University of Michigan, Harvard, and University of California, Berkeley. He also was a visiting professor at the Universities of Kyoto, Doshisha, and Osaka in Japan and at Melbourne University in Australia.

In 1947, Machlup joined the faculty of Johns Hopkins University as a professor of political economy. In 1960, he joined the faculty at Princeton University as the director of the International Finance Section and the Walker Professor of International Finance. In 1971, he continued living in Princeton, New Jersey, but left Princeton University and began a teaching tenure at New York University, remaining there until his death in 1983.

Machlup became a U.S. citizen in 1940, and it was natural for him to serve the U.S. government during World War II. He served as a U.S. Department of Labor special consultant for the Post War Labor Problems Division and also the Office of Alien Property. He later served in the U.S. Treasury Department as well.

Machlup's areas of economic interest were quite varied. With his dissertation on the gold standard in 1925, the area of international finance, and specifically the gold standard and international monetary mechanisms, was always in the forefront of his work. During World War II, he wrote several papers on foreign exchange. He continued his work on international finance through the 1950s and 1960s. He attacked Keynes's foreign exchange multiplier approach.

Machlup was a major contributor on other economic fronts as well. He supported the application of economic theory in research on industrial organization, writing two books on industrial organization to substantiate his point. In 1972, he published *Optimum Social Welfare* with coauthors Jan Tinbergen, Abram Bergson, and Oskar Morgenstern. He also revealed the problems of empirical research when questionnaires are used.

In the 1950s, Machlup began his study of the information economy, leading to a series of works on innovation and knowledge that established him as the father of the information economy. In 1958, he published *The Economic Review of the Patent System,* followed by *The Production and Distribution Knowledge in the United States* in 1962. A decade later in 1970 he published *Education and Economic Growth.* Following the publishing of *Information through the Printed Word: Dissemination of Scholarly, Scientific, and Intellectual Knowledge* in 1978, Machlup began his magnum opus on the information economy with a three-volume compilation—*Knowledge: Its Creation, Distribution, and Economic Significance*—which was published in 1980, 1982, and 1983. He died before completing what was planned to be a 10-volume series.

To further his study of international monetary mechanisms and international crisis, in 1963 Machlup assembled a group of academics to research and develop solutions. The Bellagio Group published several books and articles with solutions on the problems facing the world's currency issues. The success of the Bellagio Group established Machlup as the intellectual face for addressing the international monetary issues of the 1960s—and for reforming a monetary system on the verge of collapse. One position on which Machlup reversed himself was that of his long-standing support of the gold standard. He reversed his position on the gold standard knowing the position was considered politically infeasible for the time. While this led to an intellectual split with his mentor, Ludwig von Mises, Machlup was later instrumental in von Mises's publishing of *Human Action*, the "Bible" of the Austrian School of economic thought. The Bellagio Group was the predecessor of the Group of Thirty advisory group.

Machlup died on January 30, 1983, in Princeton, New Jersey, shortly after finishing the third volume of *Knowledge: Its Creation, Distribution, and Economic Significance.*

MACROECONOMICS

Macroeconomics is a study of behavior and decision-making that impacts an economy on a nationwide scale, and it includes such broad economic realities as inflation, employment, and money supply, as well as the government policies that influence all of these forces. Income levels and interest rates are also considered when in the measurement of a macroeconomy.

The term *economics* is derived from the Greek term *oikonomika*, a treatise put forth by the philosopher Aristotle in the fourth century BCE. *Oikos* in Greek refers to a "household," and *nomos*, which evolved from *nemein* in the same language, refers to "management of resources" (Boland 1997). An appreciation of the classical world in 16th- and 17th-century Britain caused the term to be co-opted, and thus *economics* morphed into its current form. The Greeks also provided the prefix describing this element of economics: *macro* meaning "large." By contrast, *microeconomics* refers to economic behavior on a smaller scale, such as within and among firms as well as households. The term *aggregate* is frequently used to describe the practice of taking national economic data as a whole as well.

Viewing a national economy in its totality gained credibility in the 1930s. In 1936, in his work *The General Theory of Employment, Interest and Money*, British economist John Maynard Keynes suggested that left to their own mechanizations, markets will not meet the inherent needs of a society and individuals cannot be relied upon to act in ways that will benefit the greatest number of people in society. Keynes believed that when market forces do not yield a reasonable standard of living, an economy's goals for inflation, employment levels, and economic growth can be influenced by governments for the greatest good.

Keynes's ideas emerged amid the worldwide Great Depression, the same era in which Norwegian economist Ragnar Frisch posited that a broad consideration of factors must inform an understanding of why things were as they were at the time. Awarded the first Nobel Prize for Economic Science years later, Frisch suggested in his 1934 book *Statistical Confluence Analysis by Means of Complete Regression Systems* that most economic variables are interconnected and that no variable could be studied on its own. Frisch labeled this concept econometrics, and by the 1960s, in contrast to a micro approach to the economy, the term *macroeconomics* came into widespread use.

The interconnectedness of certain major economic factors composes this view of macroeconomics. The four factors or economic goals most commonly considered in macroeconomics are production, employment, inflation, and interest rates. Aggregate (total) supply and aggregate demand are also often included in this list, but they can also be seen as aspects of the overall factor of production. It should be noted that the measures of these macroeconomic goals are in what is known in economics as a "ceteris parabis" condition. *Ceteris paribus* is a Latin expression used to express the condition that "all other things remain constant."

The first measure, *production*, is the process of turning tangible inputs into finished goods or services. A *good* is any tangible result of production including a physical product such as an ear of corn or a pair of shoes. A *service* is intangible, such as a theatrical production or cutting down a tree. An economy can improve productivity in two ways: (1) It can use fewer of its limited resources (inputs) to produce the same level of goods and services (outputs), and (2) the economy can use the same quantity of limited resources (inputs) to produce a greater level of goods and services (outputs). In either scenario, the ratio of inputs to outputs is increased, which translates into a higher standard of living. This can also be viewed from the relationship between aggregate demand and aggregate supply.

The evolution of technology has broadened the list of what could be called tangible inputs, but still falls into one of three basic categories: human resources, natural resources, and capital resources. *Human resources* are simply the people whose time, skill, and effort go into creating a good or providing a service, be it assembling an automobile or cleaning a hotel room. These and all tasks involve labor, which is the physical or mental effort expended toward an end over a perpetually precious resource time. *Natural resources* are the raw materials found in the natural world, from trees of the forests that can be processed into timber for construction to fossil fuels that can be extracted for energy needs. As tools and devices are often needed for production, *capital resources* or capital goods are the third set of inputs. Machines, vehicles, and devices that humans have created to aid in the production of other products are capital resources.

The cumulative value of all the factors of a nation's output over a period of time is known as either gross national product (GNP) or gross domestic product (GDP). GNP was used as a measurement of a nation's economy in the 1950s through the 1970s. As foreign investment in the United States and production by U.S. firms outside the 50 states grew, the GDP measure came into wider use. GDP includes all good and services produced from all sources within a nation's territory, while GNP includes production by all firms of a nation produced anywhere. Both GNP and GDP are calculated and reported by the Bureau of Economic Analysis (BEA).

A second measure of a macroeconomy is *employment levels*, or the use of human labor in the production of a good or service in exchange for compensation. As industrialization brought innovation and expansion to manufacturing in the later centuries, individuals who were willing to offer their labor to founders of various firms found themselves employed in exchange for wages. In theory, the lower the unemployment rate, with more individuals in an economy willing and able to produce the goods and services, the more workers there are earning a wage to spend on goods and services. Ceteris paribus, greater levels of employment mean more demand, and this would warrant more production expanding an economy and GDP measure. While full employment—the condition of every individual who is seeking work finding work—sounds ideal, a frequent consensus among economists is that an unemployment rate under 5 percent is de facto full employment. The Bureau of Labor Statistics (BLS), a component of the Department of Labor, measures the unemployment rate in several ways.

A third measure of a macroeconomy is the general price level of goods and services, measured by inflationary or deflationary pressures. These measures can be based on the economic activity of consumers relative to the economic activity of producers, or it can be based on an increase in the costs of an economy's inputs in producing goods and services (outputs). Thus, a related measure is the size of the money supply in an economy relative to the quantity of goods and services. These macroeconomic measures focus on inflation or deflation in an economy.

Inflationary pressures are present when consumer demand far exceeds the producers' ability to supply goods and services, and pulls prices upward. If producers' input prices rise and exceed their costs of production, the producers are forced to push output prices upward. The latter scenario, when the money supply is far larger than the amount of goods and services in an economy, is inflationary. Deflationary scenarios are simply the reverse.

Inflationary and deflationary pressures also impact the fourth measure: nominal *interest rates*. Nominal interest rates are important in an economy, because they determine the level of productive activity for major purchases like homes and automobiles. Higher nominal interest rates will slow this activity, while lower nominal in theory increase it.

Each of these elements of an economy is interdependent. Each impacts the other elements, making a macro view of the economy the more informed one. Understanding how production, employment, inflation, and interest rates interact with each other is the macroeconomic perspective of today's financial realities.

MANKIW, N. GREGORY

Born: March 2, 1958, in Trenton, New Jersey; Nationality: American; Professional Interests: macroeconomics, public policy economics; Major Works: *Principles of*

Economics (1st ed., 2000), *Intermediate Macroeconomics* (2010), *Macroeconomics and the Financial System* (with Laurence Ball) (2010).

N. Gregory Mankiw is one of the major contributors to new Keynesian economics theory. New Keynesian economic theory was developed in response to the new classical economic theorists' criticisms of the traditional Keynesian model. Through his writings and textbooks, he is considered one of the key interpreters of the neo-Keynesian theory to the general public. He also is a major contributor to the current macroeconomic policy debate and its development.

Nicholas Gregory Mankiw was born in Trenton, New Jersey, on March 2, 1958, to Ukrainian parents. Professor Mankiw holds a BA in economics from Princeton University and a PhD in economics from the Massachusetts Institute of Technology. He has been influenced throughout his career by many famous economists of differing viewpoints, including John Maynard Keynes, Arthur Pigou, Stanley Fischer, and Milton Friedman.

Mankiw's research interests include the U.S. economy, entitlements, international trade policy, price adjustment, consumer behavior, financial markets, monetary and fiscal policy, and economic growth. Mankiw's interest and study of economics has led him to author several textbooks, write a daily blog, and receive many honors. He is Robert M. Beren Professor of Economics at Harvard University. His teaching includes the very popular Principles of Economics course. He is also a visiting research fellow at the American Enterprise Institute. From 2003 to 2005, he was chairman of President George W. Bush's Council of Economic Advisers. He also maintains a blog that is read widely across the United States and the world (http://gregmankiw.blogspot.com).

Mankiw has authored several of the most popular textbooks used in high school and college economics courses, including *Principles of Economics,* in its sixth edition; *Intermediate Macroeconomics,* in its seventh edition; and his newest text, *Macroeconomics and the Financial System*, with Laurence M. Ball, in its second edition. His academic papers are published in such journals as *American Economic Review, Journal of Political Economy,* and the *Quarterly Journal of Economics.* He is a frequent contributor to the *New York Times,* reflecting the views of the new Keynesian economics.

Mankiw's contributions to new Keynesian economics highlight the disagreement with new classical economics regarding the adjustment of wages and prices. Classical and monetarist theory says that in the short run, changes in the money supply affect employment and production levels. New classical economics theorizes that wages and prices are flexible, allowing markets to clear and regain their equilibrium (rebalancing demand and supply). New classical thinkers Robert Lucas Jr., Thomas J. Sargent, and Robert Barro have criticized Keynesian theory (*General Theory of Employment, Interest and Money*), saying the Keynesian model does not explain when wage and price changes are slow, demand and supply equilibrium (market-clearing mechanism) can be achieved.

Through his writings and textbooks, Mankiw is one of the leading authors to interpret the new Keynesian theory and make it understandable to the general public. Mankiw's writings are a response to the criticisms levied by the new classical economists regarding the initial market-clearing mechanism (prices determined by equal demand and supply) first proposed by John Maynard Keynes. The new Keynesian economics suggests that markets do not clear (where demand and supply are equal) quickly—and that economic fluctuations are explained through models where wages and prices are not as mobile or flexible as the new classical economists contend. This new Keynesian model includes involuntary unemployment, along with the important role of monetary policy to adjust supply-and-demand conditions when markets do not clear (which is assumed in the new classical thinking).

In the 1990s, a combination view emerged between the new classical and new Keynesian theorists. Mankiw's textbooks reflect this consensus view of a dynamic economy—with inflexible components and market imperfections in the short run, but ultimately a dynamic economy that adjusts in the long run.

Mankiw's awards include the Wolf Balleisen Memorial Prize in 1980 and the Galbraith Teaching Prize in 1991.

MCCULLOCH V. MARYLAND

In 1790, Alexander Hamilton, the first U.S. Secretary of the Treasury, was adamant regarding the importance of a central bank to the stability of property within a nation. The First Bank of the United States was started to help manage the Revolutionary War debt. The Second Bank of the United States was established in 1816 with the intention of serving the nation's commercial and banking needs.

Unlike the power to create post offices, the power to create banks is not stated in the Constitution. However, the powers to lay and collect taxes, borrow money, regulate commerce, declare war, and raise and support armies and navies are listed in the Constitution. These powers include a considerable portion of the industry of the nation. The United States did not create a bank simply to be in the banking business, but rather as a means to carry out its expressed duties. The architects of the Constitution intended there to be inherent powers in the government, in addition to those necessary and proper to carry out the government's responsibilities. The Supreme Court case *McCulloch v. Maryland,* 17 U.S. 316 (1819) confirmed the federal government's authority to establish a national bank.

Case Summary

In 1811, the U.S. Congress lacked the one vote necessary to continue the First Bank of the United States. Consequently, in 1816, after the War of 1812, Congress set up the Second National Bank to assist in dealing with the economic consequences of yet another war debt on the nation. The Second Bank functioned as a clearinghouse; it held large quantities of state banks' notes in reserve, and it could discipline banks with the threat of redeeming those notes if there was any concern regarding unregulated currency (the over-issuing of notes). In effect, this procedure functioned as an early bank regulator.

The Second National Bank was similar in structure to the First Bank in that the government held one-fifth of the shares, but the Second National Bank had more than double the capital. The Second National Bank opened in Philadelphia and added branches in other states, one of which was in Baltimore, Maryland. In reaction to the branch bank opening in the state of Maryland, the General Assembly of Maryland enacted a tax on all banks, or branches thereof, within its boundaries that were not chartered by the legislature of the state of Maryland. This tax was based on the transactions of bank notes. Any bank not chartered by the authority of the state was required to use special stamped paper for its bank notes and, in effect, pay 2 percent of the value of the notes as a tax, or pay a general tax of $15,000 a year. Many states, particularly in the West and the South, attempted to keep branches of the national bank out of their states by passing similar state laws. The power to tax the federal bank notes had the potential to close the national bank's doors within the state of Maryland.

James McCulloch, a cashier for the Baltimore branch of the Second National Bank, refused to pay the tax. In response to the bank's failure to pay the tax or follow Maryland law, a representative of the state of Maryland took the bank deposits (totaling over $2,000) from the Baltimore branch of the Second National Bank. McCulloch was then sued for violating the Maryland Act.

James McCulloch admitted in Baltimore County Court that he was not complying with the Maryland rule to pay the tax or the annual lump sum. The county court found in favor of Maryland. The case was appealed to the Court of Appeals of the state of Maryland, which affirmed the county court's ruling. This was the culmination of a huge dispute between the federal and state governments that the Supreme Court was required to remedy.

The case was taken by writ of error (in this case a command by the U.S. Supreme Court for the records of a case, in order that some alleged error in the proceedings of that case might be corrected) to the U.S. Supreme Court. The petitioner, James McCulloch, was more than a federal bureaucrat; he was essentially the power of the federal government. The respondent was the state of Maryland.

The case was heard on February 22, 1819, in front of a seven-member court led by Chief Justice John Marshall. The Supreme Court heard oral arguments and narrowed the case to two fundamental questions. First, can the national government create a bank? This was not an unfamiliar issue. Since the opening of the First National Bank, there had been an ongoing debate in Congress as to whether or not this was within the constitutional powers of the federal government. Although there was no enumerated power granted to Congress to incorporate a bank, there was the implied power that the Court felt was inherent within the government to perform the other responsibilities and expectations the people had of the government. In addition, the power granted in the U.S. Constitution to Congress to make laws that are necessary to carry out the execution of the enumerated and expressed powers is clearly stated in the Constitution. The end result must be the legitimate accomplishment of the role of government. Chief Justice Marshall expressed the opinion of the Court that it was in fact within the power of Congress to create a bank.

Therefore, a second question followed: If it is constitutional for the government to create a bank, can a state tax that entity if it is within the boundaries of the state? The Court's retort to Maryland's claim—that the Constitution was enacted by independent states and therefore subordinate to the states—was that this claim was inaccurate. The Court expressed the thought that the Constitution was ratified by three-fourths of the states. The Constitution's reference to "We the People" is a collective response to accepting the legality of the Union. Legitimizing the Union as stated in the Constitution as the superior law of the land relegated the previous sovereignty of the states, which created it, subordinate. Therefore, although limited in its powers, the Constitution is supreme over state laws, and the states cannot apply taxes that would possibly destroy federal legislative law.

For that reason, the state of Maryland's tax on the U.S. Bank was found to be unconstitutional. In a unanimous decision on March 6, 1819, the Marshall Court reversed the judgment of the lower court. This landmark case by the Supreme Court established the precedent of supremacy of the federal government over the states.

MEDICAID

Medicaid is a U.S. government health care program for lower-income citizens. The federal program is integrated with individual Medicaid state programs. Medicaid includes a special program, called the Children's Health Insurance Program or CHIP program, to help lower-income children. Parents of children who receive CHIP benefits are not necessarily Medicaid recipients.

Medicaid and CHIP cover approximately 60 million Americans. Those insured with Medicaid include children, pregnant women, parents, seniors, and individuals with disabilities. Federal law requires states to cover certain population groups, called the "mandatory eligibility groups," and it offers states the option to cover other population groups, or "optional eligibility groups."

After meeting the federal coverage guidelines, many states grant expanded coverage above the federal minimums, especially for children's support.

Medicaid Eligibility

The Affordable Care Act of 2010 designated the national Medicaid minimum eligibility level to be 133 percent of the federal poverty level. The 2014 eligibility level for Medicaid for a family of four is $31,720.50; this is the maximum income level for a family of four to be eligible for Medicaid benefits. The federal poverty level is updated annually to ensure that eligible citizens are covered.

In addition to income-level criteria, there are further eligibility requirements for Medicaid recipients. To receive Medicaid, individuals need to meet certain federal and state guidelines regarding residency, immigration status, and U.S. citizenship documentation.

In some cases, states may apply for waivers to cover individuals who aren't ordinarily eligible for Medicaid benefits.

Medicaid Benefits

Medicaid benefits are divided into two categories: mandatory and optional. Mandatory benefits include inpatient and outpatient hospital services as well as early periodic screening diagnostic treatment (EPSDT). This benefit is important for ensuring that children under age 21 obtain appropriate care services to facilitate their physical, dental, and mental health.

Mandatory benefits also encompass nursing care, home health services, physician services, laboratory and X-ray tests, family planning, nurse midwife care, and transportation to medical care.

Optional benefits are provided at the states' discretion. States elect whether to offer prescription drug coverage and physical, occupational speech, and respiratory care services. Podiatry, optometry, dental, chiropractic, and related services are also optional. At present, all states provide prescription drug programs.

Similar to the co-pays required by many health care plans, states may also require co-pays or cost-sharing for Medicaid enrollees. The most vulnerable groups—children and pregnant women—are exempt from most out-of-pocket costs.

States also may also charge higher co-payments when individuals visit a hospital emergency department for nonemergency services. This requirement is in place because some lower-income individuals tend to use emergency room services in lieu of other types of clinics and medical facilities.

Long-Term Services and Support

The elderly are particularly at risk for depleting their financial resources due to excess medical costs. After the elderly have exhausted their financial resources, they may need to rely on Medicaid for medical care and other life maintenance support services.

The Medicaid program may also cover institutional care, home care, and community-based long-term care and support. As the U.S. population continues to age, the Medicaid program may be stressed as it is expected to cover more eligible elderly citizens.

The institutions caring for elderly Medicaid recipients are residential and cover all care for the admitted occupants. The care includes room and board. The caregiving institutions must meet certain standards, must be licensed, and must be certified by the state. Other names for these facilities are nursing homes, extended care, and senior citizens homes.

Community-Based Long-Term Services and Support

These services are designated for individuals with disabilities and chronic conditions. The care for citizens with disabilities and chronic conditions strives to maintain independence and a reasonable level of health and quality of care. There are partnerships and programs to assist these candidates.

Long-term community-based services and support vary from state to state, but the states maintain certain characteristics in common. Medicaid attempts to allow the program recipients to maintain control and decide where and with whom they live as well as what services they receive. The services strive for a high level of quality and are coordinated with all providers. Finally, due to the multicultural nature of the U.S. citizenry, the services are sensitive to the participants' individual cultural needs. In sum, the government attempts to promote self-respect, control, and independence for service recipients.

How Are Medicaid's Bills Paid?

As previously stated, Medicaid is funded by the federal and state governments. The federal government pays each state a percentage payment, called the Federal

Medical Assistance Percentage (FMAP). The average FMAP is 57 percent, but the range is from a low of 50 percent, in wealthier states, to 75 percent in states with lower revenues. The maximum regular FMAP is capped at 82 percent.

The states negotiate payments to providers, such as managed care organizations, to deliver the Medicaid services.

Children's Health Insurance Program

The Children's Health Insurance Program, or CHIP, covers approximately eight million children in families that have incomes too high to receive Medicaid benefits but that cannot afford private medical insurance coverage. This program became law in 1997.

Similar to the Medicaid program, CHIP is funded by both the federal and state governments. The federal government designed the contribution rate to be favorable to the states, in order to benefit a greater number of uninsured children.

The Affordable Care Act improved Federal CHIP funding by 23 percent. This brings the federal matching rate for CHIP to 93 percent.

States have the option of operating CHIP independently of Medicaid, as an arm of the Medicaid program, or as a combination of both types.

MEDICARE

Medicare is a U.S. government-run insurance program that helps offset the costs of medical care. The program is available to individuals over age 65, as well as certain younger people with disabilities, permanent kidney failure, or Lou Gehrig's disease (amyotrophic lateral sclerosis). The Medicare program applies to working and nonworking individuals. Since Medicare covers medical expenses only partially, an integral extension of the program is the opportunity to purchase a Medicare supplement policy (Medigap) from a private insurance company in order to cover some of the costs not included in Medicare.

The Centers for Medicare and Medicaid Services at the Social Security Department implement the program. Medicare is partially financed by the payroll taxes paid by workers and employers. The other part of Medicare funding is paid by premiums deducted from retirees' Social Security checks.

History of Medicare

President Lyndon B. Johnson signed the Medicare and Medicaid programs into law on July 30, 1965. The Medicare program was created to provide health insurance for people over age 65 at a time when insurers were not insuring senior citizens. The greatest medical financial concern during the era of Medicare's creation was that an insurmountable hospital bill would destroy an individual's finances. Medicare was created in the paradigm of the private insurance system in place in the 1960s. Private insurance offered fewer choices and assisted with much lower medical costs than we experience today. There is controversy that as health care has evolved, Medicare changes have not kept up.

Parts of Medicare

Medicare Part A is the hospital insurance. It helps cover inpatient hospital care, skilled nursing facility care, hospice, and home health care. Consumers usually don't pay a premium for Part A coverage if they or their spouse paid Medicare taxes while employed. Another name for Part A is premium-free Part A. People who are not eligible for Part A may be able to purchase this coverage.

Medicare Part B is the medical insurance portion. This part of Medicare covers a portion of the costs associated with doctor visits and other health care provider visits. Part B also offsets the costs of outpatient care, home health care, durable medical equipment, and some preventive services. Most Medicare recipients pay the standard monthly Part B premium (or charge). The Part B premium or charge is deducted from the individual's Social Security payment. Private companies offer a Medicare Supplement Insurance policy (Medigap) to help pay additional charges not covered under Medicare Part B.

Medicare Part C, or Medicare Advantage, is sponsored by Medicare-endorsed private insurance companies. Part C includes all the benefits and services of Parts A and B and usually provides prescription drug coverage (Part D) as well. For an extra cost, Medicare Advantage may also include additional benefits.

The fourth part of Medicare, Part D, covers prescription drugs. This program is also supported by Medicare-chosen private insurance companies.

Where Medicare Is Lacking

There are many health care services not covered by Medicare. For example, Medicare does not cover routine dental care, eyeglasses, hearing aids, and most long-term care. Nursing home care is not covered for Medicare patients, but it may be available under the Medicaid program for consumers with less than $2,000 in assets.

As with most government services, there are debates and criticisms about Medicare. According to the National Academy of Social Insurance (NASI) Study Panel on Medicare Financing, the biggest concerns are that Medicare leaves the elderly with large out-of-pocket costs and expensive supplemental insurance. The research estimates that typical Medicare eligible individuals spend approximately 19 percent of their income on medical care and insurance. This percentage is projected to rise to 30 percent of income by 2025 if health care costs continue their current trajectory.

Medicare, Demographic Trends, and the Future

In "The Future of Medicare" (see under "Further Reading" at the end of this entry), NASI offers some startling statistics: As the baby boomer generation (born between 1946 and 1965) ages, Medicare will be pressured. There is data to suggest that by 2030, Medicare enrollment will double to approximately 80 million people. Compound that projection with the decline in available workers supporting retirees, and there is potential for a large shortfall in Medicare funding.

In 2010, Medicare spending totaled about 3.6 percent of the gross domestic product (GDP). By 2030, according to NASI, the percentage of GDP spent on Medicare is expected to increase to 5.1 percent.

In 2014, the Affordable Care Act gave Medicare recipients expanded benefits, such as preventative service, cancer screening, and yearly "Wellness" visits, without out-of-pocket charges.

The Medicare funding projections will impact both government and consumer spending in the future. With health care costs growing faster than the rate of inflation, modern money management requires consumers to be educated about this health care insurance topic for themselves and their family members.

MENOMINEE TRIBE V. UNITED STATES

In 1961, Congress enacted the Menominee Termination Act. The act terminated the Menominee tribe's traditional hunting and fishing rights in Wisconsin. The Menominee Indians felt this act violated their property rights as given to them in the earlier Wolf River Treaty. The court case centered on the Menominee Indians' property rights as they related to Wisconsin's water and land common-pool resources (i.e., Wisconsin's public waters and lands). Also in question was whether the U.S. government would be subject to rule of law and if property rights that the government had earlier granted would be upheld. A secondary economic relevance would be the precedence set for states to collect hunting and fishing fees—that is, to generate state revenue—from the hunting and fishing activity of the states' Indian population.

Case Summary

The Supreme Court's responsibility in *Menominee Tribe v. United States*, 391 U.S. 404 (1968) was to determine if the Menominee Termination Act, enacted by Congress in 1961, terminated hunting and fishing rights granted in the Wolf River Treaty of 1854. In this treaty, the hunting and fishing rights within the territory described as the Menominee Reservation were not specifically stated, but legally implied, and would therefore constitute property rights and require just compensation. With federal recognition, the Menominee tribe had a flourishing economy. It ran a lucrative timber industry and hospital, utilities, and education systems. It paid Bureau of Indian Affairs (BIA) salaries and had other such examples of infrastructure and economic success. In terms of overall economic well-being, the Menominee tribe was categorized as prosperous within the Indian tribes of the United States.

In 1954, Congress began the process of ending recognition, and by 1961, Congress had terminated the Menominee tribe's federal recognition completely through the Menominee Termination Act. With this act, the government terminated the tribe's right to govern itself, and to receive federal support for health care, education, and fire and police protection, as well as tribal rights to lands. Consequently, the Menominee Reservation boundaries became Menominee County, Wisconsin. In preparation for this termination, the Menominee tribe incorporated the boundaries of the Indian reservation and set up a charter that enabled the tribal council to remain the governing entity. However, the tribe lost the utility, education, and hospital systems and much revenue from the timber industry. As a county, it had no tax base to support basic infrastructure. The tribe was also under the laws and jurisdiction of the state of Wisconsin. Within a few years of the termination, the Menominee tribe was categorized among the poorest within the Indian tribes of the United States. The Menominee considered the traditional rights to hunt and fish the territory as essential to economic survival.

The Menominee tribe had lived in the area that became the states of Wisconsin, Michigan, and Illinois for thousands of years. Through a series of treaties made with the U.S. government in the 1800s, the area of land they inhabited was reduced from millions of acres to just over a couple hundred thousand acres in the area of northern Wisconsin.

The current land area is referred to as an Indian reservation. Although the definition of "Indian" in the United States is complicated, the United States establishes the legal status of an Indian tribe according to laws and acts passed by the U.S. Congress.

The Menominee tribe was federally recognized as one of over 500 tribes in the United States and therefore granted self-governing powers much like a state, excluding such powers as making war and coining money. The 1961 Menominee

Termination Act changed the social, political, and economic fortunes of the tribe by removing federal assistance and placing the tribe under state authority. In addition, the termination forced a restructuring of the tribe as a corporate organization.

In 1962, tribal members Joseph Sanapaw, William Grignon, and Francis Basina were charged with violating state hunting and fishing regulations by hunting deer with headlights or flashlights, a process known as "deer shining." They admitted this act in court, but they claimed that the Wolf River Treaty signed in May 1854 secured their right to hunt and fish. The state trial court agreed and acquitted the three. The state appealed to the Wisconsin Supreme Court, which agreed that although the Wolf River Treaty did not specifically mention hunting and fishing rights, it certainly implied them, and upheld that claim. Following that determination, the court held that the Menominee tribe no longer had hunting and fishing rights due to the Termination Act by the federal government ending its treaty rights as well as its Indian recognition.

The Supreme Court would not grant certiorari (a writ to the lower court to send the case to them for review) at this point; therefore, the tribal members appealed to the Federal Court of Claims to recover compensation from their loss of hunting and fishing rights. Retaining their rights to hunt and fish within the territory established by the Wolf River Treaty as the Menominee Reservation was the essential goal. Acknowledgment of the current economic hardships faced by the tribe and pursuit of just compensation for the loss of formerly granted rights were secondary aims.

The Court of Claims held that the Menominee Termination Act did not end the tribe or its membership, but abolished federal trusteeship of the tribe. The tribe had a right to claims of the Wolf River Treaty, and therefore, the court denied the right to compensation but upheld the tribe's right to fish and hunt not subject to state jurisdiction. The opposite rulings by the Wisconsin State Supreme Court and the Federal Claims Court brought the issue to the U.S. Supreme Court.

This case is unusual in that both the Menominee (the appellee) and the United States (the appellant) argued that the decision of the Court of Claims should be affirmed. In this case, the Supreme Court invited the state of Wisconsin to participate in the court hearings as an *amicus curiae* (one who is not a party to the case, but believes the court's decision may have a relevant impact on its interest). When Congress ended federal recognition of the Menominee tribe in 1961, the hunting and fishing rights that were implied in the Wolf River Treaty of 1854 were terminated. Therefore, the state of Wisconsin argued that the Court of Claims ruling should be reversed. Consequently, the state of Wisconsin contended that the tribe should be given just compensation for that taking. However, the Menominee argument focused on the hunting and fishing rights within the current incorporated boundaries of the terminated Menominee Reservation. The tribe considered these rights guaranteed to them by the Wolf River Treaty, whether the federal government ended recognition of the tribe in 1961 or not. The Federal Claims Court was in agreement with the Menominee.

The Supreme Court, led by Chief Justice Earl Warren, heard arguments on January 22, 1968, and again on April 26, 1968; the Court decided the case on May

27, 1968. The Supreme Court held that the tribe retained its hunting and fishing rights under the Wolf River Treaty of 1854, as the fishing and hunting rights were implied in the treaty. In addition, the Court stated that these rights were not abolished by the Termination Act, but rather would necessitate specific congressional statutes, and without these plain and simple statements by Congress, these rights could not be taken away. In his dissenting opinion, Justice Stewart acknowledged the hunting and fishing rights given to the Menominee tribe in the Wolf River Treaty, but agreed with the state of Wisconsin that Congress nullified those rights with the Termination Act. Justice Stewart, joined by Justice Black, therefore would have reversed the decision of the Federal Claims Court, letting the ruling of the Wisconsin State Supreme Court stand. Of the hundreds of treaties signed by the U.S. government with the Native Americans, less than 1 percent were honored. This decision placed the Wolf River Treaty in that small percentage. However, the greater impact was in expanding the rule of law for a portion of the population with very little history of secured property rights, thereby stretching the tent of American promise over a wider group of "We the people."

MILLER, G. WILLIAM

Born: March 9, 1925, in Sapulpa, Oklahoma; Died: March 17, 2006, in Washington D.C.; Nationality: American; Professional Interests: Chairman of the Board of Governors of the Federal Reserve (1978–1979), Secretary of the Treasury (1979–1981).

G. William Miller was born in 1925 in Sapulpa, Oklahoma, but was raised in Borger, Texas. His father was a businessman who started a furniture store during the oil boom, which would later fail as a result of the Depression.

William Miller attended junior college in Texas before joining the U.S. Coast Guard. While in the Coast Guard, he pursued a degree in engineering. He graduated from the Coast Guard Academy in New London, Connecticut, with a BA degree in marine engineering. Following graduation, he served as a Coast Guard line officer in Okinawa and Shanghai. In Shanghai, he met Ariadna Rogojarsky, a Russian émigré. They were married in 1946.

After completing his service in the U.S. Coast Guard, Miller earned a law degree from Boalt Hall School of Law at University of California, Berkeley. After finishing at the top of his law school class, Miller joined Cravath, Swaine & Moore, a Wall Street law firm.

In 1956 he left the firm and joined Textron Inc. In 1960 Miller was named president of Textron, and in 1968 he became Textron's Chief Executive Officer. In 1974, he added Chairman to his titles along with CEO. While at Textron, he became a reputable business leader, winning the respect of his community and business leaders. He was credited with growing Textron into a global manufacturing firm.

Miller was involved in Democratic politics, which would ultimately lead to his appointment as Federal Reserve Board Chairman by Jimmy Carter. Before being appointed Fed Chairman, Miller served as a director at the Federal Reserve Bank of Boston. Miller endorsed expansionary monetary policy to promote economic growth rather than simply fighting inflation. He wanted the Federal Reserve to encourage investment, which he felt the Fed could control more than inflation. He also wanted to reduce consumption of foreign oil, cut government spending and taxes, and moderate wage demands and price increases. Miller believed inflation was out of the Fed's range of control, and he believed that the dual mandate of fighting inflation and lowering unemployment could be tackled together.

In 1979, President Carter appointed Miller Secretary of the Treasury. As Treasury secretary he negotiated the $1.5 billion loan guarantee to Chrysler Corporation to prevent the company from filing for bankruptcy. He also arranged both the freezing and unfreezing of Iranian assets during the 1979–1980 Iranian hostage crisis. As Treasury secretary he held government positions with the U.S. Industrial Payroll Savings Committee, and he chaired Plans for Progress for President Carter.

After completing his time as the Federal Reserve Board chairman and secretary of Treasury, Miller founded G. William Miller & Co., a Washington private investment company. Recruited by Presidents Kennedy, Johnson, and Carter to positions to combat unemployment and develop equal employment opportunities, as well as fighting inflation and promoting private investment through tax policies and his role at the Fed.

William Miller died at the age of 81 on March 17, 2006, in Washington, D.C.

MONETARIST ECONOMIC THOUGHT

Monetary policy uses instruments such as interest rates to adjust the amount of money in the economy. Monetarists believe the objectives of monetary policy are best met by targeting the growth rate of the money supply. Monetary economic thought gained prominence in the 1970s to bring down inflation in the United States and the United Kingdom. It greatly influenced the Federal Reserve's decision to stimulate the economy during the global recession of 2007–2009.

Nobel laureate Milton Friedman is a key economist associated with the popular rise of monetary economic thought. Friedman argued that poor monetary policy by the U.S. central bank, the Federal Reserve, was the primary cause of the Great Depression in the United States in the 1930s. The failure of the Federal Reserve to offset forces that were putting downward pressure on the money supply and the Fed's actions to reduce the stock of money were the opposite of what should have been done.

The foundation of monetarist economic thought is called the Quantity Theory of Money (QTM), or the Equation of Exchange. The theory is an accounting identity, meaning it must be true. QTM states that the money supply (M) multiplied by velocity (V) equals the nominal, the number of goods and services sold (Q) multiplied by the average price paid for them (P): $MV = PQ$. The only controversial variable is velocity (V), the rate at which money changes hands. Monetarist theory looks at velocity as generally stable, implying that nominal income is largely a function of the money supply. Variations in nominal income reflect change in real economic activity and inflation.

The decade of the 1970s was one of fairly constant increases in velocity validating the quantity theory of money. Nominal GDP could be predicted with the rate of money growth and a predictable velocity of money. Predictability became unpredictability in the 1980s and 1990s, when the velocity of money became quite volatile with periods of both declines and increases. This unpredictability brought into question the relationship between nominal GDP and the money supply—and by extension, the QTM.

The validity of monetarist economic thought came into question, and economists began looking for answers. Some asserted that new banking rules and changes in financial instruments were the culprit. During the 1980s, banks were allowed for the first time to pay interest on their checking accounts, blurring the difference between checking and savings accounts.

Due to this unpredictability of velocity, most economists today reject the unquestioning attention to money growth that is at the heart of Monetarist Economic Thought. Undoubtedly, the most important issue is that inflation cannot continue forever without increases in the money supply. Monitoring and controlling it should be a primary responsibility—if not the only responsibility—of the Federal Reserve.

The opposite of Monetarist Economic Thought is Keynesian Economic Thought. Keynesians and Monetarists fought head-to-head in the 1970s. Keynesians believe velocity is inherently unstable, as had been proved from 1981 and on. They do not believe that markets adjust quickly to return to potential output. Keynesians believe short-term interest rates were a more effective tool to manage the economy's health, measured by GDP, as opposed to the money supply (M) price (P) relationship of QTM. Therefore, Keynesians attach little or no significance to the QTM.

Because the economy is subject to deep swings and periodic instability, it is dangerous to take unrestricted power away from the Federal Reserve. The Fed should have some leeway or "discretion" in guiding policy. Most economists conclude that the Keynesians won the war but that the Monetarists won many battles. Because of the healthy debate, Keynesians are more convinced of the importance of the money supply and monetary policy, especially over the long run.

MONETARY CONTROL ACT OF 1980

The Depository Institutions Deregulation and Monetary Control Act of 1980 is the formal name for the piece of legislation that was passed under Paul Volcker, the Federal Reserve Chairman at the time, and signed into law by President Jimmy Carter. Prior to the Monetary Control Act, financial sector regulation was still considered weak from the Great Depression.

This act has nine titles or sections that cover many areas that will impact financial institutions. The act is considered one of the most important changes to financial institutions since 1933. The Monetary Control Act of 1980 revised previous regulations regarding bank reserves, Federal Reserve services, and deposit requirements. It changed the operations of all financial institutions and many businesses.

Prior to passage of the Monetary Control Act of 1980, depository institutions were allowed to pay only fixed interest on their deposits that had been mandated by the government since the Great Depression. Now, savers were placing funds in other savings vehicles that were less stable, and savings overall became less appealing since savers were not given a positive incentive for doing so. This alone limited banks' role and the impact they could play in financial markets.

The act addressed deregulating financial institutions that accepted deposits, simultaneously improving monetary policy controls of the Federal Reserve. The nine sections under the Depository Institutions Deregulation and Monetary Control Act of 1980 included Monetary Control Act of 1980, Depository Institutions Deregulation, Consumer Checking Account Equity Act of 1980, Powers of Thrift Institutions and Miscellaneous Provisions, State Usury Laws, Truth-in-Lending Simplification, Amendments to the National Banking Laws, Financial Regulation Simplification Act of 1980, and Foreign Control of United States Financial Institutions.

The Monetary Control Act of 1980 includes reporting requirements, reserve requirements, pricing for services, and effective dates. One portion of the Monetary Control Act that focuses on Reporting Requirements states that all depository institutions must accurately report their assets and liabilities. These reports must also be made directly available to the Federal Reserve Board, where there are other member banks or depository institutions as well as entities such as the FDIC. Another key section of the act hones in on reserve requirements, which are a huge factor and necessity in the conduct of monetary policy.

One goal the act sought to accomplish was to increase savings and create a stable, credible, and safe financial environment. A key component of the act provided for the gradual elimination on interest rate limits, and allowed interest-bearing transaction accounts. Before the act, Regulation Q assigned interest rates that could be awarded to deposit accounts. Banks were unable to pay interest on checking accounts or demand deposits, and savings account rates were significantly lower than market rates. During this time, savers retreated to accounts such as money market mutual funds, which would earn a higher interest rate but were much less regulated.

Banks were at a huge disadvantage and had an incredibly difficult time attracting savers because of these interest rate restrictions. Essentially, savers were penalized for using banks—so they sought other avenues, creating disintermediation. Disintermediation involves the flow of funds from banks to other savings vehicles.

Eliminating the restrictions on interest rates was not accomplished immediately. It took nearly six years for the transition to be completed. The result improved the banks' ability to compete in the financial markets. An incentive for savers and investors was to earn higher rates of return in the banking sector.

Monetary control was the other primary goal of the Monetary Control Act of 1980. Inflation was a huge concern during this time, reaching double digits in the late 1970s. One of the most critical components of the law was the establishment of reserve requirements that banks had to have on hand. This is perhaps one of the greatest tools of modern monetary policy, and ultimately it has a substantial impact on the money supply. Before reserve requirements were the standard for all depository institutions, only commercial banks had to adhere to this protocol. Reserve requirements state that a bank must maintain a certain level of funds either in vault cash or accounts at the Federal Reserve relative to the bank's deposits on hand. In exchange, these institutions could now use the Federal Reserve's discount window for borrowing, which was previously available to member banks only. In order to implement these changes, there would be an eight-year phase-in period of nonmember institutions. The act also allowed the Federal Reserve to begin charging fees for services they provided, such as currency and coin storage, check clearing and collecting, and wire transfers. These new regulations also gave us the FDIC insurance thresholds, expanding the coverage from $40,000 to $100,000 limit.

All of these modifications and effects of the Monetary Control Act of 1980 gave the Fed greater control over the money supply and greater monetary control and influence. Few pieces of legislation have been passed that have had a greater impact on monetary policy than the Monetary Control Act of 1980. This act benefited savers, depository institutions, the Fed's control over the money supply, and ultimately financial markets.

MONETARY ECONOMICS

Monetary economics is the macroeconomic study of money supply and the effect that government policies have on employment, inflation, and economic output. Monetary policies, implemented by central banks, determine the supply of money and the cost of borrowing. Policies may be expansionary or contractionary, and they include open market operations, required reserve ratios, and the discount rate. By controlling the supply of money in an economy, government can control inflation and can indirectly influence economic factors that affect employment and growth.

It is essential to the study of monetary economics to identify the functions of money in society. *Money* is any item or commodity that is accepted as payment for debt, goods, or services. Historically, a wide variety of items have been used as money, including shells, tobacco, salt, cattle, grain, copper and gold. It has evolved to coin, currency, and electronic transactions.

There are three functions of money: as a medium of exchange, a store of value, and a unit of account. Money as a medium of exchange allows people to carry out transactions using an item that is generally accepted as payment for goods and services and as repayment of debts. Having a medium of exchange eliminates the need for *double coincidence of wants*, the bartering process by which goods are exchanged on the basis of mutual need. *Store of value* allows money to be held for use at a later time. *Unit of account* allows money to be a standard measure for identifying the prices of goods and services.

Governments' monetary policies are usually carried out by a central bank. The organization that operates as the central bank in the United States is the Federal Reserve System. The Federal Reserve's first step in creating monetary policy is to define and measure the money supply in the economy. The Fed defines monetary aggregates by grouping types of money that the public uses in similar ways. *M1* is the narrowest definition of the money supply; it includes funds used primarily as a medium of exchange, such as currency, coin, demand deposits, other checkable deposits, and traveler's checks. *M2* is a broader definition of the money supply, and it includes all the items from M1 plus savings deposits, small time deposits, money market deposit accounts, noninstitutional money market mutual funds, and other short-term money market assets. M2 is generally assets that are used as a store of value. It is important for the Fed to know the size and rate of growth of the money supply, because both factors have a significant impact on the well-being of the economy. The goals of the Federal Reserve in implementing monetary policy are to promote maximum employment, stable prices, and economic growth.

Monetary policy consists of two general policies: contractionary and expansionary. Expansionary monetary policy increases the supply of money, and contractionary monetary policy reduces the supply of money in the economy. The Federal Open Market Committee (FOMC) of the Federal Reserve System uses the following tools to influence the money stock: open market operation, the required-reserve ratio, and the discount rate.

Open market operation, such as buying or selling government securities in the open market, has the function of expanding or contracting the amount of money in the economy. Purchases inject money into the system, which increases the supply of money. When supply is increased, the price, or interest rate, paid for money decreases. Falling interest rates stimulate growth, because they provide incentives for consumers to spend and firms to invest. Selling securities on the open market has the opposite effect, reducing the supply of money and thereby increasing the federal funds rate.

The *required-reserved ratio* is the dollar amount of deposits that banks are required to hold as cash in their vault or as deposits at the District Federal Reserve Bank in relation to the amount of checkable deposits. The amount of reserves required changes as the amount of deposits increases, and at the sole discretion of the Board of Governors. The goal of banks is to keep the amount held in reserves to a minimum, since they cannot earn interest on this money by loaning it out. Because these funds are not in circulation, they are not counted as part of the money supply. Any deposits that the bank holds in excess of the required reserves are called excess reserves, and the banks can use them to make loans or to purchase government securities. The Fed can affect the money supply by changing the amount banks are required to hold on reserves on all deposits. As supply decreases (or increases), interest rates rise (or fall).

When banks need to borrow money, they have the option of borrowing from the Federal Reserve and paying an interest rate called the *discount rate*. The Fed may increase the rate at which it is willing to lend funds to banks, which will affect the quantity of money demanded by the banks. As rates increase, demand will fall, and vice versa. When banks borrow less, the money supply decreases and provides incentives for saving rather than spending.

When the economy experiences an inflationary period, the Federal Reserve will adopt a contractionary monetary policy to decrease the money supply in the economy. The Fed does this by selling government securities, raising the reserve rate, and/or increasing the discount rate. When the economy experiences a period of recession, the Federal Reserve will adopt an expansionary monetary policy to increase the money supply in the economy. The Fed does this by purchasing government securities on the open market, lowering the reserve rate, and/or lowering the discount rate.

MONETARY POLICY

Monetary policy is the policy of determining the quantity of money liquidity in an economy. *Liquidity* in an economy is measured by the amount of cash, credit, and cash complements, such as money market mutual funds, available for purchasing goods and services. Monetary policy is the responsibility of a nation's central banking authority. An economy's *central banking authority* is the central regulatory agency responsible for regulating a nation's banking system. This central agency could take the form of a central bank, a currency board, or other central regulatory agency.

Universally, the goal of monetary policy is stable prices. In the United States, monetary policy was formalized with the Federal Reserve Act in 1913. As the United States' central bank, the Federal Reserve System has the added goal of achieving low unemployment. Central banks use monetary policy to influence interest rates—that is, the price of money. Monetary policy also determines the quantity of money in an economic system, along with the rate of the money supply's growth or reduction.

Central banks influence employment, economic growth, and the general level of prices. Using monetary policy tools, central banks influence the quantity of money, credit, and interest rates used to purchase goods, services, and productive resources. Central banks have three main tools to effectively implement monetary policy. First, a central bank can lower or raise the discount rate. The *discount rate* is the short-term interest rate the central bank charges its depository institutional customers, who borrow from the central bank mostly in overnight loans. A second tool for monetary policy is to alter the reserve requirement of banks. The *reserve requirement* is the amount of money reserves the banks, under the central bank's jurisdiction, are required to maintain in their vaults at the end of each business day.

The third, and primary, tool is buying and selling government securities (bills, notes, bonds) on the open market to influence nominal interest rates by influencing the fed funds rate. The *fed funds rate* is the overnight interest rate that banking institutions charge each other for overnight loans. In the United States, the open market operations are a weekly event of the Domestic Trading Desk at the Federal Reserve Bank of New York and the Federal Open Market Committee (FOMC) of the Federal Reserve System. In the open market operations, dealers and brokers bid for the U.S. securities, and the distribution of the securities is based on a competitive market, not on selection by the central bank.

In the United States, the Federal Reserve System is the central authority responsible for regulating the nation's banks and using monetary policy to determine the monetary size of the economy. Monetary policy is the function of the Federal Reserve System to influence the economy. Implementing the three tools of monetary policy, the Federal Reserve System can control both the quantity of money and the amount of credit in an economy.

Using the tools of monetary policy, expansionary monetary policy is applied when an economy is lagging and near the bottom of the business cycle. To stimulate and expand the economy, the central banking authority could lower the discount rate, reduce the reserve requirement, or buy U.S. securities to expand the quantity of money in the economy. Contractionary monetary policy is prescribed when the economy is accelerating, with excessive demand by consumers resulting in inflation (higher general price level); to contract and be restrictive, slowing down the economy, the central banking authority can raise the discount rate, increase the reserve requirement, or sell U.S. securities to contract the quantity of money in the economy.

Critics of Monetary Policy

Not everyone is a supporter of monetary policy. Critics of monetary policy claim that an economy is at risk the more influence monetary policy has on the economy. If the central banking authority uses monetary policy too freely ("loose monetary policy"), an economy's inflationary pressures are greater. Conversely, if monetary policy is too strict ("tight monetary policy"), the economy has deflationary pressures that keep prices, wages, and investment values declining. Critics suggest the banking authority cannot accurately predict with precision and timing the monetary policy's proper positioning within an economy at any given point in time.

A second criticism of monetary policy is timing. Critics make the claim that monetary policy has an implementation lag that makes monetary policy ineffective. They suggest that by the time any decisions regarding monetary policy are implemented, the economy would have moved on, and the current economic condition would not be the same as when the monetary policy decision was made.

MONEY

Most people would refer to *money* as the coins and bills in their wallet or the paycheck they receive from their job. Economists define *money* in terms of its three uses. Money is anything that serves as a medium of exchange, a unit of account, or a store of value. Money also has distinct characteristics that make it common throughout the world.

Money as a Medium of Exchange

Money as a medium of exchange is anything that is used to determine value during the exchange of goods and services. Without the use of money, people acquire goods and services through the barter system. This type of exchange would require a great deal of time and energy. First, one would have to find someone who wanted to barter for the items that one has, and second, the two parties would have to agree to the value of each item or service. This type of exchange works well only in small, traditional economies.

With the use of money as a medium of exchange, one only needs to find someone who is willing to pay the amount that a good or service is worth. Because money makes exchanges so much easier, people have been using it for thousands of years.

Money as a Unit of Account

The use of money as a unit of account provides a means for comparing the values of goods and services. With the use of money, one can compare the cost of an item offered at different locations because the price is expressed in the same common way in every location. For example, in the United States, the value of a good or service is expressed in dollars and cents. Other countries have their own forms of money that serve as units of account, such as the Japanese yen or the British pound.

Money as a Store of Value

When money is serving as a store of value, the currency keeps its value if one decides to hold on to it instead of spending it. The money will still be valuable and will be recognized as a medium of exchange weeks, months, or even years into the future.

Money serves as a good store of value, with one important exception. Sometimes economies experience a period of rapid inflation. If an economy experiences inflation, the saved money loses its value, or buying power, at the rate of inflation. For example, if the United States experiences 10 percent inflation during a year and someone has stored money for that same year, when that person uses that money it will have 10 percent less buying power. Therefore, when an economy experiences inflation, money does not function well as a store of value.

Common Characteristics of Money

The coins and paper that are used as money in the United States today were not always used as currency. In the past, societies have used a wide range of objects as currency. Cattle, salt, furs, precious stones, gold, and silver have all served as currency at various times in various places. Even teeth, rice, shells, and olive oil have been used as currency. Although all of these items were used successfully in the past, none of them would function very well in the economies of today. Each of these items lacks at least one of the six common characteristics that economies use to judge how well an item serves as currency: durability, portability, divisibility, uniformity, limited supply, and acceptability.

Durability

Objects used as money must withstand the physical wear and tear that comes with being used over and over again. If money wears out or is destroyed too easily, it cannot be trusted to serve as a store of value. Unlike salt, rice, or olive oil, coins last for many years. Also, when paper bills wear out, the U.S. government can easily replace them with new bills.

Portability

Currency needs to be easily transferred from one person to another. It must be able to be carried as people go about their daily business; therefore, it must be lightweight and small. Paper money and coins are very portable, which is why they are used as the primary means of currency throughout the world.

Divisibility

For money to be useful, is must be easily divided into smaller denominations or units of value. When money is divisible, people can use only as much of it as necessary for any exchange. Most currencies around the world consist of various denominations, such as 10-cent coins, 50-cent coins, $1 bills, $10 bills, and so on.

Uniformity

Any two units of money must be exactly the same in terms of what they will buy. In other words, people must be able to count and measure money accurately. A $1 bill in the United States must always buy $1 worth of goods or services in order for the currency to work accurately.

Limited Supply

Supply creates the value of items; currency must also be in limited supply in order to have value. If leaves were used as currency and your nation was filled with trees, the currency would be in too great an abundance to have any value. Therefore, in the United States as well as most other nations, the government controls the supply of money in circulation.

In the United States, the Federal Reserve System is the government-run entity that controls the money supply. It is able to monitor, distribute, and limit the amount of money available at all times. This system helps to keep the amount of money is circulation in limited supply, which in turns helps to maintain the value of the currency.

Acceptability

Finally, everyone in an economy must be able to exchange the objects that serve as the money (dollars and coins) for goods and services in said society. When one person uses a certain currency, it must be able to be reused by the receiver of the currency in that person's next transaction throughout the entire society.

In the United States, people expect that other people will continue to accept the paper and coins that are issued by the government in exchange for purchases of goods and services. The use of the money issued and accepted throughout a nation makes an economy flow more easily and with a common currency language.

MONEY ILLUSION

Inflation is an ever-present phenomenon of economies. It implies that the real value of money or the purchasing power of money has eroded, which theoretically is offset by increasing wages. The money's real value therefore does not have an invariant relationship to its nominal representation—that is, the numbers appearing on coins and notes. *Money illusion* is the failure to recognize this changing relationship. It is therefore a bias in the assessment of the real value of money. This undue influence of the money's nominal representation may extend to economic decisions made by firms, households, and individuals. If the money illusion has such consequences, it is a serious blow to contemporary macroeconomic theory.

Several types of evidence have been suggested in support of the existence of the money illusion. Firms are infrequently indexing contracts to take expected inflation into account. Prices are observed to change more slowly than supply and demand. In housing markets, the ratio of rental to purchase prices depends on nominal interest rates. In stock markets, nominal loss aversion is reflected in the reluctance to sell assets at nominal rather than real losses. Yet, such observations have other possible explanations. That the money illusion plays a role in decision-making is still conclusively supported by experiments simulating real-world decision-making. A psychological account is that people know both the nominal value and the real value of money, but that the former dominates because it is salient and, unlike the latter, does not require to be calculated. Except in cases of hyperinflation, the nominal value may also be sufficiently accurate. Investing additional effort would lead to adjustments for inflation, although not always correctly.

Money illusion is an example of a wider set of phenomena related to how the value of money and prices are perceived. Research shows that the nominal representation of the money exerts a strong influence on citizens' adjustments to the change from domestic currencies to the euro, which occurred in 2002 in 12 of the European countries that make up the European Monetary Union (EMU). As an example, Italian lire were numerically much larger than the euros that replaced them. After this change, for some time people perceived prices to be lower. Experiments have also demonstrated that such a change in nominal value affects product choices. Even two years after the euro changeover, field studies show that many citizens still faced problems in their daily economic transactions. Learning prices in the new currency rather than converting from the new to the old fostered quicker adjustments. Dual pricing (disclosing prices in both the old currency and the new), as practiced in some of the EMU countries, improved short-term adjustments but probably impeded long-term adjustments.

Tourist-spending in unfamiliar foreign currencies is another demonstrated effect of the nominal representation of prices. In the EMU countries, where the euro is a fraction of the former domestic currency (smaller nominal value), statistics showed a steep increase in spending after 2002. Furthermore, experiments demonstrate overspending and underspending, depending on whether the unfamiliar foreign currency is a fraction or a multiple of the familiar domestic currency. In the EMU, with a common currency, such effects are eliminated among citizens traveling between the countries as soon as they have learned the value of the new currency. In other countries, tourists are frequently helped by electronic charging systems converting prices in the foreign currency to the domestic currency.

A third example is depreciation of national currencies. This should have effects similar to those of the euro changeover. A difference between inflation and a currency change or depreciation is that inflation (price increases) is not in general an instantaneous shock but a creeping one. It is therefore difficult for consumers to distinguish inflationary price increases from other price changes or to assess whether the price increases are compensated by wage rises. Consistent with this, it has been shown that perceived inflation is distorted in systematic ways other than those due to the money illusion. The usual information policies to inform the public about monthly or annual inflation may need to be improved. It is clearly important that actors in markets have an accurate perception of the value of money—at present and in the future.

MONEY MULTIPLIER

The money multiplier is very closely linked to fractional reserve banking and the reserve requirement established by the Federal Reserve Board. Assuming that banks do not hold any excess reserves and that individuals deposit their money into banks, the *money multiplier* is used to calculate how much new money will be generated through the banking system from one initial deposit or a purchase of bonds or other assets by the Federal Reserve. The Federal Reserve can control the money multiplier and the money supply by increasing or decreasing the reserve requirement. The *reserve requirement* is the percentage of each deposit that banks must keep on hand rather than lending. However, individual banks can choose to keep excess reserves. This would result in a decrease in the intended money multiplier of the Federal Reserve.

To understand how the money multiplier works, one must understand fractional reserve banking. *Fractional reserve banking* is a banking system that requires individual banks to keep only a specific percentage or fraction of each deposit on hand; the excess can be loaned to consumers or business owners or used to purchase bonds and other assets.

For simplicity, the following example will be based on a banking system that loans 100 percent of its excess reserves to consumers and has a reserve requirement of 10 percent. If a banking customer deposits $1,000 into a bank, that bank will retain $100 (10 percent required reserves) and loan the remaining $900 to another banking customer. The second banking customer will use the money to purchase goods and services, which results in a $900 deposit into a second bank. In just these two simple transactions, $900 was created through the fractional reserve banking process. The second bank will retain $90 (10 percent required reserves) and loan the remaining $810 to yet another banking customer. The third banking customer will use the money to purchase goods and services, resulting in $810 deposited into a third bank. If this process continues, $10,000 of money will now be in the economy as a result of the fractional reserve banking system.

To calculate the money multiplier, use the formula (1/rr) with rr being the reserve requirement. To find how much money will be created with an initial deposit of money that was already in the money supply, such as cash held by a banking consumer, use the formula [(1/rr) x deposit] – deposit. The initial deposit must be subtracted because the initial deposit was already in the money supply. Using the example from above, [(1/0.10) x $1,000)] – $1,000, a $1,000 deposit will result in an increase of $9,000 into the money supply. If the initial deposit or bank holding was not already in the money supply, such as a bond held by a bank purchased by the Federal Reserve, the initial deposit or monetary injection is not subtracted because that money was never in the money supply. If the Federal Reserve purchased a $1,000 bond from a bank, the reserve requirement was 10 percent, and banks lend out 100 percent of excess reserves, the money supply would increase by $10,000, or (1/0.10) x $1000.

During economic contractions, the Federal Reserve will use the concept of the money multiplier to increase the money supply, which reduces key interest rates and encourages consumer and investment spending—which increases aggregate demand and, hopefully, reverses the contraction and restores the economy to long-run equilibrium. Lowering the required reserve ratio can increase the money multiplier. If the required reserve ratio is 20 percent, the money multiplier will be (1/0.2), or 5. If the required reserve ratio is 5 percent, the money multiplier will be (1/0.05), or 20.

Conversely, the multiplier can be decreased by an increased required reserve ratio. During rapid economic expansion with high inflation, the Federal Reserve can use the concept of the money multiplier to decrease the money supply to increase interest rates, discourage consumer and investment spending, and decrease aggregate demand. In theory, this will reduce inflation and restore the economy to long-run equilibrium.

While it may appear easy for the Federal Reserve to increase and decrease the money multiplier—and thus easy to increase and decrease the money supply, and have some control over economic activity—the Federal Reserve has limited control over the money multiplier. The money multiplier ultimately depends on banks lending their excess reserves and consumers depositing their money into banks. If banks choose not to loan excess reserves, the money multiplier will decrease and the potential growth rate of economic activity could slow. In addition, if consumers do not deposit their money in banks, but rather keep it at home in a safe, the banks will not be able to participate in the fractional reserve banking system and the money multiplier will effectively be zero.

Consumer confidence in the United States' fractional reserve banking system and the concept of the money multiplier is so important that many people believe that a loss of consumer confidence in the U.S. banking system was a major cause of the Great Depression (1929–1941). To restore confidence in the banking system, Congress passed the Emergency Banking Act of 1933, which created the Federal Deposit Insurance Corporation and insured banking deposits up to $2,500.

The money multiplier is dependent on (1) consumers trusting the banking system and electing to deposit their excess cash into the banking system, (2) individual banks lending out all their excess reserves, and (3) individuals being willing to borrow money from banks. If all three of these requirements are met, the money multiplier will be at its maximum. Any decrease in these requirements will decrease the money multiplier.

MONEY SUPPLY

The amount of money within a nation's monetary system is the *money supply*. The amount of money in circulation is important, because it helps central banks control economic indicators, unemployment, inflation, and deflation—that is, control price stability through monetary policy. Depending on economic needs, banks may pursue expansionary monetary policy or contractionary monetary policy. In the United States, the Federal Reserve manages the money supply. The money supply also has varying effects on the exchange rate and the business cycle.

Measuring the Money Supply in the United States

The Board of Governors of the Federal Reserve, the central bank of the United States, measures the monetary base of the U.S. economy. The base measures are called M1 and M2.

M1 is the total of cash and coins in circulation held by the public and in the financial institutions. M1 also includes demand deposits, such as checking accounts. M1 money supply measures money that is totally liquid and available for immediate use in the economy. M2 is all the money supply measured as part of M1 plus savings accounts, money market funds, and time deposits of less than $100,000 denominations. A much broader measure is called M3, which includes the M2 measured money supply along with long time deposits, larger institutional money market funds, and other large and liquid assets, such as short-term repurchase agreements.

Data on the money supply is reported by the Federal Reserve in two of their publications: H.3 and H.6 Statistical Releases.

Managing the Money Supply

The Federal Reserve controls the money supply through the Federal Open Market Committee (FOMC) and open market operations, establishing reserve requirements, and setting the discount rate to influence lending practices of financial institutions. The most common action of the three is open market operations.

Open market operations involves the buying and selling of government securities to financial institutions in the open market. This influences both short-term interest rates and the amount of money reserves held by banks and financial institutions. When the Federal Reserve wants to increase the money supply, it will purchase government securities, releasing tangible currency into circulation. When the Federal Reserve wants to contract the money supply, it will sell government securities, so the money is returned to and held by the Federal Reserve.

Another option for controlling the money supply is through the Federal Reserve's discount rate. This is an interest rate charged for overnight loans offered by the Federal Reserve to banks. When the discount rate is small, more loans are being made (likely due to a smaller discount rate) than money supply is being expanded, since the Federal Reserve is providing reserves to the banks. *Reserves* are monetary assets that banks hold on to in order to have available liquidity of money to support operations. As such, the Federal Reserve also sets reserve requirements for banks in order to set a standard for a certain fraction of deposits of these funds to be held with the Federal Reserve. To meet the requirements, there are also transactions between banks in order to meet reserve requirements; this rate is called the federal funds rate.

The money supply is crucial to national operations and monetary policy. The primary goal of monetary policy is price stability. Concurrent with price stability, the Federal Reserve uses the money supply and monetary policy to support high employment, economic growth, financial market stability, interest-rate stability, and foreign exchange market stability (Mishkin 2012). When prices are stable, investors and businesses can operate with greater surety, therefore allowing for more dynamic movement in markets and greater volume of trade.

One of the biggest impacts of the money supply is its ability to control inflation rates. When the market is flooded with currency, the value of the currency decreases, because the price of goods increases. The relative purchasing power of money decreases when there is more of it in circulation. When a nation expands its monetary base, it runs the risk of hyperinflation in the future, so it is crucial that monetary policy is controlled and sensitive to potential repercussions. Conversely, when there is too little currency in circulation, it becomes harder to come by, which can also have adverse effects on the economy. Therefore, controlling and monitoring the money supply is critical to supporting the economy and sustaining yet controlling growth.

MORAL HAZARD AND BEHAVIORAL ECONOMICS

Moral hazard is present when one party to a transaction takes actions that a partner cannot observe; these actions can be relatively risky since the individual taking these actions does not bear the burden or costs of these risks. Moral hazard often arises in organizations. In a moral hazard environment, the informed party has some control over the unobserved attribute, which can result in moral hazard behavior. Resources are often invested to monitor possible moral hazard behavior, when this behavior can be harmful to the larger organization. To induce desirable behavior, the organization often designs incentive schemes, which tie rewards or punishments to performance.

In team production, output is the joint product of several agents' contributions. Team members interact extensively, and they are accountable as a team for economic outcomes. Alchian and Demsetz (1972) suggest that there is a source of gain from cooperative activity involving working as a team. The combined entity does enjoy opportunities that are impossible for individuals acting alone to exploit. However, compensation must be based on team production, and individual contributions to output cannot be easily identified. The free-rider problem arises in this setting (Holmstrom 1982) and can result in moral hazard behavior.

Teams may enhance the social interaction among members. Team membership per se may affect the behavior of participants. It is possible that peer norms come about through processes of mutual influence. Peer effects have the potential to internalize externalities in workplaces. Some studies incorporate social concerns into the analysis of behavior inside firms. Kandel and Lazear (1992) stress the role of peer pressure among team members. They argue that teams alleviate costly monitoring of workers by relying on internal motivation through peer pressure. Social ties among co-workers are advantageous, because social sanctions are an effective way to punish those who deviate from norms of high effort. Rotemberg (1994) writes that the internal pressure for cooperative behavior is altruism. As long as workers' inputs are complements and workers can observe the others' choice of preference, workers commit to the level of altruism they have chosen.

Unlike legal rules, norms are not supported by formal sanctions. Norms often direct individuals to undertake actions that are inconsistent with selfish actions. The incentive to comply with norms derives not only from the enforcement of costly punishment by others, but also from reputation-building for oneself (Teraji 2013). The fear of punishment sometimes has a positive effect on cooperation. Fehr and Gächter (2000) indicate that many individuals are willing to punish unfair behavior at a personal cost. Potential punishers are not themselves the victims but have merely witnessed the unfair behavior. This willingness suggests that cooperation has evolved through the sacrifice of altruistic punishers who are ready to incur some costs to prevent unfair behavior. On the other hand, disobeying accepted norms may involve a loss of reputation. People are fair because they care about their reputation. They have to be rewarded for maintaining a good reputation, and they have to be willing to comply with norms. Norms are constituted by expectations shared by members in a population and are jointly recognized among the population.

MULTIPLIER EFFECT

The *multiplier effect* is a measure of how much final spending will increase when it is given an injection of additional spending in an economy. The injection of new spending is sometimes the result of expansionary fiscal or monetary policy. Additionally, the injection of new spending could be the result of private investment, such as the construction of a new manufacturing facility or an increase in new jobs to a community. Any increase in consumer income will result in new spending. As a result, the final spending amount is greater than the initial spending, due to the multiplier effect.

In a simple circular-flow economic model, money is either consumed or saved. The measures of whether the additional money is consumed or saved are the marginal propensity to consume (MPC) and the marginal propensity to save (MPS), respectively. Both measures are ratios of consuming or saving of the additional dollar, resulting in MPC + MPS = 1.

The multiplier effect is dependent on the marginal propensity to consume (MPC), which is the percentage of each additional (marginal) dollar that will be spent on goods and services. If the MPC is 0.80, 80 cents of every additional dollar will be spent on consumption and 20 cents will be saved. If the MPC is 0.80, the marginal propensity to save (MPS) is 0.20. The simple spending multiplier is used to calculate the multiplier effect or to determine how much final spending will result from any increase in new spending. The formula for the simple spending multiplier is 1/(1 – MPC) or the reciprocal 1/MPS. After the simple spending multiplier is calculated, to see the multiplier effect, simply multiply the new spending by the simple spending multiplier. If there is an additional $1,000 spent in an economic system and the MPC is 0.80, the final spending amount will be $1,000 [1/(1 – 0.80)] = $5,000.

It may seem incredible that an increase of $1,000 in spending will result in a final spending amount of $5,000 if the MPC is 0.80, but the thinking behind the multiplier effect is clear. If person A spends any additional money, that increased spending is received by person B, who spends 80 percent of person A's spending on consumption from person C, who spends 80 percent of person B's spending on consumption from person D, and this continues until there is no additional money to spend, which will result in the final spending amount. If a new road is constructed, the construction workers will use their additional income to purchase goods and services, and the sellers of these goods and services will spend their additional income on even more goods and services, and the sellers of those goods and services will spend their additional income on even more goods and services.

When the MPC increases, the multiplier effect will increase, and when the MPC decreases, the multiplier effect will decrease.

Fiscal policy changes are often the focus of discussion concerning the multiplier effect. During times of economic contraction, the government will increase spending, decrease taxes, or both. The multiplier effect can be used to predict the amount of increased economic activity that will result in an increase in government spending or a decrease in taxes. Say, for example, that the government wants to either increase spending by $1,000,000 or decrease taxes by $1,000,000. The first step is to find or calculate the MPC. In this example, the MPC will be 0.75. The second step is to calculate the simple spending multiplier, which is [1/(1 – 0.75)], or 4. The last step is to multiply the amount of government spending $1,000,000 by 4, which is $4,000,000. In this example, an increase in spending of $1,000,000 will result in an increase of final spending of $4,000,000. However, a decrease in taxes of $1,000,000 will result in a smaller increase in final spending compared to an increase in government spending, because the taxpayers or consumers must first spend the reduction of taxes that is subject to the marginal propensity to consume. If the MPC is 0.75, a decrease in taxes of $1,000,000 will yield an increase of only $750,000 in new spending, because 25 percent of the tax decrease was not spent on consumption, but saved. A decrease of $1,000,000 in taxes will result in an increase of final spending of ($1,000,000 x 0.75) x [1 – (1/0.75)], which is $3,000,000.

When an economic system experiences a decrease in spending, that decrease is also subject to the multiplier effect, which will result in a greater amount of final spending lost compared to the initial loss of spending. The thinking is the same if the government eliminates spending on a construction project. The construction workers will experience a decrease in income, which will cascade into the other sectors of the local economy, creating even more job losses and an even greater reduction in spending.

The Federal Open Market Committee (FOMC) of the Federal Reserve can influence the marginal propensity to consume by increasing and decreasing the money supply. An increase in the money supply creates downward pressure on interest rates, which incentivizes consumers to increase spending, which increases the marginal propensity to consume. This expansionary policy is intended to help the economy recover from an economic contraction. Conversely, a decrease in the money supply creates upward pressure on interest rates, which discourages consumption and incentivizes savings, which decreases the marginal propensity to consume. This contractionary policy is intended to correct for high inflation.

NATIONAL BANK ACT OF 1863

A national or central bank is not an institution that has always been part of the United States. Alexander Hamilton attempted the first national bank, the First Bank of the United States, in 1791. It eventually failed, but the Second Bank of the United States was established in 1816 when signed into law by President James Madison. It, too, failed when its charter expired in 1836, and it was not renewed by Congress. The National Bank Act of 1863, with its revisions in 1864 and 1865, tried again to create a national banking system.

Prior to these national banking initiatives, banks were state-chartered. To have state-chartered banks, without federal oversight, was the predominant formula of the banking industry until the mid-19th century. As the dates of the National Bank Act would suggest, the origination of a national bank was a response to the Civil War. As the nation became divided and the Civil War ensued, state-chartered banks were not benefiting the war effort for the Union. The National Bank Act of 1863 created national charters for banks, and the National Bank Act of 1864 revised the original 1863 act. These two national bank initiatives were the predecessor to the Federal Reserve Act in 1913.

President Abraham Lincoln desired to apply some national influence on the banking industry and exert some control over it, but he was not interested in forming a central bank. The National Bank Act had three goals to benefit the Union. The first goal was to create a system of national banks under the influence of the federal government. The second goal was to establish a new national currency to help finance the Civil War. The third goal, also intended to help finance the Union's Civil War effort, was to establish a secondary market so the federal government could sell war bonds and Treasury securities. None of these goals was very popular with Congress at the time. The National Bank Acts of 1863 and 1864 had great difficulty getting passed by Congress.

The National Bank Act of 1863 set out a mechanism for creating the national currency and the national banking system. The federal government would sell government securities to banks, and these holdings would be the backing of a national currency. At the same time, the 1863 act levied a heavy tax on the currency of state banks, the goal being to drive the state bank-backed currencies out of the system. The plan failed, and this was in part the reason for the follow-up 1864 act.

The first goal of the National Bank Act of 1863 was to permit the establishment of national banks. Essentially the same as the private and state banks that already existed, the national banks would be chartered by the federal government. National charters were good for 20 years, subject to renewal at that time. This gave the federal government regulatory control, which was quite different from the banking control by the states. Nationally chartered banks had higher reserve requirements and were required to hold more capital. Also, they were forbidden to make real estate loans; nor were they able to make large loans to individuals if the amount exceeded 10 percent of the bank's capital holdings.

Second, the National Bank Act of 1863 and 1864 set out to establish a national currency. Today, a common currency is taken for granted, but in the mid-19th century there were as many as 200 different currencies in circulation throughout the states of the Union. Quite obviously, a common national currency would make interstate and national transactions much easier. This was accomplished through the national banks, as they were required to accept each other's banknotes at a value set by the federal government. The printing of these new national banknotes was the oversight responsibility of the newly created Comptroller of the Currency office. This new office, as set out in the 1863 Banking Act, would be an office of the Department of Treasury. The comptroller would also be responsible for inspecting the national banks to ensure that they were adhering to the capital requirements and values for the new national banknotes, or currency.

The final goal of the National Bank Act was to aid in the Civil War financing for the Union army. To this end, each nationally chartered bank was required to maintain a large deposit of U.S. Treasury securities with the comptroller, collateral for offering national banknotes. In return, the bank received the new national banknotes with a value of up to 90 percent of the market value of the bonds on which they were backed. A nationally chartered bank could make loans only up to the value of the securities that the bank had on deposit with the comptroller. If a bank wished to increase its loaning capability, it needed to increase its holdings of securities with the comptroller. This form of reserve banking created a secondary market for bonds, but more importantly at the time, and to achieve its goal, it provided funds to the Union without extensive borrowing. The first nationally chartered bank was the First National Bank of Philadelphia, but this was not the first to be in business. That honor went to the 15th chartered national bank, the First National Bank of Davenport, Iowa.

A third revision in 1865 levied a 10 percent tax on state currency—that is, currency that was not federally issued. The intent was to drive state currencies, and essentially state banks, out of existence. While the tax succeeded in eliminating state currencies, state-chartered banks invented the demand deposit, or checking, account. Many state-chartered banks converted to national charters. But they did not go away. With the invention of the checking account, the number of state banks actually grew, and they again became the dominant face of the banking industry.

As the Civil War ended, so did national banking. With the lack of a central banking mechanism to oversee monetary policy, the economy often suffered extreme peaks and troughs in the business cycle. By 1865, the number of national banks had grown to over 1,500, over 80 percent of the total number of national and state-chartered banks (Flaherty n.d.).

NATIONAL BUREAU OF ECONOMIC RESEARCH

The National Bureau of Economic Research (NBER) was officially founded in 1920. It is a nonprofit private research entity that promotes better understanding of the economy, and it is the largest economic research organization in the United States. The NBER's target audiences are policymakers and academic and business professionals. Over the years, the NBER has examined such important macroeconomic issues as business cycles, economic growth, demand for money, and national income accounting.

Today, the NBER is the top economic research organization in the United States. NBER researchers are well respected in the field and are among the leading scholars of economics and business in the world. NBER researchers have included 22 Nobel Prize winners in economics, 13 previous chairs of the President's Council of Economic Advisers, and many business and economics professors at leading research universities across the United States. In dealing with major issues related to economic policies, the bureau has five guiding principles: (1) analyzing and defining economics facts and their relationships, (2) analyzing quantitative measures of data, (3) pursuing a scientific approach to all economic problems, (4) publishing the findings with utmost regard to impartiality, and (5) refraining from making policy recommendations.

Although the founders of the bureau had very different opinions on economic and social policies, they all believed strongly that social programs should be based on objective knowledge of facts and reliable quantitative and scientific research approaches. The main question was how to obtain objective knowledge and ensure that the public would accept the NBER's objectivity. This question was raised in 1916, when Malcolm C. Rorty, an engineer and statistician, discussed the idea with Nahum I. Stone, an economist. Although the two men had very different views on social and economic policies, they agreed that to have an independent organization dedicated to finding facts on controversial economic issues would represent significant progress. They concluded that in order to earn the public's confidence, the organization should include a group of well-known and well-respected economists from different schools of thought, should follow a thorough quantitative economic research method, and should include representatives of all important organized interests—such as financial, industrial, and labor—in the country.

The start of World War I in 1917 delayed the establishment of the NBER until 1920. In January 1920, with enough funding available, the bureau was legally formed. It has never had any specific theories or policies to advance; neither has it had any obligations toward any other entities. This freedom of action and impartiality in findings has been essential for the NBER to earn the public's trust. In order to assure that a scientific approach is applied in all the research conducted, the board of directors has been responsible for reviewing the design, findings, and presentation of the data in each study. Publication of the findings depends on a favorable vote from the majority on the board.

The NBER's headquarters is in Cambridge, Massachusetts. The organization's board of directors consists of economists from the top leading research universities and research organizations in the United States. In addition, it employs research associates and research fellows, with fewer than 50 employees as support staff. Wesley Mitchell, the first director of research at the bureau, set the standards high and led a very productive research staff during his 25 years of service.

The bureau's first study was about the distribution, size, industrial composition, and growth and fluctuation of the national income. Because today's economic life is centered on either making or spending money, the resulting framework could be used as a basis for many other unanswered questions—questions regarding the magnitude, process, and consequences of aggregate changes in distribution of the nation's income. It took less than two years for the bureau to complete the national income study. The results were published in two volumes. But more importantly, through this work the bureau successfully established its reputation among public and professional individuals and organizations as a thorough and reliable research organization.

Studying the national income was just a starting point in developing deeper knowledge of the economy. While finishing an initial examination of the national income, the bureau had already started investigating the geographical distribution of the income, comparing it among different states. Furthermore, in 1921, the bureau started another related study on annual savings. Later, in 1930, Simon Kuznets, a student of Mitchell's and one of the bureau's staff, started leading a series of studies on the nation's income, savings, and expenditures. This important study extended over the next three decades and was considered the initial step in estimating the gross national product (GNP) and other related statistics.

In 1921, the board's executive committee approved Mitchell's proposal to study business cycles. In 1927, with the bureau's help, Mitchell published the first part of his proposal series. The study was titled “Business Cycles: The Problem and Its Setting.” The title was the same as the first part of the study done in 1913, but the later work included many new ideas and materials.

Over the years, the bureau has completed many important studies on subjects such as the fluctuations of savings, cyclical changes in productivity, and cyclical changes in employment. The bureau’s founders established a culture of strict action. Although it is difficult to focus on important economic issues while paying attention to their symptoms, it is not impossible. The founders’ stringent principle of scientific and empirical analysis and impartiality guided the bureaus’ work from one generation to another. The NBER has earned the trust and respect of government, business, and academic professionals. Today, the bureau’s budget is more than $6 million, and there are more than 100 research associates located in the United States and abroad who conduct important domestic and international economic studies (see www.nber.org).

NATIONAL DEFICIT VERSUS DEBT

The national *deficit* refers to the amount a government spends that is more than it takes in over a given period of time, usually one year. The national *debt* is the accumulation of government deficits over time. The publicly held debt consists of the U.S. Treasury securities held by individuals, financial intuitions, and foreign governments. Another portion of the debt, called the intragovernmental debt, consists of the Treasury bonds held by agencies of the federal government, including the Social Security Trust Fund. Since the 1930s, there has not been a consistent plan to pay down the national debt, and any decreases are a result of inflation and economic growth.

Deficit

Deficit spending occurs when a government spends more than it collects in revenue in a given year. These annual deficits contribute to the national debt, which is the total amount that a nation owes. Many things can contribute to deficit spending—such as national emergencies, including wartime; maintaining infrastructure and public goods; stabilizing the economy during a recession or a depression; and government programs such as Social Security, Medicare, and Medicaid.

To cover the deficit, the government must sell Treasury bonds, which are bonds that pay a fixed interest rate and mature in 10 years. These bonds generally have low interest rates, but they are safest since they are backed by the full faith and credit of the U.S. government. When these bonds mature, they pay the face value plus interest. Commonly, these bonds can be purchased through auction—and sometimes at less than face value.

Debt

The debt of the United States can be traced back to the Continental Congress, which borrowed money to finance the Revolutionary War. When the U.S. Constitution went into effect in 1789, the United States was already $75 million in debt. The nation's first Secretary of the Treasury, Alexander Hamilton, authorized the Treasury to borrow money so it could pay interest on the national debt; he also authorized Treasury bonds to be issued for the first time. Hamilton also used tariffs and taxes to pay down the national debt.

The nation was completely debt-free under President Andrew Jackson's administration (although a series of economic crises ensued after he left the White House). The United States next went into debt as a result of the Civil War, when the federal government borrowed $2.8 billion, or 30 percent of the gross domestic product (GDP) (Gramm and McMillin 2013). The public debt increased from $65 million to $2.76 billion by 1866 (Phillips 2013).

The Great Depression resulted in a large increase in the national debt, which reached 43 percent of GDP (or $40 billion) in 1934 (Phillips 2013). The U.S. debt was high after World War II, at about 130 percent of GDP (Gordon 2011). The post–World War II economic boom created a high demand for U.S. goods and services, a demand that remained high through the 1950s. During this same period, government spending was cut immensely. An economic boom and decreased government spending helped bring down the debt-to-GDP ratio.

In the 1970s, the debt-to-GDP ratio was 39 percent (Gordon 2011), the lowest since the Great Depression. In the 1980s, a recession increased the debt-to-GDP ratio again. As the U.S. economy entered the 1990s, the debt was 58 percent of GDP (Gordon 2011). As the economic boom of the 1990s continued, the federal government achieved a budget surplus for the first time in 30 years. In 2003, however, the debt-to-GDP ratio rose again, to over 61 percent, as a result of a recession (Gordon 2011). The Great Recession was also a significant contributor to an increase in the debt-to-GDP ratio. In 2009, it reached over 84 percent and continued until it reached 100 percent (Gordon 2011). To avoid increasing debt and a potential debt crisis, a nation must grow faster than the interest rate paid on its debt, or it risks no gains in economic growth.

There are many implications of a rising national debt. Economic conditions can be affected in the form of higher interest rates and increased income taxes, as well as the depreciation of the dollar.

A key issue that contributes to the national debt is government spending. Congress has struggled to establish policies on limiting the size of the nation's debt. In 1985, Congress established *sequestration*, which means that if Congress went over its deficit ceiling or spending caps, the budget would be subjected to automatic spending cuts. The Budget Enforcement Act of 1990 introduced a pay-as-you-go concept for the nation's budget. Any spending increases would have to be offset by tax increases.

Another issue confronting Congress and the national debt is what Congress must do when the debt ceiling is reached. The *debt ceiling* is a legal limit, set by Congress, that determines by how much the federal government can exceed its current debt obligations. The amount of additional debt the federal government increases can be changed only by a vote of Congress. Consequently, when the debt ceiling is reached, Congress must decide to either increase the debt ceiling (allow the debt to increase) or shut down the government. Congress has acted to increase the debt ceiling 77 times since 1962.

Currently, the U.S. federal debt exceeds 100 percent of GDP and continues to increase. U.S. taxpayers now and in the future bear the burden of paying the interest and principal of the debt, if surpluses can be achieved. The government's options for decreasing the national debt include cutting federal spending and increasing taxes. The costs and benefits of these options must be weighed carefully to determine what is best for the future of the U.S. economy.

NATIONAL INDUSTRIAL RECOVERY ACT

The National Industrial Recovery Act (NIRA) was passed in 1933 to help the United States' struggling economy. The purpose of the NIRA was to stimulate industry and to influence consumer purchasing power. Between 1929 and 1932, manufacturing production had declined by half. The NIRA, in conjunction with the New Deal, was intended to help heal the economy.

When President Franklin D. Roosevelt and his staff put this plan into action, the United States was in the midst of one of the worst economic crises in its history: the Great Depression. The NIRA started out as a great idea.

The NIRA created the National Recovery Administration, also known as the NRA, which attempted to create a "fair" playing field between similar industries. A blue eagle was the symbol for the NRA, and businesses would proudly hang it outside their buildings to show their support. If the blue eagle was displayed outside of a business, it meant that that business was participating in the attempt to help save the economy under the provisions of the NIRA. The NIRA also created the Public Works Association, or PWA, to put the federal government in control of public works.

A positive aspect of the NIRA was that in the midst of a terrible economic time, it inspired many people. Even though statistically it did not did not jumpstart the economy and improve the Great Depression as anticipated, it did give hope to the hopeless. It gave people jobs and a reason to keep pushing onward.

In the U.S. Supreme Court case *Schechter Poultry Corp. v. United States*, the Schechter Poultry Corporation had fought against the U.S. government due to unconstitutional actions. "Congress had overstepped its bounds by regulating local commercial activity" (Schechter 1935). The Schechter Poultry Corporation won the Supreme Court case, which started the downfall of the NIRA.

In the end, the NIRA both helped and hurt the United States. By raising wage prices, it actually hurt the economy. The NIRA brought business and government together by increasing the role the government played. When the economy went down and the Great Depression hit, the government had to step in. Roosevelt's leadership did help give the economy the kick-start it needed, even though the plan did not work the way it was supposed to. When the government oversteps its bounds with businesses, the outcome is not successful, as the National Industrial Recovery Act showed.

NATIONAL LABOR RELATIONS ACT OF 1935 (WAGNER ACT)

The National Labor Relations Act (NLRA) of 1935 (29 U.S.C. §§ 151–169) affected labor laws in the United States by protecting private-sector employees' right to organize themselves into labor unions. President Franklin D. Roosevelt signed the act into law on July 5, 1935. Unofficially known as the Wagner Act, this legislation recognized New York senator Robert F. Wagner's (served 1927–1949) efforts to respond to the Supreme Court striking down the National Industrial Recovery Act as unconstitutional.

A combination of (1) worldwide labor movements against exploitive employers and governments and (2) economic conditions in the aftermath of the Great Depression provided the impetus for Congress to propose a bill that would protect the rights of workers in the United States. In the 1930s, organized labor wanted protection from employers who spied on, interrogated, disciplined, discharged, and blacklisted union members. Workers organized themselves militantly, and between 1933 and 1934 numerous strikes occurred across the United States, some of them resulting in violent confrontations between workers who were trying to form unions and institutions, including the police, that were defending the anti-union employers.

Recognizing that difficult economic conditions had caused other governments to be violently replaced by communist ideology at the hands of a disillusioned labor sector, Democrats sought to keep the communist movement out of the United States. In addition, as outlined in Section 1 of the NLRA, members of Congress believed that industrial peace was essential to a functioning economy, and that suffering employees could hinder full economic production.

As stated in Section 1 [§151] of the NLRA,

> [T]he inequality of bargaining power between employees who do not possess full freedom of association or actual liberty of contract and employers who are organized in the corporate or other forms of ownership association substantially burdens and

> affects the flow of commerce, and tends to aggravate recurrent business depressions, by depressing wage rates and the purchasing power of wage earners in industry and by preventing the stabilization of competitive wage rates and working conditions within and between industries.

The passage of the NLRA gives employees the freedom to organize and form a legally protected bargaining unit, or trade union, through which to collectively bargain terms and conditions of employment. As a last resort, if there is an impasse with the employer on reaching an agreement, the act gives legal protection for unions to take collective action against the employer, including the organization of a strike.

In the decade that followed the passing of the Wagner Act, House and Senate Republicans repeatedly attempted to repeal or amend it; they were worried that its provisions contradicted the principles of a capitalist society, that it would hinder maximum growth and profit across industry markets, and that it would indirectly promote socialist/Marxist ideology in the United States. Republicans were so concerned about the promotion of this ideology that they encouraged businesses and employers not to comply, and to file an injunction in federal court to negate the act. All efforts by House and Senate Republicans either failed to pass in one or both chambers, or were vetoed by the president.

The provisions of the Wagner Act did not apply to government workers at any level of administration (federal, state, or local). In addition, because the Railway Labor Act covers workers in the railway and airline industries, they are also exempt from coverage under the Wagner Act. Other employees not covered by the act are agricultural employees, domestic workers, supervisors, independent contractors, and close relatives of individual employers. Employees whose religious beliefs prevent their joining and contributing to unions are also exempt from any requirement to associate or financially support them (Section 19).

Section 3 of the NLRA established the National Labor Recovery Board (NLRB), whose primary duties are to oversee the unionization process of employees, as well as to provide legal and financial support to unions seeking to prosecute an employer for violations. In this capacity, the NLRB can lead investigations, collect evidence, issue subpoenas, and call witnesses to testify and provide evidence.

Section 7 of the act explicitly addresses the rights of unions in the collective bargaining process. This section states that employees have the right to self-organize and to join or assist a labor organization. The bargaining unit can bargain for the collective group through representatives of its own choosing (as outlined in Section 9), and it can also participate in activities that would provide mutual aid or protection for employees. Section 7 also outlines that each bargaining unit is allowed only one representative, that employees are allowed to discuss wages with each other to ensure fair pay, that the union is allowed to promote itself to employees, and that employers are compelled to bargain in good faith with the representative for the employee unit.

Section 8 of the act outlines what would be considered unfair labor practices by employers. These include interfering with, restraining, or coercing employees in terms of exercising their rights guaranteed in Section 7 of the NLRA, interfering in either the formation of the labor organization or in the collection of financial contributions to support it, influencing employment or promotion on condition of discouraging or exemplifying nonsupport for unions, discriminating against employees who file charges or testify against the employer in union initiated cases, and refusing to bargain with the representative for the collective unit.

The NLRA also outlines what would be considered unfair practices of labor organizations against employees and employers. These include threats of job loss or punishment for lack of support toward the union or for choosing not to be a member; refusing to process a grievance because an employee criticized the union or its officials; firing employees who left the union; misconduct during pickets, including threats, assault, or preventing nonstrikers from accessing the employer's premises; and striking over issues unrelated to employment terms and conditions.

NATIONAL LABOR RELATIONS BOARD

In 1935, the National Labor Relations Act (NLRA) created the National Labor Relations Board (NLRB) for the purpose of improving working conditions by overseeing and protecting the rights of workers to organize. The act set out a framework from which nongovernmental employees could bargain for better wages and working conditions or could decertify a current labor union if they so choose.

The NLRA covers an array of labor rights for employees. Under the act, employees are protected to form a labor union or organization, decertify a labor union or organization, and engage in collective bargaining with their employer. The act also protects employees if they do not wish to bargain collectively, or if they wish to bargain collectively without the representation of a labor union. The NLRA provides employees with the right to collective bargaining for better working conditions, including wages. Under the act, employers are forbidden from interfering with their employees' right to form a union, join a union, or participate in union activities. However, it also protects employees who do not wish to participate in such activity.

The NLRB is headquartered in Washington, D.C. There are also more than 30 regional NLRB offices across the United States. The NLRB is made up of five members. The board members are appointed for five-year terms by the president of the United States with consent of the Senate. The members are staggered so that one term expires each year. There is a general counsel for the board who is also appointed by the president. The general counsel's term is four years. The general counsel's responsibility is to prosecute unfair labor practices. A division of judges hears the unfair labor practice cases and rules on their status.

Employees or employers who feel that their rights have been violated can file an unfair labor practice charge with the NLRB. The general counsel investigates the charges and determines whether a case exists to be heard. If it is determined that a charge has merit, the case is heard before one of 40 administrative law judges. Once the decision is determined, the board encourages the parties involved in the case to comply with the judge's decision. However, the right to due process permits the party found in the wrong to appeal the decision to the board. When the party does not comply with a decision, it is the responsibility of the general counsel to prosecute and seek legal enforcement in the U.S. Court of Appeals.

J. Warren Madden was the first chair of the NLRB. Madden created five separate divisions with the NLRB. Of the five divisions, the economic division was created to address three tasks. First, the economic division collects economic data to support the NLRB's position in court cases. Second, the division researches labor relations to support the board's decision and policy-making efforts. Third, its members write papers and conduct research on labor relations history, collective bargaining, and case studies regarding labor disputes so that they may serve as experts in the area of labor relations.

Like most new, far-reaching federal legislation, the NLRA faced several constitutional issues. Fearing that the composition of the Supreme Court would make it inclined to rule against the NLRB, Madden delayed court challenges until he felt the Court would be sympathetic to the NLRB. His tactics appear to have been successful. In 1937, in *National Labor Relations Board v. Jones & Laughlin Steel Corporation*, the Supreme Court upheld the constitutionality of the NLRA. Further, the Supreme Court endorsed the NLRB's rulings in 19 cases, and denied only 2 cases.

Interestingly, the American Federation of Labor (AFL) was the NLRB's most ardent rival in court. The AFL accused Madden of pitting the AFL against its union competitor, the Congress of Industrial Organizations (CIO). The two labor organizations would later merge to create the powerful AFL-CIO labor union.

In 1938, after prompting from the AFL, an investigation of the NLRB by the House Un-American Activities Committee confirmed that Madden had hired at least one member of the Communist Party of the United States: a 1940 House of Representatives Special Committee investigation was led by an antilabor representative, Howard W. Smith from Virginia. The committee's efforts led to major restructuring of the NLRB and expansion of the board from the original three members to the current five. The two investigations damaged the NLRB's reputation with both the public and Congress. While President Roosevelt supported the

NLRB, the reputational damage of the investigations has been connected with the eventual passage of the Taft-Hartley Act of 1947.

NATIONAL LABOR UNREST, 1894

The Panic of 1893 and the ensuing depression was a peak in civil unrest and the development of unions. The unionization movement grew in reaction to wage cutting during the depression. The year 1894 would see some of the nation's bloodiest strikes, starting with a national coal strike in April followed by a Pullman strike in the summer.

The United Mine Workers and the Knights of Labor called for a national strike in April 1894, and more than 200,000 miners were involved nationwide. The Knights of Labor, who called for an eight-hour day, led the strike. The two-month strike was bloody, violent, and deadly, and at least 11 miners died in the Connellsville region of Pennsylvania. One of the problems prompting the strike was that mining companies were unable to meet their payrolls. The strikers became what was called a "roaming army of Huns." The Hungarian, Polish, and Slavic workers united in the new union, which pushed the owners with violence. "Scabs" were often beaten to death, and mines were dynamited.

The strike was widespread, universal, and national, and thus news reports of the strike were diffused and inconsistent. Violence and deaths occurred in Alabama, Illinois, West Virginia, and Ohio. Governor William McKinley of Ohio ordered out troops and mounted machine guns on railcars. The strike lasted about eight weeks, as the workers broke along ethnic lines. But again, the rural nature of the operations often suppressed press reporting.

The economy ultimately helped end the strike. The coke companies in the Connellsville area brought in more than 2,000 black and Italian workers as scabs, paying recruiting agents $3 per person. The owners hired an army of 1,000 deputies at $5 per person. The economy, scabs, union division, and the hired army ended the strike in Connellsville by June 1894. The Knights, representing the unskilled laborers, were involved in much of the fighting. There was bitter infighting between the Knights of Labor union and the United Mine Workers, mostly over the unskilled Hungarian and Slav workers' elimination from the union. The H. C. Frick Company was considered worker-friendly, so the Hungarians did not target Frick mines. In return, Frick often used Hungarians, blacks, and Italians for strikebreakers and would allow them to stay on in the workforce if they proved themselves.

The unsuccessful national strike led to the rise of the United Mine Workers of America (UMWA), which had 20,000 members by 1890 and had become the dominant union for the mining districts. The 1890s was a decade of depression, however, and the UMWA lost members. Still, the foundations of the UMWA were strengthened in the Panic of 1893, and the universal strike resulted in the UMWA replacing the Knights of Labor and smaller groups. The UMWA affiliated with Samuel Gompers' American Federated Labor. The new union elected John B. Rae to lead it, paying him a salary of $1,000 a year.

The disaster of the national strike highlighted the lack of unity among the miners. To win future labor battles, the membership needed to change and promote new leadership. The UMWA began to embrace all races and religions in its membership and adopted the motto "United We Stand, Divided We Fall." The UMWA did call a national strike against the soft coal industry—soft coal was needed for steel production—and won recognition in the midwestern coal mines.

The Pullman Company and its "company" town were at the center of another major labor strike that would spread like the Great Railroad Strike of 1877. Pullman City was 14 miles south of downtown Chicago near Lake Calumet. The strike lasted three weeks, and at its peak it involved more than 250,000 men in 27 states. Strike-related violence resulted in the death of 13 strikers, more than 60 wounded, and property damage valued at more than $340,000 (the equivalent of about $9 million today). The strike was the effort of the American Railway Union headed by socialist Eugene Debs.

The trouble started in May 1894 with a layoff of 3,000 of Pullman's 5,800 employees at the Chicago plant. In an effort to save jobs, George Pullman cut the wages of his remaining employees by 25 percent. Pullman had seen orders for his rail cars plummet as a result of the Panic of 1893. Pullman was labor-friendly, but he was hardheaded and a poor communicator. He had been hailed by many as a paternal capitalist, but Pullman was no Carnegie or Westinghouse. He ran Pullman City as a profit center. Workers were required to live in Pullman City, where Pullman provided all the utilities, services, and housing for a profit. Pullman charged rents 25 percent higher than in surrounding neighborhoods. In addition, he purchased water from Chicago at 4 cents per thousand gallons and sold it to his town at 10 cents. Even the clergy were charged rent on churches in Pullman City, and the library charged a fee, too.

Members of the American Railway Union asked that the rents in the Pullman worker town be reduced. Pullman ended up firing the union representatives, which brought union president Eugene V. Debs into the disagreement. Pullman then locked out the employees. Things quickly escalated to a strike as Pullman announced a regular dividend to its stockholders. The strike started to evolve along related railways, as three-quarters of the rails moving in and out of Chicago closed. The union called for a nationwide boycott of Pullman cars, and railroad workers across the nation refused to switch Pullman cars.

President Grover Cleveland got involved, hiring 3,600 special deputies and sending 6,000 troops to Pullman City. The troops had the full protection of the U.S. government. Not wanting another Haymarket Riot or Railroad Strike of 1877, Cleveland thought he would get national labor support, given the reputation of Pullman as labor-friendly—but he did not. The newspapers supported Cleveland initially, but the support was short-lived.

Pullman used scabs and strikebreakers at the factory, which caused violence. Federal involvement inspired more rioting by the workers as the unemployed joined in. On July 7, the strike erupted into shootings and deaths as troops clashed with workers in Chicago. The strike started to spread across the country along the railroads. Cleveland was forced to get a federal injunction against the strikers based on the fact that the strike interfered with delivery of the U.S. mail. It was the first time the federal government had used an injunction to stop a strike.

The strike ended with the heavy federal crackdown, but the courts took over to avenge the upheaval. The result of the Debs strike would change the landscape of American politics. Eugene Debs was sentenced to six months in prison for disobeying the injunction, and he would later form the American Socialist Party. The Sherman Antitrust Act was used to support the conviction, and the Supreme Court upheld the use of the act against labor. In addition, the Supreme Court upheld the use of the federal injunction because of interruptions to the U.S. mail. In 1897, the Supreme Court of Illinois forced Pullman Company to divest itself of the City of Pullman. The United States Senate launched investigations that resulted in a condemnation of Pullman's use of paternalism to profit from workers.

NOISE POLLUTION

Noise pollution consists of all the myriad sources of irritating (and often unhealthy) sounds emanating from other people and other things in the world around us. Loud noises from any source can be physically harmful; numerous studies have shown that chronic exposure to moderate to high levels of noise is linked to a wide variety of physical and psychological problems, including hearing loss, aggression, elevated stress, and such cardiovascular effects as hypertension. As a result, a number of studies have tried to measure the impact of living close to a source of noise such as a busy road or airport. In addition, as people move to large cities where expensive housing translates into dense living conditions, residents may be subjected to yet another source of noise that has received much less academic and policy attention: neighbor noise. Some of this noise is caused by inconsiderate behavior, but other noise related to everyday living may more rightly be attributed to poor acoustic insulation from inadequate planning and building.

If you walk on a hard wood floor, practice the drums, or teach your dog to speak on command, chances are you will not chafe at the sound of your own steps, beats, or barks. However, noise coming from the outside world that is not under your control may have a very different psychological effect, depending on your tolerance (or perturbability) for such things. Thus, to the extent that the noisemakers of the outside world do not take into account the full harm being inflicted on nearby ears when they're making decisions about the level of (loud) activity to engage in, noise pollution—like many other forms of pollution—is an externality.

In economics, there is naturally an interest in calculating the costs of noise pollution and comparing these costs to the costs of noise abatement policies. However, there is no off-the-shelf observable market price for noise reduction, so researchers must infer a price from people's behavior. One popular approach to valuing noise is to use hedonic house price regressions to analyze the relationship between house prices and proximity to noise sources (usually airports) in order to estimate a shadow price of noise from the market data. All else being equal, if similar homes sell for less the closer they are to the airport, the conditional difference in price is interpreted as the market discount attributed to the noise problem. The imputed noise costs found by many of these studies are substantial: for example, one study finds a $200,000 house would sell for $20,000 to $24,000 less if its residents will be exposed to airplane noise.

In theory, with perfect information and costless mobility, in equilibrium house prices should completely compensate the noise differentials; the average homeowner should be left observationally indifferent between house #1 with noise level *x* and house #2 with noise level *y*. In practice, however, information on noise is often difficult to observe (or elicit from sellers), and mobility is far from free. Many people who optimally chose a home 5 or 10 years ago may find themselves in a suboptimal noise situation years later for a number of reasons: increases in local traffic, changes in airplane flight paths, or loud new neighbors next door (indeed, many new urban apartment dwellers have faced a rude welcome upon discovering heretofore-hidden sources of noise once they move in, a factor that may help explain the popularity of renting in big cities). Furthermore, many housing markets are highly regulated, with a large amount of rationing. For all these reasons, house prices may not fully compensate for undesirable characteristics like noise, and there will be residual welfare costs.

A further complication in using hedonic methods arises due to heterogeneity in individuals' tolerance toward noise, with more perturbable people self-selecting into quieter areas, and more noise-tolerant people self-selecting into louder areas (taking advantage of the lower prices). This self-selection leads to a downward bias in any estimate of the average welfare costs of noise; we cannot necessarily interpret the difference in house prices attributed to noise differentials as the total cost that would be imposed on a particular individual exposed to that noise.

Given these difficulties, several alternative approaches to hedonic models have also been used to measure the welfare impacts of noise. One is to use a contingent valuation and another is a stated-choice method, where subjects are asked to give their willingness to pay for alternative levels of different attributes. These methods are prone to various forms of strategic and recall bias, and thus they remain somewhat controversial.

A third method that has been used more recently is to use data from the happiness or life-satisfaction surveys that are now available, many of which ask questions about both household income and exposure to various forms of pollution, including noise. Although the use of life-satisfaction data is quite a controversial subject in economics, in principle at least it should be possible to estimate the degree to which exposure to noise pollution lowers life satisfaction, and then to calculate the income transfer required to compensate for this impact. One study finds that exposure to significant levels of noise pollution lowers life satisfaction approximately as much as being disabled, and that noise alone can explain the differences in life satisfaction between urban and rural residents.

In sum, a growing body of evidence suggests that noise pollution is a serious problem that can significantly lower overall public welfare. However, as noise is an externality and often not observable before someone purchases or rents a home, the free market will not deliver an optimal solution. Instead, urban planners and policymakers should pay more attention to this issue and, when necessary, increase standards of acoustic building codes and/or the enforcement of local noise ordinances. As the world becomes increasingly urbanized, enhanced attention to noise control will ensure that the benefits of city living are more likely to be enjoyed by all.

NON-TRADITIONAL MONETARY POLICY

Non-traditional monetary policies are often referred to as unconventional monetary policies. In recent years, the central banks in the United States, Japan, the United Kingdom, and Europe have all resorted to nontraditional policies to combat the global financial crisis and recession of 2008. Across borders the details have differed, yet in all four countries the nontraditional policies have proven successful in easing overall monetary conditions. Traditionally, central bankers ease or tighten monetary policy by adjusting a benchmark interest rate to influence the availability of credit. There are two main reasons why traditional monetary policy reached its limit in the recession of 2008.

First, in December 2008, the Fed lowered the federal funds rate effectively to zero, where it has remained ever since. The Bank of England, the European Central Bank, and the Bank of Japan have also lowered their policy rates nearly to zero, meaning those rates cannot be lowered any further to provide additional stimulus. Traditional policies' second limitation was how financial markets functioned. Normal market conditions suggest profits are obtained when the risk of the returns aligns with the profit opportunity. However, a financial crisis creates inconsistencies in interest rates across all markets. So as the Fed reduces interest rates to close to zero, traditional monetary policies suggest at some point the Fed cannot affect the interest rates that are important to consumers and businesses.

The 2008 financial crisis essentially halted spending by the private sector (consumers and producers). In response to the crisis, central banks lowered short-term rates close to zero rates. Central banks buying long-term bonds were instituted to lower long-term interest rates. This monetary method by central banks popularly became known as quantitative easing. Quantitative easing allowed central banks to purchase both short-term and long-term in an attempt to stabilize interest rates. The main problem was that interest rates obtained by quantitative easing did not align with the economy's current market forces. Without the alignment of the interest rates from quantitative easing and market interest rates, inflation and output will not stabilize.

Nontraditional policies can be identified into three groups. Group 1 involves discount window lending. This method uses one of the standard tools of monetary policy: the discount rate. The discount rate is the short-term interest rate that the Fed charges its clients for overnight loans. In 2007, the Fed began to encourage lending through the discount window to increase liquidity. Group 2 is new lending participants in the financial markets who are not identified as normal lending institutions. Finally, Group 3 the large government-sponsored enterprises. Use of this third group is a broadening of the Fed's traditional open market operations.

When central banks withdraw significant liquidity in a relatively short period of time, contractionary monetary shocks result. When liquidity is contracted in such a short period of time, quantitative easing policies make it difficult for the market to absorb the assets to be sold. Heavy market losses may result if the actions are too quick. Conversely, inflation becomes a real risk when the liquidity measures are reversed.

NORTH, DOUGLASS

Born: November 5, 1920, in Cambridge, Massachusetts; Died: November 23, 2015, in Benzonia, Michigan; Nationality: American; Professional Interests: economic history, institutional economics, cliometrics, Nobel Prize (1993); Major Works: *The Economic Growth of the United States, 1790–1860* (1961), *Structure and Change in Economic History* (1981), *Institutions, Institutional Change and Economic Performance* (1990), *Understanding the Process of Economic Change* (2005).

Douglass North was an American economist whose work in economic history and institutional economics earned him the 1993 Nobel Prize in Economics. North helped found the field of cliometrics (named after Clio, the muse of history), which applies economics and quantitative methods to the study of economic history. His interest in institutional economics shaped how the discipline views the role of institutions and property rights in economic growth. North was influential in understanding how people make choices. He was particularly interested in the way that individuals' ideas, beliefs, and prejudices influence their decision-making, often in ways that hinder growth.

Douglass Cecil North was born on November 5, 1920, in Cambridge, Massachusetts. His mother was a strong believer in education, reflected by his early schooling experiences. He attended school in Lausanne, Switzerland; Ottawa, Canada; New York City; Long Island; and Choate Academy in Connecticut. He also developed a strong passion for photography, winning several awards in high school. Though he had been accepted at Harvard University, he followed his family to the West Coast when his father accepted a new position. He did his undergraduate work at the University of California, Berkeley (UC Berkeley). His academic record at UC Berkeley was only slightly above average, although he pursued a triple major in philosophy, political science, and economics.

While at Berkeley, North became a Marxist and a pacifist. When he graduated from Berkeley, he spent time pursuing photography, working with Dorothea Lange photographing migrant workers in California for the Farm Services Administration. When World War II broke out, North joined the Merchant Marines and became a navigator. He even taught celonavigation (celestial navigation) at the U.S. Maritime Service Officer School in Alameda, California.

North returned to Berkeley after the war to continue his study of economics, graduating in 1952. By his own admission, he did not learn much economic theory there. It was during his first position at the University of Washington that the situation changed and economic theory became an integral component of his future professional efforts. As a result of his dissertation, North received a fellowship from the Social Science Research Council, which allowed him to go to the East Coast. There he attended classes taught by Robert Merton at Columbia and by Arthur Cole and Joseph Schumpeter at Harvard. North was invited to be a fellow at the National Bureau of Economic Research (NBER), where from 1957 to 1958 he worked on a quantitative study of the U.S. balance of payments from 1790 to 1860. This led to his first major work: The *Economic Growth of the United States, 1790–1860*.

Also during this time, North helped found the field of cliometrics (named after Clio, the muse of history), which applies economics and quantitative methods to the study of economic history. The field came about through a joint program of the NBER and the Economic History Association on the growth of the American economy. As a result of the program, two of North's former students, John Hughes and Lance Davis, both faculty members at Purdue University, held a conference for economic historians. That meeting was a seminal moment in the field of cliometrics, and North became involved in setting up a program at the University of Washington.

In the late 1960s, North turned his attention from American economic history to European economic history. Under the auspices of a Ford Foundation grant, North spent a year in Geneva studying European economic history. While there, North decided that neoclassical economics did not provide the proper tools for explaining the economic change in Europe from medieval times to the present.

In the area of institutional economics, one of the issues North confronted was the prevailing idea that institutions were always efficient. He found that this was not true for some economies, and he challenged the rationality postulate that provides the foundation for economic analysis. North and others found that individual ideas, beliefs, and prejudices were important factors in shaping decisions and could keep a society from developing efficient economic institutions that promoted growth. The result was that some societies would find themselves locked into dysfunctional institutions, actually providing a barrier to further development and growth.

By 1983 North was looking for a new environment to help him with his puzzles. He saw an opportunity when he was invited to join the faculty of Washington University in St. Louis. North established the Center in Political Economy as well as the Center for New Institutional Social Studies to continue to study the effect of institutions on choice. North was convinced that understanding how people make choices when the conditions are uncertain was central to further research in human behavior.

In April 1985 North was appointed editor of the Cambridge series *The Political Economy of Institutions and Decisions,* editor of the *Journal of Economic History,* and president of the Economic History Association. In 1987, he was elected to the American Academy of Arts and Sciences. In 1993, Douglass North and Robert Fogel were awarded the Nobel Prize in Economics.

Douglass North's academic appointments have included the Peterkin Professor of Political Economics at Rice University in 1979 and the Pitt Professor at Cambridge University in 1981. North was also a visiting fellow at the Center for Advanced Studies in in Behavioral Sciences and the Hoover Institute at Stanford University. He was the Luce Professor of Law and Liberty at Washington University in 1983 and the Spencer T. Olin Professor of Arts & Sciences at Washington University in 1996.

North died on November 23, 2015, in Benzonia, Michigan, at age 95.

OFFICE OF MANAGEMENT AND BUDGET

The Office of Management and Budget (OMB) is an office of the executive branch of the U.S. government. The main function of the OMB is to serve the president of the United States. As the largest of the agencies of the executive branch, it has wide-ranging duties, responsibilities, and influence with the president as well as other offices and agencies of the executive branch of government. The OMB helps the president set priorities as well as assisting in seeing that the president's agenda is implemented.

As its name suggests, the major responsibility of the OMB is to assist the president with the development of a budget and to manage the budget's the implementation and operations. The OMB is an extension of the president's influence throughout government regarding budgetary creation and execution. The OMB works with all aspects of the government during the budget process. The OMB serves the president in carrying out presidential decisions and policies on a wide variety of topics and issues, ranging from the economy to national security.

As its number one priority and responsibility to the president, developing a budget is a multilevel, multifaceted task for the OMB. Five different offices of the OMB are responsible for developing, reviewing, and executing the executive budget. These are called regional management offices, or RMOs. First, the RMOs help the president frame the spending side of the budget. The resulting plans are then compared against the funding proposals of the many offices and agencies of the federal government. From this study of the proposals and the president's spending plan, the budgetary funding priorities are established.

Once this process is concluded and the budget is in place for execution, the RMOs are then responsible for the implementation and continuing guidance of the budget, to see that its funding and management priorities are met. On a continuing basis, the RMOs evaluate, assess, and analyze the operations and implementations of the government's programs. The OMB also monitors congressional appropriations and other legislation regarding government spending.

A second area in which the OMB serves the president is in the management of the president's office and the executive office. The OMB evaluates the operational policies of the executive office regarding financial and information management, assesses the efficiency and effectiveness of the office, and assesses the systems and processes that are in place to purchase goods and services for the efficient operation of the federal government. In assessing the executive office's efficiency, the OMB reviews all regulations and policies as they pertain to the different executive offices and departments that report to the president.

The OMB is responsible for seeing not only that the executive offices operate efficiently but also that they carry out the president's priorities. An important consideration for the president is that the OMB has carefully and thoughtfully assessed the economic impact and economic consequences of the president's priorities, policies, and decisions. The OMB works closely with the legislature to be certain there is coordination between the president's agenda and that of the Congress.

The OMB also serves the president with legislative proposals and implementation of bills. When the president prepares a bill for Congress, the OMB reviews the bill before it is sent to Congress. The OMB is charged with reviewing the bill with all the executive agencies that might be affected by it, in order to ascertain their views on the proposed legislation. Once the OMB has comprehensively reviewed the bill with the appropriate agencies, the OMB "clears" the bill to be sent to Congress. Any concerns or disagreements about a proposed bill are clarified during the clearing process. Once a president's bill is sent to Congress, the OMB is responsible for submitting statements of administration policy (SAPs). If Congress passes a bill, the president calls on the OMB once again to solicit views from the impacted agencies before the president signs or vetoes the legislation.

When the president requests counsel on economic issues, the president leans on the Office of Economic Policy (EP) of the OMB, the Council of Economic Advisors (CEA), and the Department of Treasury. The Office of EP assists with developing the president's budget and helps the RMOs with their budgeting preparation and policy proposals, as well as creating economic models for gathering economic data on tax policy, labor, education, credit, and insurance.

The OMB is headed by a director. The director's main role is the management and oversight of a management agenda for all of the federal government, from IT to financial management to human resources. There are five main management offices of the OMB: the Office of Federal Financial Management (OFFM), the Office of Federal Procurement Policy (OFPP), the Office of E-Government and Information Technology, the Office of Performance and Personnel Management (OPPM), and the Office of Information and Regulatory Affairs (OIRA). Other departments within the OMB include general counsel, economic policy, legislative affairs, and legislative reference, communications, and management and operations. All five of the management offices are self-contained and include administration and policy management, as well as evaluation and assessment of the policies for which they are responsible. Each management office works closely with the RMOs to ensure that the policies for which they are responsible are being implemented appropriately and in keeping with the agenda and policies of the president. Noted former OMB directors include George Shultz, David Stockman, Caspar Weinberger, and Alice Rivlin.

OIL CRISIS OF 1979

The oil crisis of 1979 represented a turbulent transitional period in global trade. Sometimes referred to as the oil shock or second shock, the oil crisis of 1979 reflected a chain reaction to the Iranian Revolution 1978–1979, in which Ayatollah Khomeini displaced Shah Mohammad Reza Pahlavi. During the conflict, from 1978 to 1981, Iranian production of crude oil dropped by 3.9 million barrels a day. Initially, other OPEC (Organization of Petroleum Exporting Countries) members were able to offset the decrease in production, but the 1980 Iran-Iraq War further curtailed production from Middle Eastern exporters (USEIA n.d.).

The Organization of Petroleum Exporting Countries (OPEC) currently consists of 13 member-states. It was founded in 1960 in Baghdad by the Islamic Republic of Iran, Iraq, Kuwait, Saudi Arabia, and Venezuela. Since OPEC's inception, the following nations have become member-states (the year each country joined OPEC is shown in parentheses): Qatar (1961), Indonesia (1962), Libya (1962), the United Arab Emirates (1967), Algeria (1969), Nigeria (1971), Ecuador (1973), and Angola (2007). Gabon (1975) was a member until 1995, then rejoined in 2015 (OPEC 2016a).

OPEC's principal goal was to create a unified vision in which the market could be equitably controlled. The Arab Oil Embargo of 1973 and the Iranian Revolution of 1979 created global price inflation and volatility of the market, which led many nations to try to avoid dependence on OPEC, specifically Arab-based exports. The Arab Oil Embargo of 1973 was a stop order on trade of oil in response to American support for Israel in the Yom Kippur War of 1973. The resulting price spikes in crude oil created the first oil crisis in the United States. The memory of the 1973 crisis contributed deeply to consumers' panic and reaction to the 1979 crisis. Furthermore, it revealed a deep-seated distrust for the global energy trade and OPEC amid difficulties that the member nations were having creating unified goals and policies.

The effects of the crisis were felt primarily in the United States and the Western European nations. In early 1979, the global oil price was $14 barrel. Two years later it, had inflated to $38 per barrel (USEIA n.d.). Experts argue that the effects of the crisis were exacerbated in the United States due to consumer panic and stockpiling of gasoline—which further increased demand, and therefore increased prices. Philip Verleger argues that the Department of Energy encouraged inventory buildup and redistribution with the intention of balancing differences between high-consumption and high-production regions within the United States. Furthermore, these price controls and regulations made it profitable to withhold stockpiled gasoline, thereby creating a further shortage. These policies heightened the crisis and subsequent recession, where foresight to discourage hoarding of supplies might have counteracted the production cuts.

Coming out of a period of relative prosperity, the crisis created a shock in the American economy. In 1979, the United States was also entering a period where unemployment was on the rise and inflation was taking place. The Federal Reserve was debating on the proper method in which to use price controls and monetary policy to try to curtail the issues. The Fed's policy of contracting the money supply in conjunction with the oil crisis stifled inflation, but it led to the worst recession the country had experienced since the Great Depression. A consequence of the oil crisis was the impetus to move away from reliance on oil. This had trickle-down effects in many industries, where policies and innovations became more aware and tailored toward environmental friendly alternatives. The recession sparked a depression in the U.S. auto industry that was embodied by the shift from U.S.-produced automobiles to smaller, more fuel-efficient Japanese alternatives.

OKUN, ARTHUR

Born: November 28, 1928, in Jersey City, New Jersey; Died: March 23, 1980, in Washington, D.C.; Nationality: American; Professional Interests: neo-Keynesian, econometrics; Major Work: *Equality and Efficiency: The Big Tradeoff* (1975).

Arthur Okun was an American economist most noted for the economic law that bears his name. While a senior economist at the Council of Economic Advisers (CEA), Okun discovered the relationship between economic growth and changes in unemployment. He asserted that each point change in the unemployment rate equated to a change in real economic growth—as measured by the gross national product (GNP)—of between 2 and 3 percent. This inverse relationship applied with changes to either the unemployment rate or economic growth. A rise in one would create a decrease in the other, and vice versa.

Arthur Melvin Okun was born on November 28, 1928, in Jersey City, New Jersey. He received his BA and PhD degrees from Columbia University, and he began his academic career when he accepted an offer to join the economics faculty at Yale University.

Okun began public service early in his career, when he became a member of President John F. Kennedy's Council of Economic Advisers (CEA). Okun joined the CEA as an adviser in 1962 and served as a member till 1969. In 1968 and 1969, during President Johnson's administration, he chaired the CEA. While a senior economist there, Okun discovered a relationship between economic growth and changes in unemployment.

Based on data collected between World War II and 1960 (the year Kennedy was elected), Okun provided President Kennedy the data needed to make Keynesian-style tax cuts in order to boost a sagging economy. Okun asserted that a 1-percent decrease in the unemployment rate would create an approximate 3-percent increase in economic growth, measured as real gross national product (GNP). Conversely, a change in real GNP would create an opposite percentage change in the unemployment rate. While the evidence of the relationship convinced Kennedy to enact the tax cuts, the validity of the unemployment/economic growth relationship over time and the predictive relationship is now known as Okun's law.

As robust as Okun's law may be, Okun himself applied boundaries:

1. The relationship applied only to the U.S. economy.
2. The law was accurate only when the unemployment rate was between 3 and 7 percent.

He was also careful to acknowledge that many variables can cause economic growth. Okun was quick to point out that correlation between the two variables did not equate to causation between them. This correlation–causation has also been amended over time as Okun's law proves predictably strong.

Over time, Okun's boundaries have been revised:

1. Okun's law has been applied to other economies, most notably those of industrialized nations. Economists now assert that there is at least some causation to economic growth through lower unemployment.

2. Okun's law has also been converted to the relationship between the unemployment rate and gross domestic product (GDP). This relationship fell to approximately a 2-percent growth in GDP for every 1-percent reduction in the unemployment rate.

As a stagnant economy continues to plague politicians and economists, research is beginning to question the modern reliability of the predictability of Okun's law. As the global economy develops and grows, along with new technologies changing productivity variables, the relationship between economic growth and the unemployment rate and the ratios promoted by Okun faces further research and scrutiny.

Okun is also noted for his work on wealth transfer. Using taxes as the transfer mechanism, he makes his case in *Equality and Efficiency: The Big Tradeoff* (1975). He admits both the inefficiency of such an action and the complete lack of incentives for both the poor and the rich. For the inefficiency, he draws the analogy of a leaky faucet. Elements such as administrative costs and lack of incentives provide shortcomings for the tax revenues to be completely transferred. The poor lose the incentive to work by receiving the transfer of wealth, and the rich have no incentive to work since a significant portion of their marginal dollar earned will be taxed away.

Fellow CEA member James Tobin labeled Okun's law as one of the most reliable regularities in macroeconomics. Arthur Okun also served as a Brookings Institution fellow from 1969 to 1980.

Okun is also noted as being the creator of the misery index. The misery index is a simple calculation adding together the unemployment rate and the inflation rate. The index reflects the wrongs of an economy. A high misery index infers an economy in which the people are suffering (i.e., in misery) from a significant number of people out of work (high unemployment rate) while at the same time the price level is rising (high inflation), neither condition beneficial for a growing economy.

Arthur Okun died on March 23, 1980, in Washington, D.C., of heart failure at just 51 years of age.

OSTROM, ELINOR

Born: August 7, 1933, in Los Angeles, California; Died: June 12, 2012, in Bloomington, Indiana; Nationality: American; Professional Interests: economic governance of common pool resources, individual choice theory, Nobel Prize (2009); Major Works: *Governing the Commons: The Evolution of Institutions for Collective Action* (1990), *Rules, Games, and Common-Pool Resources* (with Roy Gardner and James Walker) (1994), *Working Together: Collective Action, the Commons, and Multiple Methods in Practice* (with Amy R. Poteete and Marco A. Janssen) (2010).

Elinor Ostrom's research involved local public and private stakeholders at multiple levels managing common-pool resources. Her work was acknowledged by the Nobel committee in 2009 when they awarded Elinor Ostrom and Oliver Williamson the Nobel Prize in Economics. She was the first woman to receive this honor. Ostrom died in 2012.

Elinor Awan Ostrom was born on August 7, 1933. As she was growing up, her parents fed her from their vegetable garden and orchard, taught her to knit, and enrolled her in the nearby public school. She was a competitive swimmer and an accomplished member of her high school debate team. Like many of her peers at Beverly Hills High School, she decided she was going to be the first in her family to attend college. Holding jobs as a secretary, an assistant personnel manager, and a graduate assistant, she acquired the funds she needed to attend the University of California, Los Angeles (UCLA). While at UCLA, she earned an undergraduate degree in political science in 1954 (graduating with honors in three years by attending school year-round), a master's degree in 1962, and a PhD in 1965.

She wrote her dissertation on management of the groundwater industry in Southern California. In what was to become the introduction to her life's work, she studied the West Basin in Los Angeles County. This was her first common-pool resource problem. Because Garrett Hardin's classic "The Tragedy of the Commons" had not yet been published, she was in a position to approach problems of the commons in her own way.

Ostrom was affiliated with Indiana University, Bloomington, since 1965 as a professor and as cofounder of the Workshop in Political Theory and Policy Analyses. Her distinguished career includes the position of Arthur F. Bentley Distinguished Professor of Political Science and Senior Research Director of the Workshop in

Political Theory and Policy Analyses at Indiana University. She was also the founding director of the Center for the Study of Institutional Diversity at Arizona State University, Tempe. Her topics in commons research were as diverse as forests, irrigation, and police departments.

For over a dozen years, Elinor Ostrom researched law enforcement delivery systems in six metropolitan areas. She concluded that large departments of 100 officers were no more efficient than small to medium cadres of 25 to 50 officers. Her long-term study included traffic, patrol, emergency response, and criminal investigators. She produced strong, empirical evidence that large, centralized institutions were not always more efficient than community organizations.

Based on her research, Ostrom concluded that it was indeed realistic to put the management of common resources in the hands of individuals and small groups without private property rights or centralized authority. Her findings defied popular assumptions that powerless, reasonable people were stuck in no-win situations in terms of commons management. She concluded that regime regulations or efforts to privatize to prevent waste and ruin of the commons often were not the best alternative. The empirical evidence indicated that multiple small governments operate effectively, even though they lose some of the advantages that are gained from the opportunities presented by economies of scale.

In contrast to the prevailing wisdom, Ostrom's findings showed that individuals and small parties could write their own rules and self-monitor to obtain maximum benefit from resources they shared in common. The widely held belief was that privatization was not the most favorable solution in many situations. She asserted that chaos and inefficiency were not certain outcomes without property rights, as many traditional policy makers proclaimed. She warned that broken trust within public and private partnerships had more lasting detrimental effects on achieving efficient use of the commons. Ostrom contended that a complex system of large and small public bodies along with private individuals operating at all levels was the most beneficial strategy for optimizing the use of common-pool resources.

Along with husband Vincent Ostrom (also an Arthur F. Bentley Professor at Indiana University), in 1973 Ostrom founded the Workshop in Political Theory and Policy Analyses. The focus of the workshop was to encourage collaboration among social scientists. Researchers from multiple disciplines developed common methodologies for collecting, testing, and sharing data. The workshop schedules regular meetings for scientists worldwide with similar research interests.

Elinor Ostrom has many accolades to her credit. Most notable was being awarded the Nobel Prize in Economics in 2009. In addition to being a Nobel laureate, she was honored with the John J. Carty Award for the Advancement of Science by the National Academy of Science in 2004 and the Johan Skytte Prize in Political Science in 1999. She was recognized as an honorary fellow for the International Institute of Social Studies in 2002, and received the James Madison Award by the American Political Science Association in 2005 and the William H. Riker Prize in Political Science in 2008. She served as president of the American Political Science Association and the Public Choice Society.

Elinor Ostrom died of pancreatic cancer on June 12, 2012, in Bloomington, Indiana, at the age of 78.

P

PANIC AND GLOBAL DEPRESSION, 1873

The Panic of 1873 hit the United States hard. It lasted five years, created 30 percent unemployment, and left another 40 percent of the population working for less than seven months a year. The Panic of 1873 was the first time an American panic would drag the whole world into depression. Banker Thomas Mellon called the Panic of 1873 the "most disastrous and extensive collapse since that of 1819." A quarter of the nation's 360 railroads failed, as did 20,000 other businesses. Nationwide, 3 million people lost their jobs, while daily wages fell 25 percent. Financial and political scandals of the period further rocked investor confidence.

Railroad workers suffered a 35 percent decrease in wages during the panic, and wages for Ohio coal miners dropped by half. In New York City, more than 50 soup kitchens were serving more than 20,000 hungry persons every day. There were more and more tramps on city streets, and Andrew Carnegie remarked that he had to step over tramps to get to his New York office. The *New York Times* suggested getting a dog with good teeth as protection against the tramps. Oil prices dropped from $3 a barrel to 50 cents a barrel. Agricultural products dropped a similar percentage, causing farms to fail and bringing a dramatic decrease in railroad profits.

By 1873, the U.S. economy was showing strain after years of expansion and government corruption had eroded public confidence in business. Like many panics, the Panic of 1873 started as a bank crisis in New York in conjunction with investment house problems. Within a few days, the stock market closed for the first time in its history. The main cause of the panic was railroad speculation after the Civil War. Railroads had continued to expand, building on the enthusiasm created by the Transcontinental Railroad. The panic was part of almost 100 years of exponential growth in the railroad industry, which drove a world industrial boom.

On May 10, 1869, the East and West coasts of the United States were linked via the transcontinental Union Pacific and the Central Pacific railways, creating an economic boom. In 1850, there were only 9,000 miles of track in America; that had grown to 30,626 miles of track by 1860 and 52,299 miles by 1870. Later, the government poured money into a new line—the Northern Pacific—and speculators followed quickly.

The Railroad Act of 1864 had contributed to the creation of such a system of corruption among the speculators that they were considered by some to be the worst aspects of the Act and government's participation in the railroad industry. Crédit Mobilier Company of America, for example, set the price of supply contracts for the railroads. If a shovel cost Crédit Mobilier a dollar, the company might charge Union Pacific three dollars. Crédit Mobilier also overcharged for the actual cost of track laid. The project generated dividends for its stockholders at the expense of the government.

The Union Pacific Railroad, for example, was a network of corruption: for every $3 spent by the government, less than $1 went to actual construction. The government would pay in bonds at the rate of $16,000 a mile in the flatlands, $32,000 a mile in hilly terrain, and $48,000 a mile in the mountains. In addition, for every mile completed, the railroad's builders received 6,400 acres of land, which they could sell or lease to settlers. In the early 1870s, there was a true bubble in railroad stocks. Railroads expanded with wheat production in the West, while wheat prices were falling as well. The speculation was that eventually wheat exports would make the railroads profitable.

However, the railroads were undercapitalized and were not producing profits. Grain prices had continued to fall, further reducing railroad profits. New York banker Jay Cooke, the builder of the North Pacific railroad, was behind the railroad stock bubble and involved with the overselling of Northern Pacific stock and bonds. Rumors of financial scandals within the Cooke firm started to surface. Meanwhile, the Northern Pacific was in dire need of capital, and Cooke could not sell more bonds with the rumors swirling around his firm. In early September 1873, some small railroads went under, and a stock panic started to build. On September 18, 1873, which became known as Black Thursday, Cooke's large investment house failed. Black Friday, September 19, brought the failure of others. A full-blown panic began, and the market crashed. Western Union led the crash, as stock prices fell from $75 to $59 on Black Friday.

The stock market crash started a banking panic with the public. The United States lacked the Federal Reserve System of today. Loans were "callable"—that is, a bank could call in a loan and demand immediate full or partial payment. As the bank runs reduced the cash on hand, banks had to call in business loans to generate cash, which, in turn, created a downward spiral. The panic spread quickly across the Atlantic. London had supplied a great deal of the money to fuel the American railroad expansion (more than $30 million). Europe, in total, had invested more than $240 million in America railroads. Thus, the American stock crash created a credit crisis throughout Europe as well.

Industry was suffering within weeks of the panic. In 1873, at least 5,100 firms went bankrupt; and by 1878, the peak year of the depression, more than 10,000 failed in total. It was not just manufacturing that suffered, however. The credit crisis forced H. J. Heinz's first company into bankruptcy. Some of the "kings" of Wall Street filed for personal bankruptcy. The price of wheat continued its decline during the depression and thus eroded railroads' cash on hand. As the railroads shut down, so did America's steel mills, which had boomed under the great expansion. Business activity dropped by 33 percent (in comparison, during the Great Depression of the 1930s business activity dropped by 55 percent). The depression of the 1870s would remain the "Great Depression" until overtaken by the depression of the 1930s.

PAULSON, HENRY M., JR.

Born: March 28, 1946, in Palm Beach, Florida; Nationality: American; Professional Interests: 74th U.S. Secretary of the Treasury from July 10, 2006, to January 20, 2009; Major Event: U.S. economy experienced the worst financial crisis since the Great Depression.

Henry M. Paulson Jr. is a 1968 graduate of Dartmouth College with an AB in English, and in 1970 he was awarded an MBA from Harvard Business School. After earning his master's degree, Paulson became the staff assistant to the Assistant Secretary of Defense at the Pentagon (1970–1972). He then worked for President Richard Nixon, serving as a member of the White House Domestic Council (1972–1973).

In 1974, Paulson joined Goldman Sachs, a large investment banking firm; during his 32-year career there, he rose through the ranks to become the firm's chairman and CEO. On July 10, 2006, he left Goldman Sachs to serve as Treasury secretary under President George W. Bush, where he succeeded John Snow.

Secretary Paulson was a stark contrast to the previous Treasury secretary and other appointees of the Bush administration. Paulson is a vocal environmentalist (a position that was often at odds with the Bush administration) and insisted on being a fully invested, involved, and policy-making secretary, unlike his predecessor. Little did he or the administration know that within a year of his appointment the U.S. economy would experience its worst financial crisis since the Great Depression.

As the country entered a recession in 2007, amid the bursting of the U.S. housing bubble and high default rates on subprime mortgages, Secretary Paulson spearheaded the creation of the Hope Now Alliance. This cooperative of government, housing counselors, and lenders assists struggling homeowners in avoiding foreclosure. In September 2008, Secretary Paulson engineered the rescue of the government-backed private mortgage agencies Fannie Mae and Freddie Mac. Yet the damage was already done, and these efforts could not prevent a breakdown of the major Wall Street financial institutions that were holding mortgage-backed securities.

By the fall of 2008, the banking system nearly collapsed. Secretary Paulson collaborated with Federal Reserve chairman Ben Bernanke and Federal Reserve Bank of New York president Tim Geithner to rescue Wall Street through a combination of coordinated bank mergers (Merrill Lynch into Bank of America), bank failures (Lehman Bros.), and government bailouts (AIG). What had begun as a subprime-mortgage problem in the United States evolved into a global financial crisis and drove stock markets to record lows and unemployment to record highs.

Public sentiment about the Treasury Secretary's actions during this critical economic period has been equivocal. Paulson was criticized for how he handled the financial crisis and was questioned on the decision to let Lehman Brothers fail. *Time* magazine named him a runner-up for Person of the Year in 2008, but then later listed him as one of the "25 People to Blame for the Financial Crisis." His decisiveness and provocative thinking during the worst days of the crisis—such as crafting the Troubled Asset Relief Program (TARP), which Congress subsequently passed—most likely kept the U.S. from experiencing another Great Depression.

Secretary Paulson completed his tenure with the end of the Bush presidency in 2009, and he was succeeded by Timothy Geithner. In 2010, he published a book with Barney Frank titled *On the Brink: Inside the Race to Stop the Collapse of the Global Financial System*, detailing his experiences as Treasury secretary during the global financial crisis. Since leaving public service, he founded the Paulson Institute at the University of Chicago and serves as its chair. This innovative think tank works to promote economic growth and environmental preservation in the United States and China.

The Treasury and its secretary directly impact the personal finances of consumers. The Treasury is the executive agency responsible for economic and financial activity. Its responsibilities include producing the nation's coin and currency, assessing and collecting taxes, and disbursing payments—including tax refunds and Social Security checks—to the American public. The Treasury also advises the president on economic matters and financial policy.

PHILLIPS, ALBAN WILLIAM H.

Born: November 18, 1914, in Dannevirke, New Zealand; Died: March 4, 1975, in Auckland, New Zealand; Nationality: New Zealander; Professional Interests: economic growth, Phillips curve; Major Works: "A Simple Model of Employment, Money and Prices in a Growing Economy" (1961), "Employment, Inflation and Growth" (1962).

A. W. H. Phillips was a leading 20th-century New Zealand economist who spent most of his academic career at the London School of Economics (LSE). Phillips was noted for his work on the relationship between the level of unemployment and the rate of wage inflation, illustrated by what would become known as the Phillips curve. Using his engineering knowledge, Phillips also designed and built the MONIAC hydraulic economics computer in 1949. Phillips was appointed to the prestigious Tooke Professorship in Economics at the LSE in 1958 and to a research professorship at the Australian National University in 1967. Phillips died in 1975.

Alban William Housego ("A. W." or "Bill") Phillips was born on November 18, 1914, in Dannevirke, New Zealand. Having a father who experimented with technology, he had an adventurous youth traveling through Australia (where he ran an outback movie theater) and Southeast Asia. At the age of 15, he left school to become an apprentice engineer for the Public Works Department. For the next 10 years, he worked at various jobs in New Zealand, Australia, and Great Britain. However, his civilian life was interrupted by World War II; he became an armaments officer in Singapore for the Royal Air Force. He was captured by the Japanese and held as a prisoner of war. Phillips was awarded an MBE (Military Division) for outstanding courage while under attack.

With his fascination with the interactions of sectors across the economy and his engineering training, in 1949 he developed a hydraulic model of the macroeconomy: the MONIAC (Monetary National Income Analogue Computer). It was initially known as the "Phillips Machine." The model consisted of flows of water from one container to another, representing monetary flows—for example, from consumption to income and thence, via an accelerator mechanism, to investment. "Leakages" to imports were included, and multiple models were built to represent multiple countries—interlinked by pipes. It was very well received, and Phillips was soon offered a teaching position at the LSE.

Having worked on modeling the national economic processes of the British economy with his MONIAC, in 1958 he published his own work on the relationship between inflation and unemployment, illustrated by the "Phillips curve." The curve had been described as the most influential and productive macroeconomic idea in the postwar era. Phillips observed that there is a trade-off between a strong economy and low inflation. In years when the unemployment rate was high, wages tended to be stable, or possibly fall. Conversely, when unemployment was low, wages rose rapidly, leading to inflationary pressures.

Following this publication, two other notable economists, Paul Samuelson and Robert Solow, wrote an influential article describing the possibilities suggested by the Phillips curve in the context of the United States. Although the Phillips curve has changed substantially over time, it remains an important feature of macroeconomic analysis of economic fluctuations; for example, while it has been observed that there is a stable short-run trade-off between unemployment and inflation, this has not been observed in the long run.

Phillips made several other notable contributions to the field of economics, particularly as it relates to stabilization policy. He asserted that not only is it crucial to have the right policies but also that they have to be implemented at the right time. The right policy implemented at the wrong time can make the economy worse. However, the subtlety and wisdom of Phillips's stabilization exercises were largely overlooked, as both monetarists and the Keynesians competed for policy influence. With a profound distaste for such policy manipulation, he gradually abandoned macroeconomics for Chinese economic studies.

After the 1968 student riots in London, Phillips returned to Australia for a position at Australian National University, and later he took a position at the University of Auckland, which allowed him to devote half his time to Chinese studies. He became one of the first Western economists to turn his attention to Chinese developments, anticipating the rise of the Chinese economy despite its then-perilous state. Although he did not become an academic until 1950 at the age of 36, his contributions have been significant and lasting.

A. W. H. Phillips died on March 4, 1975, in Auckland, New Zealand.

PHYSIOCRATS

Physiocracy (derived from the Greek word for "government of nature") is an economic theory developed by the Physiocrats, a group of economists who believed that the wealth of nations was derived solely from the value of land agriculture or land development. Their theories originated in France and were most popular during the second half of the 18th century. Physiocracy is noted as perhaps the first well-developed theory of economics. The group was founded by François Quesnay, whose original contribution was the truism that all wealth originated with the land and that agriculture alone could increase and multiply wealth. The Physiocrats' ideas were important not just to economists but also to the course of politics in France. Adam Smith, as a moral philosopher, considered the Physiocrats' views on the political economy to be highly aligned to his moral philosophy, and he was greatly influenced by their work. Industry and trade, according to the Physiocrats, were basically sterile and could not add to the wealth created by the land. They did not advocate neglecting industry and trade in favor of agriculture, but they tried to prove that no economy could be healthy unless agriculture was given the fullest opportunity.

The Physiocrats' main objective was to recognize the operation of the basic causes, which determined the general level of economic activity. For this purpose, they believed that it was useful to consider economic activity as taking the form of a "circular flow," as we would call it today. In this circular economic activity, the two main actions—production by producers, and consumption by consumers—are interdependent variables. As such, the actions of one will be reflected by an action of the other party. Physiocrats also tried to explain interdependence through its repetitive or circular nature, where the actions of producers and consumers continually repeat themselves creating a continual linkage to each other (i.e., interdependence). They attempted to identify the basic movements of an economy's decline and expansion activity.

Agriculture was one area where they discovered what they called the "net product," or a disposable surplus over necessary cost. Anything that increased this net product would cause an expansion in economic activity, and anything that reduced it would cause a contraction in economic activity.

Agricultural methods had to be scientifically improved, and most importantly fair prices had to be maintained for agricultural production; according to Quesnay's maxim, only abundance combined with high prices could create prosperity. This result could be obtained only if the "economic law"—which the Physiocrats envisioned as being as indisputable as the law of gravity—was allowed to act unhindered. Absolute freedom of trade was necessary to stabilize prices at a fair level, and laissez faire was to restore the economic process to its natural course, from which all further benefits would flow. To tax anything but the land was pointless, because only the land produced wealth and because manufacturers and traders pass their tax burden on to the farmer; only taxation at the very source of the wealth itself was reasonable and economical.

In addition, the Physiocrats anticipated the classical-economic insight that money is not crucial and that in the long run commodities or real goods exchange for each other, with money simply acting as an intermediary. Therefore, the key goal is not to stockpile precious metal or to follow the fantasy of a permanently favorable balance of trade, but to have a high standard of living in terms of real products. Seeking to amass specie means that people in a nation are giving up real goods in order to acquire mere money. Physiocrats believe that these people are losing rather than gaining wealth in real terms. The significance of money is to exchange it for real wealth—and if people insist on accumulating an unused hoard of specie, they will lose wealth permanently.

PIGOU, ARTHUR CECIL

Born: November 18, 1877, in Ryde, Isle of Wight, England; Died: March 7, 1959, in Cambridge, England; Nationality: English; Professional Interests: classical economics, neoclassical economics, welfare economics, public finance; Major Works: *Wealth and Welfare* (1912), *Unemployment* (1914), *The Theory of Unemployment* (1933).

Arthur Cecil (A. C.) Pigou was a British economist who is best remembered for the development of welfare economics and public finance. *Welfare economics* refers to the study of maximizing economic value to benefit society as a whole. In this direction, Pigou defined the economic concept of *externalities* before it was part of the economics lexicon. He also studied public finance, which investigates the impact of taxation and other government interventions in the economy. A star student of Alfred Marshall, Pigou rose from lecturer to professor and chair of political economy at Cambridge University. As professor, his star student was John Maynard Keynes. Pigou died in 1959.

Arthur Cecil Pigou was born in November 18, 1877, on the Isle of Wight. His father was an army officer and his mother came from a line of Irish government officials. Pigou won a scholarship to Harrow, a prestigious private school; from there he continued on to Cambridge, where he began his studies in history. Taking classes from renowned economists Alfred Marshall and Henry Sidgwick, however, convinced him to study political economy instead. He became Marshall's star student, and upon graduation he was promptly hired as a lecturer. When Marshall retired in 1908, Pigou took his place as chair of political economy. Pigou remained devoted to the teachings of his mentor, often telling his students, "It's all in Marshall."

Pigou's most famous student, John Maynard Keynes, would be less kind to his instructor. During World War I, Pigou used his summer vacations to serve in the front lines with the Ambulance Corps of the British Army. His wartime experiences affected him deeply, and they may have been what changed him from a jovial man of society to an enigmatic recluse.

Pigou developed his concept of economic welfare early in his career, with the publication of *Wealth and Welfare* in 1912. "Welfare" refers to the benefits that society gets as a result of people's decisions. It is not to be confused with the study of government welfare programs, although it might sometimes include them. However, the decisions of individual economic actors can also damage social welfare. The key is to get the most benefit at the least cost to society. Adam Smith had famously stated in *The Wealth of Nations* that when people pursue their own interests, markets will tend to make decisions beneficial for society. But Pigou noted that this is not always the case, because people's choices may involve "external" costs and/or benefits. Pigou's idea came to be known later as "externalities," a term Pigou did not use. An *externality* is a cost or benefit that is "external" to the person who makes a particular decision. Externalities can be both negative and positive. Pollution is an example of a negative externality, while education is a positive externality.

Pigou wrote that externalities might be a good place for the government to get involved. The government could put a tax on negative externalities and a subsidy on positive externalities. The effect of these actions would be to encourage the "right" or "optimal" amount of, for example, toy-making and education. These have come to be known as Pigovian taxes and subsidies. Pigou introduced a systematic way to study the social impact of personal choices, and a framework for deciding whether or not government action was necessary in a certain situation. This framework is still in use, though it has received an interesting and serious challenge by Ronald Coase and other economists, who point out that government action can produce externalities of its own.

Pigou's relatively uncontroversial life received a sudden shock when his former student, John Maynard Keynes, published the famous *General Theory of Employment, Interest and Money* (1936). Keynes used Pigou as the foil for his book, casting him and his classical predecessors as oblivious, out of touch, and uncaring of the plight of people in the real world. Pigou had indeed written that long-term unemployment was impossible as long as wages were permitted to fall. Keynes said that wages would not fall, and that the real problem was low overall demand—so the classical theory was pointless. Deeply offended, Pigou responded with counter theories of his own. He and Keynes, however, were polite to each other in personal conversation.

Although Pigou remained at Cambridge, he spent more and more time in his apartment, venturing out only to deliver lectures. His reclusive habits (especially compared with Keynes's charm and dash) made him less than popular on campus. However, it was undeniable that his ideas, especially the ones having to do with economic welfare and public finance, showed great promise. It was not long before his theories were used as the basis for determining whether the government should get involved in a matter and what the subsequent public policy might be. Laws that tax and regulate pollution and other externalities are directly affected by the pioneering work of A. C. Pigou.

Arthur Cecil Pigou died in Cambridge, England on March 7, 1959.

PIGOUVIAN TAXES

A *Pigouvian tax*, introduced by British economist Arthur C. Pigou, aims to correct economic distortions caused by *negative externalities*, which are the imposition of social costs on other parties without compensation. Without correction, negative externalities may exceed the socially optimal level. A Pigouvian tax on a good or service that generates a negative externality can restore the optimum by reducing such activities to efficient levels.

In environmental economics, Pigouvian taxes are targeted at such negative externalities as air and water pollution or solid waste. A prominent example includes carbon taxes, imposed on the per-unit generation of greenhouse gases such as carbon dioxide that contribute to climate change. Other examples include charges for nutrient loadings in effluent from wastewater treatment plants, and gas-guzzler taxes on low-fuel efficiency automobiles.

Ronald Coase believed a Pigouvian tax to be unnecessary and, in fact, a suboptimal way to correct the pollution problem. Coase argued that negative externalities such as pollution are reciprocal in that it takes both a polluting party and a receiving party to create the problem. A Pigouvian tax assigns the liability to the polluting party (which they then share via the tax burden–sharing phenomenon), and thus there is no incentive for the receiving party to take action to minimize pollution's cost on them by taking defensive action such as filtering dirty air or water or simply moving away. If the costs of the defensive actions are lower than the costs of cleaning up the pollution, social costs would be lower if the solution relied more on defensive action and less on the cleanup level dictated by the Pigouvian tax. Coase, skeptical of market intervention, argued that the Pareto optimal solution lies in a negotiated outcome between the affected parties where the correct combination of cleanup and defensive action can be agreed upon.

In 1974, Martin Weitzman published an article that contrasted price-based economic mechanisms for correcting negative externalities, such as Pigouvian taxes, with quantity-based mechanisms, such as emissions standards (or tradable permits).

Price and quantity instruments can both lead to efficient outcomes, provided that the marginal cost and marginal benefits of pollution control are known with certainty. However, if the marginal cost function is not known *ex ante*, then the preferred approach to the problem depends on the perceived relative steepness of the marginal cost and marginal benefit functions in the neighborhood of the policy space. If the marginal benefit of emissions control is relatively flat in the range of the policy outcomes considered (that is, emission reductions have similar marginal values over a wide range of outcomes), a tax is the preferred option because it minimizes the distortion from an uncertain marginal cost function by allowing the pollutant to vary at the fixed tax rate. Alternatively, if the marginal benefit of emissions control is rather steep (that is, high levels of emissions are very damaging), a quantity-based emissions mechanism, such as an emissions standard, is preferred.

On the innate preferences of some parties for the price or quantity approach, Weitzman opines:

> From a strictly theoretical point of view there is really nothing to recommend one mode of control over the other. This notwithstanding, I think it is a fair generalization to say that the average economist in the Western marginalist tradition has at least a vague preference toward indirect control by prices, just as the typical non-economist leans toward the direct regulation of quantities. (Weitzman 1974, 477)

Weitzman goes on to say that the traditional economist's confidence in the superiority of the price instrument may be misguided if it relies on the premise that the proper price to charge is known with certainty, a matter that is typically elusive in practice. The foundation of his article is that uncertainty about the cost and benefit functions underlies the uncertainty about whether the price or quantity approach is preferred. Others have extended the Weitzman framework to consider prices versus quantities in a dynamic setting that is more reflective of actual policy conditions. They show that quantity instruments, such as cap-and-trade with banking and borrowing between periods, can outperform a tax in a multiperiod setting where policies are set in one period and costs and benefits are resolved in subsequent periods. They find that the flexibility of the quantity-based approach allows firms to adjust their emissions abatement to equate expected marginal costs across periods better than a price instrument can.

To this day, many economists still favor the Pigouvian tax (price) approach over a quantity approach, albeit for different reasons than stated by Weitzman—namely, because of their revenue-generating characteristics, a consideration heightened by the prevalence of fiscal deficits throughout much of the world. Money raised through Pigouvian taxes can be used to replace distortionary (e.g., income) taxes in the current system and thereby enhance overall economic efficiency (referred to as a double dividend). While usually attributed to the tax approach, it is important to recognize that revenue can also be raised with a quantity-based emissions trading system that sells emission allowances to the regulated community through an auction or other means. The double-dividend hypothesis, however, has been extensively challenged. First, there is the relevant political challenge in ensuring that revenue raised in a Pigouvian tax system will actually be used to reduce distortionary taxes elsewhere in the system. But there have also been challenges based on theoretical grounds, given that pollution taxes themselves create distortions in the real net wage. Subsequent research has examined whether Pigouvian taxes create negative tax interaction effects with existing distortions that can negate the double-dividend benefits. The results are indeterminate, and they depend highly on the type of policy and model specification.

POLLOCK V. FARMERS' LOAN & TRUST COMPANY

The power of Congress to tax is a very extensive power. The Constitution provides for it with one exception and two qualifications: Congress cannot tax exports, and it must impose direct taxes by the rule of apportionment, and indirect taxes by the rule of uniformity. Most revenue that the federal government acquired was through tariffs, duties, and other consumption taxes (i.e., sales taxes).

The Supreme Court's responsibility in *Pollock v. Farmers' Loan & Trust,* 157 U.S. 429 (1895) was to settle the issue of whether or not a tax on income earned from property violated Article I, Section 2, Clause 3, of the U.S. Constitution. This article requires that direct taxes imposed by the national government be apportioned among the states on the basis of population.

The Panic of 1893 resulted in the United States experiencing a financial contraction in the business cycle, characterized by high unemployment rates and difficult access to capital. In response, Congress passed the Wilson-Gorman Tariff Act of 1894. Believing that this income tax violated the Constitution, Charles Pollock sued the Farmers' Loan & Trust Company in 1895. The Supreme Court reversed its previous ruling in *Springer v. United States* (102 U.S. 586, October 1880) and agreed in part with Pollock. Afterward, it became difficult for Congress to impose a national income tax that applied to all forms of income until the 1913 ratification of the Sixteenth Amendment to the U.S. Constitution.

Case Summary

Corporations cannot spend shareholders' profits in ways that are illegal. Charles Pollock believed that Farmers' Loan & Trust Company was going to do that very thing if it took his share of the net profits to pay what he alleged was an unconstitutional tax. Charles Pollock was not rich by the standards of the day, nor was he poor. He owned 10 shares in the Farmers' Loan & Trust Company of Massachusetts with a value of over $5,000, which would be close to $140,300 in 2013 dollars (BLS n.d.). Pollock's investment was not great, but the significance of his objection was not small.

Charles Pollock could not sue Congress. Therefore, he sued the corporation he was employed with in a federal circuit court, enjoining it from paying the tax and reporting the shareholders' income to the Internal Revenue officer. Other stockholders of Farmers' Loan & Trust, many of whom did not think they should pay 2 percent of their net profit to the federal government, shared in this litigation. Pollock argued that the tax was unconstitutional. He lost, and he appealed his case to the Supreme Court.

At the turn of the 20th century, the time of *Pollock v. Farmers' Loan & Trust Company*, the nation was divided on political principles. Some years earlier, opposed by the Republicans, Congress passed an emergency revenue bill, the Internal Revenue Act of 1862 and 1864, to implement a temporary income tax on the wealthy to help finance the Civil War. Prior to this time, most of the revenue the federal government acquired was from tariffs, duties, and other consumption taxes (i.e., sales taxes). In *Springer v. U.S.* (1864), the Supreme Court upheld the constitutionality of the income tax. This tax was allowed to expire, as it had been mainly an emergency measure.

In 1892, Grover Cleveland became the first Democratic president elected since the Civil War. Only months after his inauguration, the nation experienced the Panic of 1893. The economy went into a contraction phase of the business cycle, characterized by high unemployment, bank panics, and a severe difficulty in obtaining capital. President Cleveland and Congress responded by lowering tariffs and duties. In addition, in 1893 Congress and President Cleveland re-implemented the income tax by enacting the Wilson-Gorman Tariff Act.

The act stipulated that every citizen would pay a 2-percent tax on income from property, rents, interest dividends, salaries, and so forth over the amount of $4,000. This income included sales of bonds, notes, and agricultural products. In addition, all persons of lawful age having an income of at least $3,500 would be required to submit a list or record of their income to the Internal Revenue collector. Investment and banking institutions must submit that payment of tax on behalf of the investors whose interest and rent were the subject of taxation. Farmers' Loan & Trust Company, a corporation of the state of New York, held a fiduciary responsibility to its clients that required it to report the income and pay the 2-percent tax. The capital stock of the corporation was worth $1 million. There were 40,000 shares of stock at a par value of $25 per share (for publication information on the transcript of syllabus of the case, see "Further Reading" at the end of this entry). Additional assets of the corporation included property and a host of New York City municipal bonds.

The Supreme Court took the *Pollock v. Farmers' Loan & Trust* case to settle an issue with regard to whether or not a tax on income earned from property violated Article I, Section 2, Clause 3 of the Constitution, which requires that direct taxes imposed by the national government be apportioned among the states on the basis of population. Pollock argued that income derived from property was a direct tax and as such was not collected per apportionment, as was the constitutional requirement. In addition, the federal government could not tax municipal bonds any more than state governments could tax federal bonds.

When writing the opinion of the Court, Chief Justice Fuller made great effort to construe what the framers of the Constitution intended by "direct" and "indirect" taxes. It was Fuller's conclusion that even with the readings of Adam Smith at their disposal, it could not be determined what the Justices meant. The issue of apportionment and taxation was a compromise by the convention to keep the negotiations going. It was clear that the states could not tax imports, and commerce was to be regulated by the federal government. Actual apportionment within a state, however, was left to the state. Furthermore, Fuller concurred with the argument that municipal bonds were not eligible for taxation, thereby finding sections of the Wilson-Gorman Tariff Act in violation of the Constitution. The Court held that imposing taxes on personal income derived from real estate investments and personal property such as stocks and bonds was a direct tax and had not been apportioned properly among the states.

Justice White's dissenting opinion was ardent. Joined by Justice Harlan, White expressed concern that precedent had been established whereby no legal power could obstruct or control the collection of taxes. If there were a mechanism to do this, the very existence of the government might hang on the authority of an antagonistic judiciary. White stated that as long as Pollock had recourse to legal remedy after his taxes were paid, he had no grounds for a case prior to payment. In addition, White argued that to ponder the intent of the framers of the Constitution was to ignore the opinions of William Paterson, who was a contributor at the Constitutional Convention. (Justice Paterson sat on the Supreme Court from 1793 to 1806 and clearly stated that the power to tax was extensive.) Justice Harlan added in a short dissent that the framers' interpretation of direct and indirect taxation was clear and vested in the United States' plenary powers of taxation, with the exception of exports (for publication information on the transcript of Justice Harlan's dissenting opinion, see "Further Reading" at the end of this entry).

Nonetheless, Chief Justice Fuller agreed that the framers of the Constitution had aimed at compromise with the rule of apportionment, but he added that if the federal government is allowed to call a direct tax indirect, the power boundary is broken and the safeguard of private rights and private property could disappear as well (for publication information on the transcript of Chief Justice Fuller's majority opinion, see "Further Reading" at the end of this entry). The Supreme Court ruled that the Circuit Court finding was to be reversed and the case remanded with directions to enter a decree in favor of Pollock.

POST-KEYNESIAN ECONOMICS

Keynesian economics represents a school of economic thought that dispels traditional classical economic theory and has greatly influenced modern-day macroeconomics. Pioneered by John Maynard Keynes, it looked to explain economic conditions with fluctuations in aggregate demand.

Keynes argued that aggregate demand is the main driver of the economy. He argued that an increase in spending would essentially lead to an increase in employment, which in turn would lead to more spending. Speaking originally in response to the Great Depression, Keynes had pointed out the natural inclination during a recession was to save. However, spending and interventionist policy by the government to expand the money supply to increase spending would lead to economic recovery.

Post-Keynesian economics is an expansion of Keynesian economic thought. Specifically, it is the synthesis of Keynes's original ideas into the modern concept of macroeconomics. It is most commonly associated with Professors Jan Kregel and Alfred Eichner and their modern interpretations of Keynesian economics during the 1970s. Specifically, post-Keynesian economics looks at the relationship between capital distribution and economic growth. The distribution of wealth as a policy through the increase in money supply or other such government interventions can have various impacts on the economy.

Post-Keynesian economists expand on previous economic thought that intervention of the money supply can be used as a tool to prevent or mitigate financial crises by stimulating spending rather than promoting conservatism. Another tenet of Post-Keynesian thought is that at a given level of investment the capitalist gains greater share of wealth from investment than is gained from savings. To invest rather than save further stimulates the economy and promotes individual wealth for that actor. The capitalist's actions and optimism regarding investments can signify future trends in economic growth.

PROPERTY RIGHTS

A *property right* in the broad (economic) sense refers to the right, consent, or permission granted to an individual that allows that individual to act in a particular way, or, alternatively, the right of an individual to be free from the harm imposed by the actions of others. When referring to physical property such as land or a house, it might mean the right to use that property in a particular way (e.g., to paint the house bright purple), or the right to sell that property to whomever one chooses. However, not all property rights are tied directly to physical property. For example, a firm might have a property right that allows it to generate harmful pollution as a by-product of production. Alternatively, individuals might have a right not to be exposed involuntarily to pollution arising from the activities of others.

Where do these rights come from? In short, they come from society. Society determines what is or is not allowed, and therefore determines what property rights people have. These rights can be defined legally (for example, through laws, regulations, or legal rules and precedents), or they can emerge from accepted social norms. Once the rights are defined, society also needs to enforce those rights—that is, make sure that those rights are protected. For example, the enforcement of property rights is a key function of the judicial system, where courts sort out disputes about who is allowed to do what and impose consequences when they find that someone's property rights have been violated. Possible consequences include ordering an individual to stop acting in a way that violates another's rights, and/or requiring payment of compensation for damages or losses due to the violation.

Clearly, individuals care about their property rights. More specifically, an individual's utility, income, and/or wealth will depend on the assignment of property rights. For example, if landowners have a right to use their land in any way they want, the land is worth more than if they are restricted in how they can use it (or to whom they can sell it). Similarly, a firm that has the right to generate pollution without having to pay compensation for any resulting damages will earn higher profits than a firm that is prohibited from exceeding a certain level of emissions or a firm that must pay compensation for damages if that level is exceeded. Conversely, all else being equal, an individual who has a property right to clean water will generally have higher utility than a person who does not have that right, either because the water will be cleaner or because, if the water is polluted (as a result of someone else's actions), the property owner will be compensated for the resulting damages.

Although individuals clearly care about their property rights, an important economic question is the role of property rights in determining real outcomes, where *real outcomes* means the actual use of resources in the economy and the good results or bad results that are produced. For example, will society have more pollution under one assignment of property rights than under another? Will the land-use decisions that are ultimately made depend on the assignment of property rights?

In essence, property rights determine who has to pay and who gets paid when certain activities occur. Although this has implications for the distribution of income, a famous result known as the Coase theorem states that, under certain conditions, it will not affect real outcomes. Coase's key insight is that, if property rights are well defined and individuals can freely bargain (without income effects), then through bargaining they will arrive at a deal that is mutually beneficial. In addition, although the direction of payment (i.e., who pays whom) under the deal will depend on the assignment of property rights, the real outcome that the individuals agree upon will not.

The insight underlying the Coase theorem has wide applicability and has been demonstrated in a number of different contexts where mutually beneficial trades (bargains) can occur. For example, one well-known result states that, in a simple cap-and-trade system where pollution permits are initially distributed free of charge and the permit market is competitive, the pattern of pollution reductions across firms that emerges after trading does not depend on how the permits were initially distributed. Since the initial distribution of permits defines an assignment of property rights (i.e., each permit gives the holder the right to use or sell the permit), this result is a direct parallel to the Coase theorem.

Although the Coase theorem states that, under certain conditions, the assignment of property rights does not affect real outcomes (after bargaining or trade), importantly, in the real world the conditions needed for this result often fail. For example, bargaining will be difficult or costly when the number of polluters or affected individuals is large. In addition, if individuals can make irreversible investment decisions before bargaining occurs, these conditions can fail. In such cases, property rights can affect real outcomes. More specifically, actions by the government that implicitly or explicitly define property rights can, in turn, create incentives that affect outcomes. A classic example is when the government regulates the use of private property, which some argue constitutes a government taking.

In the United States (and many other countries), the government is allowed to seize private property for public use (e.g., to build a school or a road) under its power of eminent domain. However, the Fifth Amendment of the Constitution requires that the government pay just compensation to the landowner for this taking. Some argue that the same protection of private property extends to government actions that do not seize private property but rather regulate its use for a public purpose (e.g., prohibiting the cutting of timber on land that provides habitat to an endangered species). Such actions are often referred to as regulatory takings.

As a property rights issue, the question is whether such an action requires that the government compensate the property owner for the loss in the value of the property that results from the restriction on its use. The rule regarding compensation—that is, whether compensation must be paid or how much compensation must be paid—effectively defines the property right. There is considerable debate about the appropriate rule, with private property advocates on one side and proponents of government regulation on the other side. Arguments are often based on notions of fairness or justice. However, from an economic perspective, the questions are whether and how the compensation rule affects the incentives faced by the government and the property owner. These incentives determine the decisions that are ultimately made and hence the real outcomes. An economic evaluation of different rules focuses on how they affect economic efficiency, as measured by aggregate net social benefits, rather than on the fairness of the implied assignment of property rights.

The compensation rule can affect the incentives of both the government and the landowner. If the government is concerned more about its own outlays than about the costs borne by society as a whole, then if it does not have to compensate landowners for their loss, the government will view the regulation as less costly and hence have an incentive to overregulate. This argument has been used to suggest that requiring compensation will lead to better (i.e., more efficient) regulatory decisions. Although this is true, other compensation rules—such as a threshold rule that requires the government to pay compensation only for regulations that are deemed to be inefficient—can also achieve this goal. In addition, when the government has to pay compensation, typically it will have to raise the necessary funds through some form of taxation that distorts behavior and thereby generates a (deadweight) loss for society. This means that rules that can induce efficient incentives without requiring the government to always pay compensation (such as the threshold rule) will be more efficient, all else being equal.

While some have argued for compensation as a way to curb excessive regulation, most of the economic debate about compensation has focused on its impact on landowner incentives. Landowners can make decisions prior to the government action, and those decisions can be influenced by whether the landowners expect to receive compensation (and the nature of the compensation) if a government taking occurs. For example, landowners can invest in their property to improve its value. If they expect to be compensated based on the actual value of their property, they will have an incentive to overinvest since they will not internalize the risk that the private investment will be wasted if a taking occurs. This is analogous to the standard moral hazard effect of insurance. It implies that any compensation that is paid should not be tied to the actual value of the property (thereby rewarding the landowner for additional investment even if a taking occurs). Rather, if compensation is paid, it should be independent of the landowner's investment (i.e., lump-sum).

But what should the level of (lump-sum) compensation be? If the actual value of the property will influence the likelihood that the government will regulate it, then the compensation amount should equal the loss the landowner would incur under the efficient (rather than the actual) investment decision. If compensation is less than this, the landowner will have an incentive to overinvest so as to make the property more valuable, thereby decreasing the likelihood of being regulated (and receiving less than full compensation). Conversely, if compensation is more than this amount, the landowner will have an incentive to underinvest to make the property less valuable and increase the likelihood that the landowner will receive the excessive compensation. Thus, only full compensation, based on efficient rather than actual investment, eliminates these distortionary incentives.

Similarly, a landowner might be able to influence (or possibly eliminate altogether) the possibility of regulation by developing the land: for example, filling in a wetland in anticipation of a ban on wetlands development or cutting timber to destroy habitat for an endangered species that might subsequently be protected. As in the previous case, not compensating the landowner if a regulation occurs will create an incentive for the landowner to engage in these preemptive activities.

PUBLIC DEBT

Simply put, *debt* is money owed. Debt can be owed between people, organizations, and the government. *Public debt* is all debt of governments and public institutions (public schools, et al.) held by individuals, corporations, state and local governments, Federal Reserve Banks, foreign governments, and other entities outside of a government. Public debt is the obligation on the part of a governmental unit to pay a specific monetary amount to holders of legally designated claims at a point in time.

Public debit is classified into two categories: debt held by the public and intergovernmental holdings. Public debt is created by the act of borrowing. In the United States, the federal government auctions Treasury securities such as bonds and Treasury bills to foreign and domestic investors to raise money. The government sets a spending goal and sells enough securities at auction to satisfy that goal. Social Security and other government programs are financed through intragovernmental holdings, the other category of debt in the United States. The debt is repaid during a reverse transfer where the government gives up money for debt instruments.

Say, for example, that the federal government forecasts that it will need $33 billion more than it is currently collecting in tax revenue to pay for an existing program. The government could increase taxes to pay for the program, but this may not be a politically popular decision, nor would it reflect favorably in the economy. The government may also print the money, which could lead to inflation, increasing the price of goods and services in the economy. So, rather than raising revenue or printing money, the federal government raises money by issuing bonds. The money raised from the selling of the bonds will be used to finance the underfunded program. The government or government entity issuing the bonds now has public debt.

An indicator of a nation's indebtedness is the ratio of its public debt to its gross domestic product (GDP). When observed as a percentage of a nation's GDP, a rising national debt is a large problem for the economy. The more debt a nation holds, the less money there is to save or to reinvest into the economy.

Another important factor in determining the impact of debt on a national economy is ownership of the public debt. National debt in all countries is owned by various governmental and quasigovernmental agencies. Distinguishing between debts held by the banking system and debt held by the nonbanking public is important. Since central banks provide reserves for the commercial banking system, any changes in their holdings of government securities reveal important information about the economy.

The set of operations required to maintain an existing debt is public debt management, or servicing the debt. At intermittent times, debt must be rolled over or refinanced. This can cause significant issues with the management of debt. These potential management issues explain why it is so beneficial to fund national debt to the maximum extent possible. As the national debt grows, a larger share of a government's expenditure budget is consumed by interest payments on the debt. Minimizing the cost of interest payments is an important objective for debt management. Debt management must also involve macroeconomic policy and the effects that debt has on the economy.

Virtually all economists accept that some government debt can be a good thing; this is the classic Keynesian model. During recessions, the safety net of government programs financed by debt can be good for the economy—so long as the deficits during recessions are balanced by surpluses and less debt during good economic times.

Government debt also has negative effects. Interest rates may rise, because government bonds compete directly with corporate bonds for investors. There is also a crowding-out effect, in which the government absorbs a large section of the capital market and pushes out the private sector, often raising nominal interest rates. Public debt is very detailed and complex, and it is often subject to heated political debate, not only in the United States but in nations around the world.

Debt and deficits are often used interchangeably, yet they are two quite different measures. The *deficit* is the difference between government revenues and the amount of money the government spends during a fiscal year. *Debt* is the accumulation of deficits. Even though deficits may decrease, the debt will continue to increase, a connection that is often lost on politicians or the media. Deficits in the United States were high during the 1980s. Even though deficits were falling, the national debt kept growing into the 2000s. Today the United States has large deficits and a significantly large public debt.

PUBLIC FINANCE

Public finance is the study of how governments generate revenue to provide services in an economy and measure the effectiveness of the funded services. Using taxes, fees, bonds, and other financial instruments as its revenue base, a public institution provides spent on public goods and services. A *public institution* is an institution at the local, state, or federal level of government that provides public goods and services funded by the public through various public sources of revenue. Organizations or individuals responsible to the public for insuring that public revenues are collected or spent appropriately include local city or township treasurers; state treasurers and the agencies that report to them; state comptrollers; and at the federal level the Congressional Budget Office (CBO), Office of Management and Budget (OMB), U.S. Treasury, and, of course, the Internal Revenue Service (IRS).

Public finance also measures the costs and benefits of services for the economy as a whole. Public finance studies how governments provide the public with desired services and how the governments obtain financial resources to pay for these desired services at the national, state, and local levels. In most industrialized countries, government spending and taxation make up a majority of the nation's economic activity.

Local, state, and federal governments provide roads, military forces, street lights, education, police and fire protection, and many other public goods and services that need revenue in order to function. Most public goods, such as the military, exist because private citizens do not voluntarily pay for these goods and businesses have no incentives to produce them as private goods. Many public goods are such that individuals cannot be excluded from their provision and many people benefit equally at the same time.

Public finance also allows governments to fix externalities of a transaction. *Externalities* are undesirable (negative) or highly desirable (positive) side effects of a transaction, with the cost or benefit also being extended to a third party. An example of a negative externality is pollution. Pollution affects people who are not part of the original transaction and therefore not responsible for its occurrence. To correct a spillover, governments can encourage or restrict certain economic activities. Governments can finance recycling programs to encourage reducing pollution or they can pass laws restricting pollution.

Besides taxes and fees, public goods or public projects can be funded using the bond markets. Bonds are loans that investors make to a public entity (city, state, school district, or federal government). All levels of government use the bond market to finance long-term projects. Local governments might use the bond market to finance a new firehouse or police station, and a local school district will use the bond market to finance building a new school or renovating an existing one or upgrading equipment. States will finance new roads, bridges, or other infrastructure using the bond market. Because the federal government is the only level of government that can legally have a deficit and debt, the federal government uses the bond market to finance its federal debt.

Problems with financing public services are often subjective—and therefore political. Some politicians believe high taxation by government is a problem, while others believe that taxation is not high enough; some promote less government spending, while others promote more. Even with these problems and issues, public funding is a necessity. The benefits outweigh the negatives. Overall, public finance is very important in a successful economy when appropriately used by the government.

PUBLIC GOODS

Public goods are goods and services provided by a government, as opposed to goods offered by private businesses or organizations. Public goods are often defined because of market imperfections where the private market does not supply the quantity of a good that society deems appropriate, such as education. Examples of public goods are national defense, interstate highways, state and city parks, public state universities, public schools and education, public libraries, and fire and police protection. Public goods are deemed to be public goods because a society has deemed the good or service to be a valuable benefit to society.

For a good to be considered *public*, two key characteristics need to be fulfilled: shared consumption and nonexclusion principles. *Shared consumption* (which has also been known as nonrival consumption) means more than one person can receive the benefit of the good or service at the same time. Everyone benefits from the Internet or local police protection at the same time, without that benefit being diminished by anyone. Likewise, many people can enjoy a public park on a sunny day without reducing the enjoyment of other people.

While shared consumption is a necessary criterion for a public good, shared consumption does not automatically mean that a good or service is public. Golf courses definitely satisfy shared consumption, since many golfers can enjoy a golf course at the same time. However, golf courses are both a public good and a private good. While there are many public golf courses, there are also many private golf courses. The same can be said for elementary schools, colleges and universities, and campgrounds.

In the second main criterion, the *nonexclusion principle*, a person cannot be excluded from the benefits of the good or service, whether or not the person has paid to support the good or service. This nonexclusion principle best exemplifies a public good. Conversely, a private good's key criterion is that the buyer of the good has the right to decide who consumes the good. The buyer can exclude others from using the particular good. When buying a cup of coffee, a car, or a new pair of shoes, the buyer decides who benefits from the good. The buyer has the right to exclude other people from benefiting from the purchase. A public good, however, does not permit such exclusive-use decisions.

The best example of the nonexclusion principle is national defense. It does not matter if a person pays taxes to support the military. If the military becomes involved in a war or a military conflict to protect a nation's citizens, the military does not protect only those who paid taxes. It protects everyone: taxpayers and nontaxpayers alike. A public good from which everyone can benefit presents governments that provide public goods with a key problem: the free rider problem.

Public Goods

	Excludable	Non-Excludable
Rival	Private Goods (Groceries, Clothes, TVs)	Common Goods (Fisheries, Oceans, School Cafeteria)
Non-Rival	Club Goods (Parks, Golf Courses, Movie Theaters)	Public Goods (National defense, police, fire, roads)

Figure 1. Public goods

Free Rider Problem

The free rider problem is an inherent problem for every government that offers a public good. The government (whether it is federal, state, or local) is constantly confronted with how to deal with free riders and minimize the free rider issue. One key solution to the free rider issue is to increase the exclusivity of the public good. This has been accomplished through the use of tolls for roads and bridges, fees for parks, or licenses for many professional and recreational activities.

A second problem for a public good arises when ownership and property rights are not well defined. When ownership of a resource, such as the ocean, cannot be well defined, there is a tendency to overuse the good without consideration of the costs of its use. This imbalance of excess use without concern for costs leads to negative externalities such as pollution. This type of public good problem is called the "tragedy of the commons." Ownership is based on rule of capture, which results in the overuse of the good. The free rider problem has been confronted throughout history with, for example, efforts to preserve different types of fish or buffalo herds; this form of free rider problem is addressed through improved property rights. Defining property ownership and assigning property rights for a property such as a body of water is a problem for government. While no solution has been found to be perfect, this issue has been addressed through establishing quotas or increasing fees for use.

Critics of public goods suggest that governments and societies are often too quick to designate a good or service as one that should be available to all (i a public good). Critics point out that many of these goods could have been satisfactorily distributed in the marketplace as private goods. Indeed, some historically public goods have over time been transferred, at least in part, to the private sector. In some parts of the country, for example, fire protection has been transformed into a more private good, where those who do not pay the fee do not receive fire protection.

Funding of Public Goods

Public goods are funded through taxes, fees, fines, and licenses. The type of funding a public good receives is often determined by the characteristics of the public good. For national defense, for example, which is clearly shared consumption and where excluding someone would be virtually impossible, taxes are the revenue choice. Education is another example of funding through taxes, because consumption is shared and one cannot be excluded from benefiting. If the public good is an activity for which the nonrival principle does not hold and someone can be excluded, then fees or licenses are used as an incentive for people to participate and fund the activity. States often require fishing and hunting licenses for people to participate in those activities. Users are often charged a fee to enter national and state parks. One cannot drive a car without a driver's license and a license plate.

Public Goods and the Global Economy

An increasing concern as the global economy grows and expands is the role of institutions in providing an amount of certainty and order to the global economic environment. It has been argued that this lack of general international rules leads to financial crises. At issue regarding a free rider problem is the use of international public goods to define how countries choose (or not) to participate in the global economy. Global public goods can include capital flows to developing countries, international money settlements for international debts, and last-resort lending. A lack of international rules and institutions creates incentives for some nations to be free riders in solving these international issues, creating a fragile global economy. Some countries choose not to pay, but they participate in the international marketplace and international institutions such as the World Bank and the International Monetary Fund. These countries that do not pay participating fees to the World Bank or International Monetary Fund still receive emergency financial assistance from either or both organizations. These nations are essentially free riders in the global economy.

Q

QUANTITATIVE EASING

Quantitative easing (QE) is a large expansion of a central bank buying securities from its member banks, also known as open market operations. This buying creates liquidity in capital markets. The effect is very similar to increasing the money supply and is a power specific solely to central banks. In return, the central bank issues credit to the bank reserves in order to buy the securities.

The purpose of this type of expansionary monetary policy is to lower interest rates and spark economic growth. The goal of lowering interest rates is to incentivize bank customers to apply for more bank loans and to enable banks to make more loans. More bank loans help to stimulate demand by giving businesses cheap loans and giving shoppers more credit to buy goods. By increasing the money supply, QE keeps the value of the country's currency low. A low currency helps to make stocks appear like a relatively good investment to foreign investors and U.S. exports cheaper in foreign markets.

Central banks typically set the price of money by using official interest rates in order to regulate the economy. These interest rates funnel into the rest of the economy and affect the cost of loans paid by companies, the cost of mortgages for households, and the return on savings. The higher the interest rates, the more expensive borrowing is, which also makes borrowing less attractive. High interest rates also make saving more attractive, which reduces demand and reduces the amount of spending that is taking place in the economy. Lower interest rates have the reverse effect.

When the central banks want to lower the price of money (i.e., interest rate), they can do so through QE. QE is sometimes incorrectly described as "printing money," but in reality a central bank actually creates money electronically, resulting in increasing the credit in its own bank account. The central bank can then use the money to buy such assets as government bonds, equities, mortgages, and corporate bonds.

The first established use of QE was by Japan from 2001 to 2006. A more recent example is the European Central Bank's adoption of QE in 2015: The European Central Bank purchased euro-bonds in order to lower the value of the euro and increase exports. The U.S. Federal Reserve exhibited the most successful QE effort to date. Through QE, the balance sheet of the U.S. Federal Reserve more than quadrupled in 2014, making the U.S. QE the largest economic stimulus program in world history.

How the Federal Reserve uses QE illustrates the concept in even greater depth. The Fed may start by adding credit to the banks' reserve accounts in exchange for mortgage-backed securities and treasuries. The *reserve account* is the amount of money that banks have on account with the Federal Reserve. A portion of the reserves the banks are required to maintain with the Fed. These are *required reserves*. When the Fed adds credit to the reserve, banks now have more money in their reserves than they need. These additional reserves in a bank's account are *excess reserves* and banks do with these reserves as they desire. In theory, the goal is that banks will loan the excess reserves to businesses and households in the economy.

The banks also now have more money to lend to other banks. In an attempt to unload their extra reserves, banks drop the interest rate they charge. This amount is known as the federal funds rate, and it is the basis for other interest rates, such as the prime interest rate.

The Fed may also stimulate the economy through the federal government's auctioning off of large quantities of treasuries to pay for expansionary fiscal policy. As the Fed buys treasuries, demand increases, keeping treasury yields low. Considering that Treasuries are the basis for all long-term interest rates, other consumer debt rates are affordable. This is also true for corporate bonds, allowing businesses to expand more cheaply. The practice of QE helps to keep long-term, fixed interest mortgage rates low.

R

RAPID DEINDUSTRIALIZATION, 1975

The first part of the 1970s brought a crushing blow to American industry. It was the beginning of the end of America's dominance in auto, steel, and rubber production. The final economic steel boom came in 1970, masking the real structural problems of American heavy industry. The boom ended in 1972, and what followed was the rapid deindustrialization of the American economy. The root of many of the problems of great U.S. cities and industries today is the result of the rapid deindustrialization of the 1970s.

In the 1970s, the Four Horsemen of deindustrialization appeared in the U.S. economy: rising imports driven by free trade, old plants and assets, global labor competition, and rapid technological change. The late 1970s saw a loss of 32 million industrial jobs in the United States, a rate that continued into the 1980s. America's great cities of the industrial age began their decline. Deindustrialization did more than change the geography books: It changed social norms and old immigrant infrastructure in many industrial cities, including Detroit, Cleveland, Cincinnati, Youngstown, Akron, Buffalo, Trenton, Newark, Philadelphia, Pittsburgh, St. Louis, and Chicago. The loss of their industrial tax base and tax-paying workers started decades of deficit spending for these once-great cities. Families and neighborhoods—and social norms—changed with the loss of local industrial plants. Family and community safety networks disappeared, requiring government to step in. Deindustrialization continued for decades, fundamentally changing American society.

At its peak in the 1940s, the American steel industry made more than 60 percent of the world's steel, but by the end of the 1970s the total was less than 20 percent. In 1968, the steel industry and the steel unions had been pacified by a voluntary agreement with friendly nations not to dump steel. The arrangement was actually successful until the steel boom in 1970, which saw temporary steel shortages and price increases. In 1971, Congress let the voluntary agreement expire. The year 1972 was the steel industry's "last hurrah," as U.S. steel shipments started to fall rapidly, overwhelmed by competition from raw steel imports, steel parts imports, capital goods imports, and automobile imports. By 1975 the boom was a memory.

The steel collapse was followed by a collapse in auto production, as a deep recession exposed the weakness of American industry in a global market. In 1950, America was supplying almost 80 percent of the world's cars, but by 1980 that share had dropped to 30 percent. In the 1970s, 25 U.S. auto plants closed: 13 Chrysler plants, 7 General Motors plants, and 5 Ford plants. These closings affected more than 500,000 workers in the auto industry and another 300,000 in the supply chain. By 1975, the Japanese had 18 percent of the American market. By 1980, Detroit was surrendering even more domestic share—22 percent of the market went to imports. Not only did the auto supply chain collapse for the steel and the auto industries; both industries also came under the direct attack of foreign competition.

The rubber industry became the confluence of the industrial decline, collapsing in the late 1970s. During the last two years of the 1970s, Firestone, Goodyear, Goodrich, and Mohawk closed major rubber-making plants in Akron, Ohio. In all, Akron lost 30,000 rubber jobs in the 1970s. B. F. Goodrich Company got out of the tire business in 1975. Firestone shocked all observers by closing its iconic Akron plant no. 1 in 1978, followed by plant no. 2 in 1980; it ended passenger tire production in Akron in 1980. Firestone also announced the closing of 14 rubber factories across the nation. Goodyear and Mohawk stopped tire production in Akron in 1978, and Sun Rubber closed that year.

The rubber industry was crushed in the United States because its old plants, with bias-ply tire equipment, were unable to compete with radial Michelin tires from France and Bridgestone radials from Japan. The conversion to radial technology required the gutting of old plant equipment and huge capital investment. Like steel, the fall of rubber went beyond Akron, the "Rubber City." In the last five years of the 1970s, 24 rubber plants closed, 11 of them in the South. It was the one-two punch of radial technology and auto imports. The rubber industry collapse was far-reaching; it included the three core Los Angeles plants of Goodyear, Goodrich, and Firestone that had brought tire-making to America's West Coast. In 1919, Goodyear's Los Angeles plant was the first tire plant built outside of Akron. In 1975, it closed.

Deindustrialization struck many industries in 1979. Unemployed workers from Westinghouse Electric and Stauffer Chemical in New Jersey, Weyerhaeuser timber mills on the West Coast, and textile plants in North Carolina gathered around their Thanksgiving dinner tables with the same concerns as workers in Youngstown and Pittsburgh. And the problem was not confined to the Rust Belt and southern cities. Los Angeles lost seven major factories: Ford Motor, U.S. Steel, Uniroyal, Pabst Beer, General Motors, Firestone, and General Electric in 1979, and 18,000 people lost their jobs. By early 1980, more than 150 plants had closed in California. Deindustrialization struck with such speed that local politicians were unable to coordinate a response. Almost too late, congressmen in many states realized the importance of security for such national industries as steel. In both political parties, the cry to "Protect our industries" was counteracted by the rising popularity of free-trade economics.

As bad as the rapid deindustrialization was statistically, Americans stoically absorbed the impact. The norm of one-breadwinner families shifted to two-income families to restore the lost wages of good-paying industrial jobs. In larger cities, families fled the poverty and unemployment that deindustrialization had brought to their city neighborhoods by moving to the suburbs. There was a diaspora of workers to the southern states where there was job growth, albeit at lower wages. Cities taxed more and used deficit spending to counter lost industrial tax revenue.

Decades later, these industrial cities collapsed into centers of rising welfare, poverty, unemployment, crime, and eventually bankruptcy or bailouts.

RECESSION

One of the factors used to measure the health of an economy is gross domestic product (GDP). If GDP falls for two consecutive quarters (the equivalent of six months), the economy is said to be in a recession.

A recession is characterized by several factors; one of the better known of these is for unemployment to rise in the range of 6 to 10 percent. A recession generally lasts from 6 to 18 months. During a time of recession, many firms lay off workers, and production levels in the nation begin to decline.

Causes of Recession

Many factors can lead to a recession; one of these is the natural rise and fall in the business cycle, which is not easy to predict. The fluctuation of the business cycle is caused by any one of four factors: business investment; interest rates and credit; consumer expectations; and external shocks. Some factors can be more predictable than others, such as business investments, interest rates, and consumer expectations.

All of these factors can be detrimental to the economy, and in the past the government has tried different tactics to intervene in all of these situations—trying to prevent the recession from becoming a depression.

Government Intervention

Historically, economists believed the business cycle would naturally fluctuate quickly. If the economy declined, it will quickly recover on its own without government intervention. This was the common belief in 1929, when the economy took a severe downturn; the recession deepened, and by 1933 GDP fell by almost one-third and unemployment rose to about 25 percent. The United States fell into the deepest recession it had ever faced, and this became known as the Great Depression.

Since the Great Depression, both economists and the government have changed their view regarding the economy naturally correcting itself. Even though opinions vary on what role the government should take to help correct a decline in the economy, there have been recessions since the Great Depression—but none as severe.

In the 1970s, the Organization of Petroleum Exporting Countries (OPEC) instituted an embargo on oil shipped to the United States. This caused oil prices to quadruple, and external shocks were felt in the American oil market. As oil prices spiked, so did the cost of raw materials, causing the economy to fall into a contraction. Americans modified their behaviors quickly. They began to conserve energy, turned down their heat in their homes, bought smaller and more fuel-efficient cars, and began searching for alternatives to oil.

Americans purchasing smaller, more fuel-efficient cars caused great suffering for U.S. automakers. These companies were producing larger automobiles at a time when citizens were turning primarily to the Japanese automobile makers Honda and Toyota to replace their gas-guzzling American-made automobiles. This furthered the economic downturn in the United States. The response to the oil embargo was for the U.S. government and private firms to develop more of their own energy resources.

More recently, the United States suffered from a recession in the late 1990s and early 2000s. Businesses and individuals invested billions of dollars in new technology that proved to be unprofitable. The negative effects of the technology crash were felt in other industries across the nation. By March 2001, the country had slipped into a recession.

The government and economists alike hoped that the downturn would be short-term, but the terrorist attacks on September 11, 2001, resulted in a severe drop in consumer spending. Fear swept throughout the nation, bringing sharp declines in travel. The hotel, airline, and tourism industries were affected the most. Due to the nature of the terrorist attacks, consumers were afraid to fly.

In response to the 2001 recession, the Federal Reserve cut interest rates to all-time lows to help keep the economy from slipping even further into recession or depression. Unemployment continued to rise, and firms and consumers alike kept their spending very low.

By 2003 the economy was thriving again, with GDP growing at a rate of 7.5 percent over three months. However, by 2006 gas prices were rising sharply, and the economy's growth began to slow. Difficulties in the banking industry, due primarily to high-risk lending, caused the economy to fall into a deep contraction; by 2008 the country was in the most severe recession since the Great Depression. The Federal Reserve responded by lowering interest rates to the lowest in U.S. history to try and stimulate lending. Federal regulations on banking, in the form of more restrictive lending laws, made sweeping changes to mortgage lending in an attempt to prevent the crisis of 2008 from ever happening again.

REGULATION

Businesses produce goods and provide services that we all enjoy. However, in the process of producing these goods and providing these services, businesses frequently generate by-products that harm the natural environment, including humans. Sometimes these by-products are extremely hazardous pollutants that cause great environmental harm, for example, radioactive waste generated by nuclear power plants. In other cases, these by-products represent merely nuisances that cause only minor harm, for example, the noise generated by lawn mowers and other landscape maintenance tools.

Regardless of the scale, the harm generated by any business represents a burden or cost borne by someone else. Since these costs are borne by others, these costs are distinctively different from the costs that businesses normally face, such as the cost of hiring workers or renting buildings. While labor and rental costs are born internally by businesses, the environmentally related costs are born externally. Given this distinction, businesses are free to ignore external costs, leading businesses to make environmentally insensitive decisions due to this negative externality. Consequently, environmental costs are external to the market as a whole. Since the market price does not reflect environmental costs, the market price is too low, leading consumers to overconsume goods and services that harm the environment.

Fortunately, governments are able to offer regulatory methods for correcting business-related negative externalities. In the United States, major environmental regulation began in 1970 with the creation of the Environmental Protection Agency (EPA). Since then the EPA has implemented various regulatory programs designed to correct business-related externalities, for example, the Clean Air Act in 1970. These environmental regulatory programs attempt to reduce the environmental harm caused by businesses. Most regulatory programs restrict businesses' choices directly or indirectly. Other regulatory programs induce businesses to make more environmentally sensitive choices. Regulatory programs directly restrict businesses' choices generally by imposing design standards, such as the requirement to install filters on smokestacks in order to remove particulate matter. Businesses are legally obligated to meet these design standards. When businesses fail to comply, they are subject to penalties, such as fines. Regulatory programs indirectly restrict businesses' choices generally by imposing performance standards, such as the requirement to keep pollution below a certain maximum. Businesses are legally obligated to meet these performance standards, and noncompliant businesses face the risk of penalties.

Other regulatory programs induce businesses to reduce their generation of harmful by-products, that is, pollution, generally by placing a price on pollution. In essence, these regulatory programs transform the disposal of pollution into another cost of business. In the same way that businesses must pay their workers for their time, these regulatory programs force businesses to pay society for the use of its natural environment as a means of disposal. Once businesses must pay to pollute, they should lower their pollution. Since efforts to reduce pollution are not costless, no business is expected to eliminate its pollution. Instead, each business identifies the level of pollution that represents the best trade-off between the cost of pollution and the cost of pollution reduction.

A pollution charge explicitly places a price on pollution by charging businesses for each unit of pollution emitted, for example, each pound of particulate matter. A program of transferable permits, that is, cap-and-trade, implicitly places a price on pollution. A program caps the aggregate amount of pollution allowable from an identified set of pollution sources (nearly always businesses), issues the number of permits needed to match this cap (generally one permit per pollution unit), and initiates trading among the set of businesses. The buying and selling of permits within a market establishes a market price for the legal right to pollute. Faced with the need to buy permits for the right to pollute, businesses should lower their pollution. Businesses also enjoy the opportunity to sell permits, which may motivate a business to reduce its pollution in order to generate excess permits, that is, the number of permits held exceeds the amount of pollution.

The regulatory programs for correcting business-related externalities enjoy synergies with other similar efforts expended by nongovernmental agents, such as investors. In some cases, nongovernmental efforts serve merely to reinforce regulatory programs. For example, even investors who care about only the profitability of businesses may still pressure businesses to improve their environmental management. Environmentally insensitive choices increase the exposure of businesses to regulatory sanctions. If a business repeatedly violates its performance standard, the EPA may impose a large penalty, which lowers profits. Investor pressure prompts business managers to take these possible penalties seriously, thus improving the effectiveness of these penalties for inducing compliance with performance standards.

In other cases, nongovernmental efforts rely on the regulatory programs for generating influence over businesses' environmentally related decisions. For example, across the United States, members of communities located near polluting businesses are demonstrating that they are very interested in protecting their local environment. In several cases, this interest runs so deep that community members are pressuring regulated businesses to exceed their regulatory requirements, such as lowering their pollution to levels below the maxima established by performance standards. Even though the standards are exceeded, they remain important by serving as a reference point for conveying a community's interest and demonstrating a business's response to local community pressure.

In the end, regulatory programs are effective at reducing environmental harm only if businesses respond to these programs. In the time period shortly following the implementation of a regulatory program, a business is constrained by its capacity to evaluate the set of available options for reducing pollution and by its existing resources: management team, workers, building, equipment, etc. Both constraints limit the effectiveness of regulatory programs and inflate businesses' costs of complying with these programs.

Given the time to evaluate its options fully and modify its resources, a business is much better equipped to respond to regulatory programs. Businesses are more likely to identify the best-fitting approach for reducing pollution. Moreover, businesses may hire a new management team, hire additional environmental management engineers, construct a new building, and install more equipment, as well as researching and designing new technologies. All of these efforts improve the effectiveness of regulatory programs and lower businesses' costs of complying with these programs.

According to conventional economic wisdom, all regulatory programs constrain business operations, thus undermining profitability. However, based on a competing economic perspective, stringent yet flexible environmental regulation may improve profitability. In a dynamic world where opportunities arise frequently and prove difficult to assess in real time, environmental regulation forces businesses to reexamine their operations. In the process, businesses identify opportunities that allow them to comply with environmental regulation and lower production costs or improve product quality. Empirical evidence supports both perspectives, indicating that the ultimate effect of environmental regulation on profitability depends on circumstances.

The flexibility offered by a regulatory program arguably represents the most important circumstance. Design standards offer no flexibility. Performance standards offer flexibility regarding the methods for reducing pollution but not regarding the level of pollution (that is, cannot exceed the maximum). Emission charges and transferable permits offer full flexibility regarding both method and level.

Lastly, even the threat of environmental regulation may prove effective at correcting business-related externalities. Fearing the (potential) burden of future regulation, businesses may band together, especially in the form of industrial associations, in order to demonstrate to environmental agencies that the businesses are capable of self-regulation, thus preempting government regulation. For example, in 1988 the American Chemistry Council created the Responsible Care program to promote safe, responsible, and sustainable management of chemicals, which may have been designed to preempt government regulation in response to a major industrial accident in Bhopal, India, in 1984.

RIVLIN, ALICE

Born: March 4, 1931, in Philadelphia, Pennsylvania; Nationality: American; Professional Interests: fiscal policy, monetary policy; Major Works: *Systematic Thinking for Social Actions* (1971), *Reviving the American Dream: The Economy, the States, and the Federal Government* (1993), *Systematic Thinking for Social Action* (2015).

Alice Rivlin is an economist who has devoted her career to public service for the American people. She served as the first director of the Congressional Budget Office (from February 1975 to August 1983) during the Jimmy Carter and Ronald Reagan administrations. She was also the 30th director of the Office of Management and Budget (from October 1994 to April 1996), this during the Bill Clinton administration. She then became the vice chairman of the Federal Reserve from June 1996 through July 1999. President Barack Obama appointed Rivlin to his National Commission on Fiscal Responsibility and Reform in 2010. Rivlin has also worked for the Brookings Institution throughout her career. She is currently a visiting professor at the Georgetown Public Policy Institute, along with her work on the National Commission of Fiscal Responsibility and Reform.

Alice Mitchell Rivlin was born on March 4, 1931, in Philadelphia, Pennsylvania. She began her collegiate studies at Bryn Mawr College with a focus on history. She took a first-year summer course in economics with Reuben Zubrow at Indiana University and decided that economics would be more useful. She graduated in 1952, writing her senior thesis on the economic integration of Western Europe, even discussing the European monetary union. She then moved to Paris, where she held a junior position working on the Marshall Plan. She was later rejected from the public administration program at Harvard because she was of marriageable age and consequently was considered a poor student risk. She applied to Radcliffe College's (Harvard University) economics program, where she earned her PhD in economics in 1958. She is married to economist Sidney G. Winter, who is a professor at the University of Pennsylvania. She is a frequent contributor to newspapers, television, and radio, and she has written numerous books.

Instead of an academic career, Rivlin ultimately focused on policy work, as she saw this as an avenue to improving people's lives. In her book *Systemic Thinking for Social Change,* Rivlin examines how systemic analysis has positively contributed to such social action programs as education, health, manpower training, and income maintenance, and where it falls short due to inadequate data or methods. Rivlin ultimately endorses widespread implementation of social experimentation and acceptability of the federal government, with the requirement of comprehensive, reliable performance measures.

In *Reviving the American Dream,* Rivlin discusses how to foster faster growth rates in average incomes over the long run. She states that this is necessary to restore confidence in the United States as a place where people who work hard can expect to do better than their parents did. Specifically, Rivlin proposes a common tax for states to be collected on a uniform basis and a uniform rate across the country and shared by the states on a formula basis. She advocates that this policy would encourage interstate commerce and ultimately promote growth. She also writes that state tax policy should shift away from tax breaks and move toward improving services, as this would encourage an aggressive effort for states to improve their infrastructure and their education systems in order to attract business.

Rivlin not only is an economist but also was at the forefront of female representation within the profession. Rivlin recounts that her years as a graduate student at Harvard in the 1950s were not always smooth sailing. She taught mixed-gender economics classes, but initially was assigned only women tutees. When wanting to allow a swap of students with a male colleague for a research project, a senior tutor objected to the switch on the grounds that a female tutor would make male students feel second-class. In addition, Rivlin did not teach introductory economics in the spring of her second year, due to the birth of her child. The man who picked up the class in the spring announced that since a woman could not adequately teach economics, all work and grades previously given would not count. Fortunately, the department chair intervened, and Rivlin's students were able to keep their prior grades. She has maintained that she has never worried about being the only woman (or one of the few) in her government positions, as people eventually realized she was competent and not self-conscious about her gender.

Rivlin was also the director of Brookings Institution's Greater Washington Research Project. President Lyndon Johnson appointed Rivlin to serve as assistant secretary for planning and evaluation at the U.S. Department of Health, Education, and Welfare (1968–1969). She was the founding director of the Congressional Budget Office (CBO) during 1975–1983, where as head of the CBO she was known to criticize Reaganomics. In 1983, she won a MacArthur Foundation "genius" award. She was a senior fellow for economic studies at the Brookings Institution from 1983 to 1993. Under President Clinton, she served as deputy director of the Office of Management and Budget and then as its first female director from 1994 to 1996.

From 1996 to 1999, she served as a governor of the Federal Reserve (the Fed) and as the Fed's vice chair. She was also chair of the District of Columbia Financial Responsibility and Management Assistance Authority from 1998 to 2000, where she helped rescue the District of Columbia from bankruptcy. She has taught at Harvard University, George Mason University, and The New School Universities. She has served as president of the American Economic Association, and she is currently a member of the board of directors of the New York Stock Exchange. She is the author or coauthor of 16 books and numerous articles and papers.

ROBINSON, JOAN

Born: October 31, 1903, in Willesden, England; Died: August 5, 1983, in Cambridge, England; Nationality: English; Professional Interests: imperfect competition, socialism, Keynesianism; Major Works: *Economics of Imperfect Competition* (1933), *The Theory of Unemployment* (1933), *Essay on Marxian Economics* (1942), *The Accumulation of Capital* (1956), *Essays in the Theory of Economic Growth* (1964).

Joan Robinson was a remarkably complex economist. Robinson's 1933 *Economics of Imperfect Competition* confronted the prevailing neoclassical economic models of the day. For example, she was a major critic of models that suggested that equilibrium could be identified. As a lecturer at Cambridge, Robinson was an early disciple of John Maynard Keynes. She later promoted the work of Karl Marx and, sympathetic to social revolutions, she was supportive of Chinese and North Korean communism. Robinson enjoyed lively debate, often treating fellow professors as students. Robinson died in 1983.

Joan Robinson was born Joan Maurice on October 31, 1903, in England to a wealthy and distinguished family. Even during her youth, her thoughts were dominated by questions about how to create a more just and equal society. She studied at Cambridge under A. C. Pigou, and after graduation she married economist Austin Robinson. They moved to India in 1926, so Austin could work as a tutor to a maharajah. They returned to England in 1929 so that Austin could take a position at Cambridge. Not having a job, Joan sought to continue her work in economics by writing articles and a book.

The book *Economics of Imperfect Competition* (1933) expressed her belief that current "neoclassical" economic methods (as expressed by Marshall, Walras, and Pigou) did not reflect reality. Their methods were organized around the pursuit of ideal equilibrium situations, which, she argued, are illusory. Furthermore, their models assumed perfect competition, as if all products were the same and a business could be opened or shut down instantly. In her book, Robinson suggested more realistic assumptions.

Unlike many (perhaps most) economists, Robinson was not content to make minor improvements on economic theory. In her view, the reality of imperfect competition did not simply require small modifications to current economic theory; imperfect competition completely undermined current economic theory. She insisted that economists abandon the old models and seek a brand-new way of looking at the world. Her 1933 book established her as a serious and innovative economist, and she secured a position as a lecturer at Cambridge in 1934.

At Cambridge, Robinson came under the influence of John Maynard Keynes, who was also at Cambridge at the time. In Keynes's *The General Theory of Employment, Interest and Money* (1936), Robinson saw a way to completely do away with the old Marshallian view of economics. She became Keynes's greatest supporter, and she considered her own theory of imperfect competition as the way to destroy the old system. She thought that Keynes's theory of aggregate demand could become the groundwork for a new system. She was enormously disappointed, however, when Keynes himself did not seem to think his ideas were as revolutionary as she did. When Keynesianism began to be used by neoclassical economists all over the world, Robinson dismissed those economists as "bastard Keynesians" and counted such development as a severe missed opportunity.

Desperate for fresh ideas, she turned to Karl Marx, studying his work and writing a short book called *Essays on Marxian Economics* (1942). She found Marx's questions about the development of capitalism and the distribution of income to be promising, but in the end she decided that his methods were not much better than the existing ones. The book did not make her popular, for she gained the enmity of both Marxists (for finding fault with Marx) and mainstream economists (for making it seem like Marx was worth studying).

Robinson was sympathetic to the various Socialist revolutions that occurred around the world, and she was deeply hostile to American foreign and domestic policy, in particular the arms race with the Soviet Union. She was not impressed with Soviet communism either. Instead, she was highly optimistic about Chinese and North Korean communism. She took several trips to China, the first in 1953. She was also encouraged by the possibility of a social experiment comparing North Korea and South Korea, and she was convinced that communist North Korea would be far more successful than capitalist South Korea.

She was an ardent follower of John Maynard Keynes, and seemed to consider herself more of a Keynesian than he was. She desperately desired a more just society, but she cared nothing for feminism. She might have been the most important economist not to have been awarded the Nobel Prize. Yet she herself dismissed her own most important work as flawed. She claims to have lost interest in the groundbreaking *Imperfect Competition* soon after she wrote it, and said she much preferred *The Accumulation of Capital* (1956).

Joan Robinson died in Cambridge, England, in 1983.

ROTHSCHILD FAMILY DYNASTY

The Rothschild dynasty began in the 1760s with Mayer Amschel Rothschild (his surname was originally Bauer) in the city of Frankfurt, in an area of Europe that was part of the Holy Roman Empire (the area later became Germany). Rothschild became a dealer in rare coins and then began providing banking services to Crown Prince Wilhelm in 1785. Shortly thereafter, he decided to turn his focus away from profitable farm and small business loans and toward providing international government loans. It was this pivotal move that established Rothschild as one of the first international bankers and began a family banking dynasty.

Rothschild's five children furthered the banking principles he established. The five arrows on the family's coat of arms represent the banking dynasties started by the five sons: Amschel took over in Frankfurt, Salomon in Vienna, Nathan in London, Carlmann in Naples, and Jacob in Paris.

The brothers entered into a formal partnership agreement with each other that strengthened their financial hold across Europe. By keeping the financial centers within familial control, Rothschild was able to maintain secrecy over the exact size of the vast family fortune. Spreading their fortune over many international cities and varied financial instruments further insulated their fortune. Several other Jewish financial families emulated this strategy.

A major turning point came for the family in 1814, when the brothers helped Britain raise capital to help defeat Napoleon. Nathan viewed Napoleon's war efforts as a threat to the family business. The family spent a significant amount of money organizing metal shipments to the British armies and financing British allies. In 1815, loans to allies totaled about $10.1 billion (using today's average earnings).

Assisting in the war efforts also provided the family with extensive contacts across Europe. The contacts included couriers, shippers, and agents, and these contacts provided the family with essential information, keeping them one step ahead of other financiers regarding the markets.

The family developed a reputation for funding wars. The fame and influence of the Rothschilds was so widespread that the family was thought to be able to control whether wars broke out or empires continued to exist. This reputation generated many conspiracy theories regarding the family. One prevalent theory is that the family played both sides of many conflicts—including the Napoleonic Wars, the Franco-Prussian War, and World War I—in order to expand their fortune.

Other notable ventures by the Rothschilds included assisting in Brazil's independence from Portugal, financing the Suez Canal, and funding the creation of the African colony of Rhodesia.

The family wealth reached its zenith during the 19th century. Although it has diminished since then due to dilution among hundreds of descendants, the family's combined fortune is estimated to be between $350 billion and $1 trillion USD. The family is still active in many industries, including finance, real estate, and philanthropy.

S

SAMUELSON, PAUL

Born: May 15, 1915, in Gary, Indiana; Died: December 13, 2009, in Belmont, Massachusetts; Nationality: American; Professional Interests: macroeconomics, author, Nobel Prize (1970); Major Work: *Economics: An Introductory Analysis* (first published 1948).

Paul Samuelson is probably one of the most referenced and decorated of contemporary economists. Economic historians have called him the "father of modern economics," and the *New York Times* once referred to him as the foremost academic economist of the 20th century. He authored the best-selling college economics textbook of all time: *Economics: An Introductory Analysis*. In 1970, Paul Samuelson was the first U.S. economist to receive the Nobel Prize in Economics. Samuelson died in 1994.

Paul Anthony Samuelson was born on May 15, 1915, in Gary, Indiana. He received his bachelor of arts degree in 1935 from the University of Chicago. Paul Samuelson went on to Harvard University, where he was awarded his PhD in 1941. His early economic influences at Harvard were noted economists Wassily Leontief, Joseph Schumpeter, and Alvin Hansen. At the age of 21, while a doctoral student at Harvard, Samuelson wrote his first published article: "A Note on the Measurement of Utility."

In 1940, Samuelson accepted a position as assistant professor at the Massachusetts Institute of Technology (MIT), where he would remain till his retirement. Paul Samuelson was more than the author, and later coauthor, of the most widely used college textbook in history. During his tenure at MIT, Samuelson worked in the fields of international trade, welfare economics, consumer theory, applying nonlinear dynamics to economic analysis, and public-private choice allocation. In each of these areas, Samuelson has been credited with adding notably to the body of economic knowledge. In terms of economic philosophy, he referred to himself as a "right wing . . . New Deal economist"—that is, a Keynesian.

In 1938, he introduced a way to measure consumer choices and satisfaction-witnessing consumer behavior. This became known as the revealed preference theory. In 1941, he and economist Wolfgang Stolper developed the Stolper-Samuelson theorem in trade theory. This theorem proposed, under certain conditions, that when a resource is scarce, trade will lower real wages and thus protectionism will raise real wages. Stolper-Samuelson would submit that trade between developed and developing countries lowers the wages of the unskilled labor in the developed country that is competing with the lower unskilled wages in the developing country. The Stolper–Samuelson theorem was influential in the later international trade models.

Another area of economics in which Samuelson was well known is public finance, where he is recognized for his efforts in resource allocation between public and private goods and services. One thing that set Samuelson apart from other economists of his time was his use and application of mathematical analysis. In 1947, Samuelson published *Foundations of Economic Analysis*, in which he illustrated the importance of mathematics to the science of economics. In 1948, he published the first edition of what was to become the best-selling, most widely used economics textbook in history: *Economics: An Introductory Analysis*. Since the first edition in 1948, "Samuelson" has been translated into more than 40 languages. Many consider it the most influential economics textbook published since World War II. The Keynesian approach that Samuelson presents had a great influence on the United States' embrace of John Maynard Keynes's theories.

During World War II, from 1941 to 1945 Paul Samuelson served on the National Resources Planning Board and the War Production Board, as well as in the Office of War Mobilization and Reconstruction. Following the war, he served in various government positions till 1960. In 1960–1961, he was a member of the National Task Force on Economic Education. Samuelson served as an adviser to presidents John F. Kennedy and Lyndon B. Johnson, and he was a consultant to the U.S. Treasury, the Bureau of the Budget, the Council of Economic Advisers, and the Federal Reserve Bank. Along with Chicago School economist Milton Friedman, Samuelson wrote a weekly column for *Newsweek* magazine, where the two men represented opposing sides: Samuelson took the Keynesian perspective, and Friedman presented the Monetarist perspective.

Paul Samuelson was the first economist to introduce the idea of "cost-push" inflation. *Cost-push inflation* is the inflation caused by a general rise in resource prices, which includes wages. As the cost of resources increases, price increases follow. In 1960, Samuelson was particularly sensitive to and expressed concern about the issue: Even when full employment had not yet been reached, the future effects of the high employment were visible in the economy.

Along with the Nobel Prize in 1970, Paul Samuelson received the David A. Wells Prize from Harvard University in 1940 and the John Bates Clark Medal by the American Economic Association in 1947. Paul Samuelson was a member of the editorial board of the Econometric Society and was their past-president in 1951. He was elected president of the International Economic Association in 1965.

Paul Samuelson described himself as a "generalist" whose true interests were in teaching and research. Samuelson is not the only economist in the family. His nephew is Harvard professor and former presidential economic adviser Larry Summers.

Paul Samuelson died on December 13, 2009, at the age of 94.

SCHWARTZ, ANNA

Born: November 11, 1915, in New York City; Died: June 21, 2012, in New York City; Nationality: American; Professional Interests: economic and financial history, banking policy, monetary policy, international economic policy, financial policy; Major Works: *The Growth and Fluctuation of the British Economy, 1790–1850: An Historical, Statistical, and Theoretical Study of Britain's Economic Development* (with A. D. Gayer and W. W. Rostow) (1953; 2nd ed., 1975), *A Monetary History of the United States, 1867–1960* (with Milton Friedman) (1963).

Anna Schwartz worked as an economist at the National Bureau of Economic Research (NBER) starting in 1941. She has been praised for her contributions to economic history and using her historical insights to interpret current events. She is best known for her collaboration with Nobel laureate Milton Friedman in their book A *Monetary History of the United States, 1867–1960,* which outlines the importance of the quantity of money—not interest rates—in influencing monetary policy and the economy as a whole; in the work, Schwartz and Friedman also critique the actions of the Federal Reserve during the banking panics of the 1930s. Her collaboration skills, her empirical rigor, and the longevity of her research define a woman who contributed significantly to economics scholarship. Schwartz died in 2012.

Anna Jacobson Schwartz was born on November 11, 1915, in New York City. At age 18, she graduated from Barnard College and was elected to Phi Beta Kappa. One year later, she earned her master's degree in economics from Columbia University. Schwartz then married and started her family (she and her husband had four children), all while continuing to work as a professional economist. She ultimately earned her PhD from Columbia in 1964.

Schwartz worked briefly for the U.S. Department of Agriculture in 1936, and then went on to the Columbia University Social Science Research Council. In 1941, she began her work in statistical research at NBER (an association she continued for the rest of her life). Eleven years after she first joined the NBER, she began teaching at Brooklyn College, and then Baruch College for a short time along with her work at the National Bureau. In 1967, she became an adjunct professor of economics for City University of New York, Graduate Division at Hunter College. In 1969, she moved on to an adjunct professorship at New York University, Graduate School of Arts and Sciences. She served on the board of editors of the *American Economic Review* (1972–1978), the *Journal of Money, Credit, and Banking* (1974–1975, 1984–2012), the *Journal of Monetary Economics* (1975–2012), and the *Journal of Financial Services Research* (1993–2012). Schwartz was president of the Western Economic Association from 1987 to 1988. She was also the honorary visiting professor of the City University Business School in London from 1984 to 2002.

Schwartz began her academic collaboration with Milton Friedman in 1948 at the suggestion of Arthur Burns. She had recently completed work on another collaboration project with Arthur D. Gayer and Walt Rostow: *The Growth and Fluctuation of the British Economy, 1790–1850*. Many have remarked that neither Friedman nor Schwartz could have completed *Monetary History* without the other. Notably, this collaboration was carried out between New York City, where Schwartz worked and lived, and Chicago, where Friedman worked and lived. The two did meet in New York or talk on the phone occasionally, but most correspondence, editing, and other writing activity for this work was carried out using the U.S. Postal Service.

Schwartz and Friedman stated that their inspiration for *Monetary History* arose from the NBER program to study the cyclical behavior of different economic processes such as transportation, inventory management, and consumption. *Monetary History* illuminates the importance of fluctuations in the growth rate of the money stock and the business cycle, and it criticizes the ineptness of the Federal Reserve during the Great Depression. Many note that this work's greatest effect has been to focus monetary policy on the goal of price stability.

Until her death in 2012, Schwartz remained a founding member of the Shadow Open Market Committee, which was created in 1973 to act as a watchdog over Federal Reserve policy. She published numerous articles and publications over the course of her career—many in collaboration with Michael Bordo.

Until her death in 2012, Schwartz continued to work at the NBER and as an adjunct professor of economics at the Graduate School of the City University of New York. She earned numerous honorary doctorates from such prestigious schools as Williams, Loyola, Emory, Rutgers, and London City University. She was the distinguished fellow of the American Economic Association in 1993, the honorary fellow of the Institute of Economic Affairs in 1997, and a fellow of the Academy of Arts and Sciences in 2007.

Anna Schwartz died on June 21, 2012, in Manhattan, New York City.

SECURITIES AND EXCHANGE COMMISSION

In the early 20th century, the world was changing rapidly. Transportation, communication, and investing were only a few of the areas in which significant global changes were occurring. The inventions of the day were bringing with them the possibility that people from all walks of life could invest in these new inventions through the stock markets and "strike it rich." Regulating this investing frenzy was not encouraged or promoted by the federal government or anyone else. The stock market crash of 1929 and the significant loss of money by both the investors and the investees changed the environment from one from emphasizing the positives of investing in the stock market to one of focusing on only the negatives. Confidence in the markets was lost. Confidence in the economy was lost. The Great Depression was beginning.

In the mid-1930s, it was widely acknowledged that for any economic progress to occur, confidence in the banking industry and capital markets had to be restored. In 1933, Congress passed the Securities Act, and in 1934 followed it up with the Securities Exchange Act. Both acts were designed to clean up the market exchange between buyers and sellers. The acts enforced the dissemination of more information to investors and created rules by which investor transactions would occur. By cleaning up the rules of the investing game and opening the channels of information for investors, the government was anticipating a restoration of confidence and activity in the capital markets to boost the depressed economy. In addition to the rules and information changes, the Securities Exchange Act of 1934 created the Securities and Exchange Commission (SEC) to oversee and enforce the implementation of the new rules.

The new laws had two objectives. First, companies that wanted to offer securities on the stock market were now required to openly provide the public with information on their businesses, what securities they were selling, and, quite possibly most important, what risks were involved in investing in their companies. Second, the new laws stipulated that stock brokers and stock dealers, and those who sold the securities to the investing public, were to be more concerned with the interests of and honest dealings with the public investors than with the companies doing the selling. Both objectives were quite broad in nature, but it was the charge of the new Securities and Exchange Commission to do the enforcing.

As both banking and stock market investing grew, they became different in one very important way. With the creation of the Federal Deposit Insurance Corporation (FDIC), bank deposits became an insured savings tool for the general public. This insurance feature did not extend to the stock market and stock investing, which made the role of the SEC as the capital markets enforcer that much more important for the consumer. The SEC was the capital markets' police force, charged with protecting consumers from tactics such as accounting fraud, providing inaccurate and misleading information about either the company or its securities offerings, and insider trading.

While the SEC was established to enforce the new laws, its primary responsibility was to protect the investors in capital markets goods and services. Investors are the SEC's main source of information about potential unlawful activity by companies and the capital markets industry, including the stock market. To assist investors, the SEC provides educational information on many topics, issues, and activities within the capital markets industry. The material is designed to educate, inform, and alert the consumers about possible illegal activity in which they may have been unknowing participants.

President Franklin D. Roosevelt appointed Joseph Kennedy, father of future president John F. Kennedy, as the first chair of the SEC. The commission is made up of five commissioners, all appointed by the president. One is elected chair. The commissioners serve five-year terms, staggered to maintain consistency. Nonpartisanship is maintained, as a maximum of three can be from the same political party. The SEC is a dynamic commission that works closely with Congress, the Federal Reserve, and the Treasury Department to keep regulations and policies up to date and applicable to the current financial, economic, and investing environment.

The SEC comprises five separate divisions and 23 offices. The five divisions are the Division of Corporation Finance, Division of Economic and Risk Analysis, Division of Investment Management, Division of Enforcement, and Division of Trading and Markets. The offices of the SEC include the Office of the General Counsel, Office of the Chief Accountant, Office of Compliance Inspections and Examinations, Office of Credit Ratings, Office of International Affairs, Office of Investor Education and Advocacy, Office of the Chief Operating Officer, Office of Human Resources, Office of Information Technology, Office of Legislative Affairs and Intergovernmental Relations, Office of Public Affairs, Office of the Secretary, Office of Equal Employment Opportunity, Office of the Inspector General, and

Office of Administrative Law Judges. All of these divisions and offices are headquartered in Washington, D.C.

The role of the SEC has become much more important, and has expanded, in the years since its inception in 1934. Stock market investing took on a glamour that attracted many people from varied walks of life. The average citizen saw the stock market as the saving and investing mechanism for the first home, college fund, and retirement. The global economy attracted foreign investors, and the SEC broadened its outlook to incorporate global financial and capital markets. The SEC's role, responsibilities, and regulation have grown and become more complex.

SECURITIES EXCHANGE ACT OF 1934

The Securities Exchange Act of 1934 was the government's initial intervention in the securities market that would place regulation on companies that offer various types of investment products, including stocks, bonds, and other securities. In general, the goal of the act was to impose a set of rules and guidelines for companies that offered such products. The act sought to increase transparency, organization, and order as well as confidence in the market following the Stock Market Crash of 1929.

The Securities Exchange Act of 1934 was one of three major acts—along with the Securities Act of 1933 and the Public Utility Holding Company Act of 1935—that created what is known today as the Securities and Exchange Commission (SEC) and outlined the corresponding responsibilities of that organization. The Securities Act of 1933 mandated that public corporations register their stock sales and distributions as well as providing periodic financial disclosures. The Securities Exchange Act of 1934 made it possible for the SEC to, in fact, regulate the resulting exchanges, brokers, and over-the-counter markets and require proper disclosure of financial data reporting. The Public Utility Holding Company Act of 1935 essentially gave the SEC the power to break up any public utility companies that became too large and too powerful.

The Securities Exchange Act of 1934, the most relevant and powerful of all of these, focused primarily on the transactions and exchanges that occur after a company's initial public offering (IPO). Most of these trades are executed through brokerage firms, and may change hands many times during the life of the investment. The trades are typically made to earn a financial gain. Not only the brokers, but also the stock markets, are now expected to follow certain rules. The act regulates where investments are sold and who participates.

The biggest accomplishment of the Securities Exchange Act of 1934 includes not only transparency but most importantly the creation and establishment of the SEC. The SEC enforces the rules of the securities market that have been established through the Securities Exchange Act, the Sarbanes-Oxley Act of 2002, and other various regulations and rules established by the SEC itself. The SEC's direct responsibilities include ensuring that companies meet the disclosure requirements established in the Exchange Act, creating and enforcing rules for the conduct of market participants, and overseeing self-regulatory organizations. The 1934 act sought to decrease the level of fraud and insider trading occurring in the sale of securities. The act seeks to promote interstate commerce as established by the U.S. Constitution.

As mentioned previously, the act was adopted shortly after the Great Depression to assist with economic reform. The Great Depression had placed the country in a financial predicament like never before, and President Franklin D. Roosevelt promised reform and intervention to decrease the chances of it happening again. Roosevelt's New Deal was the first broad-based application of federal regulation to the economy. A component of the New Deal, the Securities Exchange Act of 1934 was aimed at ensuring securities reform. Roosevelt felt that better regulatory procedures and supervision needed to be in place in relation to the buying and selling of exchangeable investment products. He hoped to revive the public's confidence in the financial markets, and he believed he could do so by mandating clarity and transparency.

The financial sector and its participants were critics of the 1934 act. The act meant the government was intervening in a market activity. In laissez faire economics this intervention was thought to be a sin. Providing full disclosure and clarity took a lot of time, and money might be sacrificed as a result of this waiting game. For a long time, the stock market had been independent and had included little government regulation; the business sector felt this hands-off approach created the perfect atmosphere for economic progress. Despite opposition to the regulation, however, the act became law in on June 6, 1934. The act has survived several court challenges. While Congress continues to fund the SEC, the agency is not responsible for, nor does it make refunds to, investors who have lost money because of illegal company actions or noncompliance.

For a long time, the United States has been an economic and financial lighthouse for the rest of the world. Many attribute this to its market economy and how it operates, and the Securities Exchange Act of 1934 is credited for achieving this level of progress. The Securities Exchange Act of 1934 has had a tremendous effect on financial markets and investors' level of confidence in the market.

SERVICEMEN'S READJUSTMENT ACT OF 1944 (GI BILL)

As World War II came to a close, returning servicemen needed help re-acclimating to civilian life. President Franklin D. Roosevelt and Congress were keenly aware of the civil unrest following World War I, when no benefits were made available to returning military. The Servicemen's Readjustment Act, or the GI Bill, as it became known, offered a wide range of benefits for the returning GIs. "GI" was an initialism the military used to identify "general issue" military items. It later became a label for those serving in the military as well as returning veterans. The Servicemen's Readjustment Act became known as the GI Bill, or GI Bill of Rights, acknowledging those who would be receiving the benefits.

As part of his overall plan to use the federal government to achieve economic ends, President Roosevelt originally proposed a comprehensive plan to provide a wide range of benefits to only those military personnel who met means-tested criteria to be considered poor. Under the congressional leadership of Senator Ernest McFarland (D-Ariz.) and Representative Edith Nourse Rodgers (R-Mass.), who offered their own version of a GI bill, Roosevelt's means-tested plan was ignored. The final bill presented in both Houses of Congress was directed to all returning military who had been on active duty for longer than 90 days. As long as the veteran had served longer than 90 days and received an honorable discharge, he would qualify for the bill's benefits. The Servicemen's Readjustment Act was signed into law by President Franklin D. Roosevelt on June 2, 1944.

The new GI Bill included benefits ranging from loans to start a business, tuition reimbursements for those who wanted to return to school and either finish high school or attend a postsecondary school, living expenses including one year of unemployment compensation, and below-market interest mortgage loans to buy homes without a down payment. Because the U.S. economy had such massive pent-up demand for consumer goods and services following World War II, finding a job was not very difficult for the majority of veterans who wanted to enter the labor force immediately after the war. This made the no-down, low-interest mortgages a very attractive benefit for many veterans, as postwar families moved from the cities to suburbia. The other major benefit claimed by veterans was the tuition benefit. If a veteran did not return to the labor force, he most likely used the GI Bill and the tuition benefit to enter college or a vocational postsecondary school.

Most economists consider the GI Bill a major economic success for the United States. The tuition benefit alone quickly elevated the level of human capital in the United States to levels never before realized—or even considered—by most economists. When the original GI Bill ended in 1956, the number of new college graduates provided a generation with new skills and knowledge to challenge the problems of a post–World War II world. This vast new human capital made the United States the world leader in moving the world forward. Between the pent-up demand for goods and services and the rapid growth of human capital as a result of the GI Bill, the United States' post–World War II economy experienced an era of significant economic growth and rise in the standard of living for most U.S. citizens.

While the GI Bill proved to be the catalyst for economic growth and a higher standard of living in the United States, its most significant contribution to the nation's lifestyle was the foundation it established for the future treatment of returning military veterans. Since 1944 and the first GI Bill, veteran benefit programs have been established to assist all honorably discharged veterans, whether they served during wartime or during peacetime.

The use of GI Bills, especially for education, continued through the Korean War and the Vietnam War. Offspring of the original 1944 Servicemen's Readjustment Act included the Veterans' Readjustment Act of 1952 following the Korean War. The Veterans' Readjustment Benefits Act of 1966, signed into law by President Lyndon Johnson, was the first veterans' benefit bill to include veterans who served during peacetime.

Like the 1944 bill, these bills also had their critics. Many veterans did not think the bills provided enough benefits. An increase adjustment was made in 1972 with the signing of the Readjustment Assistance Act, which designated increases each year up to 1977.

However, in 1973 the rules of the game changed, and so did the incentives of the GI Bill. In 1973, the United States switched from a conscription-based military to an all-volunteer military. The Veterans Educational Assistance Program (VEAP) and the Montgomery GI Bill (MGIB) were signed into law not to provide veterans' benefits as much as to create incentives for joining the military. The VEAP is a voluntary program for military personnel to set aside part of their current pay for future use toward their education. The MGIB, a second educational benefit program, is open to all current service personnel and veterans. The MGIB-SR is available to members of the National Guard as well as the U.S. Navy, Coast Guard, Marine Corps, Air Force, and Army Reserves.

Regardless of adjustments and revisions to any future GI bills, the Servicemen's Readjustment Act of 1944 clearly had an impact on the U.S. economy that was as significant as any legislation before or since.

SHADOW BANKING

Shadow banks are financial intermediaries whose functions parallel those of commercial banks, with both types of financial institutions engaging in credit intermediation. The distinction lies first in the specific types of assets transformed. Commercial banks gain most of their immediate funding from deposits, and they use these deposits to give long-term loans. Shadow banks, rather than accepting deposits, conduct a variety of other functions to raise money and invest, such as borrowing funds from money markets, and they use the money to acquire longer-term maturities. This difference leads to many legal and practical implications.

Legally, because they are not required to abide by U.S. banking regulations, shadow banks do not qualify for emergency funding from the Federal Reserve. In addition, because the short-term funds they acquire are not from depositors, these funds are not insured under the Federal Deposit Insurance Corporation. Economists investigating the U.S. and world financial crises of the early 2000s began analyzing trends among shadow banks, often citing them as contributors to the instability that led to the financial downturns. Economist Paul McCulley first used the term *shadow banking* to define such financial intermediaries, referencing both the similarities to commercial banks and the lack of regulation that has allowed these entities to function with minimal oversight.

One conglomerate of international financial organizations, the Financial Stability Board (FSB), has defined *shadow banks* as all entities (excluding regulated banks) that engage in any of the several forms of credit intermediation. This includes maturity transformation (using short-term funds to acquire long-term assets), liquidity transformation (using liquid assets like cash to acquire less-liquid assets, like loans), leveraging (using techniques to magnify the gains or losses of investments), and credit risk transfer (transferring risk from the original lender to others). Additional organizations that are considered shadow banks are money market mutual funds and entities that use investors' funds to acquire mortgage-backed or commercial securities.

Because they are not legal banks as defined by U.S. law, shadow banks operate without the regulations and supports that commercial banks have. First, commercial banks must abide by many regulations designed to curtail their risk. Because the extent of these limits affects market activity, and thus bank profitability, shadow banks tend to enter the market at times when the market is more highly regulated. Therefore, increased regulation of commercial banks leads to increased shadow bank operations as commercial banking becomes less profitable.

Although this lack of restriction on shadow banking activity encourages market entry, the risks associated with shadow banking are amplified by the lack of government security that commercial banks qualify for. Commercial banks generally are funded by private depositors' savings and are insured by the Federal Deposit Insurance Corporation. Furthermore, commercial banks are eligible for emergency lending from the Federal Reserve. Shadow banks qualify for neither of these supports, magnifying their risk of failure.

The effects of this risk on both shadow banks and the economy at large appear in one of the most widely studied examples of shadow banking: the conversion of home mortgages into securities in the early 2000s. By pooling and distributing mortgages, organizations began transferring risk to those who purchased their securities, engaging in shadow banking. Shadow banking, especially in the home mortgage market, is now considered one of the foremost causes of the appreciation of housing values before the U.S. financial crisis that began in 2007. Having taken on excessive risk without government backing, shadow banks began failing when the economic climate deteriorated. When these shadow banks struggled, they exacerbated other issues that were facing the U.S. economy. Many economists speculate that shadow bank practices not only helped initiate the crisis but also amplified its magnitude. Economists and policymakers have begun analyzing shadow banks to find solutions that preserve their functions in the financial market while adding regulation to stabilize them and desensitize them to fluctuations in market conditions.

SHULTZ, GEORGE

Born: December 13, 1920, in New York City; Nationality: American; Professional Interests: economist, public administration, public policy; Major Works: *Guidelines, Informal Controls and the Market Place (Study in Business)* (1966), *Turmoil and Triumph: My Years as Secretary of State* (1993), *Putting Our House in Order: A Guide to Social Security and Health Care Reform* (2008), *Turmoil and Triumph: Diplomacy, Power, and the Victory of the American Deal* (2010).

George Shultz served in several executive positions in the U.S. government. He also worked as an economist, a researcher, and a political advisor, and he influenced American conservative policies for more than 50 years.

George Pratt Shultz was born on December 13, 1920, in New York City. He attended Princeton University, and directly following graduation, he joined the U.S. Marine Corp. He served during World War II and rose to the rank of captain. After the war he enrolled at the Massachusetts Institute of Technology (MIT), where he earned a PhD in industrial economics.

After graduating from MIT, Shultz rose quickly to power and influence. He became a professor of economics at MIT and shortly thereafter served as an economic adviser to President Dwight Eisenhower. He returned briefly to MIT before moving to the University of Chicago in 1957, becoming dean of the university's Graduate School of Business in 1962. Chicago was the center for free-market ideas and for the new monetarist theories of Milton Friedman. Such ideas ran counter to the Keynesianism that was popular at the time, and they prepared Shultz for his later career as a Republican policymaker.

In 1969, Shultz was appointed to the administration of President Richard Nixon, first as secretary of labor, then as director of the Office of Management and Budget. Upon taking office, Shultz and the Nixon administration faced two major economic problems: the imminent failure of the gold standard and the threat of inflation.

After World War II, the Bretton Woods Conference had created a world monetary system in which the United States set a value for the dollar tied to the price of gold; other countries set the value of their money according to the dollar. As the demand for gold fluctuated, the United States was having trouble keeping up its end of the deal, and the administration recognized that the Bretton Woods gold standard had to end. But there was a problem with this.

Going off the gold standard was likely to make the dollar less valuable, which would in turn make inflation worse. Inflation was high when Shultz took office, and though it had been declining (falling from 6 percent to 5 percent in 1970), administration officials feared that it would go back up when the gold standard ended.

A tempting option presented itself: wage and price controls. John Connally, the secretary of the Treasury, recommended that President Nixon simply mandate a 90-day freeze in wages and prices, if Congress would allow it. George Shultz claimed to have opposed the idea—he noted later that "it's always much easier to get into something like that than to get out of it"—yet the freeze continued anyway.

Although the price freeze was initially popular, it ultimately failed to tame inflation, which would continue to be a problem until the early 1980s. Shultz later summarized that wage and price controls—even when instituted by the talents of Shultz, Richard Nixon, John Connally, Dick Cheney, and Don Rumsfeld—would not work. During Shultz's years in public life, he considered wage and price controls an ineffective public policy.

Shultz replaced Connally as secretary of the Treasury in 1972, but he resigned from this office shortly before President Nixon himself resigned in the face of the Watergate scandal. Shultz spent the next eight years as a private citizen, working as president of Bechtel Corporation, the largest engineering company in the United States. As president of Bechtel, Shultz oversaw several major projects in the areas of hydroelectric power, steel factories, deep-waters ports, and other heavy industries.

In 1982 Shultz was called back to Washington, D.C., by the administration of Ronald Reagan, this time to serve as secretary of state. In this capacity, he was in charge of foreign relations for the United States at a time when the Cold War was the central concern of American foreign policy. Shultz supported an increased nuclear presence in Europe in order to put pressure on the Soviet Union, even though an expansion of nuclear arms was extremely controversial. However, he also encouraged a dialogue with the Soviet leader, Mikhail Gorbachev.

While Shultz retired from government service in 1989, he did not retire completely. He has continued to influence policy in many capacities: as a scholar at the Hoover Institute, a board member of several companies, co-chair of California's Economic Recovery Council, adviser to President George W. Bush, and other various policy-influencing positions.

SMOOT-HAWLEY TARIFF ACT. *See* Tariff Act of 1930

SOCIAL SECURITY ACT OF 1935

During the Great Depression, many people saw the fabric of American life being threatened as the unemployment rate reached extraordinary levels. Children were being abandoned in the streets or left as orphans, and wives and mothers and their children were being abandoned by husbands and fathers who could not support them or who left the home to go look for work and never returned. The elderly, handicapped, and blind were being left to the care of families, churches, or states.

The Social Security Act was signed into law on August 14, 1935, by President Franklin D. Roosevelt. The intent of the act was to establish a system to benefit older workers who had accidents while on the job or who became unemployed, and to support handicapped and single mothers with children. The original act also provided benefits for the blind and the physically handicapped. President Roosevelt was the first president to publicly support federal efforts to help the elderly.

Prior to the Social Security Act, the social safety net for older citizens was considered the province of local or state governments, or social organizations such as families or the church. The Great Depression's extremely high unemployment rate made this status quo inadequate. A national discussion ensued on how to bring a broad-based social safety net to those most affected by the Great Depression: the elderly and the infirm. There was significant national discussion of the issue; a national social safety net, as it was being discussed, was not supported by everyone. Many thought such a federal plan was an attack on personal freedom and personal space. Businesses, knowing that the cost of any government-sponsored and government-administered pension plan would fall on them, sought protection in the form of exemptions from the plan. After diverse and rigorous public debate on the topic, on August 15, 1935, President Roosevelt signed into law a new federal government–directed retirement program: the Social Security System.

The new Social Security Act had many moving parts. First, it provided universal support to the elderly. It established a national account within the Treasury to administer payments to those who qualified, including the blind. The act provided the states with aid for children abandoned during the Depression and for orphans. It also provided states with funds to provide for the health and well-being of crippled children. Partnering with the states again, the federal government provided funds to set up public health facilities and the personnel training so that facilities and health care would be adequately and professionally administered. Quite possibly the most unique aspect of the new law was that the system would be financed by both employers and employees. Finally, the act specified who would be exempt from the law (family-employed persons and businesses of fewer than eight employees), established a Social Security Board to oversee the new program, and set forth the legal terminology defining geographical inclusion (Alaska, Hawaii, and Washington, D.C.) and separation of the many parts of the new program. The only hurdle left for the new Social Security System to surmount were the court challenges that were sure to follow.

Twice the Supreme Court ruled sustaining the Social Security Act's constitutionality. Two years after the act became law, the Supreme Court ruled in *Steward*

Machine Company v. Davis to uphold the act. In a 5–4 ruling, the Court claimed that national funding to relieve the strains of such a national crisis as the Depression indeed promoted the general welfare. The second Supreme Court ruling sustaining the Social Security Act was also handed down in 1937, on the same day as the *Steward Machine Company v. Davis* case. In *Helvering v. Davis* the Court sustained the constitutionality of the federal government's right to impose a tax to fund the new program.

With the support of the Supreme Court, implementation of the act began in earnest. Yet implementation of the new program brought with it new complex administrative problems for the federal government. Key among them were registering citizens so they could receive the program's benefits, setting up the intricate system of taxing and receiving the contributions from both employers and employees, and, of course, developing a system for disbursing benefits to the recipients. In more recent times, the major challenge is the funding of Social Security in the long run.

SOLOW, ROBERT

Born: August 23, 1924, in New York City; Nationality: American; Professional Interests: macroeconomics, economic growth, unemployment, capital and interest, Nobel Prize (1987); Major Works: "Balanced Growth under Constant Scales of Return" (with Paul Samuelson) (1953), "A Contribution to the Theory of Economic Growth" (1956), *Capital Theory and the Rate of Return* (1963), *Nature and Sources of Unemployment in the U.S.* (1964), "Economics of Resources or Resources of Economics" (1974), *Growth Theory: An Exposition* (2000), *An Almost Practical Step Toward Sustainability* (2014).

Robert Solow is an American economist who produced significant work in the area of economic growth, earning the Nobel Prize in Economics in 1987. The basis of Solow's work on economic growth was the publication titled "A Contribution to the Theory of Economic Growth." In it, Solow reworked the earlier works of other economists, claiming an economy could remain at full employment when wages are flexible. He spent his entire career at the Massachusetts Institute of Technology where his office was next to Paul Samuelson's.

Robert Merton Solow was born on August 23, 1924, in New York City, the oldest of three children. His grandparents were immigrants, and he and his siblings were the first members of his family to attend college. Solow attended a public high school in New York and was a good student. In 1940, at the age of 16, he received a scholarship from Harvard, where he went to study sociology and anthropology. World War II interrupted his education; he joined the U.S. Army in 1942 and served in North Africa, Sicily, and Italy. He received his discharge in 1945 and returned to Harvard to resume his education.

It was at this point that Solow became immersed in economics. He studied under Wassily Leontief, who became his friend and mentor as well as a teacher. Solow stayed at Harvard, receiving his BA in 1947, his MA in 1949, and his PhD in 1951. He continued working with Leontief to develop the first capital coefficients in an input-output model. He also developed an interest in statistics and modeling, and on the advice of Frederick Mosteller he spent 1949 and 1950 on a fellowship at Columbia University. While at Columbia, Solow also worked on his thesis for his PhD at Harvard.

Solow's thesis won the Wells Prize from Harvard; the prize included publication of the work in book form; along with a $500 check. However, he was not satisfied with the thesis, so the thesis remained unpublished and the check uncashed. Just before starting his Columbia University fellowship, Solow received and accepted an offer for an assistant professorship at the Massachusetts Institute of Technology (MIT), teaching econometrics and statistics. As luck would have it, he was given an office next door to Paul Samuelson, beginning a lifelong relationship of friendship and collaboration.

It was at MIT that Solow published "A Contribution to the Theory of Economic Growth." This piece was the foundation of the work that resulted in his Nobel Prize. In it, Solow expanded on the work of Roy Harrod and Evsey Domar. Harrod and Domar had independently presented models suggesting that there was no reason for a balanced growth rate. The main criticism of their models is the assumption of fixed labor and capital. Solow would modify this approach with one that is more dynamic, allowing for flexible wage rates and still maintaining an economy that could maintain full employment.

That same year, he published "Technical Change and the Aggregate Production Function" in the *Review of Economics and Statistics*. The work was significant because it showed that only half of economic growth could be explained by changes in the size of labor and capital endowments. The rest, he posited, was the result of innovation; this became known as the Solow residual.

The Solow paradox is also named for him. The paradox derives from a claim he made in the 1990s, when he stated that the productivity increase from computer use was showing up everywhere except in aggregate statistics. There have been numerous studies of the paradox and just as many theories for it. None have decisively explained it.

Solow served in a professional capacity and received a number of honors during his career. He received the John Bates Clark Medal in 1961 as the most promising young economist. He received the Nobel Prize in 1987 and the National Medal of Science in 1999.

Solow served on the Council of Economic Advisers under President John Kennedy from 1961 to 1963. He was an Eastman Professor at Oxford University in 1968 and 1969. He served as a member of the board of directors of the Federal Reserve Bank of Boston from 1975 to 1980, serving as its chairman in the last two years. He was named a visiting scholar of the Russell Sage Foundation in 1999 and 2000 and became a permanent staff member in 2012. He has been awarded honorary degrees from the University of Chicago, Brown University, University of Warwick, Lehigh University, and Tufts University.

Solow has the professorial distinction of seeing three of his students follow him in receiving the Nobel Prize: George Akerlof, Peter Diamond, and Joseph Stiglitz.

Robert Solow retired from his post at MIT in 1995.

STOCK MARKET CRASH OF 1929

Black Thursday, October 24, 1929, has been called "the most devastating day in the history of the stock market." The U.S. stock market, which had begun a downward slide during the last weeks of October, eventually crashed—an event that became known as the "Great Crash." During that time, $30 billion in stock value, about the same amount as the United States spent in World War I, evaporated completely.

Causes of the Great Crash of 1929

The Roaring '20s were a time of economic prosperity. The United States had entered a new era in which anyone could become rich. Although the stock market has the reputation of being a very risky investment, it did not appear that way in the 1920s. With the mood of the country on a high, the stock market seemed to be a secure investment in the future.

As more and more people invested in the market, stock prices began to rise; this was first noticeable in 1925. Stock prices fluctuated up and down throughout late 1925 and 1926, and by 1927 the stock market was on a steady rise with no end in sight. This rapid growth enticed more people to invest in the market, and by 1928 the stock market boom had begun. The boom changed the way investors viewed the stock market: The market was no longer just for long-term investment.

By 1928 the stock market had become a place where everyday people truly believed they could quickly become rich. Stocks had become the talk of the town everywhere, by everyone. The purchasing of stocks grew exponentially. Of course, although an increasing number of people wanted to buy stocks and jump on this rapid growing investment option, not everyone had the money to do so.

A new way to get involved in the stock market craze began. The practice of buying "on margin"—which involves paying only a fraction of a stock's dollar value, usually a small percentage of the total value of the stock, and borrowing the rest of the money from a stockbroker—became common practice throughout the 1920s. The stock itself was used as the collateral for the loan. During the boom years of the 1920s, many investors who were buying on margin made fortunes. Buying stocks at low prices and watching as the stock values steadily climbed throughout the 1920s gave many investors huge profits and earned them great wealth. As long as stock prices continued to rise, stockbrokers were happy to lend money to speculators and allow investors to buy on margin. Most stockbrokers earned 20 percent interest on their loans, and if the stock prices began to fall they had the stock itself as collateral to cash in.

Many investors also wanted to make their fortunes immediately, so they began buying stocks on speculation. This type of investment is a way of gambling with short-term investments, many of which are very high-risk. From 1927 to 1929, stocks were making great gains, making them very attractive to investors who normally would have put their money in a savings account. The dramatic difference in the rate of return between a savings account and the stock market made the market an attractive gamble for thousands of Americans. Many people began investing in the stock market due to its rapid and steady gains. It seemed as if the Roaring 20s would never end, and that economic growth would continue effortlessly.

By the summer of 1929, stockbrokers had lent out more than $6 billion in margin loans to their customers. The market became saturated with investors, and some of them began to sell their stocks, causing stock values to slowly decline by the fall of 1929. Many investors did not have cash to pay for their stocks, so brokers were forced to sell off the stock, causing prices to fall even further. Seeing the slow decline in the market, other investors began to sell in a panic and more brokers began to call in their margins. The stock market decline gained speed. By the last week of October 1929 the bottom fell out of the market, with major stock prices falling by 75 percent. People who were millionaires at the beginning of 1929 were suddenly in severe debt.

Stock market investors were not the only people who were severely affected by the Great Crash. Many banks had lent their cash reserves to stockbrokers. When the brokers called in their margin loans and their customers could not repay them, the brokers lost the borrowed money. Savings deposits were not federally insured, so people who had conservatively placed their money in savings accounts instead of the high-risk stock market found their savings had vanished when the banks went bankrupt. Even worse, businesses, including banks, trying to get in on the rapid profit margin, had invested money in the market. The Great Stock Market Crash of 1929 caught millions of innocent citizens in a financial crunch—in addition to those who lost everything in the stock market.

Effects of the Great Crash of 1929

After the crash of the stock market in 1929, the economy began a downward spiral that affected every American. The textile, lumber, mining, and railroad industries began to slow productivity. The automobile and construction sectors had a decrease in orders, and farmers' incomes fell throughout the decade. The declines across the board in major U.S. industries caused incomes to drop as employers began to lay off workers. With the loss of savings, declining incomes, and rising unemployment, workers could not afford the many manufactured goods that the nation's industries had been mass-producing throughout the 1920s. This under-consumption became a major weakness in the U.S. economy and caused the country to slip even further into the deepest depression it had ever experienced. Nonconsumable goods, including radios, telephones, refrigerators, washing machines, and automobiles, were no longer in demand. Warehouses filled of these consumer goods sat full with no one to buy the products.

Adding to the economic crash, the Federal Reserve followed a restrictive monetary policy, causing credit to dry up. The nation's money supply was excessively tight. The lack of access to money limited the nation's ability to bounce back after the stock market crashed.

The crash of the stock market did not affect just the United States. Throughout the 1920s, the United States served as a bank for other nations, lending money to aid foreign industries and to help speed recovery from World War I. As Americans began investing borrowed money into the stock market, bank funds for loans to other nations declined. Congress aided in increasing the impact of the stock market crash with the passage of the Smoot-Hawley Tariff Act. This legislation was intended to aid U.S. industries, but its actual impact was to cause U.S. trading partners to retaliate with their own tariffs. International trade slowed due to lack of access to money to spend on other nation's goods, made worse by antitrade protectionist measures taken by all nations. This decline in demand for goods even in other nations added further to the cycle of under-consumption, weakening the American economy even more.

Reform Laws

In response to the massive devastation to the economy of the United States and abroad, the federal government introduced several new pieces of legislation to try to curtail future Great Crashes. As part of the New Deal, President Franklin D. Roosevelt enacted the Truth-in-Securities Act, which was designed to eliminate fraud in the stock market. Under this new law, a company that deliberately deceived investors about its financial status could be sued. Another new law, the Glass-Steagall Banking Act, prohibited banks from investing savings deposits in the stock market. Finally, the Federal Deposit Insurance Corporation (FDIC) was established to insure bank deposits in all member banks. The FDIC was created to try to help people regain confidence and trust in the banking industry again.

STOCK MARKET CRASH OF 1987

After the Great Depression and the Great Crash of 1929, many people were skeptical of investing in the stock market. In 1980, only 2.5 percent of American households held stock. Gradually, however, attitudes began to change. The development of mutual funds helped people become more comfortable with the stock market and stock ownership.

Unfortunately, the newly gained trust in the market came to an abrupt halt on "Black Monday": October 18, 1987. The Dow Jones Industrial Average lost 22.6

percent of its value, nearly twice the one-day loss that began the Great Crash of 1929. Black Monday marked the largest one-day percentage drop in market history.

Causes of the Crash

There were several reasons for the sudden crash of the market on October 18, 1987. On October 13, the House Ways and Means Committee proposed a bill to eliminate the tax deduction for loans used to finance corporate takeovers. The bill also included language to regulate the stock market. On October 16, 1987, just three days after the proposed bill was announced, stock prices fell more than 10 percent, which was the largest three-day drop in 50 years. The Dow Jones lost 22.6 percent of its value in one day, which was nearly twice the loss that began the Great Crash of 1929. The stocks that fell the most in value were those of the companies that would have been hurt the most by the proposed legislation.

Another contributing factor was the automated sell-off of stocks once the market dropped by a certain percentage. With computer trading and set points, many stocks automatically call in sell orders if the market falls. When the market began to fall due to the new legislation news, automatic sell orders began pouring in. Unfortunately, there weren't enough buyers for some of the stocks that were ordered to sell, which caused the market to drop even further.

The final factor that caused the crash on Black Monday was the Treasury secretary's announcement that the United States might let the value of the dollar fall. This would make U.S. stock prices cheaper for foreign investors. Current investors feared the drop in their stock values, leading to additional sell orders in the market at present market levels.

Effects of the Crash

Many Americans feared that a crash in the stock market would cause a recession or even a depression as seen in 1929. However, the Federal Reserve expanded the money supply by putting money into banks and liquidity into the economy. The Fed also reduced interest rates to help stimulate the economy. The result was a stabilized market, and by the end of October the stock market had risen by 15 percent. Within two years, the Dow Jones had returned to pre-crash levels.

SUGAR ACT, CURRENCY ACT, AND STAMP ACT BOYCOTTS, 1764–1765

By the early 1760s, all the British colonies in America were experiencing a postwar recession. The depression was affecting the full spectrum of industries and colonists. Most historians think that, by 1764, this recession had become America's first depression. Great Britain too was struggling with massive debts from the French and Indian War and believed the colonies should pay more of its war debts. To reduce British war debt, Parliament passed a series of acts—the Sugar Act, the Stamp Act, and the Townsend Act—that placed new duties and regulations on Britain's American colonies.

Great Britain also strengthened its restriction on the printing of paper currency in the colonies with the Currency Act of 1764, at a time when the colonies had low reserves of gold and silver. The colonies had used their reserves to pay their bills from the French and Indian War. Tight money—from currency restrictions and a shortage of specie—and new taxes from Parliament restricted the colonies' means of expanding the economy. In the colonies, these British taxes and restrictions created a major economic crisis that moved from recession to depression. Many believe this depression was the root of the American Revolution.

The Sugar Act of 1764 is better described by its name: the American Revenue Act. The act placed import duties on sugar, wine, coffee, indigo, and textiles brought into the colonies. It also required stricter enforcement of the Molasses Act of 1733. New regulations required merchants to submit customs forms. Interestingly, the act actually cut the tax rate on molasses in half, in hope of better compliance. However, the rum distilleries of New England had become adept at avoiding the taxes on rum for 30 years.

Merchants in all the colonies protested the Sugar Act—and its taxes on imports the most. Boston merchants even sent a letter of protest to Parliament. The tight money and the influx of cheaper British pewter and metal tableware destroyed the business of craftsmen such as Paul Revere. Merchants and craftsmen were also hurt by the Currency Act, which restricted colonial paper money, causing currency shortages. In effect, the return to a currency backed by gold and silver stopped the making of silverware by American craftsmen, except where the customer supplied his own silver to be melted down.

The Stamp Act of 1765 proved to be even more politically explosive during these colonial hard times, because it directly taxed goods moving within the colonies. In 1765, many prominent Boston merchants, such as Nathaniel Wheelwright, went bankrupt. The Stamp Act imposed a tax on printed materials, including legal papers, deeds, newspapers, and playing cards. This time, people took to the streets in reaction to the new act, and riots occurred in all the colonies. The lieutenant governor's mansion in New England was burned. The discontent caused by the Stamp Act gave rise to the Sons of Liberty patriotic group. Local craftsmen switched to manufacturing household goods themselves instead of buying British imports. Merchants and groups like the Sons of Liberty started local boycotts of British goods. As during any depression, the unemployed and the poor joined in the political movement out of frustration.

The Stamp Act solidified colonial governments against British taxation. Patrick Henry led the Virginia effort, Sam Adams led the New England effort, and Ben Franklin led the Pennsylvania effort. The colonies moved toward a unified front, calling a meeting of colonial representatives in New York. Representatives signed the Nonimportation Agreement to boycott British goods. Colonists enthusiastically joined the boycott, and British merchants were soon feeling the pain.

The British Parliament pressed for a compromise. It was clear that the colonies continued to be in a depression, and the urban centers had high unemployment. The Stamp Act was repealed in 1767, though Parliament reaffirmed its right to tax the colonies. Parliamentary repeal of the Stamp Act gave rise to celebrations in the streets of the colonies.

The celebrations were short-lived: The Townshend Act was passed in 1767. This new set of taxes targeted imported goods such as paper, glass, and tea. Tea became a flash point as colonists boycotted it, and a brisk smuggling trade in Dutch tea developed. Tea was the national drink; little coffee was consumed in the colonies at that time. Another unpopular element of the legislation was that the taxes helped pay for royal commissioners to enforce the Townshend Act, which took away the enforcement authority previously held by the colonists. The new customs system, where merchants had to submit customs forms, made it difficult for the colonists to cheat and elude the new taxes. Britain sent two regiments to Boston to keep the peace. Besides the obvious political issues, British soldiers added to the local economic woes by working off-hours for low wages, creating tension with the large number of unemployed. Incidents of British soldiers replacing colonial laborers in the workforce brought the lower classes into the struggle with the motherland.

The colonists boycotted more goods, and again they were successful. In 1767, New York City imported more than 350,000 pounds of tea. By 1770, after the boycott of imported British tea, fewer than 150 pounds of tea were imported into New York. Parts of the Townshend Act were repealed, but they were replaced with new parliamentary taxes in the 1770s.

The colonial economy remained stuck in recession, but a new manufacturing sector started to emerge. Lancaster, Pennsylvania, became a crafts and manufacturing center that supplied frontiersmen during the boycotts and high taxes on goods in the 1760s. In 1770, Lancaster had 13 blacksmiths, 22 masons, 15 coopers, 19 tailors, 7 hatters, 6 gunsmiths, 3 clockmakers, 3 silversmiths, more than 50 various craftsmen in woodworking, and hundreds of apprentices associated with them. In addition, the surrounding area had iron furnaces and glassmaking factories, as well as weavers and leather craftsmen.

Depressions often result in infrastructure changes in the economy. One positive side of the depression and high taxation in the 1760s was the rise of colonial manufacturing. Before the 1760s, Virginia and South Carolina exported most textiles from Great Britain. After the new taxation laws, southern plantations began to produce their own textiles. Similarly, textile manufacturers were encouraged in New England. Stocking production started in Pennsylvania. New England started to manufacture shoes, and by the end of the decade, they were supplying to the colonies to replace British imports. In addition, South Carolina and other colonies expanded their export trade in rice and indigo. By the end of the decade, colonial exports exceeded the value of imports.

SUMMERS, LAWRENCE

Born: November 30, 1954, in New Haven, Connecticut; Nationality: American; Professional Interests: public finance, labor economics, finance economics; Major Work: *Understanding Unemployment* (1990).

Lawrence "Larry" H. Summers began his economic political career as a domestic policy economist on the Council of Economic Advisers under President Reagan in 1982–1983. During the 1980s, Larry Summers wrote or coauthored over 50 papers on debt, savings, taxes, stocks, the overall economy, and more. In 1987, he was awarded the Alan T. Waterman Award from the National Science Foundation. This award, along with its $500,000 research grant, is awarded every year to honor an exceptional young scientist or engineer from the United States whose work demonstrates originality, innovation, and a significant impact within the winner's field.

Lawrence Henry Summers was born on November 30, 1954, in New Haven, Connecticut, into a family of economics professors. His parents, Robert and Anita Summers, were both economics professors at the University of Pennsylvania, and two of his uncles—Paul Samuelson of the Massachusetts Institute of Technology (MIT) and Kenneth Arrow of Stanford University—were Nobel laureates. Summers spent most of his childhood in Penn Valley, a suburb of Philadelphia. Encouraged in early childhood to take part in family discussions of economic theory and current events, Summers followed his love of the topic and attended MIT, where he received his bachelor of science in economics degree in 1975.

He taught economics for three years at MIT and was named an assistant professor in 1979 and and associate professor in 1982. As a graduate student, Summers attended Harvard University and received his PhD in economics in 1982. Summers went on to teach at Harvard, and he became one of its youngest tenured professors at the age of 28, returning to serve as the Charles W. Eliot University Professor.

In the 1990s, Summers wrote or coauthored over 50 papers and five books, including *Understanding Unemployment* (1990). He left Harvard in 1991 and became the chief economist of the World Bank (1991–1993). Later he became the U.S. deputy secretary of the Treasury (1995–1999), and then the secretary of the Treasury (1999–2001). During his tenure as secretary, the U.S. economy experienced an unprecedented period of sustained economic growth. As a result, he is considered an expert on domestic economics and a leading authority on international finance. It was during his time working with the Clinton administration that he recommended the deregulation of the derivatives contracts within the financial industry. Specifically, he endorsed the Gramm-Leach-Bliley Act, which removed the separation between investment and commercial banks—repealing the Banking Act of 1933, also known as the Glass-Steagall Act.

Summers is not without his critics, as some claim he ignored the 1990s stock bubble and later the housing bubble. He left the political limelight to become president of Harvard University from 2001 to 2006. While there, he wrote and edited a number of works, including papers for the Brookings Institution and the *Harvard Business Review,* and he coauthored a paper with Henry Kissinger for the Council on Foreign Relations. While at Harvard, he quarreled with a number of the faculty, and he resigned under pressure. After taking a year off, he returned as a professor of economics at Harvard's Kennedy School of Government.

Summers was an adviser to Barack Obama's presidential campaign and was later named director of the National Economic Council in 2009. As in President Clinton's administration, Summers held significant influence over economic policies in President Obama's administration. He frequently writes for a variety of news publications, including the *Washington Post*, *Financial Times*, *Boston Globe*, and *Wall Street Journal.*

In 1993, Summers was awarded the John Bates Clark Medal for being an outstanding young American economist.

SUPPLY-SIDE ECONOMICS

Proponents of supply-side economics posit that bolstering an economy's ability to supply more goods is the most effective way to stimulate economic growth. Based on insights derived from the Nobel Prize–winning economists Robert Mundell, Milton Friedman, and James Buchanan with economist Arthur Laffer, the supply-siders developed a new program based on tight money to stop inflation and cuts in marginal tax rates to stimulate growth during the stagflation years of the late 1970s. Supply-side theorists advocated income tax reduction in order to increase private investment in corporations, facilities, and equipment.

Many people refer to supply-side economics as "Reaganomics," because of the "trickle-down" policy espoused by Ronald Reagan while he was running for president of the United States running against incumbent president Jimmy Carter. During the 1980s, President Reagan popularized the idea that tax cuts for investors

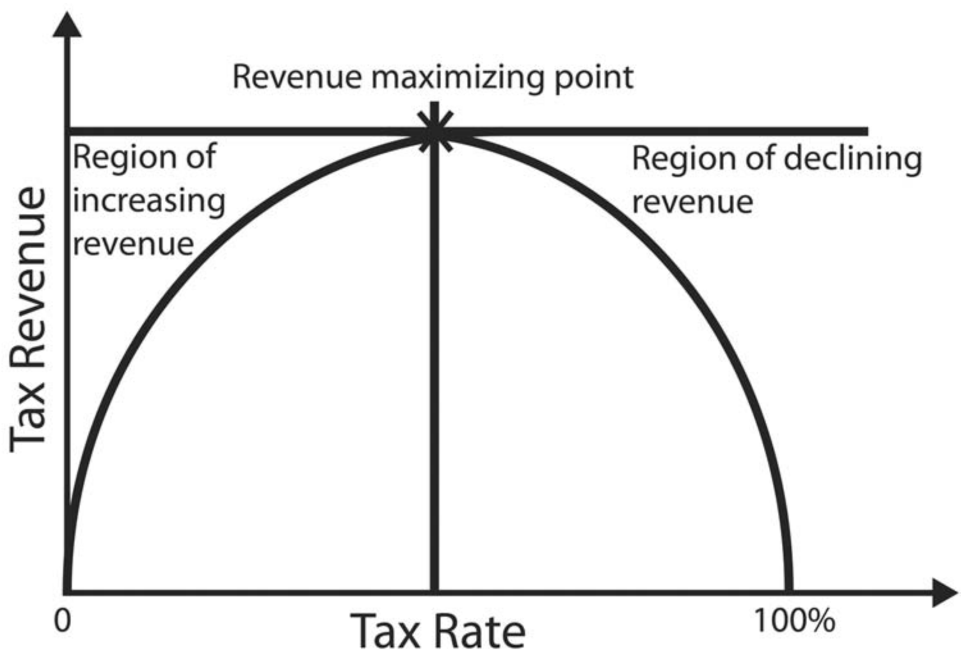

Figure 1. With the Laffer curve, the forerunner to supply-side economics, Arthur Laffer proposed that high tax rates will result in lower government revenue

and entrepreneurs would provide incentives to save, invest, and produce the economic benefits that would trickle down to the overall economy.

A basic economic principle is that aggregate demand and aggregate supply intersect to determine overall output and price levels. The supply-siders contend that an increase in supply will increase output and lower prices. Supply-siders often go further and claim that demand is largely irrelevant, since overproduction and underproduction are not sustainable phenomena. They argue that when companies temporarily "overproduce," excess inventory will be created, prices will subsequently fall, and consumers will increase their purchases to offset the excess supply.

In general, supply-side theory has three pillars: tax policy, regulatory policy, and monetary policy. Since the single idea behind all three pillars is that production is most important in determining economic growth, supply-siders are often contrasted with Keynesians, who believe that consumers and their demand for goods and services are key economic drivers.

Supply-siders argue for lower marginal income tax rates in order to tempt workers to choose work over leisure. Certain supply-siders might even argue that the government would not lose total tax revenue, because lower rates would be offset by a higher tax revenue base as a result of greater employment and productivity. This relationship between marginal tax rates and tax revenues was promoted by economist Arthur Laffer with his famous Laffer curve.

In regard to regulatory policy, supply-siders prefer a smaller government and less intervention in the free market. This is logical, because supply-siders do not support the idea that induced demand promoted by Keynesian economic theory can either rescue a recession or have a sustainable impact on growth. Unlike the Keynesian supposition that monetary policy is an important tool for tweaking the economy and dealing with business cycles, supply-siders do not think that monetary policy can create economic value. They are concerned that the Fed might either create too much inflationary liquidity with expansionary monetary policy, or alternately, might not sufficiently "grease the wheels" of commerce with enough liquidity due to a tight monetary policy. Since neither outcome is desirable, strict supply-siders fear that any action by the Fed may inadvertently stifle growth.

Because supply-siders view monetary policy not as a tool that can create economic value but rather as a variable to be controlled, they advocate a stable monetary policy or a policy of gentle inflation tied to economic growth. This principle is the key to understanding why supply-siders often advocate a return to the gold standard. The idea is not that gold is particularly special, but rather that gold is the most obvious candidate as a stable "store of value." Supply-siders argue that if the United States were to peg the dollar to gold, the currency would be more stable, and fewer disruptive outcomes would result from currency fluctuations.

Since supply-side economics implies a reduced role for government and a less progressive tax policy, the supply-side philosophy reappears during most political campaigns. Supply-side economics has become the economic philosophy synonymous with tax cuts, regardless of economic conditions.

T

TAFT-HARTLEY ACT, 1947

The labor struggles and union movement of the 1930s had changed labor relations in the United States. The struggle between labor and management rights continues to this day. Laws enacted in the 1930s properly addressed some employer abuses when the United States controlled the global market. The overextension of the 1935 Wagner Act to support the labor movement would be addressed in the 1947 Taft-Hartley Act, which also addressed some abuses by unions, such as secondary boycotts and mass picketing. An unintended consequence of the act would be a shift of industry south when the United States entered the period of globalization of production. The Taft-Hartley Act had outlawed closed shops, but permitted union shops, which required union membership after a period of time. The law did allow states to pass right-to-work laws.

The National Labor Relations Act, or Wagner Act, named after Senator Robert Wagner of New York, was the cornerstone of President Franklin D. Roosevelt's New Deal social legislation. It would end decades of struggle to unionize employees in the steel and related heavy industries. This act changed the very landscape of labor in the United States in hopes of avoiding widespread social unrest during the Great Depression. The Wagner Act would usher in a wave of unionization in the steel, automotive, rubber, mining, and electrical industries. At the start of the 1930s, less than 10 percent of America's labor force was unionized; after the 1935 passage of the Wagner Act, the decade ended with 35 percent of the labor force unionized. The act changed the role of government in labor policy. The act declared that democracy must apply in the workplace and that the means to this democracy was the right of workers to organize and bargain collectively through employee representatives. The act established a National Labor Relations Board (NLRB) to implement and oversee the Wagner Act.

The Wagner Act would face 20 years of challenges in Congress, with two major amendments: the Taft-Hartley Act in 1947 and the Landrum-Griffin Act in 1959. The NLRB today remains a type of court for employee complaints. The Wagner Act had many critics; but in the end, the Supreme Court upheld it in 1937 (*NLRB v. Jones & Laughlin Steel*). The argument over individual choice continued, and President Roosevelt tried to counterbalance the actions of some of the extreme activist supporters who wanted to expand the intent of the act. The Taft-Hartley Act addressed the right of the federal government to intervene in strikes and the right of the states to address union membership. The 1959 national strike was the first test of the Taft-Hartley Act.

At 116 days, the steel strike of 1959 was the nation's longest. At the time, the steel industry was the nation's largest industry; there were 540,000 members in the United Steelworkers of America. The root of the strike was a dispute over management control and contract clauses in the workplace. In particular, management had the right to assign the number of workers to a task, reduce the workforce by replacing workers with machinery, and introduce new work rules. It became a bitter battle in a nation totally dependent on domestic sources for steel. The strike ended when President Dwight D. Eisenhower invoked the Taft-Hartley Act. The union challenged the Taft-Hartley action, but the Supreme Court upheld it. The union eventually retained contract clauses on work rules and won a small wage increase. The right of the federal government to intervene in strikes would, however, become a seldom-used part of the act.

The Wagner Act created a number of issues that are controversial to this day. One is the wording that called collective bargaining a "right." Opponents maintain that fair treatment in the workplace suggests that collective bargaining is but one method available for solving disputes. Another issue was the so-called closed shop. Once a union was certified by an NLRB election, it could not be removed as the workers' representative. Furthermore, workers would be required to join the union to stay working at the shop.

In 1947, the Taft-Hartley Act limited the application of a true closed shop. It allowed for a union shop, which is a form of closed shop. However, under the Taft-Hartley Act, states could pass right-to-work laws to make even union shops illegal and to make sure that workers would not be forced to join the union. Today, right-to-work laws have spread in southern and western states, which want to attract heavy-industry jobs, and have prompted some northern factories to move south. In today's global market, transplanted foreign companies have favored building factories in the southern right-to-work states. Right-to-work laws have made American labor more competitive in a global market, but such factories have lower wages and fewer benefits than unionized factories. After a peak in the 1960s, industrial union membership has been in steep decline. The Taft-Hartley Act has become highly political, as the party in power controls the NLRB.

TARIFF ACT OF 1930 (SMOOT-HAWLEY TARIFF ACT)

In 1930, when the United States had begun to slip into a depression, one of the strategies that the federal government attempted to use to help the economy get back on its feet was to pass the Tariff Act of 1930 (Smoot-Hawley Tariff Act). Consumer spending was on the decline, and many workers had lost their jobs. Congress hoped the passing of this act would protect American workers from foreign competition.

History of the Smoot-Hawley Tariff Act

During the 1920s, the agriculture industry lobbied Congress for protection from the intense competition of the European farmers as it recovered from World War I. Also during this time period, overproduction had drastically reduced agricultural prices. In 1922, Congress passed the Fordney-McCumber Act to impose strict protectionist tariffs, raising the average tariff 40 percent.

In 1928, Republican presidential candidate Herbert Hoover campaigned on a platform of increasing tariffs on agricultural products. Once elected president, Hoover was influenced to broaden the tariffs to many other products. By 1929, when the U.S. economy began to slip into the greatest depression of all time, and in response to the stock market crash, protectionism was gaining strength. President Hoover signed the Tariff Act of 1930 on June 17, despite the objections of more than 1,000 economists, who had signed a petition against the legislation. The legislation became known as the Smoot-Hawley Tariff Act for the legislation's chief sponsors: Senator Reed Smoot of Utah and House Representative Willis Hawley of Oregon. Senator Smoot was chairman of the Senate's Finance Committee, and Representative Hawley was chairman of the House Ways and Means Committee. The Smoot-Hawley Tariff Act was the last legislative act in which the United States imposed definitive tariff rates.

Effects

The Smoot-Hawley Tariff Act raised the average tariff on all imported products to 50 percent and started a trade war between the United States and its trading partners around the world. Other nations responded by raising tariffs against American-made goods. The trade war that resulted decreased international trade and deepened the worldwide depression of the 1930s. Most economists blame the Smoot-Hawley Act for increasing American unemployment. The trade war had closed foreign markets to American goods and reduced international demand for all goods.

In retaliation, more than two dozen countries also passed tariff legislation to counter Smoot-Hawley. The world economy was already very fragile, and global trade had been on the decline. The act further added to Wall Street losing confidence in the economy. It was also the beginning of U.S. isolationism. Between 1929 and 1932, total U.S. trade (exports and imports) fell by approximately two-thirds. World trade fell by a similar margin, feeling the repercussions of Smoot–Hawley's impact and those of the retaliatory tariffs of other nations.

Response

President Franklin D. Roosevelt signed the Reciprocal Trade Agreements Act in 1934. This legislation liberalized trade policies, reduced tariff rates from the Smoot-Hawley levels, and began reconciling with foreign governments to reestablish global trade. It has been suggested that the Smoot-Hawley Tariff Act caused the Great Depression to be deeper and last longer. The act may also have influenced the rise of political extremism and fascism throughout Europe.

Trade wars still break out between the United States and other nations, but most disputes center on a few products. The Smoot-Hawley Tariff Act focused on all imports. Recent conflicts built around just a few products have included the Beef War of 1999 and the Steel Tariff of 2002.

European countries launched the Beef War by banning the import of American beef from cows that had been fed hormones. The United States responded by imposing tariffs on European clothing and specific foods, including certain cheeses, meats, and mustards.

The Steel Tariff dispute began when the United States introduced temporary tariffs on imported steel to help American steel producers recover from bankruptcy. Angry European nations sued and threatened to retaliate. In 2003, an international panel ruled these tariffs illegal.

Reasons for Tariffs

Why does a country impose trade barriers, such as what was done with the Smoot-Hawley Tariff Act? There are three main arguments that support protectionism: protecting workers' jobs, protecting infant industries, and safeguarding national security. Tariffs would also be initiated in retaliation against another country's tariffs on domestic goods. This was the case when other nations instituted tariffs in retaliation to the Smoot-Hawley Act.

The argument for protecting workers' jobs, which is why the Smoot-Hawley Act was passed in the 1930s, is that it shelters workers in industries that would be hurt by foreign competition. If the United States reduces tariffs on certain imports, domestic manufacturers may not be able to compete and would have to close their factories and lay off workers.

In an ideal world, the laid-off workers would take new jobs in other industries. In practice, however, retraining and relocation can be difficult. Many workers do not have the skills to work in other industries, and obtaining such skills takes time and money. In addition, industry and political leaders often do not want to shut down existing industries and lose jobs in their home regions.

The same theory is true regarding tariffs that protect infant industries from foreign competition until those industries have had a chance to acquire the ability to produce goods efficiently and at a competitive price. Once the infant industry has had time to become competitive on a global scale, the tariff can be eliminated or reduced.

There are two main difficulties with implementing tariffs to protect infant industries. First, the start-up industry lacks the incentive to become more efficient and competitive, since it is secured by the tariff from true global competition. Second, once an industry is given tariff protection, taking the protection away can be difficult. The tariff can prevent the infant industry from ever really growing up.

Safeguarding national security is the final argument in favor of tariffs. Even supporters of free trade agree that some industries need to be protected and and their goods produced within the United States, or at least they need to receive government assistance in order to reduce the country's dependence on other nations in times of crisis.

TAX AVOIDANCE, TAX EVASION, AND THE SHADOW ECONOMY

Shadow economy ("underground economy" or "hidden economy"), in the broadest sense, refers to economic activities that take place outside the official economy and are not declared for tax purposes. Some of the vast areas of shadow economy are "black" labor and tax evasion as well as do-it-yourself activities and neighborly help. The term *shadow economy* refers to both legal and illegal activities.

The assignment of economic activities to a shadow economy varies in the literature. Feige (1990) distinguishes between (1) illegal economy (production of prohibited substances), (2) unreported economy (tax evasion), (3) unrecorded economy (household productions), and (4) informal economy (black labor). Schneider (2011, 79) proposes a fourfold table, differentiating between legal and illegal activities as well as monetary and nonmonetary transactions.

The extent and growth of shadow economy can be measured with direct (audits, surveys) and indirect (indicators; simulation models) methods. As shadow economy is hardly directly measured, indicators are often used to estimate shadow activities:

1. Currency demand approach: Changes in cash flow can act as an indicator, as it is assumed that cash payment is common in shadow economy in order to leave no traces.
2. Labor market indicators (labor force participation rate or growth rate of the total labor force): If total labor force participation rate is assumed to be constant, a change can act as an indicator of shadow economic activities.

3. Discrepancy between national expenditure and income statistics: The gap between income measure of gross domestic product (GDP) and expenditure measure of GDP can be used as an indicator of shadow economic activities.
4. Physical inputs (electricity consumption): The growth of shadow economy is calculated as the difference between the growth of electricity consumption and the growth of official GDP.
5. Transaction approach: It is assumed that there is a constant relation between the volume of transaction and official GDP over time. The GDP in the shadow economy is calculated as the difference between the official GDP and the nominal GDP (which is based on the value of total known transactions in the national economy) (Schneider 2011; Schneider and Enste 2000).

Another method for calculating the growth and extent of the shadow economy is the simulation approach, which explicitly considers multiple causes of and multiple effects of shadow economy. Here, structural equation models are used to estimate unobservable variables (Kirchler 2007, 16).

The main cause of shadow economy is the rise of the burden of tax liability and social security contributions. It is assumed that a higher tax burden leads to an increase in underground economic activities. Further, unemployment, increasing regulation in the official economy and bureaucratic burden, forced reduction of weekly working hours, earlier retirement, and declining tax morale have to be mentioned as important influential factors (Schneider 2000, 82).

Tax evasion is one of the most-investigated areas of shadow economy. *Tax evasion* refers to the process whereby individuals or companies evade taxes by breaking the law; that is, they illegally pay less tax than the law mandates. Tax evasion can involve acts of omission or commission (failing to report certain assets or deliberately issued false reports), but it excludes inadvertent noncompliance resulting from lack of knowledge, memory lapses, or calculation errors.

In contrast, the term *tax avoidance* describes the process to reduce the amount of tax burden using options within the law. Tax avoidance is not illegal, although it is against the spirit of the law. Reduction of tax liability occurs by payors taking advantages of loopholes in the law.

TAX COMPLIANCE

Behavioral economics offers a considerable contribution to the understanding of tax compliance and noncompliance. Standard economic analysis suggests that straightforward monetary considerations influence decisions regarding tax compliance. However, many taxpayers comply with their tax obligations even when there is little chance of tax evasion being detected or substantial penalties imposed. Factors that affect taxpayer compliance include a willingness to contribute to the general good, attitudes toward the state and the tax authorities, perceptions of fairness, the roles of individuals in society, and accepted norms of behavior—as well as a range of such background factors as age, culture, education, gender, and occupation. While there is no doubt that auditing and penalties are essential, compliance policy may be more effective when it also follows a more behavioral approach.

Tax authorities have long used behavioral techniques to promote compliance. For example, the technique of withholding tax at the source, which dates back to the 16th century in England, exploits behavioral phenomena now known as the "endowment effect," "status quo bias," and "loss aversion." Individuals feel the loss of tax payments less if the taxes are taken before people actually receive their money rather than afterward. More recently, tax authorities have set out specifically to take advantage of insights generated by behavioral economics. For instance, one initiative led to improvements in the behavior of some taxpayers after they received letters explaining that most people in their area had already paid their taxes. More generally, compliance can be improved by more public education and the development of a sense of responsibility toward taxation. More specific communications with individuals can improve their understanding of the tax system and how to meet their obligations. Other particular insights include personalizing the language on official documents the public receives, so that people realize more easily that it is relevant to them, as well as highlighting key messages in those documents and prompting taxpayers at key points in the completion of tax forms.

It is also useful to consider what is meant by *compliance*. Sometimes the definition is cast in terms of the extent to which taxpayers formally comply with the tax law. It has then been claimed that the degree of noncompliance can be measured by the "tax gap": the difference between actual revenue and the revenue that would be received if there were 100 percent compliance. However, if taxpayers go to inordinate lengths to reduce their tax liability, it is difficult to see this as "compliance," even if their activities are technically lawful. A further complication is that, as well as raising revenue, taxation is used as an instrument of economic and social policy when the purpose of taxation is often to influence behavior. It may actually be the aim of some taxes that they be avoided. For example, it has been argued that higher taxes on alcoholic drinks and tobacco would reduce the consumption of those products and lead to improvements in the health of the population. Any such changes in behavior would constitute tax avoidance according to narrow definitions, but that would have been the intention. A better definition of *compliance* would therefore be for taxpayers to behave in accordance with the spirit as well as the letter of the law, and this is best achieved with a behavioral approach to tax compliance.

TAX FORMS: U.S. FEDERAL TAX SYSTEM

The federal tax return is calculated on Form 1040, the granddaddy of tax returns. It was created in 1913 when the current tax code was enacted. How much a taxpayer owes in taxes or is due as a refund is figured each year during tax filing season. An individual's ultimate tax bill or tax refund calculations are made on this tax return.

There are, however, three versions of the federal tax form 1040 from which to choose. In addition to Form 1040, the Internal Revenue Service offers taxpayers Form 1040A and Form 1040EZ. Each of the three individual tax return forms offers different filing options and ways to possibly reduce a tax bill. Each tax form also has its own set of requirements.

While it is tempting to file the tax return that is the easiest to complete for one's filing situation, that could be a costly move. The most complex of the returns offers the most tax breaks.

Form 1040EZ

As the name indicates, Form 1040EZ is the easiest of the three individual tax returns. This single-page tax return generally is used by taxpayers who have a relatively uncomplicated tax life, such as students or young workers.

However, 1040EZ filers must meet 10 specific requirements, listed in the form's instruction booklet, before they can file the simplest income tax return. Tax software will also guide taxpayers through the tests they must meet in order to use the 1040EZ.

Most younger taxpayers easily meet the filing status test. A Form 1040EZ filer must be a single taxpayer or, if married, must file a joint return. In either filing situation, the taxpayer(s) cannot claim any dependents.

The form's earnings limit is generally not a problem for younger taxpayers. A 1040EZ filer's income must be less than $100,000. But how that money was acquired must also be considered. It must come only from wages, salaries, tips, taxable scholarship or fellowship grants, unemployment compensation, or Alaska Permanent Fund dividends. And if tips were earned, that compensation must be shown in boxes 5 and 7 of Form W-2.

Some interest earnings are allowed for 1040EZ filers, but only if the amount is less than $1,500 for the tax year. If other types of investment income, such as dividends or capital gains, are received, the taxpayer cannot file Form 1040EZ.

For most young filers, Form 1040EZ is the correct tax filing choice. But it offers few opportunities for a taxpayer to reduce a tax bill. The form lists a standard deduction amount for single filers and another for married filers. Other than that, the only tax break on the 1040EZ is the Earned Income Tax Credit, or EITC.

This tax break is designed for workers who do not earn very much money. Because it is a credit, it reduces a tax bill dollar for dollar. If the tax bill for a single person with no dependents is $1,000 and that taxpayer qualifies for a $506 EITC claim (this was the maximum amount for 2016; amounts are adjusted annually for inflation), that taxpayer's bill is cut to $494. Even better, the EITC is a refundable credit, meaning it could produce a tax refund if the taxpayer does not owe any or little tax. If a single taxpayer owes $300 and qualifies for a $506EITC claim, the filer would get a $206 refund.

Form 1040A

Many young taxpayers find that as they enter the workforce, their financial and tax situations become a bit more complicated. In these cases, they graduate to the next level of tax filing, Form 1040A.

More taxpayers can use Form 1040A because there are no income or filing status limitations. Taxpayers with dependents can use 1040A. This two-page tax return also offers several tax deductions and credits that are not found on Form 1040EZ.

The first set of deductions is found on page one of the form. Technically, the deductions are adjustments to income. There are four adjustments on 1040A: out-of-pocket expenses incurred by educators, traditional individual retirement account (IRA) contributions, student loan interest paid, and higher education tuition and fees. These amounts are subtracted from the 1040A filer's gross income, or total income, to arrive at adjusted gross income.

Additional tax breaks are found on page two of Form 1040A, including a variety of tax credits that reduce a tax bill dollar for dollar. Of particular interest to young taxpayers are the EITC; various education tax credits (the American Opportunity or Lifetime Learning credits); and the retirement savings contribution credit, which could produce a credit up to $1,000 when a taxpayer puts money into an IRA, Roth or traditional, or a workplace retirement account, such as a 401(k) plan.

A 1040A filer, however, does not have the option to itemize expenses; the standard deduction amount must be claimed. The standard deduction is a separate dollar figure for each filing status, adjusted annually for inflation, and is usually found directly on the 1040A. The deduction amount helps reduce the taxpayer income from the adjusted gross income level to a smaller taxable income amount.

Form 1040

Form 1040, the longest of the tax returns, allows the most deduction and tax credit options. The final section on page one of Form 1040 is labeled “Adjusted Gross Income.” This section contains more than a dozen ways to reduce the taxpayer’s total, or gross, income. The tax breaks named here are often referred to as above-the-line deductions because they are listed just before the last line, where adjusted gross income is entered, of the form’s first page.

In addition to the four adjustments to income found on the 1040A, Form 1040’s above-the-line deductions include the option to deduct moving costs. This could be of use to new graduates who are taking a job that is some distance from their previous home. The job-related moving expenses are claimed directly on Form 1040.

As for credits, the same ones that appear on Form 1040A also are found on Form 1040, as well as more specialized credits such as expenses for adopting a child and offsetting taxes paid to a foreign country.

The longest of the individual tax returns also offers filers a choice of claiming the standard deduction or itemizing expenses on Schedule A. Most taxpayers claim the standard deduction. The advantage is that it is easier, as there are no receipts to collect or added forms to fill out. However, if a filer has enough itemized expenses to exceed the standard deduction for filing status, claiming itemized expenses on Schedule A is the wiser tax move.

Itemized deduction options include medical and dental expenses once they exceed 10 percent of adjusted gross income; charitable contributions; state and local income taxes paid; real estate taxes paid; mortgage interest paid; and a variety of miscellaneous expenses that exceed two percent of adjusted gross income.

For each filing season, a Form 1040 taxpayer can choose whether to claim the standard deduction or itemize expenses.

Form Filing Deadline

All three individual income tax return forms have one thing in common: They are due on April 15. If that mid-April day falls on a federal holiday or a weekend, the tax deadline is extended to the next business day.

Taxpayers who cannot finish returns by the April date can get an automatic six-month extension by submitting Form 4868 to the Internal Revenue Service. This will allow taxpayers until October 15 to complete tax paperwork.

However, any due tax—or a close approximation of the amount—must be submitted with Form 4868 by April 15, or penalties and interest on the unpaid taxes will be assessed.

TAXES

Governments at all levels (federal, state, local) need revenue to provide the public goods and services. While some people describe all government revenue as taxes, others describe government revenue as taxes, fines, fees, and licenses. Taxes are also a major topic of public debate and discussion. This is especially true regarding what the sources of government revenue should be and how much a government should tax.

Components of a Tax

All taxes have three things in common: First, all taxes have a tax base (that is, what is being taxed). The source of all taxes is either current wealth (income), accumulated wealth (property), or consumption (sales). Current wealth is defined as income and is associated with income taxes. Property taxes, estate taxes, capital gains taxes, or personal property taxes are examples of taxes where accumulated property is the source. Consumption is the source of sales taxes.

Second, a component of every tax is the tax rate. There are two types of tax rates: ad valorem or flat rate. *Ad valorem* is a Latin phrase that means “by value.” A tax whose amount is determined as a percentage of the base’s value is an ad valorem tax. A flat rate is a per-unit rate, such as an excise tax or a unit tax.

Third, every tax has a tax structure, also known as a tax system. The term *system* is relative to the accumulated effect of all taxes of an economic system. In addition, this same distinction is used to define the “structure” of a tax. There are three tax structures: A tax is classified as progressive, proportional, or regressive.

Taxes are often identified by their structure. If the burden of the tax increases as one’s income increases, the tax structure is progressive; a *progressive* tax system is one in which those with higher incomes pay a higher percentage of income as taxes. If the tax burden is equal to all regardless of income, the tax is *proportional*. If the tax is more of a burden on lower incomes, it is regressive; a *regressive* tax system is one in which the percentage of tax increases for those with lower incomes.

Then, of course, if the tax has the same burden on all income levels, it is proportional. A *proportional* tax system is one in which all income levels pay the same proportion of taxes. So while an individual tax will be regressive, progressive, or proportional, the goal of most tax systems (in a market economy) is for the system to be proportional. At the end of the day, a tax system can be of only one system: it is a progressive tax, a proportional tax, or a regressive tax.

While taxes are often the main topic of discussion and debate, from the dinner table to the halls of state and national capitols, much has been written about the relationship between taxes and tax revenues, taxes and standards of living, and taxes and public goods. One example of these theories is the correlation between tax rates and tax revenues. This theory promotes that tax rates will raise to a point at which consumers will begin to find ways to avoid taxes—participating in nontaxable activities such as black markets, getting paid in cash, bartering goods and services, and other measures. This relationship is exhibited in the theory attributed to the economist Arthur Laffer.

Federal Taxes

At the federal level, the primary tax base for generating revenue is current wealth with the personal and business income taxes. But the federal government also relies on accumulated wealth with an estate tax and current wealth with a business tax and capital gains tax on investment earnings. The federal government generates revenue on the consumption base, with excise taxes such as those imposed through utilities and telephone or communications usage. The most used tax rate at the federal level is the ad valorem ("by value") or percentage rate.

Most people who pay federal income tax are familiar with the personal income tax schedules seen every year before "Tax Day," April 15. Federal business and

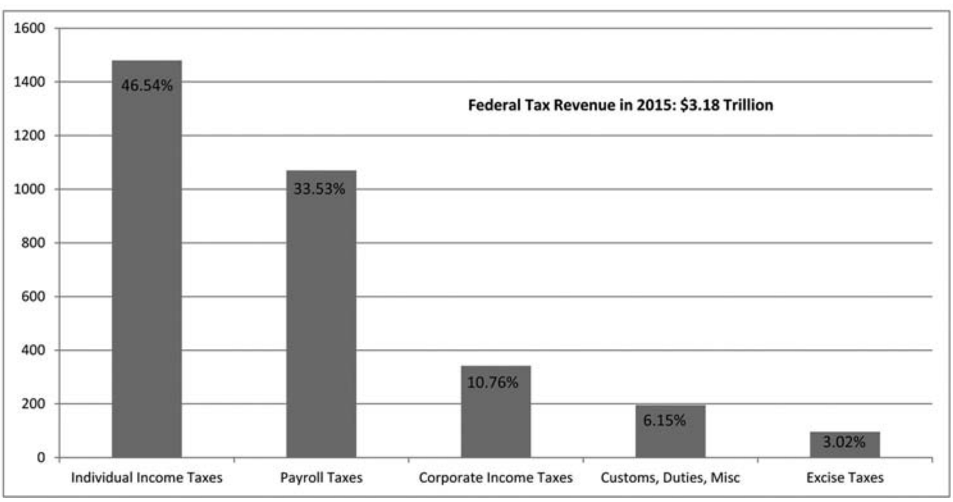

Figure 1. Components of 2015 federal tax revenues
Source: "Federal Revenue: Where Does the Money Come From?" National Priorities Project, https://www.nationalpriorities.org/budget-basics/federal-budget-101/revenues/.

investment taxes use ad valorem tax rates. Political debates on taxes often center around what level of tax rate is appropriate and fair for a particular tax base. The estate tax is also determined on an ad valorem rate. The excise or unit tax rate is also used to raise federal tax revenue. Many utility bills or telephone bills include a federal excise tax to tax our use of these services.

Historically, the federal government has tried to tax consumption of such specific goods as luxury cars or yachts, but with mixed success.

The federal tax structure is designed to be progressive, so that those whose income and wealth are greater pay a larger percentage of their income in taxes. The progressivity of the federal tax structure is tempered by the use of tax deductions, tax credits, and income or wealth thresholds and limitations. Instituting deductions, credits, and limitations is an attempt to bring the tax structure into a more proportional range. This is why the federal tax schedules for personal income taxes range from 0 percent to 39 percent. Tax schedules have historically been as high as 95 percent on the wealthiest individuals. This also accounts for only those estates that are valued at over $2 million being subject to the federal estate taxes.

State Taxes

Each state has a unique range of taxes and tax component combinations. Generally, most states strive for a proportional tax structure, even though in some states the main source of revenue is a regressive sales tax. States often neutralize the regressive sales tax by exempting the goods and services most used by everyone, such as food and prescription drugs. A state may also provide some tax credits on people's personal income taxes, based on income, to alleviate the burden of the sales tax on a family's or household's total income. Many states also impose what are often referred to as "sin" taxes: taxes levied on consumption goods that considered hazardous to one's health, such as alcohol, cigarettes, and other smoking items. These are often excise or unit taxes (specific amount per unit of good).

Many states also apply a tax on the current wealth base of income. However, some states are eliminating this tax base in favor of a broader consumption or sales tax. Most states also impose some form of business income tax or accumulated wealth tax on business inventories. Accumulated wealth is also taxed in several states through a personal property tax and business taxes. In these states, individuals pay a tax on the value of personal items such as automobiles.

A personal property tax levied by a state is an ad valorem tax rate, because the amount of tax levied is based on the value of the personal property being taxed. An automobile valued at $10,000 will have a lower personal property tax than one valued at $20,000. State sales taxes are ad valorem, as the amount of tax is a percentage of the sale.

Local Taxes

The most widely used tax base on the local level is accumulated wealth, with the property tax on real estate. The prominence of the real estate property tax at the local level dates back to agrarian communities, and the emphasis on property ownership as a statement of wealth. Local governments use the real estate property tax to fund and operate everything from the local library and public schools, to the local community college, to the upkeep of roads, to local police and fire protection. Virtually no one is exempt from paying some local real estate property tax. Real estate property taxes are paid directly through ownership of a home or property, or indirectly through rental payments on an apartment.

Larger local governmental units, especially large cities and counties, have also added taxes on consumption, with local sales taxes and excise taxes on goods such as alcohol and cigarettes. Another tax base added by large governmental units is on current wealth, with personal and business income taxes. Many large cities now levy a personal income tax on individuals who either live or work within their city limits.

The tax structure of local taxes is very mixed. Property taxes today in many locales are regressive in structure, since they no longer adequately reflect the relative wealth of the owner. Income taxes in larger cities tend to be proportional, while taxes on consumption are regressive, even when certain tax credits are applied to neutralize the regressive structure of sales tax.

Criteria of a Good Tax

While some may consider the term "good tax" an oxymoron, there is little debate that taxes are necessary for the functioning and delivering of public goods and services. Regardless of one's views on taxes, there are several criteria that determine when a levied tax is considered a good tax.

A tax is considered a good tax if the following criteria are met:

- Horizontal equity: People in same economic circumstances should pay the same taxes;
- Vertical equity: People with a higher ability to pay should pay a higher percentage;
- Stability: Regardless of the state of the economy, the tax can produce the same level of revenue;
- Sufficiency: Tax revenues should be able to fund government programs now and in the future;
- Simplicity: Administrative costs are low, in that the costs of administrating the tax are both efficient and low; and
- Neutrality: The implementation of the tax does not change either the willingness and ability of the producers to stay in the market or the willingness and ability of consumers to leave the market of the particular good or service being taxed.

Incidence of a Tax

Tax incidence is sometimes considered a component of a tax, like the base, rate, and structure. Other economists consider tax incidence a criteria for a good tax. Tax incidence refers to the question of who pays. A goal of a sales tax is to tax the consumer, since it is a consumption tax. The incidence of the sales tax is clearly on the consumer and is properly allocated, because the consumer does indeed pay the sales tax. A tax for which the incidence is not so clear is the corporate tax.

The corporate tax incidence is a topic of considerable debate. While the corporate income tax is calculated based on corporate income, does the corporation really pay the tax? Is the tax liability passed on to consumers in the form of higher prices? Do the employees pay with lower wages? Do the stockholders receive lower dividends, essentially paying the tax? Tax incidence is almost always a debate among economists, in terms of who is really paying the taxes. One thing is certain: People pay taxes, regardless of their business, personal, or social structure.

TINBERGEN, JAN

Born: April 12, 1903, in The Hague, Netherlands; Died: June 9, 1994, in The Hague, Netherlands; Nationality: Dutch; Professional Interests: econometrics, business cycle, economic policy, Nobel Prize (1969); Major Works: *Statistical Testing of Business-Cycle Theories: Business Cycles in the United States of America, 1919–1932* (1939), *Business Cycles in the United Kingdom, 1870–1914* (1951), *Economic Policy: Principles and Design* (1964).

Jan Tinbergen was an innovative Dutch economist who combined mathematics, statistics, and economic theory to develop new models in econometrics. In 1969, he shared the first Nobel Prize in Economics in memory of Alfred Nobel with Ragnar Frisch for his work developing and applying models to analyze the economic process. Tinbergen died in 1994.

Jan Tinbergen was born on April 12, 1903, in The Hague, Netherlands, the eldest of five children. His parents, Dirk Tinbergen and Jeannette van Eek, were both schoolteachers. He attended the Hogere Burger school in The Hague, which allowed middle-class Tinbergen to begin studies in 1921 at the University of Leiden after passing extra exams in Greek and Latin. Tinbergen's teacher Paul Ehrenfest proved a positive influence, as Tinbergen studied mathematics and theoretical physics. Tinbergen also started a social democratic student club and newspaper, which published his first works on unemployment and the economic depression of the 1920s. Tinbergen continued his doctorate studies under Ehrenfest, writing his thesis, titled "Minimization Problems in Physics and Economics," in 1929. This was one of the first examples of mathematical modeling. It was here that Tinbergen worked with many revered thinkers, such as Albert Einstein.

Dutch legislation allowed Tinbergen, who was a conscientious objector, to join the Central Bureau of Statistics in 1929. He remained associated with the bureau until 1945, when he became the director of the Central Planning Bureau (a position he held from 1945 to 1955). From 1936 to 1938, he worked for the League of Nations as a business-cycle research expert. In 1933, Tinbergen also became a professor of economics at the Netherlands School of Economics, Rotterdam, and taught there until 1973. Along with Ragnar Frisch, in 1969 Tinbergen was awarded the first Nobel Prize in Economics for his work creating the first macroeconomic models. His brother Nikolaas, a zoologist, also won the Nobel Prize—for physiology, in 1973—and his brother Luuk became famous for the scientific study of animal behavior.

In 1936, Tinbergen developed the first national and fully inclusive macroeconomic model for the Netherlands' economy. He later constructed econometric models of the United States and the United Kingdom, as well as for other countries. His work served as the groundwork for his business-cycle theory and strategies for economic stabilization. This application of mathematics and economics was especially useful for monetary policy. The Dutch government would later use these ideas as the foundation for their economic plans.

Tinbergen developed the idea that governments must have equal numbers of policy instruments and targets to achieve their economic goals. A target might be the unemployment rate or inflation rate, and an instrument might be some form of monetary policy. This notion of economic thought is now an underlying assumption for current economists.

Tinbergen also is known for his principle of wage ratios. The Tinbergen Norm states that if the maximum and minimum pay rates within a company exceed 1:5, the company will not work to its fullest potential.

In later years, Tinbergen continued to spotlight the need to help impoverished countries. From 1965 to 1972, Tinbergen worked as the chairman of the United Nations Committee for Development Planning, where he was advised such developing countries as the United Arab Republic, Turkey, Venezuela, Surinam, Indonesia, and Pakistan. He also advised such international organizations as the European Coal and Steel Community, the International Bank for Reconstruction and Development, and the United Nations Secretariat. He was a member of the Royal Academy of Science and an honorary doctor of 15 universities. In 1992, he received the Four Freedoms Award for his humanitarian efforts to encourage economic assistance to developing nations.

Jan Tinbergen died on June 9, 1994, in The Hague, the Netherlands.

TOBIN, JAMES

Born: March 5, 1918, in Champaign, Illinois; Died: March 11, 2002, in New Haven, Connecticut; Nationality: American; Professional Interests: macroeconomics, monetary policy, neo-Keynesian economics, portfolio theory, Nobel Prize (1981); Major Works: *Essays in Economics* (Vols. 1–4, 1987–96), *Full Employment and Growth* (1996).

James Tobin was an American economist who spent his long career explaining and developing John Maynard Keynes's *General Theory of Employment, Interest and Money*, leaving a legacy as an essential neo-Keynesian. Tobin was a strong advocate of government intervention in the economy to avoid recessions and stabilize output. He made numerous significant economic contributions, including his portfolio theory, which won him the 1981 Nobel Prize in Economics. Other notable contributions by Tobin included Tobin's q, the Tobin tax, and the Tobin model. Tobin died in 2002.

James Tobin was born on March 5, l918, in Champaign, Illinois. His father was the publicity director for the University of Illinois athletics department, and Tobin attended University High School, which was run by the University of Illinois College of Education. Tobin graduated summa cum laude in economics from Harvard University in 1939 and stayed to complete his MA degree in 1940. He interrupted his doctoral studies to work at the Office of Price Administration and Civilian Supply and the War Production Board in Washington, D.C., before World War II. Following the attack on Pearl Harbor, Tobin enlisted in the U.S. Navy. After serving on the USS *Kearny* destroyer for four years, he returned to Harvard. He finished his PhD in 1947 and then remained at Harvard as a junior fellow until 1950.

In 1950 he began his career at Yale University, becoming a full professor in 1955 and becoming the Sterling Professor of Economics in 1957. He formally retired in 1988 but stayed at Yale to continue working on his theories.

Tobin became interested in the subject of economics for two reasons: He enjoyed the intellectual challenge, and he wanted to use economics to comprehend world events. Tobin saw economics as a means to prevent human misery from recurring. His fundamental concern was how economic policies affected people's lives. He believed that the federal government could use fiscal and monetary measures to benefit society. At Harvard as a freshman, he quickly became a convert to the new theories of Keynes. He spent the rest of his life explaining and developing theoretical supports to Keynesian economics. He wrote extensively as a pioneer in the development of macroeconomics.

Besides continuing his treasured teaching at Yale, Tobin also served as director of the Cowles Foundation for Research in Economics from 1955 to 1961 and again from l954 to 1965. Tobin occasionally left his professorial post at Yale, commonly as a visiting professor at another academic institution or as a consultant, but one significant departure from academics was serving on the Council of Economic Advisers at the express request of President John F. Kennedy during l961–1962. The council produced the Economic Report of l962, which the media dubbed the "new economics." Tobin himself described this report as a comprehensive account of the theories and practices for economic growth.

Tobin was author or editor of 16 books and over 400 articles concerning economics. The topics ranged from econometrics to macroeconomics, monetary theory, monetary policy, fiscal policy, public finance, and portfolio theory and asset markets. Tobin is remembered for his work in financial analysis—especially the portfolio theory, which explained that investors should balance their portfolios with both low- and high-risk assets to minimize risk. Tobin described his portfolio theory as not putting all of one's investment eggs in a single basket.

It was accepted monetary policy that interest rates could influence capital investment. Tobin felt, however, that there was another important consideration. He developed *Tobin's q*, a measure to predict whether there will be an increase or a decrease in capital investment. The "q" is a mathematical ratio between the market value of an asset and the cost to replace it. If the ratio is greater than 1, new investment will be profitable. If the ratio is less than 1, new investment in similar equipment will not be profitable. Tobin suggested that at this point companies tend not to invest in new plants and equipment, deciding instead to purchase existing companies.

Another Tobin idea is the Tobin tax. The *Tobin tax* is a small tax on currency transactions in international markets to reduce short-term currency speculation. Tobin felt that such a tax would help stabilize exchange markets without being a burden on free trade. Today, his tax idea is often proposed as a way to raise revenue. He also developed a regression to analyze spending decisions; called the *Tobin model*, it's an econometric model investigating dependent variables within a model.

Tobin served in many professional associations and received numerous awards beyond the Nobel Prize in 1981. He was awarded the John Bates Clark Medal in 1966 and was president of the American Economic Association in l971. Tobin will be remembered through his prolific research and publications as one of the most influential macroeconomists of the 20th century, especially his lifelong contributions in explaining and elaborating on the theories of Keynes.

James Tobin died on March 11, 2002, in New Haven, Connecticut.

TOO BIG TO FAIL

The phrase "too big to fail" is used to describe a concept that arose during the 2008 financial crisis to justify why the U.S. government needed to bail out certain companies. The concept focuses on how important it is to the United States that certain businesses survive and how the failure of these businesses would be disastrous for the country. In 2008, the term was often applied to some of the nation's largest banks, because the failure of these banks could have had serious consequences for the U.S. economy. Declaring a company "too big to fail" creates an obligation for the government to intervene if the company gets into a bad situation and is on the verge of collapse. While a government bailout or intervention may be vital to the survival of a company, some people feel that this method is counterproductive. Opponents of the "too big to fail" concept believe that the company should simply be allowed to fail.

While there have been examples throughout history of companies that have been saved under the "too big to fail" concept, most of these rescues occurred during the 2008 financial crisis, with the most prominent examples being AIG and Lehman Brothers, as well as Fannie Mae and Freddie Mac. To illustrate, AIG is one of the world's largest insurers, with most of its business being in traditional insurance. AIG became involved in credit default swaps: contracts to insure against the default of municipal bonds, corporate debt, and mortgage back securities. As the mortgages tied to swaps began to default, AIG was forced to raise millions in capital. As stockholders became aware of the situation, they began to sell their shares, making it even more difficult for AIG to cover their swaps. This left AIG with not enough cash to pay the swap insurance. The government classified AIG as "too big to fail" and bailed it out, because AIG's failure would in effect trigger the bankruptcy of many financial institutions that had purchased the credit default swaps.

Another good example of this concept would be the investment bank Lehman Brothers. Unlike AIG, however, the government did not bail out Lehman Brothers. In 2008, the Treasury secretary at the time, Hank Paulson, said no to bailing out the bank. This left Lehman Brothers with no option but to file for bankruptcy. The following Monday, the Dow dropped by nearly 350 points. Widespread panic swept through the financial markets, and eventually a $700 billion bailout was needed in order to recapitalize major banks (Amadeo n.d.).

The Federal National Mortgage Association (Fannie Mae) and the Federal Home Loan Mortgage Corporation (Freddie Mac) dominated the secondary mortgage market. As the guarantors of 90 percent of all home mortgages, by the end of 2008 Fannie Mae and Freddie Mac were also deemed "too big to fail." The Treasury endorsed $100 million of their mortgages—in effect, returning them to government ownership. If Fannie Mae and Freddie Mac had gone bankrupt, the housing market crisis would have been much worse (Amadeo n.d.).

To prevent this from happening in the future, in July 2010 Congress passed the Dodd-Frank Wall Street Reform Act. This act regulates the financial markets and makes other economic crises less likely by preventing any additional banks from becoming too big to fail. This is accomplished by oversight by the Financial Stability Oversight Council, which searches for risks affecting the entire financial industry. The council also oversees nonfinancial firms such as hedge funds. In the event that any of these companies gets too big, the council may recommend that the Federal Reserve regulate the financial institution. The Fed can ask the institution to increase its reserve requirement.

An additional part of the Dodd-Frank legislation is the Volcker Rule. This rule also helps to end the "too big to fail" phenomenon by limiting the amount of risk that large banks can take. This can be done by prohibiting banks from trading in stock, commodities, or derivatives for their own profit.

TRANS-ALASKA PIPELINE

The Trans-Alaska Pipeline System (TAPS) transports crude oil from the Prudhoe Bay oilfields on the North Slope of Alaska to the Port of Valdez and the world oil market. The pipeline system, constructed from 1975 to 1977, is an engineering marvel covering over 800 miles. Crossing sensitive environmental terrain, including mountain ranges, earthquake zones, and permafrost, the pipeline opened to drilling the environmentally sensitive North Slope, which is home to vast herds of caribou. The pipeline features prominently in some of the most important environmental developments in the United States.

Vast oil discoveries on the North Slope were first announced in 1968. The timing was important for two reasons. First, oil prices doubled between 1970 and 1973, increasing pressure for rapid development of the North Slope. Second, environmental concerns also increased during this period; the National Environmental Policy Act (NEPA) was passed in 1969. Importantly, NEPA required an environmental impact assessment of large-scale projects, and the TAPS was one of the first test cases for NEPA.

The environmental impact assessment for the Trans-Alaska Pipeline was conducted by the Department of the Interior. It identified short-term impacts (e.g., erosion and noise during construction), operational impacts (e.g., discharge from tanker ballast, oil releases from tank cleaning, heat loss melting permafrost and causing instability), long-term impacts (e.g., increased public access from roads, disturbances of fish and wildlife habitat), and cultural impacts (e.g., oil revenues and outside contact accelerating cultural change on the Native communities). Also warning about the likely danger of marine and terrestrial oil spills, in its impact assessment the department included the prescient statement "The salmon and other fishery resources of Prince William Sound would be especially vulnerable to such spills." The impact assessment was highly controversial and invited public comment and court cases.

NEPA required the evaluation of alternatives to the project. One viable alternative was a Trans-Canada land route, which would have avoided earthquake zones and risky marine trans-shipment. Moreover, this alternative would have delivered the oil to the more lucrative Chicago market. In fact, the Trans-Canada route may have dominated the Trans-Alaska route based on both economic and environmental concerns.

NEPA's performance in this important test case was mixed. In the end, the U.S. Congress exempted TAPS from NEPA and rejected the Trans-Canada alternative. This congressional settlement also resolved Alaskan Native land claims and conserved large tracts of Alaskan wilderness. Despite the exemption, NEPA likely did affect the actual construction of the pipeline, which featured technological innovations to reduce the risk of earthquake damage and to lessen the impact on the permafrost.

Without TAPS, the 1989 *Exxon Valdez* oil spill would not have occurred. This costly spill heightened attention to the environmental dangers of economic development. In addition, the concept of existence value and the contingent valuation method were developed as the subsequent court cases attempted to calculate the damages to the Prince William Sound.

TAPS makes further oil development on the North Slope of Alaska possible. In particular, opening the oil deposits in the Arctic National Wildlife Refuge (ANWR) would make use of TAPS. Without TAPS, the coastal breeding ground of the caribou in ANWR would not be as threatened.

While the maximum TAPS throughput is over 2 million barrels per day, current production is only 700,000 barrels per day and declining. In addition, global climate change may melt sections of the permafrost that supports the pipeline. Although the future of the system is uncertain, TAPS has played an important role in the development of environmental and energy policy.

TREASURY SECURITIES

U.S. Treasury marketable securities are debt securities that are similar to bond investments. The U.S. government issues these debt instruments to raise funds needed to manage the federal government. Additionally, the funds raised by the sale of government Treasury securities are used pay off previously issued maturing government debt. Due to the global confidence in the U.S. government, these are widely accepted as the most secure debt instruments available worldwide. Investors seeking safe investments for the cash and fixed portions of their savings and investing portfolios frequently turn to Treasury securities investments.

There are several varieties of Treasury securities with varying characteristics: Treasury bills, notes, bonds, Floating Rate Notes (FRNs), Treasury Inflation Protected Securities (TIPs), and savings bonds.

Treasury Bills, Notes, and Bonds

Bills, notes, and bonds are the staples of the Treasury security debt offerings. Treasury notes, bills, and bond securities are differentiated primarily by their term. *Term* indicates when the investor can redeem the bonds for full face value. Treasury bills are short-term securities that mature in one year or less. Treasury notes are intermediate-term debt instruments, and they mature 1 to 10 years from their issue date. Treasury bonds are long-term and mature in 30 years.

Treasury bills are unique from notes and bonds in that they are sold at a discount to face value and upon maturity can be redeemed at full value. The difference between the discounted purchase price and the face value determines the effective yield or interest rate. Treasury bills are sold in 4-, 13-, 26-, and 52-week terms.

Treasury notes have maturities of 2, 3, 5, 7, and 10 years, and they pay interest twice per year. The interest payment amount is stated as a percentage and is called the coupon rate (a term common to most bond investments). The *coupon rate* is determined when the bond is created. For example, a $1,000 5-year Treasury note with a coupon of 2 percent pays 1 percent, or $10, every six months.

Like Treasury notes, Treasury bonds are issued with a term of 30 years and they pay interest every six months. The interest payment or coupon rate is determined at issue, similar to the Treasury note, although Treasury bonds have higher coupon rates than Treasury notes due to the inherent riskiness of longer-term debt instruments. When an investor buys longer-term debt, there is more uncertainty regarding future interest rates; consequently, investors demand higher interest rates for longer-term securities than for shorter-term debt.

Treasury notes, bills, and bonds have several qualities in common. Their minimum purchase amount is $100. They may be purchased at the Treasury auction (from the treasurydirect.gov website) or in the secondary market from a broker or financial institution. They may be held to maturity, when they will be redeemed for face value, or they may be sold at market value prior to maturity.

When a debt security is sold before maturity, its redemption price varies depending upon the relationship of the security coupon rate, time to maturity, and market interest rate. If the market interest rate, and consequently the yield to maturity, is lower than the coupon rate, then the price of the bond will be higher than par (face value), if sold prior to maturity. For example, if a $1,000 treasury bill has a coupon rate of 3 percent and the market interest rate is 2 percent, the bill will sell for more than $1,000 if redeemed prior to maturity.

Floating Rate Notes

Initiated in July 2013, Floating Rate Notes (FRNs) are the newest addition to the government's portfolio of debt offerings. A FRN has a floating interest rate, or one that changes over time along with the market interest rates. Interest on FRNs is paid quarterly.

As market interest rates rise, so will the interest rate on the FRN. Conversely, as interest rates fall, so will the rate on the FRN. The interest rate will be tied to the highest rate of the most recent 13-week Treasury bill rate. This means that rates will adjust quite rapidly to changes in interest rates.

FRNs can be purchased at auction through the government Treasury securities website (treasurydirect.gov) in denominations as small as $100. Additionally, these securities may be obtained through a broker or financial institution. Like most other government securities, FRNs may be held until maturity for face value, or they may be transferred to a financial institution where they can be redeemed at the going market rate.

Savings Bonds

Savings bonds are offered by the Treasury in several varieties: EE/E bonds, HH/H bonds, and I bonds (discussed in the inflation protected investments entry).

EE/E bonds purchased between May 1997 and April 2005 earn a variable market-based rate of return. The interest rate on these bonds changes every six months, each May 1 and November 1 for new EE bonds. Those issued after May 2005 earn a fixed rate of interest, determined at purchase. Interest payments are added to the value of the bond each month and are paid out when the bond is cashed in.

The minimum purchase amount for EE bonds is $25. An individual is entitled to purchase up to $10,000 in EE bonds each year. These savings investments earn interest up to 30 years.

EE/E bonds may be redeemed for face value any time after the bond is one year old, although if the bond is redeemed before five years, the saver loses the last three months of interest. Regardless of when the bond is redeemed, the saver receives the face value of the bond plus any interest earned according to the previous stipulations.

HH/H savings bonds earn interest for up to 20 years. H bonds were last issued in December 1979 and HH bonds were issued from 1980 through August 2004. These bonds are no longer being issued, although existing HH bonds issued up to 2004 will earn interest until 2024.

Inflation Protected Government Securities

Treasury Inflation Protected Securities (TIPs) along with inflation I bonds are discussed in the "Inflation Protected Investments" entry in Volume 3.

Savings Bonds and College Planning

There are special tax benefits for savings bond holders if the proceeds of the bond are used to pay for qualified higher education expenses in their redemption year. The savings bond education tax exclusion enables holders of Series EE and Series I bonds issued after 1989 to exclude from their income all of the interest received.

Thus, the bond interest income is exempt not only from state and local taxes, but also from federal taxes.

More information about using savings bonds for college planning is available from IRS Publication 550, "Investment Income and Expenses," and on the treasurydirect.gov website.

Tax Consequences

All Treasury securities are subject to federal tax but exempt from state and local taxes. Those E/EE and I bonds used for qualified education expenses may be exempt from federal taxes as well. This makes them excellent choices for investors and savers in high tax locations.

The government's Treasury security offerings are not widely promoted by financial advisors, as the government does not financially compensate those advisors for their recommendation. Consequently, these excellent savings tools are frequently poorly publicized or understood. However, they are very safe investments for savers and investors.

TYSON, LAURA

Born: June 28, 1947, in Bayonne, New Jersey; Nationality: American; Professional Interests: macroeconomics, industrial competitiveness, trade, public policy; Major Works: *The Yugoslav Economic System and Its Performance in the 1970s* (1980), *Trade Economic Adjustment in Eastern Europe* (1985), *Who's Bashing Whom: Conflict in High Technology Industries* (1992), *The Global Gender Gap Report 2009* (2009).

Laura Tyson is an American economist and the S. K. and Angela Chan Professor of Global Management at the Haas School of Business at the University of California, Berkeley. She is an expert in trade and international competitiveness. In addition, she is a member of President Barack Obama's Council of Jobs and Competitiveness, of Obama's Economic Recovery Advisory Board (PERAB), and of former secretary of state Hillary Clinton's Foreign Affairs Policy Board. She was the first female chair of the Council of Economic Advisers (1993–1995) and she then served on the President's National Economic Council (1995–1996) during the Clinton administration. She has published books and numerous articles on industrial competitiveness and trade.

Laura D'Andrea Tyson was born on June 28, 1947, in Bayonne, New Jersey. Her father was a World War II GI veteran who became an accountant, and her mother was a housewife. Tyson majored in economics at Smith College, graduating summa cum laude in 1969. She went on to earn her PhD in economics from the Massachusetts Institute of Technology in 1974. Tyson worked as a professor of economics at Princeton University for three years before she moved to the University of California, Berkeley (UC Berkeley), in 1977. She served as the dean of the Berkeley Haas School of Business from 1998 to 2001 and as the first female dean of the London Business School from 2002 to 2006. She was the only woman to head a major U.S. business school (UC Berkeley), and she was the first woman to lead a top 10 international business school (London).

Tyson also founded the London Business School's Center for Women in Business. While Tyson was working in London, the United Kingdom's Department of Trade and Industry appointed her chair of a task force on nonexecutive directors; one significant contribution of the task force was an in-depth report on the recruitment and development of nonexecutive directors. Tyson has since returned to the UC Berkeley, where she is the S. K. and Angela Chan Professor of Global Management at the Haas School of Business.

As a part of the Obama and Clinton teams, Tyson greatly influenced the presidents' domestic and international monetary policy. As chair of the Council of Economic Advisers, she provided guidance and analysis on all economic policy concerns, the economic forecasts, and the annual *Economic Report of the President*.

Tyson has published many books and articles on trade, industrial competitiveness, and the transitions of European countries to market systems. Her studies include a focus on worldwide trends in gender gaps for women in education, economics, politics, and health. In academia, her work centers on globalization, trade liberalization, the impact of high technology, and domestic economics. She regularly promotes the benefits of globalization for domestic economies, yet some fear she may favor protectionist measures (due to the Berkeley campus's reputation for anti-globalization). Tyson advocates concern for issues such as global warming and environmental impact, but she promotes the ethical responsibility of the businesses involved.

In addition to her work at UC Berkeley, where she was cited as the winner of its Distinguished Teaching Award, Tyson is also a senior adviser at the McKinsey Global Institute, Credit Suisse Research Institute, and The Rock Creek Group. She continues to write opinion columns for such sources as the *New York Times*, *Business Week*, and *The Financial Times*. Tyson is a member of the World Economic Forum's Global Agenda Council; the National Academies' Board on Science, Technology and Economic Policy; and the National Academies Committee on Research Universities, to name a few. She serves on the boards of directors and advisory boards of companies such as Morgan Stanley, AT&T, Newman's Own, and the Peter G. Peterson Institute of International Economics.

UNEMPLOYMENT

Unemployment is the working state of someone who is willing and able to work but not working currently. Unemployment is measured in several different ways by several different organizations, some private and some public. The most widely accepted and quoted measure, the unemployment rate, is the responsibility of the Bureau of Labor Statistics (BLS), an agency of the Department of Labor.

Economists study unemployment as one barometer to achieving a major economic goal—high employment. The BLS collects data on a variety of employment and unemployment conditions. The BLS also determines the size of the labor force, which is a variable in determining the unemployment rate. It establishes the definition of an *unemployed worker*. Individuals are classified as unemployed if they are over 16 years of age and do not currently have a job, but are able to work and are actively pursuing employment. No measure of unemployment is precise. All measures of unemployment and methods of collecting data have some flaws along with their benefits. Unemployment rates and other unemployment and employment metrics give economists portions of the labor picture. It is up to economists, policymakers, and the public to take these aggregate measures in total to create an accurate picture of an economy's capacity for labor.

Economists recognize four categories of unemployment: frictional, cyclical, structural, and seasonal.

Frictional Unemployment

Frictional unemployment is a type of unemployment that occurs when a person is between jobs. Frictional unemployment is considered only temporary, since typically, as soon as the unemployment occurs the person begins to search for employment almost immediately.

There are many causes of frictional unemployment. People may decide to leave their jobs on their own accord. Their reasons for leaving may include low pay, little or no opportunity for growth, desire to further their education, and a difficult work environment or undesired location. Another cause is the fact that some people may overlook certain jobs because they feel that those jobs are below their skill level, or they may simply believe that an available position is "below" them. Likewise, an employer may look at the résumés of a pool of job candidates and decide that none of the applicants have the skills necessary to do the job, when in fact they do. Finally, frictional unemployment may be temporary due to certain life events, such as a woman taking maternity leave from her job, or a teacher taking a sabbatical.

Another way to understand frictional unemployment is to think of it as a period in which a person is searching for employment opportunities, or simply the period in between jobs. Unemployment is always present in the economy, resulting from temporary transitions made by workers and employers, or from workers and employers having inconsistent or incomplete information.

Cyclical Unemployment

Cyclical unemployment is job loss that occurs when the economy enters into a period of recession and there are more people seeking work than there are jobs available. In reaction to less consumer demand for goods and services, businesses lay off workers as production need decreases. These workers are then temporarily unemployed, until the cycle changes and employers can rehire when the economy expands and consumer demand increases. Cyclical unemployment is a part of the business cycle. The most common method economists apply to calculate the cyclical unemployment rate is to subtract the unemployment rate at the *bottom* of the business cycle from the unemployment rate at the *peak* of the business cycle. The difference between these two numbers is what economists call the cyclical unemployment rate.

Structural Unemployment

Structural unemployment is unemployment that occurs when an industry goes through a transformation in the way it produces the good or service of its industry, and the skills of the former employees do not match the new skills that are needed in the new industry.

Seasonal Unemployment

Seasonal unemployment occurs as a result of a job being able to be performed only during specific seasons of the year. Often the term *seasonal* conjures up visions of the summer jobs of high-school and college students or the part-time jobs that retail stores add during a holiday season. While those jobs are included in the Current Establishment Survey (see below), seasonal unemployment also includes jobs that are weather-dependent. More specific to northern states, seasonal unemployment includes career jobs such as highway construction and housing construction.

Natural Rate of Unemployment

Recall that the definition of *unemployed* applies to someone who is both willing and able to work. Frictional unemployment includes those who are between jobs and new entrants into the workforce. Between frictional unemployment and structural unemployment in some industries in the economy, it is virtually inconceivable to imagine that every person willing and able to work is working. The *natural rate of unemployment* refers to the lowest rate of unemployment that a society can reasonably achieve, knowing that there will always be some frictional and structural unemployment in the economy. What, then, is the unemployment rate at which the economy can be considered to be at full employment? The natural rate of unemployment can also be viewed as the point at which the economy is operating at full employment, or the point at which unemployment has reached equilibrium. The natural rate of unemployment is an arguable point between economists. Whether that unemployment rate is 3, 4, or 5 percent, economists agree that there is a percentage window at which full employment is considered achieved, even without the percentage being zero. At that point, most adults who want to be working are, in fact, working.

Non-Accelerating Inflation Rate of Unemployment

Under the philosophy of John Maynard Keynes, an economy can reasonably continue to add jobs—that is, lower unemployment—without creating demand-pull inflation, as long as the economy is in an economic downturn or recession. However, when the economy recovers and economic growth is at the peak of the business cycle, a significantly low unemployment rate translates into a large increase of people and money demanding goods and services. This scenario poses the challenge of determining what low unemployment rate will translate into too much new demand such that prices are forced to rise—that is, inflation. The lowest unemployment rate possible to achieve without translating into inflation is called the Non-Accelerating Inflation Rate of Unemployment (NAIRU). This unemployment measure enters economists' discussions when an economy is operating at close to or at full potential. At this point, economists become concerned about an overheating economy where inflationary prospects are high, often instigated by excessive consumer demand for goods and services.

Measures of Unemployment

For economists, politicians, and investors, unemployment measures are arguably the most awaited economic metrics. To get as clear a picture of the labor force as possible, three key types of measures are taken: household survey, establishment survey, and weekly unemployment claims. Each measure reveals a distinct aspect of the labor force. Unemployment data—which are collected and released by the Bureau of Labor Statistics (BLS), an agency of the Department of Labor—are released by the BLS on the first Friday of each month at precisely 8:30 a.m. The BLS makes revisions to its data as far back as two months. Sometimes these revisions can be quite significant and can impact or alter the decisions of investors and politicians. Since consumer spending is approximately two-thirds of the U.S. economy, unemployment data become a portrait of the economic spending habits and income profile of consumers.

Current Personal Survey (also known as the Household Survey)

The BLS collects the current personal survey data by surveying 60,000 homes across the country. All sectors of the economy are surveyed, including farm and nonfarm workers, domestic helpers, and those who are self-employed. According to the BLS, the response rate to the survey is approximately 95 percent. The survey includes questions on whether the respondent is employed or not, and if so, if the work is part-time or full-time, and if the respondent is not employed, is the respondent looking for work. With the data collected from the current personal survey, the BLS determines the size of the civilian labor force, the number of people employed, and the unemployment rate. Every survey has its shortcomings, and the household survey is no exception. The current personal survey suffers the same deficiency as all surveys, which is the honesty of the respondents.

Current Establishment Survey (also known as the Establishment Survey)

For the current establishment survey, also known as the payroll survey, the BLS surveys over 400,000 companies and government agencies in 500 different industries. The surveyed companies employ approximately 45 percent of the labor force, or 40 million workers. This survey is different from the current personal survey in a number of ways. First, it looks only at nonfarm workers and it is not concerned with age. Second, the current establishment survey does not distinguish between full-time work and part-time work. The key focus of this survey is to determine the number of jobs created or eliminated. Third, since the current establishment survey gathers data from only employers and workplaces, it does not count self-employed workers who work out of their homes. While both the current establishment survey and the current personal survey collect very different information, they tend to move in the same direction, showing similar unemployment pictures of the economy.

Weekly Unemployment Claims

The third unemployment measure is the weekly claims for unemployment insurance. This leading indicator is based on the actual numbers of unemployment claims filed, as recorded by each state's unemployment agency. Since this measurement of unemployment is obtained through actual claims numbers, its accuracy makes it a good indicator of future economic conditions. From the trend of these data, it is possible to gauge the number of unemployed who are no longer receiving payments, and potentially the number of discouraged workers.

A *discouraged worker* is an individual of working age who is unemployed and is not currently pursuing a job. Although they are usually willing and able to work, discouraged workers have given up finding gainful employment due to a variety of factors. Due to these real or perceived limitations in the job market, these individuals have become "discouraged." Discouraged workers are not included in the unemployment rate, and they are not considered to be in the labor force.

The level of employment can have a significant impact on the growth of an economy. An economy at less than full employment has underutilized resources, which translates into fewer people participating as both producers and consumers. Yet an economy at a level considered full employment is an economy with full, or close to full, utilization of the resources and capacity of consumers purchasing goods and services. There is often a fine line between the two scenarios.

UNITED STATES TREASURY

The United States Treasury is one of the oldest executive departments. It was created through an act of Congress in 1789. At its inception, the primary function of the Department of Treasury was to manage the monetary resources of the United States and issue reports on the public credit. However, the roles and responsibilities of the various bureaus have become increasingly complex.

The U.S. Treasury Department is an executive agency tasked with promoting the economic well-being and financial security of the United States. The mission of the U.S. Treasury Department is to sustain a stable economy and stimulate the conditions for economic growth, as well as to protect the reliability of the U.S. monetary and financial systems and manage the finances of the U.S. government. The Treasury Department is linked to the Federal Reserve System, which acts as the central bank for the United States Treasury.

The Treasury Department is the guardian of U.S. financial resources and is a key player in the world economy. It is organized into various departmental offices, which include domestic finance, economic policy, office of the general counsel, international affairs, legislative affairs, management, public affairs, tax policy, terrorism and financial intelligence, and the office of the treasurer. These departments, headed by assistant secretaries and undersecretaries, are collectively responsible for formulating policy and managing the department as a whole. The larger component of the Treasury is its several operating bureaus, which are responsible for carrying out specific tasks. These bureaus make up the overwhelming majority of the Treasury's workforce, and they include such divisions as the U.S. Mint, the Bureau of Engraving and Printing, and the Internal Revenue Service (IRS).

The Treasury's basic functions, carried out by the various bureaus, include collecting taxes, duties, and monies paid to and due to the United States; paying all bills of the United States; issuing bonds, currency, and coinage; managing government accounts and the public debt; supervising national banking institutions; enforcing federal finance and tax laws; and investigating and prosecuting tax evaders, counterfeiters, and forgers. This means the Treasury is responsible for regulating national banks, determining international economic policy, collecting income and excise taxes, issuing securities, and manufacturing coins and bills for circulation.

The U.S. Treasury is headed by the secretary of the Treasury, appointed by the president and confirmed by the Senate. To date, there have been 76 Treasury secretaries, from Alexander Hamilton in 1789 to Jacob (Jack) Lew (appointed by President Obama and confirmed by the Senate in 2013). As the chief financial officer of the government, the secretary of the Treasury reports to the president of the United States and serves as a member of the president's cabinet; publishes annual reports on the state of the nation's finances; and has the primary responsibility for formulating and recommending tax policy and other domestic and international economic and financial policy initiatives.

Another important role within the Treasury Department is the treasurer, who has oversight over the Bureau of Engraving and Printing and the U.S. Mint and deals with any issues pertaining to coinage and currency. There is also an inspector general, who reports to the deputy secretary with an independent and objective review of the department's operations. The inspector general must keep Congress fully informed about problems and deficiencies relating to the administration of the department's programs and operations.

The Treasury Department currently has a budget of about $13 billion, and a staff of more than 100,000 employees. The functions of the Treasury Department have become more expansive in response to the increasing needs of a more sophisticated and developed nation. The Treasury Department works with the White House administration to pursue policy initiatives that are in line with the presidential administration, such as raising the debt limit, making housing affordable, or reforming Wall Street.

The department also works with other federal agencies, as well as with foreign governments and international financial institutions. Its goals in doing so are to encourage global economic growth, increase standards of living, and, if possible, predict and prevent economic crises. The Treasury Department does what it can to improve national security by identifying security threats and supporting the financial systems by providing safeguards against those threats. A reorganization of the department in 2003 moved several law enforcement agencies out of the Treasury Department, including the Bureau of Alcohol, Tobacco and Firearms, which moved to the Department of Justice; and the Secret Service and Customs Service, which moved to the Department of Homeland Security.

UNITED STATES TREASURY BILLS, NOTES, AND BONDS

Treasury bills (T-bills), notes (T-notes), and bonds (T-bonds) are marketable securities from the U.S. government. The government sells these savings and investment instruments to the general public, banks and other financial institutions, investment and brokerage houses, wealth sovereign funds, and other nations. The funds raised are used to pay off maturing government debt and raise the cash needed to operate the federal government. Investors not actually receive a certificate with the purchase of a U.S. Treasury bill, note, or bond. The investment is followed in a system of accounts that generates continuing statements and balances. What differentiates T-bills, T-notes, and T-bonds is that each has a longer term to maturity (T-bills are the shortest and T-bonds the longest). Each has a stated interest rate, paid semiannually until the Treasury matures.

Treasury Bills

Treasury bills are short-term obligations issued with a term of less than one year. Because they are sold at a discount from face value, they do not pay interest before maturity. The interest is the difference between the purchase price and the face value. They are often used for achieving the same saving goals or purpose as a money market fund or a savings account. Since their short maturity provides liquidity, holders of the bills often use them to allow easy access to the money. Conversion from a Treasury bill to cash can be quickly completed by a bank or a broker.

A Treasury bill is also similar to the popular zero-coupon bond. Unlike the T-bill's cousins, the T-note or T-bond, a zero-coupon bond does not make periodic interest payments. A Treasury bill is purchased at a discount from its face value (par value). The receiver of the bill will then receive the full face value at the time of maturity.

Treasury Notes

Treasury notes are intermediate to long-term investments. The maturities of T-notes are typically 2, 3, 5, 7, and 10 years. Treasuries of this maturity are often purchased by individuals for their long-term savings or investment needs. Because interest is paid twice a year, T-notes make sound, safe investment tools for retirement or other long-range goals.

Treasury Bonds

For the Treasury, the goal is to provide additional debt that will appeal to investors while keeping financing costs low. Bonds are sold by the U.S. Treasury Department. Treasury bonds cover terms from longer than 10 years to 30 years. Interest is paid semiannually, as with the T-note.

Treasury bonds are often called floating-rate notes, or "floaters." Floaters are securities with rates set periodically. Floaters can offer shorter-term safety, hedging against the potential of rising interest rates.

U.S. Savings Bonds

For the noninvesting, nonfinancial career person, probably the most popular of all the U.S. Treasuries is the U.S. Series EE or Series I savings bond. An individual can purchase up to $5,000 in any given year. The bond can then be redeemed at any time after 12 months. If the bond is redeemed before 12 months, an interest penalty is imposed. A popular gift among parents and grandparents, the Series EE savings bonds are sold at one-half their face value. So to buy a $100 Series EE U.S. savings bond as a gift only costs $50. If the bond purchase is made electronically, the face value can range from $25 up to $5,000. Paper Series EE bonds are sold in the more traditional denominations ($10, $25, $50, $100, etc.).

The interest rate paid at maturity on Series EE bonds depends on when the government issued the bond. If the bond was issued later than May 2005, the interest rate is fixed based on the 10-year U.S. Treasury note. The "fixed" interest rate is a bit of a misnomer, since the 10-year U.S. Treasury note interest rate is adjusted semiannually. Series EE bonds issued between May 1997 and April 2005 earn interest based on a floating rate.

The holder of the Series EE bond does not receive the interest until the bond is redeemed. If the bond is redeemed within five years, three months' interest is forfeited. The U.S. Treasury guarantee is the maturity date of Series EE bonds does not go beyond 17 years. If investors really want to earn interest on Series EE bonds, they can let the bonds earn interest for up to 30 years.

Many of the characteristics of the Series EE bonds apply to the Series I saving bonds. The major difference between them is the built-in inflation adjustment mechanism of the Series I bond. The main distinction is the way in which interest is paid. A Series I bond pays interest that is partially fixed and partially adjusted for inflation. Another benefit of holding Series EE or Series I bonds is that the income tax on the interest earned does not have to be paid until the bonds are redeemed. Parents and grandparents are big fans of the Series EE and Series I bonds as a way to help pay for college.

Treasury Inflation-Protected Securities

Treasury Inflation-Protected Securities (TIPS), were introduced by the U.S. Treasury in 1997 as a hedge against inflation. These securities used the Consumer Price Index (CPI) to determine and adjust the value of the principal, taking into account the current impact of inflation on the principal's real value. TIPS pay a fixed rate of interest, paid semiannually on the new inflation-adjusted value of the principal.

When TIPS mature, the holder receives either the higher inflation-adjusted principal (if inflation has impacted the initial value), or the original principal amount (if deflation—a general decrease in the price level—has occurred). Due to this inflation-adjusted mechanism, interest rates on TIPS are usually lower than other Treasuries with the same maturity.

There are several ways to purchase U.S. Treasuries. They can be bought, and redeemed, through commercial banks, brokers, or investment professionals. They can be purchased directly from the government, usually by broker-dealers, although some individuals can go the direct route. Another way to own U.S. Treasuries is to buy into a mutual fund specializing in Treasuries. The popular Series EE bonds can be purchased at local banks or directly from the U.S. Treasury. Some employers offer a Series EE bond-buying program as a benefit to their employees.

V

VOLCKER, PAUL

Born: September 5, 1927, in Cape May, New Jersey; Nationality: American; Professional Interests: financial economist, monetarist, chairman of the Federal Reserve Board (1979–1987); Major Work: *Good Intentions Corrupted: The Oil-for-Food Scandal and the Threat to the U.N.* (with Jeffrey A. Meyer and Mark G. Califano) (2006).

Paul Volcker became chairman of the Federal Reserve Board in 1979, during a period of historically high inflation rates accompanied by low economic growth rates, a condition known as stagflation. During such periods, economic policymakers are presented with a dilemma, since the policy to control inflation will often result in depressed economic conditions, including high unemployment. Volcker, unlike previous Federal Reserve Board chairmen, implemented an unpopular monetary policy in order to lower inflation rates. At the time, his actions were widely criticized. Although the policy was unpopular and had negative consequences, Volcker was successful in lowering and controlling the inflation rate.

Paul Adolph Volcker was born on September 5, 1927, in Cape May, New Jersey, and grew up in Teaneck, New Jersey. He graduated from Princeton University in 1949, obtained an MA from Harvard University in 1951, and studied at the London School of Economics after graduate school. Volcker has been awarded more than 50 honorary degrees recognizing his contributions as an economist.

Volcker's first job, as an economist at the Federal Reserve Bank of New York, began in 1952. In 1957, he left government employment to become a financial economist at Chase Manhattan Bank. In 1962, he returned to government service in the Department of Treasury as the director of financial analysis; in 1963, he was promoted to deputy undersecretary for monetary affairs. Volcker returned to the private sector in 1965 as vice president of Chase Manhattan Bank. Again returning to government service in 1969, he was appointed to the position of undersecretary for monetary affairs at the Treasury Department. While serving in this capacity, he was an important participant in ending the Bretton Woods agreement, which had established exchange rates based on gold, and removing the United States from the gold standard. With the Bretton Woods agreement dissolved, the dollar and other currencies were allowed to float in determining their values. Next, Volcker became a senior fellow at the Woodrow Wilson School of Public and International Affairs at Princeton University in 1974, before becoming president of the Federal Reserve Bank of New York from 1975 to 1979.

Volcker was appointed chairman of the Federal Reserve Board in 1979. His appointment took place in the midst of an economic period known as stagflation. During stagflation, inflation rates are abnormally high and economic growth rates are low. Inflation peaked at 13.5 percent in 1981. Immediately upon becoming chairman, Volcker implemented a monetary policy targeting money supply growth as a way to drastically lower inflation rates. To accomplish this, Volcker increased the federal funds rate to a high of 20 percent, and the prime rate rose to 21.5 percent in 1981. This policy was widely criticized, since the effect was to radically increase unemployment (9.7 percent in 1982 and 9.8 percent in 1983) and produce high interest rates (30-year fixed mortgage rates exceeded 13 percent), which further slowed economic activity. However, by 1983 the inflation rate was down to 3.2 percent; Volcker's policy worked and inflation was brought under control. For many Americans, he went from being the villain to being the conqueror. Volcker left the chairman position of the Federal Reserve Board of Governors in 1987, and he was replaced by Alan Greenspan.

After leaving the Federal Reserve, Volcker joined the small investment banking firm of James D. Wolfensohn Inc. In 1996, he became chair of the Independent Committee of Eminent Persons (which became commonly known as the Volcker Commission), investigating money held in Swiss banks by Holocaust victims. The result of the Volcker Commission's investigation was to draw attention to a relationship between the Swiss banks and the Nazis. The commission's findings led to a $1.25 billion settlement to Holocaust survivors and their families.

Volcker has served on a number of committees and foundations, including as chairman of the International Accounting Standards Committee Foundation (2000–2006); as head of an investigation of accounting practices of Arthur Andersen, which was responsible for auditing Enron (2002); as the lead the UN's investigation of the UN oil-for-food program for Iraq (2004–2005); and as chairman of the Economy Recovery Advisory Board under President Barack Obama (2009–February 2011).

While serving on the Economy Recovery Advisory Board, in 2009 he proposed what became known as the Volcker Rule, which would have severely restricted commercial banks from capital market and trading activities—hedge funds, private equity funds, commodities trading, and derivatives—by separating commercial banks from investment banks. The rule he proposed was not enacted, but a less stringent version was passed in the Financial Reform Act of 2010.

Descriptions of Volcker include phrases like irascibly honest, an inflexible man of integrity, Mr. Incorruptible, and a fair and strong leader in troubled times. At six feet seven inches tall and armed with a determined personality, Volcker has been an imposing and unyielding policymaker who did what other chairman were unable to do. He reined in inflation during a time of double-digit inflation rates, but is also criticized for putting the American economy into recession. Politically, Volcker is considered a Democrat; however, during his government service he maintained a reputation for being non-partisan. Volcker's economic perspective is one of caution, faith in markets, and common sense.

WAGE AND PRICE CONTROLS, 1971

The inflation of the Vietnam War era would combine with the elimination of the gold standard to create U.S. price and wage inflation at uncontrollable levels. On August 15, 1971, President Richard Nixon announced a series of economic measures to address accelerating inflation, which was approaching 6 percent. The price controls Nixon announced and his removal of the gold standard created major short-term and long-term economic changes, but inflation would not be fully resolved until the 1980s. (It would peak at 15 percent in March 1980.) The period would become the standard reference point for the impact of inflationary pressures on American business.

Although the wage and price controls imposed by President Nixon had mixed results, the event marked the problem of inflation that marred the decade of the 1970s. The wage and price controls bought time for Nixon to win the 1972 election, but the decade-long inflation trend continued unabated for years. Ultimately, it would take a recession in 1980 and a tight money policy by the Federal Reserve to end the brutal inflation of the 1970s. In the short run, the U.S. effort to fight inflation would lead economists to use monetary policy to address the problem of inflation. In the long term, the removal of the gold standard would lead to free-floating currency values.

The origin of the crisis goes back to a surge of spending for the Vietnam War and the Great Society programs of President Lyndon Johnson in the late 1960s. By 1969, inflation was on the rise. The public had a mixed view of inflation. The big unions were protected with contractual cost-of-living adjustments to their wages and salaries. People on fixed incomes or employees lacking cost-of-living adjustments faced a major loss in purchasing power. Most were pleased with the rise in housing prices; however, prospective new owners were being priced out of the market. Price increases for food, cars, and consumer goods were looked at as a major negative. Still, others enjoyed the high rate of return on their savings.

The U.S. government was running large deficits, but the economy was picking up as the Federal Reserve was easing its monetary policies. Inflation was causing major problems in international markets as well, especially once the United States moved off the gold standard. More accurately, there was a de facto gold standard that allowed the Federal Reserve to continue to print money beyond the point where the currency had 100 percent gold backing. The dollar was losing value, causing Arab oil barons to view their petro-dollars—the U.S. dollars that they were paid for their oil—as devalued. The gold coverage of the dollars printed dropped to 22 percent, which created a lack of confidence in the dollar among foreign countries. The dollar was eroding further, as foreign countries demanded gold in exchange for their dollars, and the U.S. Treasury was being drained of its gold reserves. Germany was the only country aggressively addressing inflation with its economic policies, as they feared it more than deflation, having suffered superinflation in the 1930s.

Starting in 1969, the United States entered a period of high prices and shortages. Newspapers fueled the fire with stories of price-gouging. The public worried as countries such as France demanded gold in payment for its dollars, thus taking gold out of the United States. The value of the dollar fell, and headlines in the United States newspapers blamed the problems on an exchange crisis caused by foreign countries. The huge increase in the U.S. money supply was being overlooked. The Nixon administration wanted both low interest rates and low unemployment and encouraged the Federal Reserve to print money to get those results. High housing costs were causing trouble for the postwar baby boomers who were about to enter the housing market. Public opinion was demanding that the government take action to address these problems.

On August 15, 1971, President Nixon announced a three-pronged approach: a wage and price freeze, a 10-percent import surcharge, and the end of the convertibility of the U.S. dollar to gold. In the short run, the approach worked; but it had many long-term ramifications. By 1976, the world's major currencies were floating and their values were no longer under government control. The long-term impact of Nixon's policies on the American economy is clouded by other major economic shocks, such as the Arab oil embargo.

Historically, price-fixing has shown few positive effects. The policy was tried on a major scale by the ancient Romans, by the Soviet Union, and during the French Revolution and World War II. The results were the development of black markets in goods and material shortages. For decades, the black market was a way of life in the price-controlled Soviet Union. Adam Smith had predicted this 200 years earlier. Even America with its wartime price controls on meat had learned a hard lesson after World War II. These controls eventually led to scarcity of the product whose price was being controlled. Consumers even rejected the policy, realizing that a cheap price for meat was of little value if there was no meat available to buy.

Nixon was well aware that price controls would create shortages, but the political environment required some action. Nixon's wage and price controls were short-lived, but his decision to end the convertibility of the dollar into gold remained the long-term legacy of his actions against inflation. The great wave of inflation returned in 1974, fueled by the Arab oil embargo and the pushing of the money supply to keep unemployment low. Eliminating the gold standard freed the Federal Reserve to pump unlimited amounts of money into the system.

The wage and price controls did little to change the underlying causes of the 1970s inflation. Another result of the 1970s inflation and stagflation was a rethinking of Keynesian economic policies. Before the 1970s, Keynesian economists believed inflation and unemployment were inversely related; that is, high inflation meant low unemployment. This relationship was known as the Phillips curve. The thought behind the Phillips curve was that the high demand (reflected in high prices) seen in times of inflation required more workers to be hired, thus driving down unemployment.

The stagflation of the 1970s, however, showed that high inflation and high unemployment could coexist. Milton Friedman led the rethinking of Keynesian theories. Friedman showed that the Phillips curve shifted in the 1970s as businesses adapted to long periods of inflation. Workers and management started to take inflation into account in their wage negotiations. The bottom-line result of the 1971 wage and price controls was that they signaled the beginning, not the end, of an economic crisis. Inflation would continue into double digits, and a new economic condition that would be known as stagflation occurred: the United States was in an economic recession yet inflation continued to rise.

WAR FINANCING CRISIS, 1776

America had been in and out of major wars since the 1740s, but seeking its independence by going to war with Great Britain created special economic problems for the colonies. Because Great Britain was the main holder of colonial debts, war with Britain would relieve some debt problems for the colonies; however, the colonies themselves lacked gold and silver to back the printing of their own currency. The war would also cause America to lose its main trading partner: Great Britain.

Money would be needed to purchase such key war materials as gunpowder. As in past conflicts, American factories could be ramped up to manufacture some war materials, but not everyone supported the war. Furthermore, some merchants, traders, manufacturers, and businesses were suspicious of paper money after the inflationary problems of the 1740s, 1750s, and 1760s. They were leery of beginning to produce war material only to be paid with worthless currency.

The American Revolution would be as much a financial crisis as a political conflict, and victory would be as much financial as military. The colonists, however, realized that continued economic ties with Britain provided no better future either. It was time for economic freedom as much as for political freedom. Not surprisingly, the northern urban centers and the southern plantation owners were the centers of support for revolution, as they had been the most negatively affected by the British mercantilism that had harmed and constricted the colonial economy for decades.

By 1774, the die of war was cast. British soldiers were in the colonies enforcing oppressive regulations and acts of Parliament. The colonists were organizing a boycott, and the British were blockading major ports. The First Continental Congress met in Philadelphia. A major boycott was being planned; but before that, merchants such as Robert Morris of Philadelphia sent many ships filled with flour to Europe to obtain goods and establish credit before the fighting began. Credit had already been tightened in anticipation of a major conflict with Great Britain.

Congress formed the Committee of Safety and filled it with prominent merchants. The committee's first assignment was to arm 4,500 soldiers. The most critical need was for gunpowder, and Robert Morris was given the first government contract. Fulfilling the contract was a high-risk investment of Morris's ships, but the profit would be more than 30 percent, high enough that one successful shipment could pay for two or three lost shipments. American merchants like Morris would find war to be profitable. Morris was able to establish a European trade that had gunpowder, cannon, and arms flowing into America before the Declaration of 1776. Congress started to print continental dollars and to let contracts for war materiel. The public lacked confidence in paper money, but there was little silver or gold available for Congress to use in the fight.

In late 1775, Robert Morris was a key member of many congressional committees and had procurement responsibilities for the Congress. Many in Congress were upset with the profit margins of the merchants, but these profits brought victory by giving merchants the incentive to risk their money and property against the British navy. British blockades began in 1776 as the war officially started.

Benjamin Franklin was able to get a secret credit deal from France that would prove critical to the American war effort.

Morris established a trading network throughout Europe and the colonies. He had, for example, been given sole responsibility for the Virginia tobacco trade. American ships were also sailing in search of British ships to capture for their cargo and money. The economics of war often received little attention, but the America victory depended on it. Morris's network supplied the muskets, gunpowder, blankets, lead, and money to support Washington's famous Christmas Eve crossing of the Delaware to defeat the Hessians. During this campaign, the enlistment period was up for many of Washington's soldiers, and they were due to return to their homes in the next few days. Washington offered a $10 bounty for soldiers to sign up for another year. Morris was able to collect the necessary funds in coin to hold on to the soldiers.

It would be a long war and would involve a string of financial ups and downs. Congress considered imposing new taxes to support the war, but that was politically impossible as the war was being waged over British taxes. In 1777, Congress, hoping to borrow money to help pay for the war, approved the issuance of $5 million in certificates paying 4 percent. There was a lot of competition with individual states, which were issuing their own certificates at the 4-percent rate. The bonds found few takers until Congress raised the interest rate to 6 percent. Still, by the end of 1777, more French loans were needed to pay for the war. Morris set up an informal bank that sold six-month certificates, and the bank circulated paper notes to be used as currency. This bank was successful with providing credit for merchants, who preferred bank notes to continental dollars.

As 1780 approached, all forms of paper money that had been issued were highly inflated. The state of circulating currency was a mass of state-issued paper, continental dollars, and some interest-bearing bank notes. The crisis peaked in 1781, when 10 regiments of Pennsylvania soldiers, tired of the lack of supplies and pay, marched on Congress. This was not an isolated rebellion, but it was the largest to directly threaten Congress. Congress was printing money to pay for the war, with no formal agreement between the individual states to back the money—that is, to accept the responsibility to pay back the debts after the war. Congress decided that the currency and the war financing required central control, and Robert Morris was named superintendent of finance. The need for unity in taking responsibility for the war spending ultimately resulted in the ratification of the Articles of Confederation.

Morris founded a private national bank to issue currency backed by silver and gold. The idea was to attract patriotic investors and French support. Most important, Morris used the bank as a central bank to control the value of the currency. Under the bank, all states would share the war debt. However, Morris planned to use poll taxes, import taxes, excise taxes, and land taxes to pay off the debt. He used a 6-percent interest rate to attract foreign money. Morris also aggressively sold grain to Spain for gold and silver to back his new bank. Many critics looked at Morris as a financial alchemist, and they could not understand why he was buying back continental dollars and bank paper while limiting new money. The French were still giving loans to the colonies because manufacturing gunpowder and other war supplies had created an economic boom for France, and France's earlier investments required them to stay for the long haul or lose everything.

Morris also proved creative in saving money on supplies for the army. He replaced an elaborate system of government agents and army supply officers with contractors who became responsible for collecting and delivering supplies to the army. This also allowed the army to put more troops in the fight. The use of contractors was years ahead of its time, but the system worked extremely well in the North. Merchants lined up to bid on contracts at the rate of 10 cents per soldier per day. If supplies were captured by the enemy, the government would cover the loss. The concept would come to be frowned on by the professional armies of Europe, however, because of the lack of control over contractors. (The idea would be resurrected by the Bush administration during the Iraq War.) The problem of pay, however, was not to be resolved for over a decade.

George Washington had spent years begging soldiers to stay on with little money available for pay. Some of these soldiers still had worthless paper dollars from the French and Indian War. The average soldier was patriotic, but the soldiers were also farmers and laborers with families to feed. The years of fighting had taken their toll, and although a military end was in site, inflation and a lack of hard cash were big obstacles to success. Even Washington's ultimately successful southern campaign to Yorktown was in jeopardy for lack of funds. But the arrival of the French fleet brought not only troops but also kegs of silver coins for the soldiers' pay.

The American victory at Yorktown brought money from Holland—the first major loan outside of France. The financial work of Robert Morris had been behind the ultimate American victory, but it took another 10 years to settle the debt created. The pattern of war, boom, inflation, peace, and recession that had been seen in the past was repeated during the Revolutionary War period and would be repeated in the future.

WATER POLLUTION

The economics of water pollution is complicated by several features. Water pollution causes externalities or third-party effects—usually (and literally) downstream effects. Unless those external costs are internalized by the polluter, there will be downstream effects. Rivers and lakes or surface water, groundwater, and oceans are all at risk for water pollution. Additionally, there are multiple sources of water pollution that require different solutions or policies. These sources include point source pollution, nonpoint source pollution, atmospheric deposition of pollution, groundwater contamination, and ocean pollution. Finally, the pollutants entering the water bodies may be either fund pollutants or stock pollutants. The environment has some absorptive capacity for *fund pollutants*; common examples of fund pollutants are nitrogen and phosphorous, which are not harmful in small quantities but can cause eutrophication in larger quantities. *Stock pollutants*, on the other hand, are those for which the environment has little or no absorptive capacity; these are persistent pollutants that accumulate in water bodies and in the food chain.

Point source pollution can be traced back to a specific discharge pipe, making it easier to control and to monitor. The timing of pollution can also be determined with some accuracy. Pollution control authorities have focused (until recently) control efforts on point sources such as sewage treatment plants and production facilities such as paper mills.

Nonpoint source pollution is pollution that runs off the land when it rains. Runoff from farms, roads, golf courses, and residential lawns is included in this category. Predicting the timing and quantity of nonpoint source pollution is difficult, so until recently, this type of pollution was ignored. Now, however, it is understood that nonpoint source pollution accounts for a majority of water pollution, so recent attention has focused on regulations and incentives for controlling nonpoint source pollution.

Groundwater contamination usually results from toxic or harmful substances leaching into underground aquifers. For oceans, the main sources of pollution are ocean dumping and oil spills. Oil spills from tankers and from offshore drilling sites are not uncommon. Ocean pollution from trash is becoming a large problem in certain areas, where plastics are accumulating.

Water bodies are also becoming polluted when air pollution falls to the ground. Called atmospheric deposition, this occurs when it rains (wet deposition) or when pollutants become heavy and fall to the ground (dry deposition). Air pollutants like sulfur dioxide cause acid rain, and heavy metals such as mercury (a by-product of burning coal and trash) contaminate water and are found in fish tissue. Most food products made from freshwater fish and many saltwater fish are listed with fish consumption advisories for children and women of childbearing age due to mercury contamination.

Traditionally, water-pollution control policies have relied on command and control, or regulations limiting the amount of pollution that can be discharged into a water body. Early examples in the United States include the 1899 Refuse Act (a part of the broader Rivers and Harbors Act) and the Water Pollution Control Act of 1948. The Water Pollution Control Act of 1948 included regulations on waste discharges as well as economic incentives in the form of subsidies for the construction of wastewater treatment plants. Subsidies lowered municipalities' costs for building expensive wastewater treatment plants that might not have been built otherwise. The 1972 amendments to the Water Pollution Control Act, or the Clean Water Act (CWA), gave the EPA authority over setting effluent limits for water-quality protection. The CWA requires that dischargers of pollutants obtain permits called National Pollutant Discharge Elimination System (NPDES) permits for their discharges. Other, more recent policies include the Safe Drinking Water Act of 1972, the Total Maximum Daily Load (TMDL) program of the Clean Water Act, and laws on ocean dumping.

Most of these policies rely on expensive command-and-control regulations. The regulations do not offer flexibility or cost-effectiveness, but are based on industry-wide or technology-based standards. Recently, however, watershed-based trading (or water-quality trading) has gained attention as a way to achieve a standard at lowest cost. Pollution trading of any kind relies on the idea that polluters (facilities, factories, sewage treatment plants, etc.) tend to have very different costs for pollution control. Trading works if there is enough variation in costs that high-cost sources can buy allowances from lower cost of control sources. If high-cost-of-abatement sources buy allowances at less than their marginal cost of cleanup and low-cost sources sell for higher than their marginal cost of cleanup, the same standard can be reached, but at a lower total cost.

Many trades have taken place across similar types of polluters (e.g., point source to point source). But watershed-based trading may also be an appealing option for point sources that have already been forced to clean up a significant portion of their discharge—so much so that additional treatment could be extremely expensive. If those point sources instead subsidized the treatment of a nonpoint source, the same reductions could be met at much lower cost. For example, the marginal (additional) cost of abatement rises with abatement. Imagine two sources: one point source that is half-way up its own marginal cost schedule, and a nonpoint source that has not cleaned up at all. The nonpoint source may have higher overall marginal costs of cleanup, but is not yet on the curve (abatement = 0). In this case, the total cost of abatement is lowest if the nonpoint source, rather than the point source, cleans up the next unit. An example is Lake Dillon, Colorado. Lake Dillon was experiencing excess phosphorous pollution. The sewage treatment plant opted to build a buffer around a local golf course to keep phosphorous from fertilizer out of the lake, rather than build additional sewage-based treatment.

Some watershed-based trading, however, relies on complicated ambient trading ratios, which restrict trades. The Long Island Sound nitrogen trading program in Connecticut functions more like an ambient tax than an ambient trading program. The ambient trading ratios change with distance north and east of the hotspots in Long Island Sound. As such, the price is not determined by the market, but is set by the state. Still, a tax program offers an incentive for pollution control and is more cost-effective than a strict regulation. This program is expected to save $200 million, or 20 percent over the life of the program, compared to command-and-control approaches.

While rarely used for water-pollution control in the United States, effluent charges, or taxes, have been used extensively in Europe. Some of these are combined with effluent standards, while others are used as incentives for firms to reduce pollution more than is required by the standards. Most recently, charges have been used for heavy metals.

Policies related to oil spills rely heavily on the legal system, but oil spills—in particular, the *Exxon Valdez* spill of 1989—opened the door for nonmarket valuation methods such as the contingent valuation method to become valid tools for natural resource damage assessments.

For ocean pollution, the complexities include enforcement and the vast expanses the pollution can travel over. Oil spills, toxics, and plastics pollution in the ocean are all harmful to marine life and to beach recreation. While liability for an oil spill might be obvious, sources of plastics pollution are many and diffuse.

Do the benefits of water-pollution control policy exceed the costs? The evidence is mixed. The benefits of water-pollution control policy are tricky to estimate, and policies that rely on command and control are expensive to implement. Co-benefits from air-pollution control policies further complicate the measurement of benefits. For example, policies aimed at reducing sulfur dioxide emissions from coal-fired power plants have reduced emissions considerably. These reductions have also improved water-quality conditions.

Using cost-effective policies would help reduce costs considerably while leaving benefits unchanged. Moving toward policies that utilize economic incentives will help. Water-quality trading is one step in that direction. Economic incentive approaches offer flexibility and can stimulate change.

WEBER, MAX

Born: April 21, 1864, in Erfurt, Prussia; Died: June 14, 1920, in Munich, Germany; Nationality: German; Professional Interests: political economy, social sciences, sociology, economic systems; Major Works: *The Protestant Ethic and the Spirit of Capitalism* (1904–1905), *Economy and Society* (1921–1922).

Max Weber was an influential German political economist and sociologist. His work traced the roots of capitalism from within the Protestant religion. He also examined the connections between religion, culture, and economic systems of Chinese Confucianism and Taoism, Indian Hinduism and Buddhism, and ancient Judaism. Many would consider Weber, as well as Karl Marx and Emil Durkheim, a founder of modern social science. Weber died in 1920.

Maximilian Weber was born on April 21, 1864, in Erfurt, Prussia, the oldest of six children. His father, Max Sr., a lawyer and politician, and his mother, Helene Fallenstein, well educated with strong Calvinistic convictions, created a prosperous and intellectually engaging household. Weber's brother Alfred eventually became a noted economist and sociologist as well. Weber studied law, economics, and history at the University of Heidelberg in 1882 and then at the University of Berlin in 1884. In 1886, he passed his "Referendar" examination (similar to the American Bar examination) and earned his doctorate in law magna cum laude in 1889. His dissertation focused on South European trading companies of the Middle Ages. Weber earned notoriety after he conducted research into the conditions of rural laborers in the East Elbian provinces of Prussia and recommended breaking up large estates for use by workers and as an incentive to keep workers in the area. In 1894, he accepted a position as a professor of political economy at Freiburg University. In 1896, he moved on to the University of Heidelberg.

In the summer of 1897, Weber and his father had a notable confrontation regarding Weber Sr.'s treatment of his mother. Weber's father died shortly thereafter, without the two reconciling. Weber began to suffer symptoms of a nervous breakdown, causing him to spend the summer and fall of 1900 in a sanatorium forcing him to give up his professorship in 1903. Weber slowly returned to academia as a private scholar, writing many influential works. He later helped to shape the well-known social science journal *Archiv fur Sozialwissenschaften und Sozialpolitik* with Edgar Jaffe and Werner Sombart.

At the beginning of World War I, Weber founded and managed nine military hospitals as part of the Reserve Military Hospitals Commission. During World War I, Weber's political views slowly became more public, until in 1917 he campaigned for constitutional reform of postwar Germany with universal suffrage and the empowerment of parliament. At the end of the war, Weber was asked to join the German Armistice Commission at the Treaty of Versailles as well as to help draft the Weimar Constitution. In 1919, he taught at the universities of Vienna and Munich and continued to write.

Throughout his life, Weber did not shy from either controversy or political debate. He ran unsuccessfully as a liberal Democrat for a parliamentary seat. His wife, Marianne Weber, became a leader of women's rights and Weber also publically supported universal suffrage. Their home in Heidelberg became a gathering place for intellectuals and writers.

Weber was a founder of modern sociology. He believed that a social scientist's work should be value-free; he advocated a rigorous separation of fact and value. His most famous work, *The Protestant Ethic and the Spirit of Capitalism*, is a comparative study of world religions and economic systems. In it, Weber argues that the morality of Protestantism, specifically Calvinism, is the catalyst for entrepreneurship and capitalism. The Protestant work ethic, he states, encourages people to accumulate wealth. Protestantism also encourages thoughtful, rational stewardship, which means that Protestants are likely to reinvest their wealth rather than spend it. Weber's analysis of Protestantism is accompanied by various explanations of why capitalism does not develop in places with different religions.

In another influential work, *Economy and Society,* Weber describes rationalization as a shift from value-oriented social organization and action to one of goal-oriented organization and action. He darkly describes this change as a "polar night of icy darkness" that ultimately traps human life in the control of bureaucratic organizations.

Weber's methodology and his systems of classification are also noteworthy. Weber introduced the distinction between social class (one's relationship to the market), status class (religion and reputation), and party class (political affiliations), as the three classes that work together to determine one's potential future.

Weber felt that the study of economics should also include economically relevant and conditioned phenomena, or as he described it, social economics. He advocated for interdisciplinary work between economics and sociologists.

Max Weber died in Munich on June 14, 1920, from pneumonia.

WELFARE STATE

A welfare state emphasizes programs that provide citizens with a minimum standard of living, seek to redistribute income, and bridge the gap of inequality that exists.

A welfare state contributes to short-term stability for those who meet requirements for welfare (or social welfare) programs. A welfare state may include such public programs as Temporary Aid to Needy Families (TANF), unemployment compensation, and other transfer payments, such as Social Security and Medicare, that work to aid those who meet the criteria for benefits. The effect of these programs is to redistribute equity based on taxes and transfer payments. The welfare state may also include some private benefits that employees receive from their employers, nonprofit charities, or government subsidies. One example of this is health care insurance—in which employees pay only a portion of their health care costs, with the rest being covered by the employer.

The welfare state is heavily tied to full-employment policies that are meant to support it. If more people are working, there are more people paying taxes, and some of this tax revenue can be used to support the welfare state. In addition, programs like unemployment compensation allow workers to be selective about accepting a job; this may cause some to remain unemployed longer while they hold out for a higher-paying job.

The modern welfare state is attributed to the programs of Otto von Bismarck of Germany in the 1870s. Bismarck's programs included sickness insurance and medical care, pensions, and a minimum wage. These programs helped him to win the support of Germany's working class, and by 1913, most of Germany's workers were covered by social programs. These ideas later spread to other countries, such as the United Kingdom, in the 1900s. The United States adopted welfare-state programs in the 1930s during the Great Depression.

The extent of a welfare state varies by country and region. There tends to be a more extensive welfare state in Europe than in other regions. Market economists such as the late Milton Friedman and supply-side economists such as Arthur Laffer argued that countries with an extensive welfare state have less economic growth compared to countries with fewer government-sponsored provisions. The two economists believed that low-skilled workers hurt the economy, pushing wages down and increasing unemployment rates.

Comparatively, the United States can be said to be a partial welfare state, with fewer provisions compared to European countries. The effectiveness or level of a welfare state relates to other factors, such as unemployment and fiscal policy. There are more demands on a welfare state when there is high unemployment or when the economy is struggling, such as during a recession or a depression. If a country has high debt, this generally means there is less money available for a welfare state.

The United States began to establish the infrastructure of a modern welfare state as a result of the Great Depression and the New Deal programs instituted by President Franklin D. Roosevelt. The Social Security Act of 1935 gave benefits to retirees as well as to the unemployed and disabled. Initially, the intent of the program was to help alleviate the poverty of the large numbers of people who were unemployed as a result of the Great Depression. Before passage of this act, the elderly were dependent on charity and personal savings when they could no longer physically work. The program was later expanded through the Federal Income Tax Contributions Act of 1937 in order to collect payroll taxes from people who were employed. The revenue from these taxes was to be used to fund Social Security payments to those receiving benefits.

In the 1960s, the U.S. welfare state expanded under President Lyndon B. Johnson's Great Society War on Poverty programs. President Johnson drew much attention to poverty and the standard of living in the United States; he signed Social Security Amendments in 1965, which established the Medicare and Medicaid programs. The programs aimed to provide health insurance for the elderly and the poor, and the programs were a result of years of research on poverty and income inequality. The implementation of these programs led to a further study of the welfare state, and it was realized that poverty must be addressed to help people achieve a higher standard of living.

In a modern welfare state, most social programs are created to benefit the unhealthy and the poor. Sometimes the welfare state is referred to as "workfare," because people need to meet certain requirements, such as having a job, in order to receive benefits. Workfare works best when unemployment is low. Political parties and interest groups also play a role, and some seek to reexamine the benefits that people receive as a result of the welfare state.

Today, there are many political and economic pressures on the welfare state. Conservatives favor retrenchment when it comes to the welfare state, while progressives and populists favor expansion. The conservatives fear that if unemployment becomes too high during periods of economic recession, the welfare expansion will place too large a burden on government spending. Progressives promote expansion of the welfare state in order to ensure that the social safety net covers all who are entitled.

WHISKEY REBELLION, 1794

As part of Alexander Hamilton's initiative to pay down the federal war debt, tariffs and excise taxes were used to raise money for the new United States. In 1791, President George Washington and Treasury Secretary Alexander Hamilton imposed an excise tax on whiskey, believing it to be one of the least offensive taxes possible. The tax would be used to pay off the national debt, to support road building, and to bolster the national bank, all of which these officials believed would benefit frontier areas such as Pennsylvania. Hamilton also preferred this excise tax to a further increase in tariffs, which had become the federal government's major source of income. The excise whiskey tax, however, would hit small farmers in western Pennsylvania particularly hard. The Whiskey Tax Rebellion would be the first armed challenge to the new government and its authority to collect taxes, as well as the first antigovernment military action by citizens since Shays' Rebellion in 1786–1787.

Rye whiskey was a mainstay of western Pennsylvania's Scotch-Irish farmers. Whiskey was a favorite manufactured product of grain farmers, because grain was a low-density, low-cost commodity not worth the cost of transporting long distances. Monongahela rye distilled in Pennsylvania, for example, was easy to transport down the Ohio–Mississippi River system, making its way via New Orleans and the Atlantic to the East Coast and to the taverns of Europe. When Pennsylvania was a British colony, its whiskey production had been controlled and taxed, but the remoteness of the Monongahela Valley outside Pittsburgh made it almost impossible for British tax collectors to do their work. In fact, the area had been populated by Scotch-Irish citizens who moved there to avoid British taxes on whiskey and iron. The resistance to British taxes had been part of the American Revolution, and feelings ran deep in the country and in the valley against the new government's right to impose taxes. Although the Scotch-Irish were a major segment of the nation's population and had been loyal supports of the revolution, the whiskey rebels themselves were a very small minority.

General John Neville, a local Revolutionary War general, was chosen to enforce the whiskey tax, even though he had initially opposed it. The tax schedule varied, ranging from 6 to 10 cents a gallon (a gallon of rye whiskey sold for a dollar). For months, the resistance was modeled after the colonists' resistance against British taxes. The resistance to the whiskey tax also had national support in the western counties of Maryland, Virginia, North Carolina, and South Carolina. Even within the Washington administration there was division: Thomas Jefferson opposed Hamilton on such a federal tax. The Pennsylvania Scotch-Irish mustered a militia and burned the estate of tax collector General Neville. The rebels also burned the estates of distillers who paid the tax.

This Whiskey Rebellion was the first test of the strength of the new federal government to act within the individual states. Jefferson was publicly sympathetic to the whiskey rebels, but Hamilton thought the rebellion required decisive action by the government. For months, Scotch-Irish militia roamed western Pennsylvania attacking federal agents. The predominantly Scotch-Irish frontier was split politically over the tax, with anti-tax followers in the Jeffersonian Republican Party and supporters of the tax in the Federalist Party. This political and ideological divide was an early example of a basic political split that exists to this day. The fact was that less than one percent of the area's whiskey distillers were delinquent in paying their taxes. Most were supportive of the federal government because the government had been one of the biggest purchasers of their whiskey for army rations.

The radical core of the rebellion was the local Democratic-Republican clubs. In August 1792, they held a convention in Pittsburgh to discuss options. The convention had few moderates in attendance, with the exception of Albert Gallatin, a future secretary of the Treasury under President Jefferson. Gallatin had served on the Pennsylvania constitution ratification committee, which had voiced opposition to taxes but had supported a strong federal government. This position was more consistent with that of the majority of voters. Gallatin was elected to Congress in 1790 to represent Allegheny, Washington, and Fayette counties. This congressional district included Pittsburgh and was the heart of pig iron production and use. He was elected to the United States Senate in 1793, when the Pittsburgh convention failed to obtain a solution from the federal government.

By 1794, the crisis had reached a peak, and federal agents were determined to collect the back taxes that were due in western Pennsylvania. A rebel army of 600 men was mustered at Braddock's Field, eight miles from Pittsburgh, to oppose the tax collectors. The army swelled to 7,000 as they marched on the city of Pittsburgh. The rebel leader, Revolutionary War general James MacFarlane, was killed in the clash.

While following Hamilton's advice, Washington proved as adept as always at handling these early challenges to a strong central government. Congress had already passed the Militia Act of 1792, which required a judge to deem federalization of troops necessary. In addition, the president had to issue a formal order for the rebels to stand down. Still, western Pennsylvania was the frontier and wanted total economic freedom. Washington and Hamilton reacted, federalizing an army of more than 12,000. As the federal army marched toward Pittsburgh, the insurrection fell apart, and its leaders fled to Kentucky and Tennessee. Some of the leaders were arrested and tried, but Washington pardoned the two who were found guilty of treason; further, he refused to impose any form of retribution or to succumb to the pressure of many critics who wanted him to require loyalty oaths from the rebels. Washington's popularity rose dramatically throughout the nation after his skillful handling of the Whiskey Rebellion.

The Scotch-Irish people were fiercely independent, which naturally drew them to the wild frontier areas of the new country. After the Whiskey Rebellion, the Scotch-Irish distillers in Pennsylvania moved west again to avoid federal taxes. Many left the Monongahela Valley for Kentucky and Tennessee, which would become the center of the American whiskey industry. Many Scotch-Irish stayed, however, and built banking and manufacturing empires in Pittsburgh. Elections in the following years showed strong support for the authority of the government to apply "sin taxes" like the whiskey tax. The Whiskey Rebellion had a lasting impact on America's politics and government. It actually created a political rift within the Scotch-Irish community: a group of Federalists and capitalists supported a strong federal government, and an independence-minded group supported the Jeffersonian model of more limited government. One lesson the federal government also learned was that it needed to proceed slowly on the use of its taxing authority. Few additional internal taxes were needed by 1795, as the trade tariffs that were already imposed gave the government healthy surpluses with which to pay down its debt. The federal government also responded to the western Pennsylvania protest by providing the local area with more military protection and increased road-building.

WHITE, HARRY DEXTER

Born: October 9, 1892, in Boston, Massachusetts; Died: August 16, 1948, in Fitzwilliam, New Hampshire; Nationality: American; Professional Interests: economist and U.S. Department of the Treasury official instrumental in creating the Bretton Woods Agreement.

Harry Dexter White was an U.S. Department of the Treasury official and an American Keynesian economist. He was one of the founding fathers of the post–World War II economic system known as the Bretton Woods System. This system paved the way for the West to win the Cold War, dominating the 20th century. Harry also influenced the development and design of the economic system's institutions, which included the International Monetary Fund (IMF) and the World Bank.

Harry Dexter White was born on October 9, 1892, in Boston, Massachusetts, to Joseph Weit and Sarah Magilewski—Jewish immigrants from Lithuania, which then was a part of the Russian Empire. Harry later adapted the American spelling of Weit to White and added his middle name Dexter later in life. White worked in his family's hardware business and was a first lieutenant in the infantry of the U.S. Army during World War I. As a first lieutenant, he served in the European theater of war between April 1917 and February 1919. When White returned home, he directed the American Expeditionary Force Orphan Asylum for two years. He did not begin his serious university studies until he was 30 years old. In 1922 White attended Columbia University; then he attended Stanford University, where in 1924 he received his bachelor's degree and in 1925 his master's degree. White went on to receive his PhD from Harvard University.

White taught at Lawrence University in Appleton, Wisconsin, until 1933. In 1933, Harvard University Press published White's PhD thesis, titled "The French International Accounts, 1880–1913." His PhD thesis won the David A. Wells Prize, which is awarded annually by the Department of Economics at Harvard University.

In 1934 Jacob Viner, an economist at the Treasury Department, offered White a position at the department. He became a top advisor to Secretary of the Treasury Harry Morgenthau Jr. on international financial affairs. On November 1, 1934, White became principal economic analyst in the Treasury Department's Division of Research and Statistics. This marked the beginning of his government career, and eventually led him to the position of assistant secretary. He was later sent to England to research monetary and economic questions; he met several British economists there, which led him to gain a new sense of monetary cooperation between the United Kingdom and the United States. White was also able to meet the father of Keynesian economics: John Maynard Keynes. In 1936, White became assistant director of the Division of Monetary Research, and in 1938 he became its director. He was appointed assistant secretary of the Treasury, in charge of the Division of Monetary Research. In 1941, Harry Morgenthau Jr. placed him in charge of all of the Treasury Department's international matters.

Harry Dexter White drafted the U.S. blueprint for the IMF. He also was influential in formulating the Morgenthau Plan and in developing Harry Morgenthau's monetary proposals after World War II. Once the war was over, White organized institutions of the Bretton Woods System, including the forerunner of the World Bank (International Bank for Reconstruction and Development) and the IMF. He designed those systems with the intent to avoid a repeat of the complications that had led to the Great Depression.

In 1946, President Harry Truman named White the first IMF Executive Director, although he resigned just a year later. Toward the end of World War II White had an advisor, Professor Ray Mikesell, who stated that Harry wanted a closer cooperation with the Russians. In August 1948 White was accused of spying for the Soviets and was brought before the House Un-American Activities Committee. He denied all the charges.

Many believe the stress of the hearings led to White having a heart attack three days after the hearings. Harry Dexter White died on August 16, 1948 in Fitzwilliam, New Hampshire.

WILLIAMS, WALTER

Born: March 31, 1936, in Philadelphia, Pennsylvania; Nationality: American; Professional Interests: government in economy, minimum wage, private property, libertarianism; Major Works: *The State against Blacks* (1982), *South Africa's War against Capitalism* (1990), *Do the Right Thing: The People's Economist Speaks* (1995), *Race and Economics: How Much Can Be Blamed on Discrimination?* (2011).

Walter Williams has served as the John M. Olin Distinguished Professor of Economics at George Mason University in Fairfax, Virginia, since 1980. He is the author of 10 books and over 150 publications, his work appearing in scholarly journals such as *Economic Inquiry* and the *American Economic Review* as well as popular publications such as *Newsweek* and *National Review.* He frequently appears on television and radio programs such as *Nightline, Face the Nation*, and *The Rush Limbaugh Show*. He is known for his libertarian views, including the limited role of government intervention with respect to minorities.

Walter Edward Williams was born on March 31, 1936, in Philadelphia, Pennsylvania. William's mother, Catherine, raised him in a single-parent home, living at one point in the Richard Allen housing projects. He is second cousin to basketball player Julius Erving, otherwise known as "Dr. J." After graduating from Philadelphia public schools, Williams spent two years as a taxi driver before becoming a private in the U.S. army. Williams began college as sociology major at California State College in Los Angeles before switching to economics. Although he earned a D in his economics first course, he persevered and ultimately earned his bachelor's degree in economics from California State College in Los Angeles in 1965. He received his MA in 1968 and his PhD in 1972, both in economics from the University of California, Los Angeles. Williams studied under Nobel laureates Armen Alchian and Milton Friedman. He also began a lasting friendship with visiting economist Thomas Sowell. Williams began to question whether government social programs like minimum wage and affirmative action were truly helping those in need. Williams taught for eight years at Temple University in Philadelphia before joining the economics faculty at George Mason University in Fairfax, Virginia, in 1980.

Williams's work is doubtful of the effectiveness of government social programs to promote prosperity. In his 1982 book, *The State against Blacks,* Williams argues that government initiatives such as affirmative action only serve to hurt minorities and stifle their economic progress. He writes that college admission requirements should be equal for all, and that minorities do not benefit from artificial measures designed to boost their enrollment numbers. Williams believes that substandard test performance by minorities is the result of substandard secondary education and family breakdown. He writes that the government has a monopoly on public education, which leads to low quality with a lack of competition. Government programs such as welfare reward childbirth out of wedlock, thus contributing to the collapse of black communities. PBS used his book *The State against Blacks* as the basis for its documentary *Good Intentions.*

In addition, Williams argues that minimum wage laws price low-skill workers out of the market and increase unemployment. In 1977, the Joint Economic Committee of Congress asked him to write about minimum wage. Williams reported that black teenage unemployment was lower than white teenage unemployment before minimum wage and higher after. His research also found that the Davis–Bacon Act of 1931, which required high worker wages for federally financed construction projects, was designed to discriminate against workers based on their race.

Similarly, in *South Africa's War against Capitalism* (1990), Williams argues that South African apartheid was not created for white exploitation but as a reaction to World War I, designed to encourage the hiring of higher-paid white workers. Williams again promotes his belief that capitalism without government intervention will provide the highest standard of living for all.

Williams's overall support for deregulation and laissez-faire government can be described as libertarian. Williams is one of the few scholars to defend individuals' right to sell their body organs. He continues to write a nationally syndicated weekly column that is carried in approximately 140 newspapers and on multiple websites. He regularly participates in national debates, conferences, and lectures, as well as providing expert testimony before congressional committees on public policy issues. He serves on the boards of Grove City College, the Reason Foundation, and the Chase Foundation and on the advisory boards of the Cato Institute, the Landmark Legal Foundation, the Institute of Economic Affairs, and the Heritage Foundation. He has received numerous awards, including the Foundation for Economic Education Adam Smith Award, and he is a Hoover Institution national fellow and a Ford Foundation fellow. Williams is a member of the Mont Pelerin Society and the American Economic Association.

WORKS PROJECTS ADMINISTRATION

In 1935, as part of the Emergency Relief Appropriations Act, President Franklin D. Roosevelt signed an executive order creating the Works Progress Administration (WPA). (The name was changed in 1939 to the Works Projects Administration; Congress dissolved the WPA in 1943.) The federal agency's primary goal was to put to work millions of mostly unskilled laborers who had been left unemployed as a result of the Great Depression. As the largest of the federal New Deal assistance programs enacted by President Roosevelt, the WPA provided employment in projects such as highways, parks, public buildings, and other public works. More than three million employees were paid mostly subsistence wages, working for a monthly average of $42.

Managed by Harry Hopkins, Roosevelt's close adviser and the national director for the program, the WPA was designed to provide government jobs for employable workers on government relief and give them an incentive to seek more stable work elsewhere. Both Hopkins and Roosevelt posited that the WPA could reduce the number of able-bodied "reliefers." Thus the Roosevelt administration went on to spend more than $10 billion, leaving the unemployable to be cared for by the state. According to Hopkins, it was worth it to administer the more-costly WPA as a work relief program rather than to dole out direct relief, since the WPA gave workers pride in earning an income while taxpayers received government services.

The main purpose of the WPA was to direct those most affected by the Great Depression—namely, unskilled and semiskilled workers—into various projects, including the construction of such infrastructure as dams, bridges, roads, airport runways, buildings, and schools; another parts of the WPA focused on school lunches, concerts, plays, books, works of art, and other public works. The majority of those employed worked in construction. The WPA was designed to employ 3.5 million workers at a $5 billion cost. After continual taxpayer criticism of prior agencies simply giving out handouts or overpaying for services—as did the WPA's predecessor, the Civil Works Administration—the government moved away from direct relief to low-wage work relief. The consequence was an organization that provided useful work at a relatively low cost.

The lion's share of WPA workers, roughly 80 to 90 percent, was male. However, a women's division was created to offer appropriate work and commensurate pay for women. Women's influence in this division, called the Division of Women's and Professional Projects, was much greater than the overall 12–19 percent representation women had in the WPA.

Y

YELLEN, JANET

Born: August 13, 1946, in Brooklyn, New York; Nationality: American; Professional Interests: macroeconomics, unemployment, fiscal policy, monetary policy; Chair, Federal Reserve System Board of Governors; Major Work: *The Fabulous Decade: Macroeconomic Lessons from the 1990s* (with Alan Blinder) (2001).

Janet Yellen has served the academic sector in the classroom and served the public sector as an advocate for the American people. She shared her knowledge of economics at Harvard University, the London School of Economics and Political Science, and the University of California, Berkeley, and she applied that knowledge while serving on the board of governors of the Federal Reserve System. Yellen assumed the position of the chair of the Board of Governors of the Federal Reserve System in 2010.

Janet Louise Yellen was born on August 13, 1946, in Brooklyn, New York. She graduated summa cum laude from Brown University in 1967 with a degree in economics, and she earned her PhD from Yale University in 1971. Yellen taught at Harvard as an associate professor from 1971 until 1976. She also taught at the London School of Economics and Political Science from 1978 until 1980, when she accepted a position with the University of California, Berkeley (UC Berkeley). She is professor emeritus at UC Berkeley's Haas School of Business and has served as the Eugene E. and Catherine M. Trefethen Professor of Business and Professor of Economics, also at UC Berkeley. She specializes in macroeconomics with an emphasis in the causes and effects of unemployment.

President Bill Clinton nominated Yellen as the chair of the Council of Economic Advisers in 1997, after she served as a member of the board of governors of the Federal Reserve, a position she was appointed to in 1994. Her efforts were focused primarily on the stabilization of foreign exchange rates and international trade. Her work during the 1990s helped lead her into numerous leadership positions during the latter part of the decade and into the 21st century.

Yellen was named president and chief executive officer of the Twelfth District Federal Reserve Bank at San Francisco in 2004. Her work on the current state of the U.S. economy has prompted her testimony toward guiding appropriate macroeconomic and monetary policy for the betterment of the American people. She believes that policy should improve the lives of those it governs. Her emphasis has been on promoting policy that will reduce the breadth, depth, and frequency of economic downturns as well as focus on long-term, sustainable growth over time. These policy changes are paramount in promoting a higher standard of living for the American people. Her work has emphasized understanding the disparity of wage increases over the past 30 years, at the same time that she has explored the implications of attaining education and the impact of technology on the workforce.

Yellen's contributions to the economic community are vast, as she has worked in both the Federal Reserve System and the classroom. She has written papers, taught classes, and helped shape monetary policy in the United States.

Aside from these positions, she was a member of the Council on Foreign Relations, the American Academy of Arts and Sciences, the Group of 30, the executive committee of the Bay Area Council, and a research associate of the National Bureau of Economic Research. She served as president of the Western Economic Association, vice president of the American Economic Association, and fellow of the Yale Corporation, and has worked with a number of other organizations.

After serving as vice chair since 2010, Janet Yellen was named chair of the Federal Reserve System Board of Governors in 2014, a position she will hold through January 2018. She is also chair of the Federal Open Market Committee.

Volume 1: Foundations of Economics

Preface

When I was in graduate school a professor described the subject of economics as the "clothesline of life." There were several meanings to his phrase. One, there are many ways to approach the world of economics. Two, economics is a living, breathing discipline we use to play out our lives every day. Economics is part art, part science, part history, and all human behavior. If one digs down into the subjects of life, one will find a component of economics in virtually every subject. Economics surrounds us daily. *Economics: The Definitive Encyclopedia from Theory to Practice* has been created in a way to make economics come alive. Within our four volumes, including the comprehensive glossary, document excerpts, and other appendices, *Economics: The Definitive Encyclopedia from Theory to Practice* explores all corners of economic history, the individuals who gave economics life, the economic events that have shaped our world, and the foundational concepts and ideas that make, define, and sculpt our economic world.

We began this project with several goals. Our first, and most important, was to assemble a comprehensive and varied collection of entries on economic history, personal finance, money and banking, environmental, and behavioral economics, to name a few of the subdisciplines that hang from the "economics clothesline." An extension of that first goal was to provide a comprehensive, readable, one-stop resource for the general reader as well as for students, teachers, and researchers of economics, personal finance, and entrepreneurship.

To do so required assembling a diverse collection of economics material. Contained within the four volumes of the *Definitive Encyclopedia* are the people who laid the groundwork for economics as a science, the historical events upon which economics grew, and the concepts and ideas on which they built their legacy. I strongly believe we have accomplished these goals.

Volume 1, Foundations of Economics, is the "economics clothesline." In Volume 1 we present the people, concepts, history, the events, and places and institutions on which economics is built. It includes basic economic concepts such as opportunity cost and marginal analysis. Also included are the business tycoons who shaped the early U.S. economy, such as Henry Ford and John D. Rockefeller. No book on foundations of economics would be complete without the economists who laid the groundwork for economics such as Adam Smith, John Maynard Keynes, and Friedrich Hayek. Not to be forgotten are the political leaders whose contributions to their respective economies during their lives is still with us today, including U.S. president Ronald Reagan, Great Britain's Margaret Thatcher, and the Soviet Union's Joseph Stalin.

Volume 2, Macroeconomics, is our big picture volume. As the title suggests, Volume 2 focuses on the institutions, people, events, and places that have shaped the roles and responsibilities of the economy as a whole—the macroeconomy. Volume 2 presents the different methods and ways in which economies are measured and also explores government's role in the economy. Macroeconomics is about the institutions that measure our economies, such as the Bureau of Economic Analysis (BEA) or the Bureau of Labor Statistics (BLS). Key political figures such as Winston Churchill and President Franklin D. Roosevelt are featured for their economic contributions to world history.

Volume 3, Microeconomics, takes on markets, prices, and looking at the economy under the proverbial microscope. Volume 3 presents how markets function and the institutions that allow markets to work more efficiently and equitably for both the producer and the consumer. In Volume 3 you will find the concepts, economists, institutions, and historical events along with major market events such as the transitioning of the automobile industry and the economic bubbles, such as the "dot-com" bubble, that have determined the behavior and interaction of producers and consumers in today's modern economy. In Volume 3 we explore subfields such as environmental economics with entries such as "Tragedy of the Commons," "Clean Water Act," and "Clean Air Act," along with other environmental issues. Personal finance is a highlighted subfield in the "Annuity," "Debt Credit Counseling," and "Health Insurance" entries.

Volume 4, Global Economics, is the volume of the future. Volume 4 encapsulates the first three volumes in the context of an ever-growing global economy. Barring a cataclysmic event, today's world will continue to get smaller and smaller, translating into a more global economic community. Volume 4 includes concepts such as "Comparative Advantage" and "Balance of Payments." Volume 4 introduces the reader to the individuals changing the world, such as Muhammad Yunus and his Grameen Bank. As the new rules of a global community take shape to include all of the world's 7 billion inhabitants, at the forefront of those conversations and debates are the global institutions: the International Monetary Fund (IMF) and the World Bank, along with the United Nations.

Of equal value to the teacher, student, and researcher are primary documents in economic history; a list of Nobel laureates in economics; a timeline of economic events; and a glossary. The Primary Documents section includes 27 documents, such as the Tariff Act of 1930 and the Financial Reform Act of 2010, better known as the Dodd-Frank Act. The *Definitive Encyclopedia* would not be complete without highlighting some of the most important documents that have shaped the economic landscape of the United States. The Appendix of Nobel laureates highlights those individuals who have changed the course of economics. The Timeline presents key events in the global economy from 1776 to 2016. The Glossary presents a second layer to the all-inclusive nature of the *Definitive Encyclopedia*. Approximately 1,000 additional concepts, people, and events in the Glossary go beyond the four volumes' 850-plus entries.

Throughout my career in economics and economic education one of my main concerns has been that economics often has been presented as a subject beyond the scope of the average reader. In compiling *Economics: The Definitive Encyclopedia from Theory to Practice* we took aim at that notion head-on. Our goal was to bring to both the general and experienced student of economics a readable source to better understand the economic world around them. I strongly believe we have succeeded in this goal.

Of course, a project of this magnitude would not be possible without a team of highly dedicated contributors. I owe a huge debt of gratitude and big thank-you to the contributors without whose efforts this project would not have succeeded. My team of contributors possessed the quality and expertise needed for this project. As some of the best college professors and high school AP economics teachers anywhere, they represent all that is good about economic education. I am humbled they would give of their precious time to be part of the team. I owe them a major debt of gratitude. I owe a debt of gratitude as well to Jillian Davidson for her research and editing assistance.

I would like to thank Brian Romer for bringing me onto this project and then passing the baton into the capable hands of Hilary Claggett, Patrick Hall, and the rest of the ABC-CLIO team who had a hand in this project's development. Thanks for making us look good. I also need to thank my many colleagues, students, and friends who also provided support, feedback, and a kick in the pants when necessary. Most of all I need to thank my family and friends for putting up with me during this time. There were times I was a bit like the candy bar commercial. I owe a big thanks to each and every one of them for their patience and understanding. Finally, I dedicate this project to my mom and my four daughters—Branda, Laura, Jillian, and Mary. They say behind every successful man is a woman. Well, I don't know about being successful but I do have five very precious women behind me. This is for you.

David A. Dieterle

Introduction to Volume 3: Microeconomics

The next time you make a trip to your local grocery store, play a little game. Take a moment to look at the variety of products you purchased and ask yourself, "How did they know I was going to come into this store for these items at this minute so that they had the items on the shelf for me to purchase? I did not phone ahead or place my order by email; yet when I arrived my items for purchase were here waiting for me. How did they know?" The answer might surprise you. Then again, this being an economics essay, maybe not. The answer: the miracle of markets.

Adam Smith called it the "invisible hand." Alfred Marshall called it "the scissors." However one describes it, the powers of the market are insurmountable. The market may lose a game or two early on, but in the end the market will always win out. That is why the term *market forces* is so powerful. The market is a force to be reckoned with daily. It will always get its way or serious economic consequences will result.

The power of the market lies in its simplicity. Unfettered (we will return to this in a moment), the power of the market is in the information it provides the market participants: the buyer and the seller. The market provides an economic traffic light. It tells both buyers and sellers when to go, when to slow down, and when to stop.

Before we get too far ahead of the story, let's define a market. A market is any transaction that includes a buyer and a seller. Every transaction, from exchanging toys with the neighbor as a child to global exchange rate transactions, takes place in a market. Markets are everywhere, whether we are aware of them or not. We participate in several markets a day. Every market has three components: a buyer, a seller, and a market price.

An economy is made up of many markets. Some are at the macro level, including the product, resource, financial, and foreign markets. Within these macro markets are literally thousands of smaller markets, each with a seller, a buyer, and a market price. It is important to point out that a "smaller" market is a relative distinction. Within the macro's resource market is the labor market. By size of participants, the labor market is hardly small yet it is only one component of an economy's total resource market available to producers. From the study of these many smaller markets we get the term *microeconomics*.

In any market, when a buyer and seller agree on an acceptable value for the exchange to occur, they have arrived at a market price. The market price gives the buyer important information for that market. It tells the buyer that the seller is willing and able to produce the good at that price. It provides the buyer comparable value information with other products. Knowing a true market price informs the buyer about the opportunity cost and trade-off value of the product. In return, the market price informs the seller about the willingness and ability of the buyer to purchase the good or service. It also provides the seller with valuable opportunity cost and trade-off information in the allocation of the resources necessary to produce the good or service. The market price is the traffic signal of the market. It conveys to both buyers and sellers when the allocation of resources are proportionately allocated to the willingness and ability of buyers to exchange their money for the product. The market price indicates “go,” “slow,” or “no” in allocating resources in that particular market.

One final, critically important point is that the market price provides this information regardless of whether the buyer and seller know each other. The last time you bought a loaf of bread, did you know the farmer who raised the wheat, or the miller who ground the wheat, or the baker who baked the bread, or the delivery person who brought the bread to the store, or the store manager or clerk who put the loaf of bread on the shelf just for you? We might know one or two of the individuals in this supply chain but almost certainly not all. Those within the supply chain probably don’t know everyone involved. The miracle of the market is that all of these individuals have faith that the market price will accurately reflect buyers’ willingness and ability to exchange their money for that loaf of bread. It is Adam Smith’s invisible hand truly at work.

But what happens to markets when the market price is not allowed to function properly and does not give accurate market information? What actions of buyers and sellers occur when there is inaccurate market information? When the market gets distorted through a party other than the buyers and sellers involved in the transaction, inaccurate information produces other-than-optimum market results.

Market distortions appear when a third party, usually the government, makes the decision to intervene in the market transaction process between buyers and sellers. Market distortions are overt decisions by a third party to interfere with a free market transaction. Either the third party believes the market price is too high or that it is not high enough. In both cases, the decision to intervene changes the information buyers and sellers receive from the new set price.

If the third party wants to benefit the buyers, it will intervene with a price ceiling. A price ceiling tells both buyers and sellers that the set price for the good or service is below the market price. This move makes for happy buyers, and so many more buyers will enter the market. Sellers, on the other hand, will not be so happy. The lower price discourages some sellers from being in the market, so they either exit the market or don’t enter at all. This new information results in many more happy buyers who now want to participate in the market. However, the sellers are unhappy, so this new information results in fewer sellers. The market result of the price ceiling intervention is a shortage of the product—too many buyers and too few sellers. Rent controls imposed by cities are a prime example of a price ceiling and the resulting shortage.

The other market intervention is when the third party believes the market price is too low. In this case, it will counter with a price floor. Again, a price floor informs buyers and sellers that the market price is unacceptable, but for a different reason. A price floor is a guarantee of a minimum price to the seller regardless of the market conditions. The price could be more, but it will go no lower than the price floor. Price floors make the sellers very happy. The information they receive from a price floor is that they can produce all they are able to and sell it at a guaranteed price. Potential sellers recognize the opportunities and enter the market, resulting in many more sellers. The buyers, however, are not as happy. They know they will have to pay a higher-than-market price for the product. Some will find substitute products and leave the market. The new nonmarket price information creates a market with many more sellers producing more than the buyers who remain are willing to buy, resulting in a surplus. Two popular examples of a price floor are agricultural price supports and minimum wage. In both instances, surplus agricultural product and labor result.

Finally, there are times when the buyers and sellers do not play nice with each other and a referee is necessary. The referee is usually the government, which sets rules to encourage the two parties to play fairly. The breadth and depth of government's role as a referee has been and always will be debated ad nauseam. However, there are instances when either the buyers or the sellers need a credible court system to protect them from those who can't play by the rules. This is especially true in market economies, and private property is the cornerstone. Only with a highly credible court system and rule of law to protect the property rights of both buyers and sellers can an economy function and reach its highest potential. Peruvian economist Hernando de Soto suggests that the lack of a credible court system to protect the rule of law and property rights is a key distinction between developed and developing nations.

Markets are the engines of any economy. Market forces are just that—forces. Throughout history, nations and both economic and political movements have tried to harness these forces and have ultimately lost. Microeconomics is the study of how an economy can get the most efficient and optimum allocations so that those economic engines operate to their maximum potential.

As you explore the world of microeconomics, may the market force be with you.

A

AFFORDABLE CARE ACT CASES

It is rational to assume that virtually all Americans will enter the health care market at some time in their lives. In addition, it is safe to infer that without health insurance (the financial means to pay for products and services in the health care market) many Americans will experience economic hardship during this exchange. Some will not be able to pay at all. For them, the products or services are provided without cost. The cost is shifted to those with the means to pay. Thus, the consequences of this market on the nation are to economically burden the individuals who have the ability to pay and redistribute income to pay the cost of health care for those who cannot. As in the case of Social Security, the authority of the federal government to attempt to remedy financial shortcomings and aid the general welfare comes into question with *Health and Human Services v. Florida et al*. This case was a combination of two other cases, all three of which posed fundamental constitutional questions. The Supreme Court viewed this case not in terms of whether it was good or poor public policy but rather from the perspective of whether Congress had adhered to constitutional principles. The court upheld the power of Congress to change the market of an economic good—in this instance, the health care market—by requiring most Americans to purchase health insurance.

Case Summary

There is an adage that history tends to repeat itself; however, people learn little from history and in the future will repeat the arguments of the past. This was a case where the United States headed straight back to the future. In both *Pollock v. Farmers' Loan and Trust Company* (1895, income tax) and *Helvering v. Davis* (1937, Social Security tax), when government exercised its taxing power, the debate began anew. In 2010, Congress passed the Patient Protection and Affordable Care Act (ACA). Congress crafted this piece of legislation and the accompanying taxes to deal with negative externalities and social issues related to the health care market. This sparked a national debate on the appropriate role of government within the market system as well as a lively discourse on what constitutes taxes, commerce, and states' rights.

Historically, the roots of health care in the United States were in private enterprise, subject to the rules of the marketplace. The majority of the nation's health care infrastructure was owned by private companies, either for profit or nonprofit. Health care was delivered through practitioners in medical fields that, over the years, have increased and specialized. These providers functioned within a market system and were vital in promoting the general health and well-being of citizens. Any intervention deemed appropriate for the government was restricted to state legislatures. Two centuries later, this structure has evolved into a joint effort, both public and private. The facilities and practitioners have remained mostly private. The unique factor that differentiates this market is the means by which payment is made. Today, this is known as health insurance. The time when a physician could be paid with a chicken and Aunt Sophie's apple pie has mostly disappeared. The health care market and the health insurance industry are inextricably entwined. Private and public health care facilities and insurance companies exist together. Currently, government programs provide the majority of health insurance. These include Medicaid (government health insurance for the indigent); Medicare (government health insurance for the elderly); Children's Health Insurance (government health insurance for indigent children); TRICARE (civilian health benefits for military personnel, retirees, and their dependents); and the Veterans Health Administration (government health care for disabled veterans). Most Americans not covered by these programs purchase health insurance through their employers or other private companies. In all cases, whether private or public sources, the choice to purchase insurance had always been up to the consumer. This free entry into the market changed with the passage of the ACA.

The cost impact of the existing mixed public-private system is controversial, but what remains constant is that health care as a percentage of the U.S. gross domestic product (GDP) is substantial. From a market perspective, this system of third-party payment removes the consumer from the role of main determinant affecting the cost of products and services. Instead, government health insurance providers reimburse at rates that may not reflect the natural equilibrium of the market. Add to this other medical factors, such as higher-priced technologies, more extensive diagnostic testing, and new treatments with various nonmedical practices, and the result is cost shifting from government rates to higher rates for the same services from private payers. As a consequence, the overall cost of health care in the United States has increased.

In March 2010, the ACA became law, creating considerable changes in health insurance. The goals of the act included making affordable health insurance available for all Americans and reducing the costs of health care for individuals and the government. It proposed mandates, subsidies, and insurance exchanges as mechanisms to reach these goals. The main tools for increasing insurance coverage were creating state-based insurance exchanges and expanding Medicaid eligibility. A central component of this legislation was the health insurance mandate, requiring all Americans to buy health insurance or pay a fine for not participating.

Soon after the ink dried on President Obama's signature, Florida and 25 other states, two individuals, and the National Federation of Independent Business (NFIB), among others, filed lawsuits against the federal government challenging the constitutionality of the individual mandate. They claimed that the expansion of Medicaid, wherein the states either followed federal directive or lost their original money from Washington to provide health care for the indigent, was unconstitutional. Judge Roger Vinson of the U.S. Federal Court for the Northern District of Florida agreed with the plaintiffs that the commerce clause of the Constitution limits Congress's authority and declared the entire law unconstitutional. This case, along with others, was appealed to the Eleventh Circuit Court of Appeals, where a three-judge panel affirmed Judge Vinson's decision regarding Medicaid and the individual mandate, claiming that it exceeded Congress's authority as enumerated in the Constitution. This set the stage for a showdown in the U.S. Supreme Court.

The Supreme Court took the appeal and combined three cases: *Florida et al. v. Department of Health and Human Services et al.*; *National Federation of Independent Business et al. v. Kathleen Sebelius, Secretary of Health and Human Services, et al.*; and *Department of Health and Human Services et al. v. Florida et al*. The responsibility of the Roberts Court in this case was to determine whether or not Congress had exceeded its constitutional powers by requiring the individual mandate and whether the requirement to the states to expand Medicaid or lose funding was coercion. In addition, there was discussion of whether or not the right to sue the government over a tax before the tax had been paid was even admissible under the Anti-Injunction Act of 1867.

The Court scheduled an unprecedented six hours of oral argument (a normal case would take only one hour) in an effort to anticipate the complexity and significance of this case.

The justices listened to and questioned seven different attorneys. At the end of the day, the Court ruled that the Anti-Injunction Act did not bar the Court from hearing this petition. It also found that Congress does have the authority under the commerce clause and the taxing and spending clause of the Constitution to require that most Americans purchase health insurance. Finally, the Court ruled that Congress did exceed its powers of federalism when it pressured states into the conditions imposed on them if they did not expand Medicaid, as proposed by the guidelines of the ACA.

Chief Justice Roberts wrote the majority opinion. He stated clearly that the Court did not impose an opinion as to the law itself but rather determined if the law was constitutional. With regard to the mandate, the Court held that the goal of affordable health coverage would not be obtainable without nationwide participation. This was how insurance companies functioned, having enough healthy participants to cover those in need. This provided for the general welfare and was within the realm of Congress's power. However, the idea that states could be coerced into compliance with federal mandates by withholding funds for crucial services was indeed a violation of states' rights.

In politics, a national crisis is often seen as an opportunity to pursue an agenda. This was not an easy agenda. Health care never has been. But neither was the 16th Amendment or Social Security, and some would argue that the crisis for that legislation was even more acute. In his dissent, Justice Kennedy, along with Justices Scalia, Thomas, and Alito, stated that the commerce clause of the Constitution did not permit Congress to create commerce where it did not already exist but rather to regulate it where it was already happening. They thought that the framers of the Constitution would not condone this type of intrusion upon the market. Scalia argued that mandating that all Americans purchase funeral insurance because eventually we would all die was absurd. The Constitution protected the right of consumers to decide what products or services they would purchase, and Congress did not have the police power to preempt this right.

There has been much political discourse regarding health care. There will be much more. What is clear is that this case established as constitutional the most significant health care reform in a generation.

AGRICULTURAL DEPRESSION AND THE DUST BOWL, 1930s

By 1933, the Great Depression had spread to all parts of the U.S. economy and throughout the world, but farming would be hit harder and longer than the general economy. In particular, the high plains of Texas, Oklahoma, New Mexico, Kansas, Colorado, and parts of other midwestern states would see steep economic declines. Windstorms and soil erosion affected more than 100 million acres of farmland, and more than a million farmers lost their farms.

Although the Great Plains are prone to drought and even dust storms, the climatic conditions of the 1930s were considered a 300-year event. Farmers had suffered for most of the early 1930s as rapid deflation destroyed crop prices and the Depression gripped the world. Many were on the verge of bankruptcy when the drought and winds came in the late 1930s. The soil-laden winds not only took away precious topsoil but also destroyed homes and equipment. Farmer bankruptcies soon drained the remaining small-town banks that had proved resistant to the industrial downturn; in the late 1930s, small-town banks were failing at a higher rate than urban banks.

The devastating combination of economic and climatic conditions destroyed millions of lives and caused a great migration to California. More than 2.5 million residents migrated out of the Great Plains. State and local governments were in no financial position to handle such a huge interstate migration, and in the places where they relocated, the local residents often resisted these "Okies." The homeless migrants were often forced to settle in camps. Early on, California was a favored destination, but by the late 1930s most migrants were going north to the factories. By the late 1930s, the agricultural depression had become a unique combination of problems, requiring government involvement at many levels.

The roots of the Dust Bowl go back to the farming boom of the late 1920s. Higher crop prices throughout the world brought more American land into cultivation. The amount of land under cultivation tripled between 1925 and 1930. Rapid cultivation, at times, led to poor soil management. In 1931, a series of droughts spread throughout the plains states. In 1933, a wave of windstorms started to hit the American plains. These storms would often last days, moving millions of tons of soil east. The dust often covered eastern cities and included unusual phenomena, such as red snow in New England. The year 1935 was famous for its so-called "black blizzards," which occurred throughout the Dust Bowl. These black blizzards turned day to night and reduced visibility to five or six feet. Many died of dust pneumonia.

In 1932, peanuts dropped to under three cents a pound. The first response of Congress was to offer low-cost loans to peanut growers, but this did little for the small farmers and not much for the large ones. The New Deal Congress of 1933 tried to introduce direct price supports for peanuts, but this was a failure. The New Dealers saw the farm and peanut problem as a supply/price issue. So the next step was to restrict production and pay farmers not to grow. To finance the payments, taxes were placed on the peanut processors. The program ended when the Supreme Court ruled the processing tax unconstitutional. In general, price support and management programs had mixed results at a very high cost. Another problem of government interference was the passing of high tariffs, which other countries joined. Tariffs had minimal effects on industrial production but did force crop prices down and reduce exports.

By 1933, the economic impact of the lack of crops and soil erosion was overwhelming; the problem of a shortage of animal feed followed. Land price deflation and bankruptcies brought more economic problems. Some farmers abandoned their farms. President Franklin D. Roosevelt was forced to fight the Depression on two fronts. His agricultural program was aggressive; some parts of it were eventually deemed unconstitutional. In 1935, the Natural Resource Conservation Service was established to address soil conservation. In addition, the Federal Surplus Relief Corporation (FSRC) was formed. With meat prices falling and production costs rising, the FSRC purchased six million pigs to stabilize prices. The meat was packed and distributed to the poor. In 1935, Roosevelt formed the Drought Relief Service, which purchased cattle (most were unfit for human consumption) for as much as $20 a head to save farmers from bankruptcies.

The Roosevelt administration tied its employment programs to farm relief programs with the Civilian Conservation Corps, which consisted of men between the ages of 18 and 26, selected from the public welfare rolls. The men were relocated to camps with free room and board. They earned $30 a month, of which $25 was sent back to their families. Enrollees served six months and could re-enroll up to two years. By the time the operation concluded in 1942, more than 3 million people had served. One of the main projects was the planting of tree wind breaks throughout the country. More than 3 million trees were planted. In addition, the corps trained farmers in soil conservation and antierosion practices. The government also paid farmers a dollar an acre to implement these programs. It is estimated that these practices reduced wind erosion by 50 to 70 percent. Farmers also shifted away from corn and wheat to animals and hay to diversify their farms.

AIR POLLUTION

Air pollution typically results from negative production externalities where some activity like driving, generating power, or manufacturing creates a spillover that affects third parties. Excessive levels of airborne chemicals are typically broken down into two categories: criteria pollutants (e.g., lead, ozone, sulfur dioxide) and toxics (i.e., carcinogens). Both can cause adverse health outcomes and other harmful impacts like limestone deterioration, crop damage, and unsightly skylines. Unpriced in markets, these negative effects offer prime examples of market failures or incomplete markets as their producers do not take the external harm into account in their decision-making.

The resulting overproduction of air pollution also has textbook remedies, including conventional command-and-control (CAC) regulations, Coasian property rights–based approaches, and Pigouvian-style emissions taxes. Rigid CAC mandates traditionally dominate air pollution policy. They control pollution by regulating the technologies used to emit or abate (e.g., catalytic converters, smokestack scrubbers) or by setting performance standards (e.g., New Source Performance Standards, ambient ozone concentration limits). Most notable of these efforts is the 1970 Clean Air Act (CAA) and its subsequent amendments. Significant reductions in emissions and improvements in air quality in the United States followed many of these regulations.

Incentive-based approaches like emissions charges or tradable emissions permits are increasingly popular alternatives to CAC for air pollution control. Permits and charges have different strengths and design issues, although in principle either can achieve efficient air quality. Tradable permits or cap-and-trade programs serve to create markets and promise cost-effective abatement. The theoretical advantages of this approach to curbing air pollution actually got tested when the SO_2 Trading Program of the 1990 CAA Amendments was implemented. (SO_2 stands for sulfur dioxide.) This cap-and-trade program was successful in both environmental and economic terms. Southern California also successfully implemented an extensive NO_x cap-and-trade program, the Regional Clean Air Incentives Market (RECLAIM).

Basic regulatory tools of permits, charges, or standards are applied to air pollution emissions or ambient concentrations. Permits, tradable or not, target quantity controls, whereas charges address prices. Standards-based approaches typically mandate technologies for emitting or abating or set thresholds for emissions or ambient concentrations that might require additional efforts to attain. Standards have proven popular among policymakers despite the disconnect with the fundamental nature of air pollution externalities. Restricting polluters' choices is an inefficient substitute for aligning their private costs of pollution with social damages.

The economics of air pollution control distinguishes between uniformly and nonuniformly mixed pollutants. Lower-atmosphere pollution involves nonuniformly mixed pollutants, where the emissions' harm depends on their source location. Cost-effective control policies for these pollutants require spatially differentiated rules or penalties (and typically dispersion modeling to predict source-specific impacts at one or more receptor sites).

Measuring the economic value of air pollution damage helps us to understand the scope of the problem and design policy solutions. For example, Pigouvian taxes derive from these marginal damage estimates. Some of the earliest research in nonmarket valuation involved air pollution. Economists frequently use hedonic pricing to identify the implicit value of air quality improvements from variations in housing sale prices. Another revealed preference method, averting behavior, measures economic value by observing how people invest in things like air filters to avoid pollution damage. Economists also use the contingent valuation method to directly measure the value individuals place on air quality improvements. Recent valuation work has emphasized responses to air quality variation across markets in a general equilibrium sense (e.g., people's willingness to pay for cleaner air may change after they relocate and housing prices change in response to air quality changes).

For nonuniformly mixed pollutants, this local variation in air quality implies that the damage caused by emissions depends on their time and place as much as the quantity emitted. Properly designing a Pigouvian tax scheme or a permit market to account for this spatial and temporal complexity can complicate matters. Cap-and-trade allows pollution in some areas to rise, halting the SO_2 trading market. Cost-effective policies, possibly leading to localized air pollution hot spots, pose thorny environmental justice considerations, especially in light of how people cluster nonrandomly. Recent studies, however, find no evidence that minorities or the poor fared worse under the SO_2 or RECLAIM trading schemes.

Polluters respond to changes in air pollution regulations by reducing emissions and also by relocating their activity. Regions with stricter regulations under the CAA see business move to locations with lower restrictions, which act as pollution havens. Grandfathering or exempting older technologies may enhance political feasibility of some regulations, but it also results in more inefficiencies and environmental damage. The flexibility under cap and trade facilitated switching to low-sulfur coal and shifting pollution control efforts to plants with lower abatement costs. As expected, innovation under CAC focuses on reducing compliance costs (e.g., scrubbers with lower operating costs) while innovation under cap and trade advances environmental effectiveness (e.g., better removal efficiency for scrubbers).

Producing information as a public good has also been used to address air pollution externalities. Local air quality advisories, for instance, both inform averting behavior and offer opportunities to voluntarily curb emissions on peak days. Unsurprisingly, the strongest behavioral impacts occur for sensitive populations reducing exposure, while altruistic emission reductions are harder to detect. The Toxic Releases Inventory informs the public about firms' toxic air releases, letting them adjust their home-buying choices or investment decisions to avoid toxic assets.

Air quality trends reflect the idea that, despite the growing scale of economic development, firms can shift to greener activities and the dirty industries that remain can operate more cleanly. The frontiers of air pollution control involve difficult challenges, such as better addressing mobile sources, air toxics, indoor air, and interactions among various pollutants (e.g., NO_x and SO_x, criteria pollutants, and greenhouse gases) and greater cooperation among regulatory regimes.

Economic analysis shows how major efficiency gains can be achieved through adopting incentive-based policies. Yet these approaches are limited in practice, especially where transaction and information costs are high. Moreover, as air pollution remedies initially focused on cleaning the air, and then reformed to do so more efficiently, they now seem to be under increasing pressure to do other things, like advance equity, jobs, and climate change goals.

AKERLOF, GEORGE

Born: June 17, 1940, in New Haven, Connecticut; Nationality: American; Professional Interests: social economics, Nobel Prize (2001); Major Works: "The Market for 'Lemons': Quality Uncertainty and the Market Mechanism" (1970), *Animal Spirits: How Human Psychology Drives the Economy, and Why It Matters for Global Capitalism* (2009).

George Akerlof is known for his work in growth theory and how markets work. As a Keynesian economist, he had a unique perspective, emphasizing the social aspect of economics. His economics is interdisciplinary in scope, incorporating sociology, psychology, and social psychology into his economic thought and writings. Examples of the topics he popularized in his work and writings are looting and bankruptcy. He won the Nobel Prize in Economics with Michael Spence and Joseph Stiglitz in 2001 for their work on asymmetric information in markets.

George Arthur Akerlof was born on June 17, 1940, to a Swedish father and German-Jewish mother in New Haven, Connecticut. His father, an accomplished chemist, relocated on several occasions, finally settling in Princeton, New Jersey, where young Akerlof spent his formative school years. While in elementary school, he remembers his first insights into the world of economics. During a period when his father was unemployed, Akerlof realized there was a spin-off effect by which others would also lose their jobs, resulting in less money being spent in the economy. Even at an early age, he realized that this domino effect would create an ever-shrinking economy. Young Akerlof had had his first encounter with Keynesian economics.

Growing up during two great American events, the Great Depression and World War II, Akerlof had a very inquiring social perspective as a young man. His interests ranged widely in the social sciences from history to economics. His brother, who frequented the lab with their father, followed in their father's footsteps to become a scientist. Such was not the path for young George Akerlof.

His interests and academic intrigue led his studies in the direction of economics and the social sciences. Contrary to his family's advice to pursue a career in law, Akerlof went to Yale and excelled in his studies as a young economist. He received his bachelor's degree from Yale in 1962. He continued his graduate studies in economics, earning his PhD at the Massachusetts Institute of Technology (MIT) in 1966. He accepted a position at the University of California, Berkeley, receiving tenure in 1969. It was during this time at Berkeley that he wrote "The Market for 'Lemons,'" which would later be the work on which his Nobel Prize was based.

In 1973 and 1974, Akerlof served on the Council of Economic Advisers as a senior economist during President Nixon's presidency. Due to his lack of a research background, lack of ability to write like a bureaucrat, and lack of loyalty when it came to party politics, he considered himself ill-suited for the position. However, professionally, he considered the experience quite rewarding, broadening his skills in the areas of both labor economics and empirical economics.

Having failed to receive a promotion to full professor at Berkeley, Akerley served on the Federal Reserve Board in Washington, D.C., for a year. He then accepted a position at the prestigious London School of Economics. During his appointment at the London School, he was the Cassel Professor of Economics with Respect to Money and Banking.

Upon his return to Berkeley, where he still had a faculty appointment, Akerley's research focus changed. He had previously focused on the macroeconomic impact of microeconomic structures, including asymmetric information and jobs. His research now addressed issues such as fairness and the social traditions regarding unemployment. The paper he wrote and presented on involuntary unemployment led to his interest in sociology, which led to additional writings on economic theory with a sociology base.

Several theories and ideals were made popular by Akerlof through his writings. One was "identity economics" as discussed in the *Quarterly Journal of Economics* (2000). The topic of looting was addressed in "The Economic Underworld of Bankruptcy for Profit" (1993), which he coauthored with Paul Romer. His paper "Efficiency Wage Models of the Labor Market" was coauthored with his wife and fellow economist, Janet Yellen. Continuing his integration of the social sciences with economics, Akerlof and coauthor Robert Shiller proposed a macroeconomic framework that incorporates human behavior in their book *Animal Spirits*. Incorporating all the idiosyncrasies of human behavior, they explore economic policy issues joining economics and psychology.

During his career as an economist, George Akerlof was honored with many prizes, awards, prestigious fellowships, and positions. His accomplishments include the Lawrenceville Medal, serving as the nonresident senior fellow at the Brookings Institution, the Guggenheim Fellowship, the Richard and Rhoda Goldman Distinguished Professor in the College of Letters and Science, studying as a Fulbright fellowship scholar, and serving as a fellow of the Econometric Society and a fellow of the American Academy of Arts and Sciences.

The Nobel Prize in Economics, the most prestigious honor in economics, was bestowed on Akerlof in 2001. The prize was awarded jointly to George Akerlof, Michael Spence, and Joseph Stiglitz for their analyses of the asymmetric information nature of markets. The study for which Akerlof is most noted is his previously mentioned study on asymmetric information in reference to the used-car market. "The Market for 'Lemons': Quality Uncertainty and the Market Mechanism" discusses how imperfect or asymmetric information in the market for used cars creates market failures and alters behavior in consumers. This Nobel-honored article was first published in the 1970 *Quarterly Journal of Economics.*

Akerlof has served as the Koshland Professor of Economics at the University of California, Berkeley. He is married to a fellow economist, Janet Yellen, who serves as current chair of the Federal Reserve Bank's Board of Governors and is a professor of economics at the University of California, Berkeley. His son, Robert, currently serves as postdoctoral associate in applied economics at his father's graduate alma mater, MIT.

ALTERNATIVE ENERGY

Alternative energy is a catch-all term that encompasses any new form of energy generation used or promoted in order to avoid the negative consequences of energy forms currently in use. Historically, there has never been a perfect energy source. All forms of energy production have exhibited some negative consequences, be they bads such as waste and garbage outputs or negative externalities including air pollution and unpleasant visual effects. The search for an alternative energy source that alleviates the most harmful negative consequences of whatever energy source is currently predominant has been an ongoing quest.

The first alternative energy source can be considered to be coal, as a substitute for wood. Prior to the Industrial Revolution, wood was prevalent, cheap, and easy to burn, but its overuse devastated entire forests in Europe. In addition, burning wood in small, often windowless abodes led to pollution and safety hazards. At different times in history, coal, whale oil, and petroleum have all been seen as alternative energy sources and as solutions to then-prevalent energy problems.

The most popular alternative energy sources today are solar power (including photovoltaics and solar thermal power) and wind power. They are considered alternatives to fossil-fuel-based energy generation (from coal, petroleum, and natural gas), which predominate worldwide energy production at the start of the 21st century. Both solar and wind power solve what is seen as the most prevalent negative consequence of fossil-fuel-based energy generation: air pollution. This includes air pollution from chemicals, particulate matter, organic compounds, toxic materials, and the emissions that lead to climate change.

Solar and wind power are also popular because they are renewable sources of energy production and so do not suffer the negative consequence of diminishing supplies. They are also domestic sources of energy production and so are not dependent on imports from what may be hostile countries. Finally, solar and wind power have the technical capability to be distributed, meaning they are what is sometimes referred to as decentralized energy generation sources. They can be placed on individual homes and in small areas and do not rely on large, single generation stations that can be susceptible to large-scale blackouts, terrorist attacks, or other centralized vulnerabilities.

Other alternative energy sources that are popular today include geothermal, hydrogen, fusion, algaeoleum, and tidal power production. Geothermal, algaeoleum, and tidal power are all renewable energy resources, and so they relieve the negative air pollution consequences of today's fossil-fuel-based energy production techniques. They are also, for the most part, domestic-based energy resources and so help to alleviate national security concerns. None of them are necessarily decentralized forms of energy generation, however, and their relative technical immaturity (as compared to solar and wind power) is a drawback.

Hydrogen and fusion are not officially renewable energy resources. Hydrogen could be considered a renewable if a renewable energy source was used to power the electrolysis process involved in production, but this is not always the case. While both hydrogen and fusion may be domestic-based energy resources, they are based on relatively immature technologies and so suffer from that drawback as well.

There are some renewable energy technologies that are only controversially considered alternative, and they include nuclear power and hydropower. Both nuclear power and hydropower are emission-free and so alleviate the most common negative consequence of fossil-fuel-based energy production: air pollution. However, they suffer from other environmental problems that make them unattractive to some advocates of alternative energy solutions.

Nuclear power produces highly radioactive wastes that must be stored and safely disposed of for long periods of time, and hydroelectric power traditionally comes from large dams that block free-flowing rivers and disturb natural riverine ecosystems. Newer forms of smaller, run-of-river hydroelectric plants avoid the negative consequences of large dams and reservoirs, but their potential physical implementation is limited, and so they will never serve as the predominant solution to worldwide energy needs. Nuclear power and hydropower, therefore, as with most alternative energy sources, solve some problems but not others. In the end, the bottom line remains that there still is not a clear winning alternative energy solution.

The viability of any particular alternative energy source is also greatly tempered by practical implementation considerations. Large-scale switching to any of the alternative energy solutions mentioned would be extremely costly. Capital costs would be incurred in building the new generation plants (and retiring the old fossil-fuel-based plants, especially if they were to be retired early), and it is likely that energy distribution mechanisms (for example, the electricity grid or the network of automobile refilling stations) would have to be revamped or entirely rebuilt as well. Such switching costs are not given as much attention in the academic literature (or the press) as the basic R&D and generating costs for producing alternative energy, but they are likely to be considerable and would hamper efforts to switch to any true alternative energy solution before the technology and benefits of doing so are absolutely certain.

This becomes a bit of a chicken-and-egg problem. In order to switch to an alternative energy solution, more consumers need to demand it to make the switch cost-viable. But until the alternative energy solutions are cost-viable, few cost-conscious consumers will demand them. Overcoming the high burden of substantial switching costs will be difficult for any single potential alternative energy solution or any proposed combination of solutions.

This implies that, as has historically been the case, alternative energy solutions tend to penetrate the market slowly, over many decades, and often in companion with traditional energy solutions. They rarely disrupt entire markets but instead slowly infiltrate them. Alternative energy solutions, when developed, are long-term goals, not short-term salvations.

AMERICA INVENTS ACT OF 2011 (LEAHY-SMITH ACT)

The America Invents Act of 2011 updates the patent system to encourage innovation, job creation, and economic growth. The last major patent reform was the Patent Act of 1952. The America Invents Act of 2011 was sponsored by House

Judiciary Committee chairman Lamar Smith (a Republican representative from Texas) and Senator Patrick Leahy, a Democrat from Vermont. On September 16, President Obama signed the America Invents Act of 2011 into law.

Patents encourage innovation and business growth, providing inventors and innovators protection from duplication and copycat theft. The act helps the nation's innovators and job creators, who rely on the patent system to make new products. The act implements a first-inventor-to-file (FITF) standard for patent approval and creates a postgrant review system to filter out bad patents.

The America Invents Act affects three main parts of the economy: job creation, patent office reforms, and legal reform. For job creation, the act protects the rights of inventors for their original inventions and encourages business growth by speeding up the patent process so that entrepreneurs and innovators can quickly turn their inventions into businesses. The adoption of the FITF system ends the need for expensive discovery and litigation to establish priority dates while also ensuring priority dates through simple and inexpensive provisional applications.

The act also builds on the Bayh-Dole Act, which permits universities and small businesses to keep title to their inventions in exchange for fulfilling a series of obligations: disclosing the invention to the federal agency funding the research, electing to retain title, and filing patent applications. The 2011 America Invents Act adds extra patent protections to the previously mentioned Bayh-Dole Act while also changing various timing requirements, such as the contractor having to file a patent application within one year. The America Invents Act also assists the Patent and Trademark Office (PTO) in addressing the backlog of patent applications.

Its 15 percent surcharge (which became effective September 26, 2011) aided the PTO's hiring of new examiners and other personnel. The act also provides some relief to patent owners to practice their inventions. Before this act, failure to mark the product as patented meant the patent-marking statute operated as a forfeiture of damage. Since the act was implemented, however, patent owners no longer have to include the patent number on the product. Instead, they can merely put "patent," along with an address of a website that posts the patented article with the patent number, saving the cost of new manufacturing equipment every time the patent changes.

The America Invents Act of 2011 influences legal reform. The act not only creates an administrative program for review of business method patents, it also provides additional options to challenge the validity of an issued patent. It adds a new procedure called the postgrant review (PGR). A petition for PGR can be based on lack of enablement, lack of utility, and/or failure to comply with written description requirements. If the petition is granted, oral proceedings and a chance for the patent owner to amend the patent may be allowed.

Lastly, the America Invents Act affects patent office reform. It creates an anti-fee diversion (before this act, the patent application fees were diverted by congressional appropriators to other government programs) and ends the practice of fee diversion at the PTO. This effectively lowers taxes on innovators and innovation. It also ensures continued congressional oversight by both the judiciary and the Appropriations Committee in the House and Senate. The act allows the PTO director to adjust fees to better accommodate market conditions and reduce the time it takes to review and issue a patent to get the product into the market quickly and efficiently. To summarize, the America Invents Act creates cost-effective alternative legal forums that will provide a simpler way to review questions of patentability, reducing the costs of frivolous litigation against job creators.

ANNUITY

An annuity is a type of insurance contract that provides the owner with a stream of payments for a fixed term or lifetime in return for an upfront payment or payments (Ferro 2010). Annuities originated centuries ago in ancient Rome. The present forms of annuities are sold by insurance companies to individuals desiring a monthly payment during retirement. Annuities are a combination investment/insurance product.

Although retirees in the United States receive annuity payments from the government in the form of Social Security, this benefit was not designed to provide 100 percent income replacement for all retirement expenses. The Social Security annuity gives workers a monthly payment during retirement. The payment is calculated based on the amount retirees contributed to their Social Security account during their working years. Since the Social Security payment is less than the amount earned while working, many individuals save and invest for retirement in order to supplement government Social Security payments.

An annuity is an income option for an individual or couple's retirement financial management. The annuity holder receives regular payments to create a secure retirement income stream. A major drawback for the annuity purchaser is that since annuity contracts depend on one's life expectancy, if the annuitant dies sooner than expected, he or she may forfeit thousands of nonrefundable dollars paid in advance to the insurance company.

Funding an Annuity

Before the holder receives annuity payments, the annuity must be funded. The money for the annuity may be paid to the insurance or investment company in a lump sum, through regular salary transfers, or in several lump sums. The insurer structures the payments so that ultimately the insurance company pays out less in benefits than it earns in aggregate. Some policyholders may receive more in benefits than they paid in, while others receive less. After receiving the annuity payments, depending on the stipulations of the contract, the annuity policy issuer invests the funds in either fixed or variable securities (stocks, bonds, or other financial assets) in order to compound the returns of the initial contribution.

Types of Annuities

Annuities convert current or previous funds into income for the future. There are a myriad of contract, fee, and payment structures. The annuity product is extremely complex with hundreds of varieties.

This section breaks down the basic types of annuities into immediate and deferred. Within each of these categories there are fixed or variable payment options. The terms and conditions vary from contract to contract, and the documents are long and complicated. It is important for the annuity purchaser to review them to understand the benefits (Zook 2013).

In the case of a single-life annuity, the payment continues until the annuitant's death. A joint-life with last survivor annuity makes payments to the annuitant, and upon his or her death, the payments continue to a second designated party, usually the annuitant's spouse, until that person's death. This type of annuity typically carries a lower payment to the individual than a single-life annuity because it is paid out over two lives (the individual annuitant and the spouse).

Immediate or Deferred Annuity

The two broad categories of annuities are immediate and deferred. Their aptly named categories describe the relationship between payment into the annuity and withdrawal.

The immediate annuity is the simplest type of annuity. Investors pay in a lump sum and receive guaranteed monthly payments for life or for a predetermined period. According to the Standard Insurance Annuity Answer Booklet, "The U.S. Tax code dictates that every annuity payment is a combination of return of principal (is not taxed) and payout of income (is taxed at normal-income rates)." This spreads tax obligations out over time.

A deferred annuity has two phases: accumulation and distribution. Accumulation is the period during which the annuity is funded, frequently through salary transfers. While accumulating, the funds in the annuity grow tax-free and may be invested in a variety of financial assets. Upon the withdrawal phase, the annuitant can take income monthly or in a onetime lump-sum payment.

Fixed, Variable, and Equity Index Annuities

Within each broad type of annuity, immediate and deferred, there are a variety of categories. Fixed, variable, and equity index annuities describe how payments are calculated and in what type of assets the annuity funds are invested.

A risk-averse individual might choose a fixed annuity. The payout guarantees a fixed minimum payment set at the time the annuity is purchased. The disadvantage with this type of contract is that in periods of high inflation, the payment does not increase. There are also fixed-rate annuities in which the interest rate paid on the annuity is set at purchase and is guaranteed not to fall below a minimum level.

Variable annuities are riskier than fixed. The annuity funds are invested in mutual funds, usually selected by the annuitant with the hope of growing the annuity funds by investing in equities that have a history of higher growth rates than cash assets. The risk is that at withdrawal equity markets may decline, thereby reducing the funds available for payout. The annuitant may choose a minimum payment option for additional security.

Equity index annuities are a combination of fixed and variable annuities. The funds are invested in a broad stock market index such as the Standard & Poor's 500 (S&P 500), and the annuity value is tied to the growth of the index. Minimum payouts are set and may be increased based on the growth of the benchmark stock index.

Annuity Considerations

Gustavo Ferro (2010) cautions that purchasing an annuity entails weighing the possibility of losing one's funds due to early death against that of outliving one's retirement savings. In order to counteract the possibility of dying soon after annuity payments begin, there are contracts that guarantee a minimum number of payments.

Another consideration for an annuity purchaser is the complexity of the annuity product itself. According to Hube (2011), there are approximately 1,600 types of annuity products. In addition to the basic annuity structures listed above, there are countless variations, including structures with tax advantages and interest rate, inflation, and investment risk protections. The magnitude of differing annuity products makes the decision to purchase an annuity cumbersome and confusing.

The security of the annuity is of prime concern. Since the purchaser is depending on the financial strength of the issuing company to provide lifetime income, one must be certain that the issuer of the contract is in stable financial condition. Rating agencies such as A. M. Best and Standard & Poor's rate the stability of insurance companies, according to *Consumer Reports Money Advisor* (2011).

The fees and commissions can be quite high. Thus, the annuity purchaser needs to understand in what way and how much the issuer is being compensated as well as any ongoing fees.

Recently, discount investment brokers such as Vanguard and Fidelity entered the annuity marketplace with lower-cost and higher-benefit annuity options. Without a direct sales force, compensated solely through commissions, discount brokers may offer more economical annuity options for retirees.

If annuity payments are not tied to inflation, the annuitant runs the risk of a loss in purchasing power due to increases in the inflation rate. If one receives $750 per month at the outset of retirement and inflation increases at the historical rate of 3 percent per year, in 20 years, the $750 per month will only have the purchasing power of $407 per month. Retirees without an inflation increase in their annuity payment can lose close to half of the value of their payment during the next 20 years, according to the inflation calculator at Vertex42.com.

As Americans live longer, there is a growing need for a product that gives lifetime monthly income. The annuity is an important option for retirees to fund their future. Although as with any financial product, when choosing an annuity, it is important to research the options and consider fees to ensure the purchaser receives the greatest income payment for the annuity cost.

ARBITRAGE

Arbitrage is buying a good and then immediately reselling it in another market for a higher price or a profit. Arbitrage opportunities can be found in most markets but are usually short-lived due to the adjustment in prices based on the supply and demand for the arbitrage good in both markets. Arbitrage opportunities usually exist for three primary reasons: there is a difference in how the good is valued between markets, the good is priced incorrectly, or there is an advantageous exchange rate fluctuation.

In order to take full advantage of an arbitrage opportunity, the markets in which the arbitrage good is purchased and then immediately sold must participate in free trade. If protective tariffs or quotas exist between these markets, the arbitrage opportunity will be limited. First, to explore a difference in the value of a good between markets, one needs to establish that there are two countries that currently do not trade. If country A can easily produce the good but the citizens of country A do not value the good, that creates a very low price for the good (surplus and very little demand). The citizens of country B place a high value on the good but because of their limited factors of production for the good, they are not able to produce enough to meet the demands of their citizens, which causes the price of the good to be very high (shortage and high demand). If these countries trade, the citizens of country A will produce the good and sell it to the citizens of country B for a larger economic profit compared to simply selling it to the citizens of country A. This arbitrage opportunity will be short-lived because eventually the increase of supply in country B (provided by country A) will drive down the price in country B, and the decrease in supply in country A will drive up the price in country A, creating a "world" price for the good. Both countries would essentially share the "world" demand and the "world" supply of the good, creating a true "world" price.

Natural disasters often create arbitrage opportunities based on the value of the good between markets. Imagine that a hurricane devastates South Florida, which creates a larger than normal demand for generators. It is reasonable to suspect a resident of Michigan would purchase as many generators as he could in Michigan, load them in a truck, and sell them to the citizens of South Florida for a steep profit. Many communities have laws against this type of arbitrage to protect their citizens from price gouging; but one might question whether citizens are truly helped by this protection. Without the profit incentive to deliver these generators to the citizens of South Florida, they may be forced to live without electricity for a few extra days.

Arbitrage opportunities exist for goods that are priced incorrectly. Instead of two countries, as in the previous example, consider two markets that could be in the same community. Imagine a consumer walks into market A, notices that a good is extremely underpriced, and purchases as much of this good as she can. She then sells the good for a profit in market B at the established market price. This arbitrage opportunity will exist until market A realizes that the good is priced incorrectly or until the supply and demand for the good balances in each market, creating a single price for the good in both markets.

The last opportunity for arbitrage is a large fluctuation in exchange rates with prices remaining stable in both countries. Comparing countries again, if the exchange rates in both countries A and B were equal to each other (one A currency equals one B currency) and then the central bank of country B vastly increases the money supply of country B, which would depreciate the currency of country B, creating a new exchange rate of one A currency equaling two B currency. Prices have not changed in either country. Citizens in country A could purchase twice as many goods in country B by exchanging their currency for the currency of country B, purchasing twice as many goods in country B, and reselling them for a profit in country A.

This will be much easier to understand if we use an example with real numbers. If a citizen of country A took $100 of A currency and exchanged it for $200 of B currency, purchased 200 dollar-store items in country B, and then shipped those goods to country A and sold them in a country A dollar store, that citizen would now have $200 of country A currency. This arbitrage opportunity would also be short-lived because as the citizens of country A continued to demand the currency of country B, the value of the currency of country B would continue to increase until the arbitrage opportunity was eliminated.

While arbitrage opportunities do exist, they often have short life spans due to the changes in supply and demand in each market, government regulations prohibiting arbitrage opportunities, and trade restrictions.

ARROW, KENNETH

Born: August 23, 1921, in New York City; Nationality: American; Professional Interests: general equilibrium theory, welfare theory, economic growth, Nobel Prize (1972); Major Work: *Social Choice and Individual Values* (1951).

Kenneth J. Arrow is an American economist. In 1972, he, along with Sir John Hicks, won the Nobel Prize in Economics for his work on general equilibrium and welfare economics. Arrow is also known for his work in the area of public choice; he introduced and defended the impossibility theorem in his dissertation.

Kenneth Joseph Arrow was born on August 23, 1921, in New York City. He did his undergraduate work at the City College of New York, where he received a bachelor of science in social science with a major in mathematics in 1940. He went on to receive an MA in mathematics from Columbia University in 1941. At that point, he switched to the Economics Department at Columbia for further graduate work, having completed his PhD course work in 1942, although he was still in search of a dissertation. His dissertation research was interrupted by military service during World War II in the U.S. Army Air Corps, where he served as weather officer, rising to the rank of captain. It was here that he had his first published paper, "On the Optimal Use of Winds for Flight Planning."

Upon his return from the military, Arrow was at Columbia for a brief period before joining the Cowles Commission at the University of Chicago in 1947. Time spent with other young econometricians and mathematically oriented economists proved to be a significant influence on him.

Arrow became affiliated with the RAND Corporation in 1948 and continued that relationship into the 1970s. It was early in his time at RAND that he arrived at an idea for his dissertation. He sought to apply the newly emerging field of game theory to large groups, such as countries. His research was published in 1951 under the title *Social Choice and Individual Values*. The work introduced the "impossibility theorem," which stated that, given certain assumptions, it was impossible to find a voting construct that would provide an outcome that most voters preferred. This provided and continues to provide great insights into social welfare theory as well as voter behavior in the public arena.

In 1949, Arrow joined the Economics Department at Stanford University, where he would stay until leaving to join the faculty at Harvard in 1968. While at Stanford, some of his most significant early works were published: the aforementioned *Social Choice and Individual Values*, several articles on competitive equilibrium with Leonid Hurwicz from 1958 to 1960, and his contribution to "Toward a Theory of Price Adjustment" in *Allocation of Economic Resources* edited by Moses Abramovitz in 1959. Also while at Stanford, Arrow won the John Bates Clark Medal in 1957 and began his research into economic growth. His article "The Economic Implications of Learning by Doing" is a precursor to modern growth theory and the role of human capital.

In 1968, Arrow accepted a position at Harvard University. He would remain on the faculty at Harvard until he returned to Stanford in 1979. While at Harvard, Arrow continued his work in the areas of information, market efficiency, and public choice, producing several articles and books of note. These include *Public Investment, the Rate of Return, and Optimal Fiscal Policy* (with Mordecai Kurz) in 1970; *Essays on the Theory of Risk-Bearing* in 1970; *General Competitive Analysis* (with Frank Hahn) in 1971; and *The Limits of Organization* in 1974. Each of these provided insights into the role of information in markets or decision-making. Arrow also produced significant research in the economics of discrimination and of health care.

Upon his return to Stanford in 1979, Arrow became the Joan Kenney Professor of Economics and professor of economic research. During this second period at Stanford, he continued his work on the impact of information in the market and decision-making as well as providing important insights into topics as widely divergent as income distribution and globalization.

Arrow retired in 1991 but remains professor emeritus at Stanford. He continues his research into areas of information economics, growth, and the environment.

ASSET BUBBLES

An asset bubble occurs when the price of a financial asset reaches levels that are well above historical norms or intrinsic value. Considering that intrinsic value can vary widely, a bubble is considered to be a result of the misconception that an asset's intrinsic value has increased or that the asset is worth more today than it once was.

Furthermore, some bubbles are easily detectable, such as stock market bubbles. This is because traditional valuation methods can be used to identify areas of extreme overvaluation. For example, a financial valuation metric such as an equity index that is trading at a ratio twice that of historical trading value is a good indicator of a potential bubble. On the other hand, some bubbles are harder to detect and can only be identified in retrospect.

Some common themes identified throughout the history of asset bubbles is that most individuals involved tend to ignore the multitude of red flags that signal a bubble on the horizon. Another common theme apparent throughout history is the bigger the bubble, the greater the damage it inflicts when it finally bursts. Five of the largest asset bubbles in history included the Dutch tulip bubble, South Sea bubble, Japan's real estate and stock market bubble, the dot-com bubble, and the most recent housing bubble.

Dutch Tulip Bubble

One of the earliest records of an asset bubble occurred in the 1630s in Holland. Between November 1636 and February 1637, tulip prices increased by 20 percent before plummeting by 99 percent in May of 1637. According to Earl A. Thompson, a former UCLA economics professor, this incident is known as "tulipmania," and it consumed most of the Dutch population. At its peak, some bulbs cost more than a luxury home.

South Sea Bubble

Formed in 1711, the South Sea Company was promised a monopoly by the British government on all Spanish colonies of South America. With the assumption that the South Sea Company would have the same success as the East India Company, investors jumped at the opportunity to buy shares. As directors of the company exaggerated the potential success, shares surged more than eight times from January to June in 1720 before finally collapsing in subsequent months, causing severe economic crisis.

Japan's Real Estate and Stock Market Bubble

This bubble is a good example of how an overly stimulated monetary policy can fuel an asset bubble. In the early 1980s, the Japanese yen surged by 50 percent and triggered a recession in 1986. In order to counteract this incident, the government created a program of monetary and fiscal stimulus. This attempt was speculatively successful and resulted in Japanese stocks and property values tripling by the peak of the bubble in 1989; at that point, the property value of the Imperial Palace in Tokyo was greater than that of the entire state of California. The bubble burst in 1990.

Dot-Com Bubble

Following the introduction of the Internet, hundreds of dot-com companies achieved multibillion-dollar valuations immediately after going public. The NASDAQ Composite, which houses most of the dot-com companies, skyrocketed to a peak of over 5,000 in March 2000. The index crashed shortly after, plunging nearly 80 percent by October 2002, leading to a recession in the United States.

U.S. Housing Bubble

From 1996 to 2006, U.S. housing prices nearly doubled, with most of that surge occurring from 2002 to 2006. Coupled with the record high housing prices, there were several other cautionary signals in the market at the time, such as mortgage fraud and subprime borrowing. U.S. housing prices peaked in 2006 and then fell to roughly one-third of their value by 2009. The U.S. housing boom and bust had rippling effects throughout the global economy and caused the largest recession since the Great Depression in the 1930s.

ASYMMETRIC INFORMATION

Asymmetric information refers to a situation where one individual in a transaction has access to information that is important to the potential outcomes of the other individual(s) but where this information can be kept private until after the transaction is complete. Asymmetric information is important in the study of economics as individuals with private information can use it to their advantage. This can lead to an imbalance of power and to exchanges that disadvantage the uninformed party.

When an individual's private information, such as regarding religion, relates to a fixed preference of an individual or an immutable characteristic of an object, such as a home's location, asymmetric information gives rise to an adverse selection or hidden information problem.

The term *adverse selection* was originally used in insurance to describe a situation where an individual's propensity to buy insurance is positively correlated with his or her likelihood of needing such insurance. If all individuals are offered an identical insurance policy with a premium equal to the average payout, safe individuals will opt out of the policy, leaving an adverse pool of remaining policyholders. To compensate for this adverse pool, an insurer must raise the premium. However, this increase in price will lead to even more individuals opting out of the policy. This unwinding process may give rise to a "market for lemons," where only individuals with high levels of risk are willing to accept insurance contracts and insurance premiums are extremely high.

To prevent market failures, hidden information can be partially reduced through signaling and screening. A signaling strategy is when individuals who have private information take actions that may be costly to them by revealing the private information, but doing so in such a way that individuals with different characteristics don't have an incentive to follow. For example, in the context of the hiring process, a potential employee's ability and productivity may be private information. However, a potential employee may signal such ability through his or her educational attainment. By doing so the potential employee risks others doing the same and increasing competition. Screening strategies are adopted by individuals to induce the other party to reveal information through his or her choices. A screening strategy typically involves offering a menu of choices and letting the informed party pick the one that is best for him or her. For example, an airline offers a first-class seat with a high price and high level of service and an economy-class seat with a lower price and a lower level of service. Individuals, whose initial willingness to pay for service is private, self-select into the product best suited to them. This self-selection reveals information about individuals' preferences.

When an individual's private information relates to his or her potential future actions, asymmetric information gives rise to a moral hazard problem or a hidden action problem. In a moral hazard problem, an individual—typically referred to as the agent—may take an action that improves the expected outcome to the other party—the principal—but which is costly and unobservable. For example, an individual who parks a car at a gas station and wants to run in to buy something may find it convenient to leave his or her car running to keep it warm. This action increases the potential the car will be stolen but is hard for the insurance company to observe. In order to make the car owner less likely to take such risky actions, the insurance company will impose a deductible to make the owner more cautious. Or, a finance company and its employees might engage in highly risky investments if the prospective returns are high but the risks are borne by other parties. To avoid such behavior requires decision-makers to bear the costs of their risky choices.

AUMANN, ROBERT

Born: June 8, 1930, in Frankfurt, Germany; Nationality: Israeli; Porfessional Interests: mathematician, game theory, Nobel Prize (2005); Major Work: *Lectures on Game Theory* (1989).

Robert Aumann was the first to introduce the formal analysis of infinitely repeated games, focusing on noncooperative encounters, a subject of game theory. Game theory is a branch of both economics and applied mathematics. Economics is like a game in which action is or is not taken based on the anticipated actions of other players in the game. Outcomes result from the encounters between players who have mixed, similar, or opposing interests from each other. Based on these interests, players may or may not cooperate for any set of outcomes. Aumann's research showed that noncooperative relations or encounters, over the long run, hold up—this is known as the "folk theorem." In 2005, Aumann was awarded the Nobel Prize in Economics.

Robert John Aumann was born on June 8, 1930, in the city of Frankfurt (on the Main), Germany, into an orthodox Jewish family. His mother was college educated in London, and his father made a comfortable living as a wholesale textile merchant. In 1938, the family lost all their assets as the Nazis were coming to power. They then emigrated to New York. While in high school, Aumann found a passion for mathematics, especially working mathematical axioms, proofs, and Euclid's geometry constructions. In college, Aumann's passion for mathematics grew as he found analytic and algebraic number theory fascinating.

Aumann completed his PhD at the Massachusetts Institute of Technology (MIT). In his undergraduate years, he preferred to study classical mathematics; however, at MIT his interests moved toward modern branches of mathematics, such as algebraic topology. His focus was in knot theory, a branch of algebraic topology. Aumann's thesis was published in the *Annals of Mathematics* in 1956.

According to Aumann, his knowledge of game theory was limited to early conversations he had had with MIT instructor John Nash (also a Nobel economics laureate). After earning his PhD, Aumann began his research in game theory in order to solve a problem given him as a consultant for the Analytical Research Group (ARG): How do you defend a city from an attack by an air squadron, knowing that most are decoys, yet a few of the aircraft have nuclear weapons?

Aumann is most recently known for sharing the 2005 Nobel Prize in Economics with Thomas C. Schelling. The cowinners described their contribution to economics and game theory as the ability to use game-theory analysis to broaden the understanding of conflict and cooperation.

Aumann's research and publications include extensive collaborations with over 30 award-winning scientists. His notable collaborators include Thomas C. Schelling, Lloyd Shapley (coauthored the book *Values of Non-Atomic Games*), and Michael Maschler. He has also collaborated with John Harsanyi, Reinhard Selten, Gérard Debreu, Dick Stearns, Herb Scarf, Harold Kuhn, Jim Mayberry, Jacques Dreze, Mordecai Kurz, Sergiu Hart, Bezalel Peleg, Adam Brandenburger, Frank Anscombe, Abraham Neyman, Benjy Weiss, Micha Perles, Joe Kruskal, Roger Myerson, Roberto Serrano, and Motty Perry.

AUTO IMPORT CHALLENGE, 1965

The decline of the American auto industry has resulted in more permanent job losses than any other event in American history. The auto decline has meant millions of lost jobs and the bankruptcy of American cities such as Detroit, Flint, and Akron. The first signs of this new world order came in the 1950s in auto manufacturing. The story of the rise of Japanese imports and Toyota in the United States is really a story of America's entrance into the global economy.

In the late 1950s, Toyota and Nissan's small cars offered little threat to the big luxury car market of the United States. Toyota struggled even to find a good price for its vehicles. The year 1965 would be the start of a revolution in the American auto industry and the beginning of the end of American manufacturers in their home market. This economic crisis had deep roots that would end more than 40 years later with General Motors and Detroit in bankruptcy.

In the mid-1960s, these first few foreign car imports into the United States targeted a niche in the American market. This had been a prewar goal of Japanese automakers. In 1936, the Japanese government passed the Automobile Manufacturing Industries Act with the express purpose of breaking the American car monopoly. Toyota and Datsun took the lead before the war and then took up the old goals after the war, taking advantage of favorable trade laws. A small but growing import market arose in postwar America with the entrance of the Volkswagen Beetle, which was launched in 1949. Although the sale of a small Toyota in the American market was hardly noticed by the American press, it was a strategic project, not a tactical move. To the Japanese automaker, it was guerilla warfare, like Apple and Microsoft working quietly in the shadow of giant IBM. Toyota was looking to be a major player in America, but the plan was difficult from a product standpoint.

Toyota opened its headquarters in Hollywood more as a statement than as a functioning office. In 1958, the sale of the first Toyota Toyopet at America's first Toyota dealer in San Francisco hardly started a flood of imports; in fact, the Toyopet proved unsuccessful in the American market. The Toyopet was a small, scaled-down car that was never popular in the United States, but the experience changed the future of imports. The failure of the Toyopet model inspired the development of the Toyota Corona for the American market in 1964. The Corona was a six-passenger car with a lower price tag, higher quality, and better gas mileage than the sedans of the Big Three U.S. automakers.

In 1965, Toyota Corona sales hit 6,400 vehicles, and by 1967, sales reached 71,000 vehicles and continued to double every year until 1971. Toyota's quality became its trademark as it captured the small-car market in the United States; the cars were carefully inspected before delivery to the United States. With a growing reputation for quality, Toyota introduced the Crown, a semiluxury car. In 1969, Toyota launched the Corolla, which would become the best import seller and America's favorite small car.

America had risen to the small-car challenge only to be thwarted by quality and safety issues with its cars. General Motors had released its Corvair in anticipation of the foreign challenges. The Corvair had an air-cooled engine and rear-wheel drive, which challenged a popular import—the Volkswagen Beetle. The Corvair had many revolutionary design elements and was named Motor Trend Car of the Year for 1960. It was also on a 1960 cover of *Time* magazine, which hailed its engineering.

Even with all the safety concerns that arose, the Corvair proved highly successful, and GM sold 1.8 million of the cars in the 1960s. In the first four years of its sales, however, the Corvair was hit with more than 100 lawsuits, but these remained below the public's radar until the 1965 publication of Ralph Nader's *Unsafe at Any Speed.* The major impact of the book would be the unanimous passage of the 1966 National Traffic and Motor Vehicle Safety Act, which addressed the rising fatalities and injuries in cars in the 1960s. The act represented a major shift in safety responsibility from the individual consumer to the federal government and forced auto manufacturers to add such features as safety belts and stronger shatter-resistant windshields. General Motors and the American automakers would stop producing smaller cars for a time, effectively ceding the small-car market to their overseas rivals.

AUTO PACT OF 1965

The Auto Pact of 1965 was a free trade agreement between the United States and Canada specifically in the automotive sector, which included both vehicle parts and newly produced/assembled vehicles. A significant impact of the Auto Pact of 1965 was that it provided evidence that free trade agreements can increase economic prosperity. The Auto Pact of 1965 was the forerunner of future free trade agreements such as the 1994 North American Free Trade Agreement (NAFTA). There were many positive outcomes of this trade agreement, but perhaps the most meaningful was the evidence that free trade creates wealth through comparative advantage and specialization.

The Auto Pact of 1965 allowed the major North American automotive manufacturers to aggregate and integrate their production processes in the United States and Canada to engage in a greater degree of specialization between the U.S. and Canadian automotive markets. This specialization created greater economies of scale and reduced production costs for all manufacturers. In addition to specialization, the Auto Pact of 1965 integrated U.S. and Canadian automotive markets. This integration created a single automotive market and allowed for the streamlining of marketing strategies between the U.S. and Canadian automotive markets as well as increasing the consumer base for each market. The Auto Pact of 1965 led the way for the globalization of the major automotive manufacturers as well as the automotive market.

Even though the Auto Pact of 1965 greatly reduced protective automotive tariffs between the United States and Canada, it did not completely eliminate them. In order for an automotive part or assembled vehicle to avoid tariffs, it had to satisfy a myriad of requirements. Vehicles or parts produced outside of North America were still subject to preexisting tariffs. While the Auto Pact of 1965 was a true test of the theory of comparative advantage and the economic theory that free trade creates wealth through specialization, it was extremely limited in scope. However, the Auto Pact of 1965 was considered by most economists to be highly successful for both the automotive manufacturers and automotive consumers of the United States and Canada. In addition, it was proof that trade liberalization policies could create wealth in each country. It was also evidence that trade barriers could be removed without a major disruption in the size of the domestic labor force.

BANDWAGON EFFECT

The character of Robinson Crusoe has been used to describe the rational behavior of the economic person. Crusoe, shipwrecked on a deserted island, makes decisions independent of others, since there are no others. He estimates costs and benefits as they appear to him alone, equates them at the margin, and a decision arises automatically in his consciousness.

However, in the real world, we are influenced by others. One type of influence is known as the bandwagon effect. Bandwagon behavior is also known as an "informational cascade" (Hirshleifer 1995). People copy the decisions of others regardless of what their own internal signals are telling them, leading to what some would refer to as irrational or bounded rational decisions.

Studies have shown that the probability that an individual will make such a substitution increases as the percentage of other people who have already made such a substitution rises. People "hop on the bandwagon" regardless of any underlying data. Gary Becker argues that an upward-sloping demand curve could result from the bandwagon effect. In his 1950 article, Leibenstein develops an upward-sloping demand curve that he calls a Veblen demand curve.

In the famous Asch experiments, Solomon Asch of Swarthmore College showed students a single line and a group of three lines next to it and asked which of the set of three was closest in length to the benchmark single line. Students who knew the purpose of the study replied first and answered incorrectly. The actual student participants then answered, also incorrectly despite the fact that the correct answer was obvious. Similar bandwagon effects were found in voting behavior. Among 180 University of Kentucky students, about 125 were given information about the expected winner of a political race. Among Independents, the majority favored whichever candidate, Democrat or Republican, they were told was expected to win.

The implications of being influenced by others leads to what Leibenstein refers to as bandwagon, snob, and Veblen demand curves. Here we focus on the bandwagon effect. In standard economic theory, the market demand curve is the horizontal sum of the individual demand curves. At price P1, Moe buys 5, Larry buys 6, and Curly buys 162. The market demand at P1 is 5 + 6 + 162 = 173. However, if Moe, Larry, and Curly are dependent on at least one of the others, the market demand will not be the horizontal sum of the individual demand curves. Rather, how much Moe buys depends on how much Larry buys, and Curly buys an amount that is dependent on how much Moe buys. This is because the utility received from a product is affected by external factors.

In Leibenstein's analysis, each individual's demand depends on his or her expectation of total demand. The individual's demand (D) when he or she expects total demand to be 200 is greater than when he or she expects it to be 100. In other words, D200 is to the right of D100. If we add up what all consumers would buy if they believe that total market demand is 100, we arrive at a market demand curve of 100. D200, D300, . . . , Dn is each a market demand curve if all consumers believe that total market demand is 100, 200, 300, and . . . Dn units, respectively. D100 is to the left of the other demand curves.

On D100, if the price is P3, Qd will be x1. If the price falls to P2, under standard economic theory, consumers will purchase more by moving down D100: Qd becomes x2. However, at the lower price, consumers believe that others are buying more—200. D100 shifts to the right to D200. Yes, contrary to economic theory, a price change leads to a change in demand. At P2 along D200, Qd is x3. Any reduction in price yields a larger increase in Qd. The bandwagon demand curve is thus more elastic than the normal demand curve.

BANKING TRENDS: ELECTRONIC AND INTERNATIONAL

Traditionally, banks have delivered products and services to consumers through a physical bank and its branches. However, the financial services industry is transforming with the help of the Internet, technological evolutions, deregulation, globalization, and the impact of competitive and regulatory forces. As a means to adapt to the ever-changing industry, banks have started to rely on supplemental channels of distribution and alternative strategies to gain competitive advantages.

Electronic Banking

Considering the traditional methods, banks delivered their products and services to customers solely through physical banks and branches; as technology evolved and many businesses were forced to change their traditional modes of operations, banks were expected to do the same. It was apparent to banks that relying solely on the traditional modes of operation was no longer suitable given the evolution of the rest of the world.

The increased pace of technological advancements combined with the growing global economy set the stage for the banking system to change from its traditional operations to mobilizing and guiding financial resources more effectively. In an ever-increasing competitive environment, better financial distribution strategies reaching the maximum number of customers provides a competitive edge to banking institutions in the marketplace.

Specifically, electronic banking, also known as electronic fund transfer (EFT), uses computers and electronic technology in place of checks and other paper transactions. Moreover, transactions as such are initiated through devices like cards or codes that allow customers to authorize or access their accounts remotely. Many financial institutions use debit cards and personal identification numbers. Some common technological advances include ATMs, direct deposit, personal online banking, electronic check conversion, and debit card purchases or payment transactions.

International Banking

International banks surpass the functions of domestic banks by linking financial partners across countries and helping people and businesses engage in international trade and finance. Additionally, international banks aid in foreign currency exchange rates and holding inventories of foreign currencies.

Over the last three decades, international banking has expanded tremendously. Its prominence and geographical coverage reflect the two most important aspects of the role international banks play in the global economy. Namely, international banking has been an important element aiding in a broader process of globalization and integration. Historically, it has expanded simultaneously with international trade and performed key functions for the business of international firms. Additionally, the foreign banks involved in local operations have helped to spark the development of financial systems in emerging markets while also helping to alleviate communication gaps. In the future, the demand for financial services from multinational corporations and rapidly growing markets will help to solidify the continual shaping of international banking and its contribution to economic progress.

Moreover, the role of international banks in the global economy is closely related to that of international financial markets. Each function performs and assumes complementary responsibilities that together create resilient market infrastructure and overall healthy financial systems. For example, international capital markets often ease the funding strains of large corporations when bank credit contracts. Conversely, banks are the main source of external financing for households and medium-sized companies, whose access to credit markets can be restricted by asymmetric information issues.

BARGAINING POWER

Bargaining power is the ability to claim a share of a pie commensurate with one's resources and potential in a dispute against several (one or more) competitors. A pie can be explicit, such as birthday cakes, partition of inheritance, or collective bargaining agreements between employers and employees. Other examples, such as decisions of boards of directors, parliamentary votes over a legislation bill, or sanctioning decisions of the United Nations Security Council, implicitly feature several competing partitions of the available resources, wherein the winning proposal entitles each voting party to its particular share, such as corporate dividends, benefits to the party's electorate, or geopolitical advantages. Bargaining may also be said to take place in the market between parties—buyers and sellers—over the competitive price of a good. It is not simply a matter of supply and demand mechanically determining prices (Porter 1998).

The bargaining problem itself arises whenever (1) there are resources (potential surplus) to be divided, and (2) parties (players) have conflicting interests over this division. These characteristics allow the bargaining problem to be represented as a game (game theory) and warrant association of parties with players, shares with utilities, and resulting (predicted) partitions with game-theoretic solution concepts, such as the Nash equilibrium or the Shapley vector. The canonical formal definition of the bargaining power of a player is, then, the share of a pie attributable to the player according to the game-theoretic solution—that is, the ability of each player to claim his or her expected payoff in the game.

Measurement of bargaining power depends on the type of game, bargaining protocol (rules of bargaining), and solution concept. In bilateral negotiations, the general solution concept for an arbitrary (unstructured) bargaining game is given by the Nash bargaining solution (Nash 1950; see also Kalai and Smorodinsky 1975). This concept is silent about the bargaining process but characterizes its outcome as a maximized joint product between the shares s1 and s2 accrued to players 1 and 2, respectively, and the default payoffs (d1, d2) they receive if they fail to reach the agreement (the disagreement point). This value, (s1–d1) x (s2–d2) is called the Nash product and predicts an equal share where bargaining power is equal. But if certain parameters change, such as reducing the payoff to player 1 (she has less to lose if there is no agreement) this increases her bargaining power and ultimately her share of the pie. This solution has been extensively studied in applications and has been connected to the bargaining outcomes under sequential bargaining protocol.

In the Stahl-Rubinstein bargaining game protocol, two players make offers on how to divide the pie. Player 1 makes a proposal that player 2 may either accept, terminating the game, or reject, in which case the pie size shrinks by a discount factor and the move passes to player 2. The game continues and the pie size continues to shrink until one player accepts the offer. Rubinstein derives a unique subgame-perfect equilibrium in this game, where player 1, who moves first, should offer a particular share to player 2, who should immediately accept the offer. This solution captures the first-mover advantage of player 1, who has greater bargaining power from the outset.

Multilateral bargaining problems are addressed within the frame of cooperative games, on the basis of the Shapley vector, with nontransferable utility given by a finite set of players (N) and assigned values of utility to each subset (coalition) of players. Shapley and Shubik and Banzhaf use this concept in a multilateral bargaining framework. Suppose each of N players has a particular number of votes and may propose different divisions of a single pie. Now consider all possible sequences of gradual coalition formation and calculate all those instances at which some (pivotal) player, joining a particular coalition, makes it a winning instead of losing team. The bargaining power of every player is measured as the ratio of number of instances in which this player is pivotal to the number of all instances when any player is pivotal. Various generalizations of this index have been proposed for different bargaining protocols and are extensively applied in political science.

BAUMOL, WILLIAM J.

Born: February 26, 1922, in New York City; Nationality: American; Professional Interests: entrepreneurship, economic growth, industrial organization, antitrust economics, regulation; Major Works: "Detrimental Externalities and Non-Convexity of the Production Set" (1972); *The Theory of Environmental Policy*, 2nd ed. (1988); "On the Increasing Role of Economic Research in Management of Resources and Protection of the Environment" (2010).

William Baumol was born on February 26, 1922, in New York City. After receiving his BS from the College of the City of New York in 1942, he undertook graduate study at the London School of Economics, earning his PhD in 1949. He taught at Princeton University for 43 years, where he is now professor emeritus and senior research economist. He has also taught at New York University for more than 36 years, where he currently holds the Harold Price Professorship of Entrepreneurship in the Stern School of Business. Professor Baumol is the author of more than 40 scholarly books and has written over 500 articles published in peer-reviewed journals as well as the popular media. Among his many honors and awards, he was elected fellow of the Econometric Society in 1953, fellow of the American Academy of Arts and Sciences in 1971, and distinguished fellow of the American Economic Association in 1982.

Baumol's research in economics has covered diverse areas of the discipline, including, among others, entrepreneurship and innovation, economic growth, industrial organization, and antitrust economics and regulation. His seminal contributions include a model of the transactions demand for money, the sales-revenue maximization model, an analysis of cost disease, the theory of contestable markets, and the concept of super-fairness. Most recently, Baumol has focused on entrepreneurship and innovation, with *The Economist* magazine remarking that "thanks to Mr. Baumol's own painstaking efforts, economists now have a bit more room for entrepreneurs in their theories" (March 9, 2006).

In the field of environmental economics, Professor Baumol is best known for his textbook on the theory of environmental policy, coauthored with Wallace Oates. First published in 1975, this book has become a standard reference in many graduate-level classes in environmental economics due to its comprehensive coverage of both the theory of externalities and the design of environmental policy, with chapters on topics such as imperfect competition and externalities, optimal pricing of exhaustible resources, marketable emissions permits, and international environmental issues.

Specifically, Chapter 8 of the book, drawing on his joint work with David Bradford, concerns Professor Baumol's major contribution to environmental economics: understanding the relationship between externalities and the technical concept of nonconvexities in production sets. If an industry imposes a large enough negative externality on another industry, the normal conditions for maximizing social welfare break down due to the fact that the production set becomes nonconvex—that is, the production possibilities frontier is no longer concave in shape. Instead of the normal unique equilibrium where market-clearing prices ensure that a concave production possibilities frontier is tangent to a convex community indifference curve, there are potentially many local equilibrium outcomes in the presence of externalities. In such a setting, market processes may not result in a socially optimal outcome; instead, the point at which an economy ends up will have to be chosen collectively. As a consequence, Pigouvian taxes, designed to internalize the social costs of an externality, may actually move the economy away from a social optimum.

BECKER, GARY

Born: December 2, 1930, in Pottsville, Pennsylvania; Died: May 3, 2014, in Chicago, Illinois; Nationality: American; Professional Interests: behavioral economics, economic growth, Nobel Prize (1992); Major Works: *The Economic Approach to Human Behavior* (1977), *Uncommon Sense* (2009).

Gary Becker was an American economist who applied to the study of economics the idea that individuals are rational, optimizing creatures seeking to maximize wealth or other utility. In doing so, he was able to offer explanations for many behaviors outside the traditional sphere of economic activity. In 1992, he won the Nobel Prize in Economics for his application of economic analysis to human behavior and interaction, including nonmarket activities.

Gary Stanley Becker was born on December 2, 1930, in the small coal-mining town of Pottsville, Pennsylvania. His family moved to Brooklyn, New York, when he was quite young. Upon graduating from high school, Becker attended Princeton University, graduating summa cum laude with a BA in 1951. He then went to the University of Chicago for graduate work, receiving an MA in 1953 and a PhD in 1955.

Becker held the post of assistant professor at the University of Chicago from 1954 to 1957. It was during this time that he developed several influential relationships, including with Milton Friedman (Nobel Prize 1976) and Theodore W. Schultz (Nobel Prize 1979). It was here that he worked on *The Economics of Discrimination*, which grew out of his PhD dissertation. In it, Becker used economic analysis to examine the effects of prejudice on the economic life of minorities, including earnings, employment, and occupations. Becker showed that, contrary to the Marxian view, discrimination hurt the person who discriminated, especially in competitive situations. The work received good reviews in major journals. However, Becker felt his research and work were not having an impact. Despite encouragement from Friedman, Schultz, and others, in 1957 Becker left the University of Chicago, accepting a joint appointment at Columbia University and the National Bureau of Economic Research (NBER).

While at Columbia, Becker began focusing on the role of human capital in the economy. He published *Human Capital*, which was a result of one of his first research projects for NBER in 1964. In 1967, he authored *Human Capital and the Personal Distribution of Income*. That same year, he won the John Bates Clark Medal. Becker recognized education as an investment in human capital and an important component for economic growth. While at Columbia, he began to produce articles on topics that had previously been viewed as "noneconomic," the economics of the family and the economics of crime. He also instituted workshops, modeled on the workshops at the University of Chicago, about labor and "related" subjects. But as he and his later codirector, Jacob Mincer, felt that most subjects were "related," the workshops were wide-ranging and drew significant student interest.

While he remained affiliated with NBER, Becker left Columbia and returned to the University of Chicago in 1970. It was at this time that he became friends with George Stigler, and they coauthored a number of articles. He continued to expand his own research in the studies of "noneconomic" activity.

The Economic Approach to Human Behavior was published in 1976. Becker saw family formation, family size, and family dissolution as choices subject to rational, utility-maximizing objectives. His *Treatise on the Family* was a major work on the subject and was followed by numerous articles using economics to shed light on family activity. In 1983, Becker was offered a joint appointment by the Sociology Department at the University of Chicago, which he accepted. This was verification that his method of analysis had gained validity outside of the economics profession.

In 1985, Becker was approached by *Businessweek* to write a monthly column on economic issues. He accepted on an experimental basis because he had previously written only for academic audiences. However, his writing style improved as he learned to make his case without using professional jargon and in a shorter format. He produced a number of books for general audiences, including *The Economics of Life* (with Guity Nashat-Becker) in 1996 and *Uncommon Sense* (with Richard Posner) in 2009.

In addition to being a member of the NBER, Becker was affiliated with the Hoover Institution and the American Enterprise Institute for Public Policy

Research. He was active in the American Economic Association (serving both as president and vice president), the Econometric Society, and the Economic History Association. Becker was elected to the Mount Pelerin Society, the American Academy of Arts and Sciences, the National Academy of Sciences, and the Pontifical Academy of Sciences.

He received honorary degrees from a number of institutions, including Hebrew University in Jerusalem, Princeton University, Columbia University, the Warsaw School of Economics, University of Economics in Prague, and Harvard University. In addition to winning the Nobel Prize for Economic Sciences in 1992, he received the National Medal of Science in 2000, the Heartland Prize in 2002, the Hayek Award in 2003, the Presidential Medal of Freedom in 2007, and the Bradley Prize in 2008. Becker died on May 3, 2014, in Chicago, Illinois, at the age of 83.

BEHAVIORAL LAW AND ECONOMICS

Behavioral economics is one of the most significant developments in economics over the past 30 years. The field combines economics, psychology, and sociology to produce a body of evidence that individuals' choices depart from those predicted by neoclassical economics in a number of decision-making situations. These departures from rational-choice behavior are said to be the result of "cognitive biases"—that is, systematic failures to act in one's own interest because of defects in one's decision-making process.

Emerging close on the heels of behavioral economics has been the "behavioral law and economics" movement, which explores the legal and policy implications of cognitive biases. This is derived from the Kahneman and Tversky (Kahneman 2003) heuristics or errors and biases approach to behavioral economics. The resulting regulatory agenda reflects a philosophy of so-called "libertarian paternalism," a seemingly oxymoronic phrase coined by proponents Richard Thaler and Cass Sunstein to describe legal interventions that both (1) increase the individual's economic welfare by freeing him from the limitations of his cognitive biases; and (2) thereby change the individual's behavior without limiting his choices. In other words, the promise of behavioral law and economics is to regulate so as to improve economic welfare by more closely aligning individuals' actual choices with their "true" or unbiased preferences without reducing their liberty, at least as it is represented by the choices available to them.

Critiques of behavioral law and economics and its promise of increasing welfare have raised three types of concerns: Behaviorists (1) cannot reliably discern an individual's "true preferences"; (2) consistently fail to account for the full social costs of a proposed intervention; and (3) threaten individual liberty.

Behaviorists reject the standard assumption among economists that, by choosing *x*, an actor reveals that he expects to be better off with *x*. Untethered from the standard economic approach to welfare, the behaviorists declare by fiat what they expect a rational individual would or should do—thereby justifying the imposition of "correct" choices by a third party, contrary to the behaviorist promise to maximize economic welfare by the individuals' own lights and undermining the behaviorist claim to the title of "libertarian."

A second concern regarding behavioral law and economics is that it proceeds from premises that ignore the often significant costs of intervention. For example, Sunstein and Thaler claim the selection of a default rule is "inevitable." This may be so, but it neither requires nor implies that the state—or anyone else—must be the one to select the default rule. Neither governments nor individuals can make error-free choices; the pertinent question concerns their comparative performance. Behaviorist prescriptions for intervention assume regulators enjoy a comparative advantage over private economic actors in recognizing, gathering, and processing the data required to identify each individual's "true preferences."

Finally, the behavioral law and economics regulatory agenda can present a substantial threat to individual liberty. John Stuart Mill argued for the value of autonomy for its own sake, that is, apart from what one does with one's autonomy or the consequences of its exercise. As Amartya Sen would later point out, this consideration relates to "the process aspect of freedom."

Behaviorists in general do not place any value upon the "the process aspect of freedom." Sunstein and Thaler in particular claim to preserve the choices now open to people; however, that is not always the case, and it is never without cost to the person whose preference is different from theirs. Limiting the range of decisions to be made by individuals or burdening those who would make an officially disfavored choice tends to infantilize the public. Effective decision-making is learned by trial and error, that is, by making a decision and either getting feedback about, or directly observing the success or failure of, one's decision as a means of reaching one's goal.

If individuals are to realize their full potential as participants in the political and economic life of society, they must be free to err in large ways as well as small. So long as behavioral law and economics continues to ignore the value of economic welfare and individual liberty of leaving individuals the freedom to choose—and hence to sometimes err (according to specific benchmarks)—in making important decisions, "libertarian paternalism" will not only fail to fulfill its promise of increasing welfare while doing no harm to liberty; it will pose a significant risk of reducing both.

BENTHAM, JEREMY

Born: February 15, 1748, in London, England; Died: June 6, 1832, in London, England; Nationality: English; Professional Interests: utility theory; Major Works: *Defense of Usury* (1787), *An Introduction to the Principles of Morals and Legislation* (1789).

Jeremy Bentham was an English philosopher, jurist, and legal and social reformer. His concept of the utility of consumer satisfaction, and its impact on markets, is still a major influence on economic and political thought today. Bentham quantified the utility of individual actions on the basis of the utility (satisfaction) gained by the action. Bentham's approach to studying decision-making is known as utilitarianism. His utilitarian critiques of law helped to promote liberal social and legal reform. Bentham died in 1832.

Jeremy Bentham was born in Spitalfields, London, England, on February 15, 1748, to a wealthy Tory family. He was discovered reading a multivolume history of England as a toddler and went on to study Latin at age three. His grandfather and father were both lawyers and expected Bentham to follow in their footsteps. At the age of 12, he was sent to Queen's College, Oxford, where he earned his bachelor's degree. He continued at Lincoln's Inn to study law with a student seat in the King's Bench division of the High Court. Bentham earned his master's degree in 1766, trained as a lawyer, and was called to the bar in 1769.

Bentham disappointed his father by spending most of his time focused on the theoretical aspects of legal abuses within the English system rather than practicing law. Bentham was dissatisfied with the complexity of British law. He spent the remainder of his life criticizing the existing law and suggesting ways to improve it.

Bentham was influenced by philosophers of the Enlightenment and by thinkers such as John Locke, David Hume, Baron de Montesquieu, and Claude Adrien Helvetius. Bentham felt that many of the problems of his day resulted from the accumulation of inherited power in the hands of a few wealthy landowners.

Bentham emphasized reason over tradition and clarity in the use of terms. He sought to eliminate the use of any legal words that led to "fictitious" ownership. He did not believe in "natural rights," "natural law," or "social contracts." Bentham felt that any people within a society always had some kind of restriction imposed upon them. Laws were necessary for social order and well-being and must have government to enforce them. Without law, anarchy would result. Bentham believed that the individual's economic and personal best interest is reflected in the use of a government elected by the people.

Bentham wrote *Defense of Usury* in 1785 while visiting his brother, an engineer in the Russian armed forces. In it, Bentham shows himself as a follower of Adam Smith but critiques him for not following the logic of his own principles.

One of Bentham's most significant contributions was his moral principle of utilitarianism, outlined in his book *An Introduction to the Principles of Morals and Legislation* (1789). A basic tenet of utilitarianism is that pleasure and pain motivates all human action. This thesis is also known as psychological hedonism. The right action or choice is that which causes "the greatest happiness for the greatest number." All individuals refer to utility or satisfaction in their choices, either explicitly or implicitly, and it is morally appropriate to pursue the action that maximizes pleasure.

Bentham devised a method to assess the moral status of any action, called the hedonic or felicific calculus. The ancient Greek philosophy of hedonism promotes the idea that pleasure seeking is one's moral duty. Bentham's method of calculating the pleasures and pains of a course of action, however, allows for an objective public discussion. He advocated that it was the role of the legislature to identify different interests and make decisions to promote the most satisfaction for the most people.

This became known as utility theory, a way of measuring consumer behavior. The principle of utility theory emphasizes human equality, as each person's happiness counts the same as every other person's. Bentham's ideas proved influential to his peers. They helped to shape his student John Stuart Mill's viewpoints and became a significant part of liberal political objectives. Bentham was declared an honorary citizen of France due to his correspondence with leaders of the French Revolution. He also convinced Adam Smith to change his views on interest rates.

Bentham believed monetary expansion was the key to achieving full employment. He advocated the use of minimum wage and guaranteed employment to make this happen. His work laid the foundation for the maximization principle in the economics of the consumer, the firm, and the optimum in welfare economics.

Bentham is also credited with helping to shape contemporary philosophical and economic vocabulary with terms such as *international*, *maximize*, *minimize*, and *codification*.

His work greatly influenced political reform in England and neighboring countries. Upon his death, Bentham left his large estate to finance the University College of London—one of the first English universities to admit all regardless of family background or political belief. His cadaver, as his will instructed, was dissected, embalmed, dressed, and placed in a chair in a cabinet in the hallway of the main building of the University College of London. Although Bentham published few books during his lifetime, he was a prolific writer, producing 10 to 20 manuscripts daily until his death. The University College of London's Bentham Project is working to publish a complete edition of Bentham's works and correspondence.

Jeremy Bentham died on June 6, 1832, in London, England.

BLACK MARKET ECONOMY

The black market economy generally refers to illicit and illegal trade and economic activity. The market is not a physical place but rather includes collective illegal economic activities. Sometimes it is referred to as the underground market. The underground economy and black market are not synonymous. The black market engages only in illegal activity. Black market activities are usually controlled by either corrupt governments or organized crime.

The black market is said to have originated with rationing during World War I in the Soviet Union as a response to government regulations associated with the Communist era. It then emerged and expanded in Britain in World War II. Because the food supply and international trade were stymied by German U-boat presence around Britain's primary waterways, a food ration was put into effect. However, it also limited the availability of certain other desirable items, such as cigarettes, alcohol, sugar, and certain meats. Consequently, there was increased market demand to obtain illegal goods. *Spivs* was a term that was applied to those operating in the black market.

The activities of the mafia and gangsters during Prohibition are the most famous examples of the black market economy. The International Monetary Fund (IMF) asserts that illegal money or barter transactions that constitute the black market are stolen goods, drug dealing and manufacturing, prostitution, gambling, smuggling, and fraud, and could also include the illegal hiring of employees and tax evasion strategies. Most black market activities operate using cash transactions or barter since these are more difficult to track.

Since these activities operate outside of the regulations and sight of the government, they can skew the data of the real economy. These oversights can be problematic to larger themes of policy creation, enforcement strategies, social science, and foreign policy. Most illicit activity is in direct relation to regulatory changes within the government. For example, if gun control laws were to be tightened in the United States, the black market economy would grow to fill the void in the market. This would mean that government would also have to implement enforcement strategies to counteract this eventuality. Frequently, rogue actors of the black market gain cult hero status for rejecting government controls and embodying the rights of the people. However, there is also danger involved with their activities, especially in activities related to potentially harmful products like illegal alcohol, firearms trade, or tobacco.

The black market economy is extremely important because it recognizes the natural flow of activities during recessions and regulatory periods. It can often be seen as an indicator of the demands of the people that are not being filled or that are being restricted by economies. During recessions, the black market economy often creates job opportunities for the unemployed, even though that employment or activity might be illegal. Robert Capps of *Wired* magazine estimates that small, illegal, off-the-books businesses account for trillions of dollars in global commerce and employ half of the world's workers (Capps 2011). Furthermore, in many developing nations, unofficial business transactions and black market entrepreneurs represent the real growth opportunities in those economies. These could lead to future legal and economically stimulating partnerships and innovations.

In modern times, the online platform Silk Road represented a tangible black marketplace until its shutdown in 2013. The website operated using bitcoin, which was allegedly harder to track than regular currency. The site facilitated illegal activities from drugs and weapons sales to stolen goods to murder for hire. Despite the arrest and shutdown, the creator and administrator of the Silk Road, Ross William Ulbricht, asserts that the black market will always exist and evolve to fit the needs and desires of the people. The Silk Road represented an evolution of the black market economy that could pave the way for similar innovations in untraceable payments and online connectivity for the purpose of illegal activity. However, the collapse of the Silk Road should also signal the increase in cyber intelligence and tracking abilities of government enforcement agencies.

BONDS

Bonds are financial instruments issued by a company, municipality, or government in order to raise capital for its financing needs. Bonds can be seen as a loan owed by an issuing entity (bond issuer) to the lenders (bondholders) with a set payment schedule. Bonds are classified as fixed income investments in the investing community, meaning they usually pay an interest payment (coupon) that is the same, or fixed, throughout the life of the bond.

As a result, the bondholders receive periodic interest payments at predetermined intervals over the life of the bond, usually once or twice per year. The interest payments are determined by the coupon rate at issue and are paid if a bond is held to the end of its issued life. Upon maturity of the bond, the principal value is repaid along with the final interest or coupon payment. For example, a semiannual 10-year treasury bond of $1,000 par value issued with a 3 percent coupon rate has interest payments of $15 (3% x 1,000 x 1/2) paid twice per year over a period of 10 years. At maturity—that is, at the end of 10 years—the principal of $1,000 is repaid along with the final $15 coupon payment.

Bonds are secured by the assets of the bond issuer and are said to be in default if the issuer misses a payment. In the case the bond issuer files for bankruptcy, bondholders as creditors have a right of lien on the bond issuer's assets.

Factors Affecting Bonds

The bond price is dependent on the coupon rate, the time to maturity, the credit quality of the issuer, and the current level of interest rates. When interest rates increase, bond prices fall, and when interest rates decrease, bond prices increase. The sensitivity in the price of a bond to changes in the interest rates is called *duration*. For example, when interest rates rise, a bond with duration of five years will fall in price more than a bond with similar characteristics but with duration of three years.

A bond with a higher default risk or lower credit rating is forced to pay a higher interest rate in order to compensate for its additional risk. Longer-term bonds usually pay higher interest rates than shorter-term bonds, holding all other factors steady. This is because the purchaser must wait a longer time to receive the return of his or her principal, and with time comes uncertainty.

Classification of Bonds

Bonds can be classified based on maturity, nature of interest payments, type of issuing entity, and credit characteristics. Bonds that are issued with a fixed coupon rate are called *fixed rate bonds*, and bonds that have a coupon rate tied to market-based interest rates like LIBOR (London Interbank Offered Rate) are called *floating rate bonds*. For example, a bond with a coupon of LIBOR + 100 basis points (bps) (1% = 100 basis points) is considered a floating rate bond, and the difference between coupon and the reference market rate (LIBOR, in this example) is referred to as *spread*. The above bond is said to have 100 bps spread over LIBOR.

Bonds are issued by various entities, including corporations, governments, municipalities, and educational institutions. Government-entity issued bonds are classified as treasury and municipal bonds. Corporate bonds are issued by companies and corporations.

Treasury bonds are the bonds issued by the U.S. government. They are marketable securities and are classified as treasury bills (maturity of less than one year), treasury notes (maturity between one and 10 years) and treasury bonds (maturity of over 10 years). Securities issued by national governments (other than U.S.) are referred to as sovereign bonds.

Municipal bonds are bonds issued by states, municipalities, and local government agencies to meet their funding needs and are secured by specified revenues coming from taxes or project-based revenues. Municipal bond interest payments are generally tax exempt, and this provides a tax advantage to the investors. Depending on the certainty around revenues associated with municipal bonds, most have lower interest rates than corporate bonds.

One might think that a municipal bond, secured by a city's revenues, would be quite safe. Unfortunately, if a city has financial troubles, the bondholders can suffer with loss of principal or missed coupon payments. Recently, Detroit, Michigan, has experienced deep financial difficulties, and its bondholders are plagued with uncertain coupon payments and redemptions.

Corporate bonds are the bonds issued by corporations; they are considered riskier than treasury and municipal bonds. As a result, the yield on these bonds is greater than that of the treasuries; the difference is referred to as *spread over treasuries*. The spread is determined by the credit quality of the issuer, a measure of the ability of the issuer to meet payment obligations.

Credit rating agencies like Standard & Poor's and Moody's rate the bond universe based on the quality of the issuer, and this forms the basis for the above classification. For example, bonds that are rated between AAA and BBB are considered investment grade, with AAA being the highest credit quality. These bonds generally have higher yields and lower risk of default. Bonds that are rated BB and lower are considered high-yield bonds (also known as junk bonds). Bonds that are rated C or below are considered to have very high default risk.

Although most bonds make coupon (interest) payments throughout the life of the bond, some bonds are issued without ongoing coupon payments. These bonds are called zero coupon bonds and are sold at a discount to their final maturity value. The interest rate is calculated using the difference between the discounted purchase price and the final maturity face value of the bond. Consider a five-year zero coupon bond bought for $8,000 and redeemed in five years at maturity for $10,000. The $2,000 difference between purchase and redemption values is equal to a 4.56 percent yield or interest rate.

What Is the Size of the U.S. Fixed Income Universe?

Other classifications of bonds include mortgage-related debt, money market funds, and asset-backed securities. According to Securities Industry and Financial Markets Association (SIFMA), as of June 2013, the total outstanding debt financed with U.S. bonds is $38.7 trillion, consisting of $11.3 trillion in treasuries, $9.4 trillion in corporate debt, $8.1 trillion in mortgage-related debt, $3.7 trillion in municipal bonds, $2.5 trillion in money market funds, $2.1 trillion in federal agency securities, and $1.6 trillion in asset-backed securities.

How and Why Do Investors Buy Bonds?

Bonds are not traded on an exchange, and investors are not able to buy and sell them through a broker as easily as equities (stocks). Many individual investors invest in the bond market by investing in bond mutual funds or bond exchange traded funds (ETFs). Some large individual investors and institutional investors buy individual bonds directly in their portfolio.

Bonds provide diversification to an all-equity portfolio because of their lower risk (higher in the capital structure) compared to equities. With the periodic interest payments, bonds are a source of regular income in a portfolio and hence are preferred by many investors.

BROKEN WINDOWS

The term *broken windows* refers to a class of social phenomena that conditions individual behavior on the signaling effect of the behavioral outcomes of other individuals, which are interpreted as the prevailing social norm. Examples of such signals include, but are not limited to, litter spread on the floor, graffiti on the walls, and broken windows in the surrounding houses (hence the name), which is typically observed in urban environments. The broken windows theory does not require or rely on observing actual behavior (breaking, littering) of other members of the society. Instead, it posits that people react on the observed evidence of other people's behavior and its imputed interpretations.

The term was coined by Kelling and Wilson in a popular article published by *The Atlantic* magazine in 1982 in the context of community policing, which remains a point of focus of broken windows theory. Their argument (inspired by an earlier experiment by Philip Zimbardo in 1969) was that people who live and act in a neighborhood with large social and physical disorganization and degeneration are systematically more inclined to antisocial behavior than the same people located in an integrated and dignified environment. When the evidence of disorder becomes sufficiently striking, reaching a tipping point, this induces ordinary people to switch to delinquent behavior, potentially leading to further vandalism, petty crimes, and general degradation and criminalization of the area.

One of the implications of this theory is that restoring order and dignity to the slummy city areas would improve people's behavior and eventually lead to the area's reincarnation, especially if properly supported by the authorities. On these premises, the city of New York (and some others) in the early 1990s adopted the policy of "quality of life" for its citizens and "zero tolerance" to all sort of crimes. Over the subsequent decade, the city experienced a dramatic improvement in living conditions, including a dramatic fall in crime rates. But the instrumental (causal) role of broken windows–related policy in repairing the quality of urban life remains questionable in the literature. Critiques of the broken windows theory, such as Sampson and Raudenbush, argue that correlation between criminality and the environment does not imply causation but is normally mediated by social cohesion, group identity, and other confounding factors, as well as endogeneity of the environment to crimes. Bad areas may be created by bad people just as bad people are made bad by their area of residence. But careful experimentation in various contexts appear to confirm the core premise of the broken windows theory. However, its general validity remains debatable, especially in cross-cultural contexts.

BROWNFIELDS

The term *brownfield* or *brownfield site* means an industrial or commercial site that is idle or underused because of real or perceived environmental pollution. Examples of brownfield sites include factories, chemical plants, old dumps, rail yards, abandoned hospitals, dry-cleaning facilities, and by some classifications, former gas stations. Contamination may be actual (confirmed by tests) or perceived (based on past uses of the property). Some jurisdictions now designate property contaminated with controlled substances, such as meth labs, as brownfields.

Brownfield sites exist worldwide. Between one-half million and one million brownfield sites exist in the United States alone, depending on whether or not former gas stations are included. There are many more contaminated properties that have not been officially designated as brownfields as well as more severely contaminated properties that fall under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA); these severely contaminated properties are better known as Superfund sites.

The U.S. Environmental Protection Agency (EPA) has the responsibility of regulating contaminated properties. In 1995, during the administration of President Bill Clinton, the agency announced its Brownfields Action Agenda after it recognized that owners were abandoning less-contaminated properties in fear of being held liable under the existing Superfund legislation. The Superfund liabilities included holding past, present, and future property owners responsible for all cleanup costs.

In addition, the EPA cleanup standards often resulted in the property being restored beyond its original, predevelopment condition. The potential cost involved in such efforts discouraged any type of redevelopment or reuse. The EPA responded by granting the states considerable freedom to establish programs to evaluate and clean these less-contaminated properties as a way to encourage their redevelopment. The EPA, sometimes in conjunction with other government agencies, also provided small grants for evaluation, cleanup, and redevelopment of these sites. These funds attracted a few developers to participate in cleaning and reusing these properties.

Eight years after brownfields legislation was first proposed, Congress created the designation at the federal level by amending the CERCLA statute to add Title II, Brownfields Revitalization and Environmental Restoration Act of 2001. President George W. Bush signed the act into law in 2002. Title II codified those parts of the EPA program that were deemed successful. The brownfields designation, and exemption from CERCLA standards, sought to further encourage redevelopment by providing the following: limiting the financial liability for certain innocent owners and purchasers of the property as well as owners of adjacent properties; treating prospective redevelopers differently than the owners under whom the contamination originally occurred; authorizing the EPA to provide funding for site assessment, cleanup, technical assistance, and insurance for revitalization programs; and setting different cleanup standards depending on the planned use of the revitalized property, including the use of engineered barriers to allow contamination to be left in place instead of requiring the removal of all contamination. Brownfield site redevelopment projects continue to be regulated by the states, many of which have their own brownfields legislation, and by state environmental agencies with assistance from the federal government.

Revitalizing and reusing brownfields is of great consequence because these properties have a potentially large impact on their communities. Brownfields that are not redeveloped may become eyesores, dragging down neighboring property values and discouraging other revitalization programs in the surrounding area. Additionally, brownfields may become safety and health threats to the neighborhood, which typically are already lower income and disadvantaged. Another consideration is that, unable to develop brownfield land, developers will build on previously unused properties (greenfields) typically far from city centers, contributing to urban sprawl. On the other hand, without the potential Superfund-type cleanup costs looming, brownfield sites have much to offer potential developers. Most brownfields are found along existing transportation corridors, with utilities already in place, and many sites are near city centers, making them attractive for infill development. Redeveloping brownfields has the potential to revitalize depressed areas, provide jobs during cleanup and at the businesses established after redevelopment, increase the neighborhood tax base and property values around the revitalized property, and redress possible environmental inequities.

Redeveloping brownfields is not without controversy. The biggest question is whether the costs of cleaning and reusing brownfield sites are greater than the associated benefits. Currently, there is no way to generalize the successes since each property presents its own challenges to cleanup and redevelopment. Because insurance companies are increasingly willing to cover at least a portion of the developer's risk of unknown liabilities, another economic consideration is whether the use of federal and state funds to help in the evaluation and cleanup of these properties is an efficient use of scarce resources or whether to encourage a more market-based approach to revitalizing these sites. There is also a question about whether the legislation favors redeveloping brownfield sites that offer the largest return on investment as opposed to removing contaminated sites from impoverished areas. Finally, there is not yet enough experience with redeveloped brownfields to examine possible long-term health effects or to ensure that cleanup measures will be monitored and enforced over time.

Although the brownfields designation was intended to encourage redevelopment and reuse of such properties, obstacles remain. Many property owners resist the brownfields designation due to its perceived stigma. Private developers are often unwilling to take on the potential financial and market risks associated with redeveloping brownfields, especially in lower-income communities. Many nonprofit and community organizations that have attempted to redevelop brownfields in these neighborhoods have had difficulty obtaining the funding needed for assessment and cleanup due to the investment risk perceived by some lenders and investors. In addition, some sites may be too small for profitable redevelopment. Furthermore, conflicts may arise over the proposed reuse, and the community may ultimately resist the plans for redevelopment. For example, developers may favor industrial and commercial uses, while nearby residents may prefer parks.

The EPA has stated that cleaning and reusing brownfield sites provides economic, environmental, and social benefits. However, the costs of redeveloping brownfields must be measured against the benefits of such an undertaking. In addition, future efforts need to focus on removing any lingering obstacles. For example, expanding the role of the private sector, and market institutions such as insurance should not be neglected. Encouraging increased public–private collaboration and funding may also spur additional redevelopment projects. Finally, a more transparent method of prioritizing contaminated sites would help to ensure that those areas having the greatest potential value for redevelopment also have the greatest opportunity to attract the needed attention and funding.

BUBBLES

Economic "bubbles" develop when the price of a product or asset is much greater than its fundamental value, which is determined conventionally according to the efficient market hypothesis, which states that the price of an asset is backed by "fundamentals." In this case, the price of a stock is determined by a company's worth, its expected future earnings, and expected future dividends. When an asset's valuation is inaccurately high and a bubble is created, the asset's price can drop quickly when the bubble bursts. The recurrence of bubbles throughout history suggests that other factors must be involved in causing the price to be too high (or, in some cases, too low). These variables include behavioral and psychological factors, which can cause individuals to behave differently than how conventional economic theory predicts and lead them to value an asset more or less than its true worth.

There are several assets throughout modern history that have been subject to bubbles. The first documented bubble was the Dutch tulip bubble (1634–1637) followed, a century later, by the South Sea bubble (1720). The bursting of the U.S. stock market bubble in 1929 was a cause of the Great Depression, the greatest economic downturn in world history. More recent bubbles include the Japan stock market and housing bubbles (late 1980s), the worldwide Internet bubble (late 1990s), and the U.S. housing bubble that began to burst in 2006.

A "bubble" is a situation where a fast rise in the price of an asset (the formation of the bubble) is followed by a sharp drop in the price of the asset (the bursting of the bubble). Given that the inherent values ("fundamentals") of products and assets conventionally do not rise and drop so rapidly, researchers have looked to behavioral and psychological factors to help explain these sharp price changes.

One of the main behavioral factors relevant to bubbles is representative heuristics (Tversky and Kahneman 1974), which explains how individuals can extrapolate too much information from small samples of data. In other words, individuals may conclude that if the price of a stock, house, or tulip has recently increased, it will continue to increase. Another factor, belief perseverance (Lord, Ross, and Lepper 1979), states that people tend to hold on to the original opinion they form, even when presented with contrasting evidence. Therefore, with regard to bubbles, positive beliefs about a certain asset are likely to stay positive. In addition, Thaler and Johnson (1990) describe the "house money effect": Once someone has made money on an asset, he or she becomes less risk averse and may try to make even more money on that asset, thus pushing up its price and inflating the bubble further. Barber and Odean (2008) illustrate that people are more likely to buy stocks mentioned in the media, which would make them more likely to buy stocks involving new technologies, whether the breakthrough is radio in the 1920s or the Internet in the 1990s. "Herding" can also be a factor in the creation of bubbles. In the absence of perfect information, individuals follow the leader in their investment behavior, hoping that the other person knows better than they do the direction of price movements. All of these factors help to explain how asset valuing may diverge from fundamentals.

In addition to these behavioral and psychological factors, substantial changes in technology and in economic practices can also affect bubble formation. Perez (2002) posits that technological innovations bring seemingly limitless opportunities but also much uncertainty about the future of the new technology. This uncertainty creates challenges in accurately determining the value of companies associated with the new technology, leading to speculation. Examples include the difficulties in the mid-1990s (and still today) of evaluating the role of the Internet in our lives. Perez also documents similar situations that occurred prior to the stock market crash of 1929 (which, in addition to radio, included technological developments in electrical machinery and automobiles), such as the "canal mania" leading to the panic of 1797, and the "railway panic" of 1847 in Britain.

Changes in economic practices can also lead to and/or augment bubbles. For example, the U.S. housing bubble in the 2000s was formed in part by lending institutions granting subprime loans, leading to a large increase in housing demand and the price of real estate.

While there is a general consensus that bubbles exist, there is also debate as to the actual magnitude of a bubble because of the challenge of determining how much of a price increase is due to fundamentals. For instance, in examining the stock market crash of 1929, McGrattan and Prescott (2004) argue that given changes in intangible capital (patents) at the time, stocks were priced correctly. Researchers who favor the efficient market hypothesis (Malkiel 2003) explain that although bubbles exist, they are the exception rather than the norm. They argue that the efficient market hypothesis can still explain market behavior most of the time—market fundamentals simply need to be measured more accurately. On the other hand, Shiller (2000) and Akerlof and Shiller (2009) argue that bubbles are a critically important phenomenon in market economies that can't be explained using traditional economic theory and require the intervention of behavioral variables such as animal spirits and herding as core explanatory variables.

BULLYING AND ECONOMIC EFFICIENCY

Workplace bullying is an important noneconomic variable that can have a direct and significant impact on productivity and, therefore, on the size of the economic pie and on a firm's competitiveness. Bullying outside of the workplace, including bullying at home or at school, across age cohorts, can have an indirect effect on productivity, impacting on the capability of the bullied individuals to increase their productivity over their life cycle. Conventional economics assumes that the key determinants of productivity are traditional variables such as increases in the capital stock employed per worker, firm size, formal education, on-the-job training, and technical change, where the latter is assumed to be exogenously given. The conventional model assumes that the quantity and quality of effort is fixed, if not maximized. In other words, it is maintained that firms are operating x-efficiently. Firms are doing the best they can, given their factor inputs (such as labor and capital), and given technology. Since bullying has its greatest impact on effort input, the potential impact of bullying on productivity is assumed away by assuming effort is fixed and that firms are x-efficient in production.

Workplace bullying is more pervasive than sexual harassment. Various estimates suggest that 20 to 30 percent of employees are subjected to different levels of workplace bullying. It generally takes the form of *persistent* mistreatment of individuals (the key being persistent), often taking the form of nonverbal, verbal, psychological, and even physical abuse. But the latter is not the dominant form of workplace bullying. More specifically, workplace bullying takes the form of overworking employees without reasonable compensation, unfair compensation for work done, stealing credit for work, persistently failing to acknowledge an employee's achievements, unfairly blaming (especially in public) an employee for the bully's or corporation's failures, blocking opportunities for career advancement, intimidation, setting up the employee to fail in assigned tasks, and isolating an individual from his or her peers or superiors.

Most workplace bullying stems from management—those further up in the corporation's decision-making hierarchy. But workers can also bully other workers in an environment where bullying is either tolerated or celebrated. Often individuals are humiliated and intimidated to get them to work harder or more effectively.

This can be viewed as a low-cost strategy, sometimes as part of a corporation's managerial culture, to induce employees to work in the interest of the corporation or its management or board. But workplace bullying often serves to increase the utility or level of satisfaction of the bully without having any anticipated positive productivity outcomes. For example, from the perspective of the bully, bullying enhances the bully's position within the corporation relative to those further down the corporation's hierarchy. And relative position is an important noneconomic determinant of many individuals' utility or level of well-being.

Workplace bullying increases stress levels of the bullied individuals and other employees. It signals the possibility that those employees who are not being bullied are next on the list. It pollutes the workplace environment and increases the extent of conflict within the corporation, which reduces the extent to which it can perform efficiently. Cooperative employer–employee relationships yield higher levels of productivity. Overall, bullying reduces the incentives for employees to work hard and well. It also increases the probability that the bullied and even their colleagues will retaliate against the bully and the organization by reducing the quality and quantity of their effort inputs. The former includes employee errors in the process of production, sabotage, workplace accidents, and litigation. Bullying increases absenteeism and quit rates, which also increase production costs. Workplace bullying negatively impacts on the overall well-being of an organization's workforce.

Given that the quality and quantity of effort is variable, the impact of workplace bullying on productivity can easily be identified. All other things remaining the same, lower productivity will increase average costs, and this could reduce the overall competitiveness of the firm. However, this need not be the case of organizations, such as government agencies or universities, that need not pass the test of the market, at least in terms of cost competitiveness. But even in the competitive sector, higher-cost organizations (where bullying increases production costs) can easily survive if protected from market forces by subsidies, tariffs, and tax breaks. Also, such organizations can survive if the reduced productivity is counterbalanced by lower wages or deteriorating working conditions, leaving average costs unchanged. If bully-induced productivity falls by 10 percent and the firm's labor and other costs fall by 10 percent, average costs will remain unchanged. Organizations dominated by bullying can, therefore, remain sustainable over time, even though they reduce society's per capita income.

BURSTING OF THE DOT-COM TECHNOLOGY BUBBLE

Throughout history, assets such as gold, stocks, bonds, and even tulips became more expensive than their intrinsic value. Consumers and investors must recognize the causes and occurrences of asset bubbles in order to avoid participating in the herd mentality and underlying economic factors that lead to overvalued asset prices and inevitable corrections. The 2000 technology stock bubble and subsequent crash highlights the importance of understanding how bubbles can affect personal finances.

The technology stock bubble began as U.S. stock market prices accelerated from a 10.4 percent annual return between 1990 and 1995 to a 21.2 percent annual return between 1995 and 2000. The U.S. stock market capitalization (total number of shares outstanding multiplied by the share price for each corporation) tripled between 1995 and the stock market peak in 2000. International stock prices increased during this period as well, although not as rapidly as those in the United States, at an annualized rate of 7.9 percent (Kraay and Ventura 2007).

Driving the run-up in stock prices were the real and perceived increases in productivity. With the advent of groundbreaking technological advances and an exploding technology sector, investors believed that productivity advances would continue indefinitely. This persuaded investors to pay more and more for the "miracle" technology stocks.

A positive economic environment encouraged the asset price bubble. Low inflation and interest rates during the late 1990s aided the robust stock market advances. The historically low U.S. budget deficit and increased productivity during the 1990s led people around the world to invest their monies in highly efficient U.S. companies, further driving up stock prices. The highly productive technology sector led the advance in stock market prices. For example, during the 1990s, Intel (INTC), the stock market darling, exploded from a low split-adjusted price of \$0.79 in August 1990 to its peak of \$50.88 in March 2000. That level of growth represents an unrealistic and unsustainable 50 percent return per year.

Stock Market Psychology

Rational economic factors explain only part of the growing asset prices in this and most asset bubbles. Market psychology and behavioral finance factors explain another part of the excess run-up in stock prices. Market factors such as supply and demand imply that assets are fairly priced and for the short periods of time when a stock might be overvalued, demand will decline for that stock, causing its price to fall to fair value; however, this efficient market theory does not explain the whole story.

Behavioral finance helps to explain the occurrence of bubbles such as the technology stock bubble of the late 1990s. Herding, similar to that in animals, is also a well-documented human behavior observed in the context of economics as early as 1759, when Adam Smith (1723–1790), father of modern economics, described how individuals who imagine themselves in another's situation tend to mimic that person's behavior. John Maynard Keynes (1883–1946), another renowned economist, further popularized the idea that contagious "animal spirits" among investors can move the markets, another description of human herding behavior (Baddeley 2010).

When markets are moving upward, investors, afraid of missing the run-up in prices, rush in. Frequently, as prices become more and more overvalued, the prior stock price appreciation prods investors to buy in at inflated prices. This herd mentality, in direct contrast to the concept that individuals behave rationally, causes asset prices to rise beyond their intrinsic value.

Hyman Minsky (1919–1996) described bubbles as a natural outgrowth of periods of economic stability (Bodie, Kane, and Marcus 2011). Investors assume the stability will continue into the future and so are willing to take on more risk. This is an example of framing, another behavioral bias that says decisions are impacted by the perception of the environment in which they are made. In other words, during the late 1990s, the economy was strong, asset prices were rising, and investors believed this golden economic environment would continue indefinitely.

Alan Greenspan, former head of the Federal Reserve Bank, described this herding behavior as "irrational exuberance" (Pollock 2013). During the late 1990s, when Greenspan pointed out the inflated asset prices, another problem with asset prices was implied. The markets were inflated, but when they would return to fair value was uncertain. That reality describes a fundamental problem with asset price bubbles: even when one identifies overvalued assets, it is impossible to predict when the bubble will burst and the asset prices reverse course. Only hindsight correctly identifies the bursting of inflated asset prices.

The Upward Stock Market Trend Reverses

In 2000, the euphoria dissolved as markets finally reversed direction. According to the National Bureau of Economic Research, U.S. productivity fell in 2000, which ignited the stock market decline. Thus began the 30 percent drop in equity prices that occurred during the first three years of the 21st century. Investors were unwilling to buy overvalued assets from other investors. Thus, as demand declined, market forces pushed stock prices lower and lower.

Fiscal budget deficits began to rise in 2001 when the Bush administration came into office. These deficits were in stark contrast to the low budget deficits and small surpluses of the 1990s. The Middle East military conflicts added to the budget deficits.

By 2004, the U.S. budget deficit had reached 4.8 percent of the gross national product (GNP). U.S. public debt grew from 33 to 37 percent of GNP from 2001 to 2004 (Kraay and Ventura 2007). The National Bureau of Economic Research draws a relationship between the stock market bubbles, budget deficits, and current accounts (relationship between U.S. expenditures and income).

One theory states that as the bubble bursts, stock prices fall, and there are more sellers than buyers for the existing equity investments, the government offers more debt investments and gives investors an alternate place for their funds. Since stock values are declining, investors choose alternate opportunities, such as investing in government debt. This increase in government debt subsequently continues growing the budget deficit. Unfortunately for investors who previously enjoyed large capital appreciation from investing in the rapidly increasing stock market of the 1990s, government debt does not offer the same level of returns.

Just as the exaggerated increase in stock prices late in the 1990s was difficult to explain solely with economic factors, so was the rapid turnaround in market prices. Additionally, the theory that budget deficits and increased government debt is the benevolent U.S. government's solution to replace the inefficient and overvalued equities of the late 1990s is an insufficient explanation.

Behavioral economics also describes individuals' activities in a declining market. As investors follow one another to the exits and begin selling their assets, stock prices decline and the herding behavior works in the opposite way to burst the investment bubble.

During the 1990s, the U.S. economy, and to a lesser degree international markets, experienced a confluence of positive business and economic circumstances along with optimistic psychological factors. Asset prices exploded during this golden period, reaching unsustainable levels. The bursting of the dot-com technology bubble was inevitable. The wise consumer who understands historical economic and personal finance bubbles and subsequent reversals is more likely to avoid following the crowd into overvalued investment opportunities.

BUSINESS CYCLE

A business cycle is the overall fluctuation in the economy due to changes in production, aggregate supply, consumer aggregate demand, and unemployment. Fluctuations of the business cycle are periodical but not predictable. They are irregular ups and downs of economic activity measured by the fluctuations in gross domestic production and other macroeconomic variables, such as unemployment.

The business cycle defines four stages of an economy: contraction, when the economy starts slowing down; trough, when the economy hits bottom, also known as a recession; expansion, when the economy starts growing again; and peak, when the economy is in a state of exponential growth, usually resulting in inflation.

Periods of contraction are often indicated by widespread pessimism and negativity around the economy or an increase in unemployment. A declining stock market (bear market) can also be a signal of a contracting economy. A bear stock market is a market in which investors are very pessimistic about the economy and therefore the prices of securities. This pessimism leads to falling securities prices. As investors anticipate losses and continue selling, pessimism grows.

A positive economic outlook by both consumers and producers signals an economy in the expansion mode of the business cycle. An expansion will also include increasing employment and activity in stock markets, or a bull market. In a bullish market, financial securities go up.

Business cycles are important when countries are considering combining currencies. If the countries are not in the same business cycle, one country will lose by possibly having to devalue its goods and services to align with the country whose monetary policy fits the business cycle. In the contraction phase, GDP growth rates usually decline to the 1–2 percent level before turning negative. The 2008 recession was so impactful because the economy immediately shrank 2.7 percent in the first quarter of 2008, gained 2 percent in the second quarter, and fell another 2 percent in the third quarter, before declining 8.3 percent in the fourth quarter. The economy declined again in the first quarter of 2009 by 5.4 percent.

In the trough phase, GDP growth may still be negative but not as bad as in the contraction phase; this occurred in the second quarter of 2009, when GDP contracted a mere 0.4 percent.

In the expansion phase, GDP growth turns positive again and is expected to be in the 2–3 percent range. Managed well, the economy can stay in the expansion phase for years. The current expansion phase started in the third quarter of 2009, when GDP rose 1.3 percent. This was the result of stimulus spending from the American Recovery and Reinvestment Act. Four years into the expansion phase, the unemployment rate was still above 7 percent because the contraction phase was so harsh.

The peak phase is when the economy's expansion slows. The end of the peak phase is usually signaled by the last healthy growth quarter before a contraction begins. In the 2008 recession, the peak occurred in the third quarter of 2007, when GDP growth was 2.7 percent.

The business cycle is affected by the forces of supply and demand. When consumers are confident, they buy now because they know there will be future income from better jobs, higher home values, and increasing stock prices. As demand increases, businesses hire new workers, which further stimulates demand. This is the expansion phase. If demand is higher than supply, the economy can overheat. This combination of excess demand and the creation of risky derivatives created the housing asset bubble in 2005. If demand is not lowered with higher taxes (fiscal policy) or higher interest rates (monetary policy), the peak will not be far off. In addition to demand, the business cycle is heavily dependent on the availability of capital. Too much capital will turn a healthy expansion into a peak, often causing inflation. At this point, a stock market correction may indicate that assets are overvalued, creating fear and a contraction. The Federal Reserve lowers interest rates to spur the economy into expansion during a trough. It raises rates during an expansion to avoid too much of a peak.

BUSINESS STRUCTURES

Business structure is a term used to describe a specific type of business with certain characteristics and regulations. Business structures seek to earn a profit by providing a good or service to the public. A business structure can take many forms, including, but not limited to, a sole proprietorship, a general partnership, a limited partnership, a limited liability partnership, a corporation, or a limited liability company. Business structures also vary based on the number of owners, access to capital, length of life, and level of liability.

One common type of business structure is a sole proprietorship, in which one person controls the day-to-day operations of the business. This type of business is considered the easiest to form due to the lack of red tape and paperwork. Owners of this type of business assume all risk and reward for their business as they face unlimited liability and limited life. Another limitation is access to capital based on the individual's access to resources or loans. The business is not seen as a separate entity, and owners report profits or losses on their personal tax return. In some cases, businesses that begin as a sole proprietorship may expand into one of the other business structures.

Another type of business structure is a partnership, in which two or more people own a business. Partnerships are the only business structure that can be formed with a verbal agreement, although a formal partnership agreement is highly recommended to prevent any misunderstandings. Partnerships generally have access to more capital, and partners may bring specific skills to the business.

There are also several types of partnerships. In a general partnership, all partners are responsible for the losses or gains of the business. In a limited partnership, the limited partner is only responsible for his or her investment and does not play an active role in actually running the business. In this case, there is at least one general partner who handles the day-to-day affairs of the business. In a limited liability partnership (LLP) all partners have limited liability and are not responsible for the debts incurred by other partners. Examples of this include law and accounting firms.

A corporation is a business structure that is a legal entity separate from its owners. Forming a corporation requires more paperwork than other types of businesses and is subject to incorporation fees. This type of business involves the selling of stock to shareholders, who serve as the owners of the business. Usually a board of directors is selected by the shareholders to run the day-to-day affairs of the corporation. A corporation has limited liability and unlimited life but also faces heavy government regulations and high start-up costs. A major disadvantage of a corporation is double taxation, where it is taxed based on profits and shareholders must pay taxes on dividends earned. Corporations that are designated as S corporations do not face double taxation since they are taxed as a partnership.

A limited liability company (LLC) business structure includes elements of both a partnership and corporation, and the owners are referred to as members. Members of an LLC are not liable for debts of the business, making it similar to a corporation. However, a big difference from a corporation is that in an LLC income taxes are paid by its members through their personal income tax.

Individuals interested in setting a business structure must carefully weigh the advantages and disadvantages of each type when deciding which is best for them.

CAP AND TRADE

Emissions trading, or cap and trade, is an environmental policy tool used to control pollution by setting a mandatory cap on emissions and allowing for flexible means of complying with these approaches. Successful cap-and-trade programs will possess characteristics such as strict environmental accountability without inhibiting economic growth, as well as reward innovation, efficiency, and proactive actions.

The policy tool first begins with setting a maximum amount of emissions per period—or in other words, an overall cap. This cap is chosen in order to achieve a desired environmental effect and is delegated to all sources of emission, which cannot exceed the cap limit. The other part of the equation, or the trade, creates a market for allowances, enabling corporations to meet or come in under their allocated emissions limit. The less they emit, the less they pay.

As stated previously, the cap sets a maximum allowable level of pollution and penalizes companies that exceed their emission allowance. The cap serves as a limit on the amount of pollution a source, or corporation, can emit and is measured in billions of tons of carbon dioxide, or equivalent, per year. Emitters of pollution are permitted allowances, such as one allowance per ton of carbon dioxide or other equivalent heat-trapping gases. The total amount of allowances will be equal to the cap, and companies may emit only the amount of allowance they are allocated. Moreover, the cap includes all major sources of pollution, thus limiting emissions throughout the entire economy. This includes electric power generation, natural gas, transportation, and large manufacturers. Each year the cap is lowered in order to reduce the amount of pollutants released into the atmosphere.

Some emitters will find it easy to match their number of allowances and thus reduce their carbon footprint. Others, however, may find it more difficult. The trading aspect of cap and trade allows corporations to buy and sell allowances. This leads to more cost-effective pollution cuts as well as an incentive to move toward greener, eco-friendly technology.

As an example, one company may be able to cut its pollution in a cheap and easy manner. This leaves the company with extra allowances, which it can sell to other companies. Conversely, a company may find it more difficult to reduce its emissions or may only be able to make long-term investments to reduce its emission level. The option to trade allowances gives companies the option to meet their cap. Overall, trading provides a significant incentive to reduce global emissions.

CARTELS

A cartel is an explicit arrangement among suppliers in an industry to manage output and prices in order to capture additional profit. The presence of an explicit arrangement distinguishes cartels from other forms of strategic interaction in oligopoly environments. A successful cartel must (1) identify a profit-enhancing level of sales for the cartel, (2) assign output or sales quotas to cartel members, (3) monitor cartel member sales, and (4) be able and willing to punish excessive sales by cartel members.

Since Adam Smith's *Wealth of Nations* was published in 1776 (or earlier), economists have taken note of cartel behavior. Smith wrote, "People of the same trade seldom meet together, even for merriment or diversion, but the conversation ends in a conspiracy against the public, or in some contrivance to raise prices." Given the widespread benefits to suppliers that arise from forming a successful cartel, it is perhaps surprising that many industries are not so organized. The lack of widespread cartelizing may be evidence of the difficulties of maintaining a cartel, of the success of public policies against cartels, or both.

Because the profit-enhancing level of sales is below the competitive level of output, cartels will require some or all of their members to reduce sales. The resulting higher prices will leave members curtailing sales in which the marginal revenue from added output is greater than the marginal cost, presenting cartel members with the constant opportunity for short-run gain at the expense of other cartel members. The chief challenge a cartel faces is in maintaining member compliance, and quotas are given to curtail the constant temptation to cheat. Diversity of positions among cartel members—high-cost versus low-cost producers, short-term versus long-term time horizon, and so on will further complicate cartel operations.

When discussing natural resource cartels, economists have an easy example: the Organization of Petroleum Exporting Countries (OPEC). Unfortunately, OPEC is a bad example. OPEC only loosely satisfies the conditions of a rigorous definition of *cartel*, and most serious studies of the organization find it has failed to sustain world oil prices at higher than competitive levels. But there are several examples of durable natural resource cartels, and certain natural resource industries are particularly susceptible to cartelization. In addition, successful cartelization reduces industry output. Robert Solow claimed that conservationists and monopolists are philosophical friends, with a cartel also being the conservationist's friend. Natural resource economists have taken a special interest in cartelization for these reasons.

Historically, several natural resource industries have experienced attempts at cartelization, and some industries have sustained cartels for several years. Over the 20th and 21st centuries, cartels have emerged for diamonds, bauxite (aluminum ore), tin, magnesium, and yellowcake (uranium ore), among others. Unsuccessful or disputed cases of cartelization include petroleum and copper.

OPEC likely attracts the most attention, both among professional economists and the public, due to the high value of petroleum and the association between OPEC and the energy crises of the 1970s. Five members formed the organization in 1960, largely to protect exporting nations from a price cut imposed by the international oil companies, which exercised significant control over the world market at that time. The public took little notice of OPEC until Arab members imposed a boycott on exports to the United States in October 1973 and a subsequent tripling of world oil prices to over $12 a barrel in 1973 dollars. OPEC became a convenient scapegoat for politicians in oil-importing nations such as the United States.

At the time, the public took little notice of how U.S. price controls and associated policies created the domestic energy crisis and boosted OPEC's economic power, because lower prices discouraged domestic production and encouraged consumption. The repeal of petroleum price controls in the United States, along with the high-price-induced supply response by non-OPEC producers, diminished OPEC's economic influence after 1980. Although economic analyses of OPEC continue to support a variety of views of the organization's influence and success, many analysts have concluded that the apparent influence of OPEC is largely due to the actions of Saudi Arabia.

Cartelization in the diamond industry presents a clear contrast to the petroleum market experience, with the international diamond cartel perhaps being the most successful and longest-lasting cartel. The De Beers family of companies began in South Africa in 1888 and soon controlled over 80 percent of worldwide diamond production, successfully dominating marketing channels that took South African diamonds to European markets. Over the 20th century, as diamond mines in other countries were developed, the company expanded horizontally to maintain some control over supply and vertically to better manage distribution. The company quite willingly built up a large stockpile of diamonds to accommodate purchase agreements with suppliers while controlling the supply, and therefore the price, of diamonds reaching the consumer market. The stockpile also represented a potential threat to any supplier who wished to bypass the cartel, as it could easily flood the market with the quality and color of stone the supplier had to offer. At the beginning of the 21st century, increasing supply from producers outside of the De Beers organizations, principally from Australia, Canada, and Russia, and the increasing political taint associated with so-called "conflict diamonds" led the company to reduce its scale and shift its marketing strategies. However, De Beers remains in the business of promoting orderly competition in diamond markets.

In addition to the periodic market influence of OPEC in petroleum and the enduring market dominance of De Beers in the diamond business, other producer groups have struggled to capture the excess profits available through cartelization; some have succeeded. The International Copper Cartel, created in 1935, controlled about half of world production, but noncartel supply was too elastic in response to price increases, and the cartel was unable to significantly increase price. A cartel in mercury production was sustained by formal agreement from 1928 until 1950 and continued less formally afterward, aided by low-cost conditions and cartel-supporting government policies in Spain and Italy. The formal agreement was dissolved after an Italian mining company violated marketing restrictions. Informal cartelization continued to have influence through the 1960s but faded as low-cost production emerged in numerous countries around the world. The uranium ore (yellowcake) market was cartelized by a secret arrangement in 1972 among the largest non-U.S. producers, some privately owned and some state owned, in the face of inelastic and readily predictable demand driven by the growth of nuclear power. The cartel was aided by international agreements monitoring movements of uranium and by the enthusiastic support of the governments of exporting nations. When the agreement became public, however, it was rapidly abandoned in the face of pressure from importing nations.

CERTIFICATE OF DEPOSIT

Certificates of deposit (CDs) are a cross between bank savings deposits and investment vehicles such as bonds. They are usually purchased at banks and include characteristics of basic savings accounts. The depositor places funds in the bank and receives interest payments. The interest rates paid on CDs are usually higher than those paid on savings accounts.

Certificates of deposit, like some investment products, have a term or maturity attached. For example, CDs may be bought to mature in three, six, or nine months or in one to several years. Like a traditional bond, when the CD comes to maturity, the holder receives the original or face value back plus the interest earned. CD owners who redeem the CD before maturity sacrifice a week's to three months' interest in exchange for the early withdrawal (called an early withdrawal penalty). Some banks automatically reinvest or roll over the proceeds from the CD at maturity.

Interest Calculation

The interest calculation on a certificate of deposit influences the ultimate return to the investor. There are several methods of calculating interest. Annual percentage yield (APY) is the effective annual rate of return and considers the impact of compounding interest or the interest paid on prior interest earned. The annual percentage rate (APR) is calculated using simple interest and does not pay interest on the prior interest received. Thus APY is higher than APR. When comparing CD interest rates, it's important to note which type of interest rate is used.

For example, Lily purchases a $1,000 five-year CD at State Bank with a 3 percent interest rate paid and compounded semiannually (APY). At the end of six months, she receives $1,000 x 0.5 x .03 = $15. Add this amount to $1,000 and her CD is worth $1,015 after six months. At the end of year one, she receives $1,015 x 0.5 x .03 = $15.23. The value of Lily's CD at the end of year one is $1,015 + $15.23 = $1,030.23.

Had the interest been calculated with the annual percentage rate and not compounded (APY), her CD would have been valued at $1,030 at the end of year one, since the 3 percent return was paid only on the original $1,000 ($1,000 x .03 = $30). With APR interest the CD earns $15 every six months. In contrast, with APY interest, each interest payment is greater than the last because the 3 percent interest is paid on a growing base.

Safety and Insurance

Certificates of deposit are considered safe investments for several reasons. The redemption amount is clearly stated at the time of purchase and will not vary. For example, buy a $1,000 one-year CD with a 2 percent interest rate (APR) paid at maturity and in one year the CD can be redeemed at $1,020. There is no risk of losing principal or interest as one might in a stock or bond. The only uncertainty is inflation risk. If inflation increases, the purchasing power of that $1,020 will decline and the same dollar amount will buy less.

Banks offer insurance to depositors through the Federal Deposit Insurance Corporation (FDIC). All deposits held at insured banks are protected against loss if the bank fails. All types of deposits, including CDs, are covered by FDIC insurance up to $250,000 per depositor per bank.

Types of CDs

Historically, CDs were designed as simple investments. The traditional CD pays a fixed interest rate over a predetermined period. At the end of the term, the investor withdraws the money or uses the funds to buy a new CD, called a rollover.

New types of CD emerge as the finance industry evolves and consumers demand more sophisticated products. Bump-up CDs answer the concern that interest rates might rise during the tenure of a CD and cause the investor to miss out on higher yields. These adjustable-rate CDs allow investors to exchange their current interest rate for a higher one if rates on new CDs of a similar term rise during the investment period. This option is usually offered as a onetime rate increase during the life of the CD.

There is a liquid CD for investors willing to trade a lower interest rate for greater flexibility. This account allows investors to withdraw all or part of the account penalty free. A callable CD gives the bank the right to recall the CD after a set period. In contrast with the liquid CD, a callable CD typically pays a higher interest rate in exchange for the uncertainty of the instrument's term. Banks will issue these types of CDs when they are concerned that interest rates will decline.

A zero coupon CD does not pay annual interest and generally promises a higher interest rate. The CD is bought at a discount to the final redemption value. The interest is calculated by comparing the final payment with the initial amount invested. Although annual interest is not paid, tax is usually due each year on the proportion of reinvested interest.

Brokered CDs are purchased in investment brokerage accounts and issued by national banks. These offerings give investors flexibility to invest outside a hometown or an online bank. In fact, investors can purchase brokered CDs from several banks in their investment brokerage account. Because they are issued by a bank, the FDIC insurance applies. Brokered CDs can be bought and sold from other investors through a brokerage account after issue in the secondary market.

Who Invests in Certificates of Deposit?

Certificates of deposit are safe investments for consumers to gain higher interest payments than they would with traditional savings accounts. These investments are great for targeted expenses. For example, if you are saving money for a down payment on a home in three years, you need to keep the money readily accessible (or liquid) and safe. If you buy a three-year CD, your money will be available when you need it, and it will earn a bit more interest than if you'd left it in your savings account.

Certificates of deposit are among the safest places for consumers to invest their cash for any short- and medium-term (five years or less) financial needs.

CHRYSLER BANKRUPTCY, 1979

The late 1970s saw the appearance of the Four Horsemen in the American auto industry. Imports of foreign-made cars due to free trade, old plants and assets, global labor competition, and increases in the price of gasoline as a result of the energy crisis devastated the Big Three automakers: General Motors, Ford, and Chrysler. Chrysler would be the first to feel the impact of a flood of Japanese imports in the 1970s. With its big cars, Chrysler was also hit particularly hard by the energy crisis, though it seemed to have been able to beat the energy crisis of 1974 and reported a profit in 1977. The fall of the shah of Iran sent gasoline prices soaring in 1978, and by 1979 Chrysler was facing a billion-dollar loss.

A Chrysler bankruptcy seemed likely as the nation entered a recession. Chrysler accounted for about 8 percent of the American auto market, and a bankruptcy threatened the loss of 200,000 jobs and a potential devastating blow to an auto-supply chain under great pressure from Japanese parts. The possibility of a Chrysler bankruptcy sent fear across the nation, so dealers, suppliers, and the United Automobile Workers pushed for a political solution to prevent it. In response, Congress passed the Chrysler Loan Guarantee Act on September 7, 1979. Chrysler then scaled back its operations significantly, which helped fuel the 1982 recession. Still, the government loan guarantee resulted in a turnaround for Chrysler, and the company paid back the loan by 1983 with a profit of $350 million for the government.

Chrysler's problems started with the Arab oil embargo of 1973. The American auto industry was caught off guard with large gas-guzzlers in their showrooms. Sales of imported gas-efficient cars surged, and even though the embargo lasted only six months, buying patterns were changed forever. Oil had been less than $5 a barrel, but at the end of the six-month embargo, oil would be $18 a barrel with daily movements as high as $22 a barrel. By the mid-1970s, the Japanese had captured 18 percent of the American car market. With its lineup of big cars, Chrysler lost the most.

The problem of Chrysler's big cars was exacerbated by the Corporate Average Fuel Economy (CAFE) regulations enacted by the U.S. government in 1976 as part of its environmental movement and fuel-saving efforts. However, the measures hit American automakers in the worst period in their struggle against imports and oil shortages, forcing them to reduce car size and weight and sell more small cars, even if they were not profitable. The combination of the oil crisis and these regulations ended American dominance in the world auto industry. More than 27 auto plants closed, resulting in the loss of more than 500,000 jobs. Chrysler lacked the capital to retool its factories and accounted for 13 of those closings.

Chrysler had a brief market reprieve in 1978 when consumers started buying big cars again, but the fall of the shah of Iran sent gasoline prices soaring once more and sent consumers running to buy small cars. That same year Chrysler hired Lee Iacocca, who had been one of Ford Motor's most successful product managers and had the Mustang to his credit. At Chrysler, however, Iacocca came into a basically bankrupt company that had no money to pilot the production of new products. His first task was to go to Washington, D.C., to negotiate a bailout. It was clear that without government help the company faced bankruptcy. The popular belief was that even Chapter 11 bankruptcy could not save the company. The death of Chrysler augured a serious blow to a failing American economy in 1979. The United Automobile Workers represented a major political force at the time, and the potential for huge job losses in the industry made Congress amenable to a deal.

The political pressure from both sides resulted in what many see as a very balanced approach. The federal loan guarantee came with a number of attachments and requirements. The final deal looked much like Chapter 11 bankruptcy and certainly followed Chapter 11 guidelines for bankruptcy, unlike what happened during Chrysler's subsequent 2009 bankruptcy.

The deal allowed Chrysler, with the help of the secretary of the Treasury, to pressure its suppliers to allow Chrysler to pay off $600 million in debt for 30 cents on the dollar. Many small suppliers were hurt by this deal, but a full bankruptcy would have been worse. At least $700 million of preferred stock was reduced to nondividend equity. The agreement called for operating cuts, including a salary reduction program, that resulted in the loss of 62,000 white-collar jobs. These cuts were particularly hurtful to middle-class families in the midst of a recession. The company gained concessions of more than $600 million from the autoworkers' union, which meant Chrysler workers made $2 an hour less than General Motors and Ford workers. The government also helped by granting Chrysler more government contracts, although in 1982, Chrysler sold its Defense division to General Dynamics for $348 million.

Most observers still claim the bailout was a success. In the first quarter of 1983, Chrysler reported a $170 million profit. In September 1983, Chrysler repaid the full government loan, seven years ahead of schedule. Iacocca would bring on new products in the 1980s, such as the minivan. Chrysler went on to buy the American Motors Jeep brand in 1987. Some argue that, unfortunately, Chrysler's success came at the expense of Ford and General Motors as the domestic manufacturers' share of the American market continued to drop.

CLAYTON ANTITRUST ACT OF 1914

The Clayton Antitrust Act of 1914 was written to strengthen the government's control of monopolies and monopolistic activities that weakened trade in the United States. The Clayton Act further strengthened the antitrust laws originally expressed in the Sherman Antitrust Act of 1890 by allowing people to sue if they could prove damage by an illegal arrangement to restrain trade. According to the Clayton Act, a successful plaintiff in such a case would be allowed to recover three times the damages sustained. The purpose of this rule was to encourage private lawsuits against conspiring oligopolists.

Historical Antitrust Legislation

For centuries, throughout England and the United States, judges have deemed agreements among competitors to reduce quantities and raise prices to be contrary to the public good and the free-enterprise system. They have therefore refused to enforce such agreements. The Sherman Antitrust Act of 1890 codified and reinforced this policy. The Sherman Act established a legal boundary for contract law. The act also stated that every contract or attempt to restrain trade or commerce among states or with foreign nations was illegal.

Under this original antitrust legislation, any person who monopolized or attempted to monopolize any part of the trade or commerce among states or with foreign nations would be deemed guilty of a misdemeanor with a punishment of a fine not exceeding $50,000 or by imprisonment not exceeding one year, or both punishments, at the discretion of the court.

The Clayton Antitrust Act, signed into law in 1914 by President Woodrow Wilson, supplemented the Sherman Antitrust Act. The Clayton Antitrust Act made the following illegal: price cutting, rebates, and exclusive contracts specifically for the purpose of eliminating the competition. The act excluded two groups: labor unions and agricultural cooperatives.

So long as they were peaceful, the act allowed strikes, pickets, and boycotts. It also restricted the court's ability to issue injunctions against organized labor for the purpose of strikebreaking. This particular piece of the Clayton Act expressly defined labor as not a commodity or "article of commerce." This was seen as a win for the labor force in the United States. Workers hailed the law as labor's backing force. Businesses, however, continued to assert that labor should not be protected in this way.

The act further increased the punishment for breaking said antitrust legislation. It became more punitive with the introduction of the triple damage rule. It also strengthened the government's powers and authorized private lawsuits.

The antitrust laws give the government various ways to promote competition. They allow the government to prevent mergers, and they prevent companies from coordinating their activities in ways that make markets less competitive.

It has been the job of the Federal Trade Commission and the Department of Justice's Antitrust Division to watch firms closely to ensure that they are not engaging in unfair trade practices. Actions such as predatory pricing, the formation of cartels and/or monopolies, are considered illegal under the current antitrust legislation.

Under the Clayton Antitrust Act, the government even has the power to prevent mergers that might lead to reduced competition and higher prices. The government must act carefully to make the right decision when considering the merging of two or more companies. While some mergers hurt consumers by reducing competition, others can actually leave consumers better off. Mergers that lower prices, provide more reliable products or services, and create a more efficient industry are allowed.

Antitrust Laws in Modern Times

Since the 1980s, government officials have had a difficult time proving monopoly power in the courts. Judges have mostly held that large companies are not bad just because they are large. If the market is promoting competition, company size should not be an issue and the government should not interfere.

In 1997, the Justice Department and the Federal Trade Commission released new guidelines for proposed mergers. Now, companies that want to merge have the chance to prove that the merger would lower costs and consumer prices or lead to a better product.

Before the Justice Department rules on whether to allow a merger, it tries to predict a merger's effect on prices and service. It is a fine balance between allowing market freedom and protecting consumers. The Supreme Court has embraced many antitrust principles that began in the 1980s.

CLEAN AIR ACT

The Clean Air Act (CAA), one of the most significant U.S. environmental protection laws, authorizes the Environmental Protection Agency (EPA) to issue regulations affecting almost every sector of the economy. The Office of Management and Budget (OMB) prepares a report to Congress each year on the costs and benefits of all federal regulations, and it has consistently found that air pollution regulations issued by EPA's air program account for the largest share of both costs and benefits across all federal regulations. In its 2012 report, OMB notes that the annual benefits of air regulations are between $82 and $557 billion (the large range is based partly on OMB assumptions about uncertainty in the value of mortality risk reductions), and annual costs are between $22 and $28 billion. These benefits and costs are primarily associated with reduced public exposure to just one air pollutant: fine particulate matter.

Passed in 1970, the CAA was significantly influenced by earlier legislation, including the Air Pollution Control Act of 1955, the CAA of 1963, and the Air Quality Act of 1967. These early laws began the process of defining the roles of federal and state governments in addressing air pollution, especially when it crosses state boundaries. The 1970 CAA was the first environmental legislation to grant far-reaching powers to the federal government to regulate air pollution sources and to establish ambient air quality standards that apply nationwide.

The 1970 CAA established National Ambient Air Quality Standards (NAAQS) to protect public health in polluted areas. To allow states some autonomy in addressing their own unique circumstances, the CAA gave state agencies flexibility in defining how the national standards would be achieved. Each state was authorized to prepare its own State Implementation Plan, although federal approval of the plan was still required. The CAA also requires New Source Performance Standards to limit air pollution emissions from stationary (industrial) sources, National Emission Standards for Hazardous Air Pollutants to reduce emissions of particularly toxic air pollutants (air toxics), and a mobile source pollution control program.

The CAA Amendments of 1977 established a New Source Review program for areas of the United States not attaining the levels of the NAAQS. This program mandated stringent controls on new industrial sources and required emissions to be offset by reductions from other industries in the area. Similarly, a Prevention of Significant Deterioration (PSD) program was established for areas attaining the NAAQS, with the goal of preventing air quality in these areas from deteriorating to levels that would exceed the NAAQS. PSD generally requires new or modified emissions sources to install modern emissions controls, improve workplace practices, or a combination of both.

The CAA Amendments of 1990 were developed to address several deficiencies that had been identified as the original CAA was implemented. In crafting the CAA Amendments of 1990, Congress particularly wanted to address three major environmental threats: acid rain, urban air pollution, and air toxics. Also, there was considerable interest in making the nation's air pollution permit program more workable and in improving compliance with regulations through a strengthened enforcement program. The 1990 Amendments included six major titles: Air Pollution Prevention and Control (Title I), Emission Standards for Moving Sources (Title II), General Provisions (Title III), Acid Deposition Control (Title IV), Permits (Title V), and Stratospheric Ozone Protection (Title VI).

One notable feature of the amendments was its reshaped air toxics program, which required the EPA to publish a list of source categories responsible for emissions of 189 air toxics and to issue Maximum Achievable Control Technology (MACT) standards for each category (the air toxics list was subsequently reduced to 188 when one air pollutant was determined to be nontoxic). A distinction was made between major sources, defined as facilities that emit at least 10 tons per year of any single air toxic or 25 tons per year of any combination of these pollutants, and area sources, which have toxic emissions that are less than these amounts. Examples of area sources are auto body shops and dry cleaners, which individually do not emit much pollution but, taken together, represent a large source of air pollution.

MACT standards for new sources are based on the application of emission control technology equivalent to the best controlled similar source found anywhere in the United States, although EPA is allowed to take into consideration costs, other environmental impacts, and energy requirements when considering whether to go beyond the required level of control. For existing sources, the standards are based on the average of the best-performing 12 percent of existing sources. To control emissions from area sources, EPA may elect to establish standards based on generally available control technologies or operating practices. Note that while MACT standards are technology based, EPA must examine health risk levels at regulated facilities after eight years and tighten the standards if necessary to reduce any remaining unacceptable risk (referred to as residual risk).

Another prominent feature of the 1990 amendments was the new permitting authority. Previously, a new facility's pollution control requirements may have been scattered among numerous state and federal regulations, some of which were hard to identify or contained conflicting requirements. The amendments attempted to simply this process by incorporating all of a source's permit obligations into a single permitting document (called a Title V Permit) and by having the source pay a single permit fee to cover agency administrative costs. This program was designed to simplify permitting requirements for both the source and the agency, to ensure compliance with all applicable requirements, and to facilitate enforcement.

The amendments addressed mobile sources in several ways. Tighter emission standards were established for both automobiles and trucks, and manufacturers were required to reduce emissions from gasoline evaporation during refueling. Fuel quality was also controlled by reducing gasoline volatility and the sulfur content of diesel fuel, by requiring cleaner (reformulated) gasoline for cities with serious ozone problems, and by specifying higher levels of alcohol-based oxygenated fuels to be produced and sold during the winter months in areas exceeding the federal carbon monoxide NAAQS.

The 1990 amendments added a number of market-based provisions to reduce emissions. The most successful of these was the Title IV program to reduce emissions that cause acid rain. The acid rain program established a federally managed cap-and-trade program that capped sulfur dioxide and nitrogen oxides (NO_x) emissions from power plants and set up a market for trading pollution allowances. In addition, Title I allowed for the use of economic incentives in developing regulations to reduce emissions of volatile organic compounds (VOCs) from consumer and commercial products. Any fees collected are to be placed in a special fund in the U.S. Treasury to carry out the activities of emissions reduction. An example of how this has been implemented in regulations is an EPA rule to reduce VOC emissions from manufacturing of coatings (e.g., paint). In this rule, a market-based option was included that enables companies to continue manufacturing architectural coatings with VOC contents higher than the limits included in the final rule through payment of a per-gallon exceedance fee amounting to approximately $2,500 per ton of excess VOCs. The CAA Amendments also provided for a fee-based incentive to encourage attainment of the national ozone standards. Severe or extreme ozone nonattainment areas that do not attain the standards by their attainment dates can be assessed a fee of $8,900 per ton of NO_x and VOC emitted (where exceeding 80 percent of a base amount).

CLEAN WATER ACT

The principal law governing surface water pollution in the United States is the Federal Water Pollution Control Act, commonly referred to as the Clean Water Act, listed in Title 33, Chapter 26 of the United States Code. Originally enacted in 1948, this law was significantly revised and expanded in 1972 with its goal "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters." Major amendments to the act were passed in 1977 and 1987.

Federal action to control water pollution can be traced as far back as the Refuse Act, a section of the Rivers and Harbors Act of 1899, but this law was primarily aimed at promoting water navigation. The 1948 Federal Water Pollution Control Act was the first federal law designed specifically to reduce water pollution. It authorized the federal government to engage in research into water pollution, but the states remained responsible for their own local water quality.

However, in 1972, growing public awareness and concern for controlling water pollution led to amendments that consolidated the authority to regulate surface water pollution within the newly created Environmental Protection Agency.

The 1972 law established a still-unmet national goal of eliminating the discharge of pollutants into navigable waters by 1985, with an interim goal of establishing water quality sufficient for recreation and the protection and propagation of fish, shellfish, and wildlife by 1983. It also set the national policy of prohibiting the discharge of pollutants in toxic amounts, and it provided for federal financial assistance for the construction of publicly owned waste treatment works. Industries were required to install the best practicable control technology, and municipal wastewater treatment plants were required to meet secondary treatment standards by 1977. Industries were required to meet a stricter standard, the best available technology (BAT) economically achievable by 1983 (later extended to 1989).

In 1977, the law was amended and given its moniker, the Clean Water Act. These amendments established three categories of pollutants: conventional, nonconventional, and toxic pollutants. The BAT requirement was still applied to toxic and nonconventional pollutants, but a new level of treatment called the "best conventional technology" was created to deal with conventional pollutants (total suspended solids, biochemical oxygen demanding materials, fecal coliform, pH, and oil and grease). In 1987, another set of major amendments phased out the construction grants program, replacing it with the State Water Pollution Control Revolving Fund. Under this program, states contribute matching funds to a revolving loan fund for wastewater treatment, which is then repaid and made available for future construction in other communities.

The 1972 amendments shifted the authority for pollution control to the federal government and allowed EPA to set technology-based, numerical effluent limits on the amount of discharges that can come from point sources (discrete conveyances of pollution, such as pipes or man-made ditches). The limits are enforced by requiring point sources to hold a discharge permit specifying the pollutants that the source must control, numerical or narrative limits on those pollutants, and time periods for how often the source must monitor for that pollutant.

States are required to submit to EPA the designated uses for navigable waters (e.g., recreation, fish and wildlife propagation, public water supply, industrial and agricultural uses, etc.) and to submit water quality criteria identifying the maximum concentrations of various pollutants that support these designated uses. If the technology-based effluent limits do not achieve the designated use for a water body, the EPA may set a total maximum daily load (TMDL), which is the maximum amount of a pollutant from all sources that may be discharged into that water body. If all water quality standards are met, antidegradation policies and programs are required to keep the water quality at acceptable levels.

The Clean Water Act is primarily designed to control pollution from point sources (i.e., pollution that comes from readily identifiable sources) but has done little to address nonpoint-source pollution. Nonpoint sources may be contributing more than 50 percent of total water pollution today, but most are not subject to effluent guidelines. The 1987 amendments directed states to develop and implement nonpoint pollution management programs and did provide limited federal financial assistance, but it did not require federal pollution limits, and there is no federal enforcement mechanism for these sources. States (but not the EPA) may require nonpoint sources to implement best management practices to meet a TMDL.

The Clean Water Act continues to evolve, not only through Congressional amendments but also through court action. In 2009, the Supreme Court held that the EPA could use benefit-cost analysis in establishing technology-based standards for cooling water intake requirements for power plants. In 2012, the Supreme Court unanimously ruled that property owners had the right to challenge the government's threats to fine them for alleged Clean Water Act violations without waiting for the EPA to attempt enforcement.

The success of the Clean Water Act can be measured by the water quality benefits it produces. Since 1982, the EPA has valued the monetizable benefits of its actions under this statute using benefit-cost analysis. Over time, this valuation has improved and utilized more sophisticated water quality models, but the EPA is currently not able to value all of the benefits that it produces. Benefit transfer has proven difficult because of the lack of a single measure of water quality across states. It is possible to estimate benefits-based improvements in ecological outputs rather than water quality, but this requires ecological production functions that are often difficult to estimate. In addition, more recent stated-preference techniques may be needed to adequately measure the passive-use values that can contribute substantially to the total economic value of water quality improvements.

Ronald Coase wrote little compared to other famous economists, but what he did write made a tremendous impact on economic thought. Two of his journal articles have started new subfields of economics: the economics of property rights and the economics of law.

Ronald Harry Coase was born on December 29, 1910, in Willesdale, England, just outside London. His parents were not well educated, both of them having dropped out of school by the age of 12. As a boy, Coase's weak legs required him to wear metal braces; as a result, he was sent to a school for physically handicapped children. When he was 12 years old, he was admitted to a quality grammar school, and in 1929 he enrolled in the London School of Economics. In his last year at school, he took a study tour to the United States. During his visit he examined the structure of American industries. It was here, before he even graduated from college, that Coase developed the concept of transaction costs and gained his essential insight into the workings of companies, for which he was to become famous.

Upon graduation he taught at various British universities and, with the onset of World War II, entered government service, first for the Forestry Commission and then for the Offices of the War Cabinet. After the war, he continued to teach college classes and also worked on a doctoral dissertation. Upon earning his PhD in 1951, he immigrated to the United States, where he taught at the University of Buffalo, the University of Virginia, and finally the University of Chicago, from which he retired in 1979. After retirement, however, his work did not stop. He continued as a researcher at the University of Chicago in law and economics—a field that he himself had created.

When Coase visited the United States in 1931–1932, he collected data and made observations about how firms really work. In doing so, he stumbled across a question for which no one had produced an adequate answer: Why do firms (companies) exist? If people can specialize in whatever job gets them the most value, how could it possibly be efficient to hold workers captive in large companies? Should it not it be more efficient to make individual contracts with individual workers for each necessary task? Coase pointed out that all firms are like little socialist economies: Instead of individuals deciding what kind of economic activity to pursue, they have to follow orders from their managers.

In an article entitled "The Nature of the Firm," Coase solved this problem by discussing the idea of transaction costs. Each economic exchange has certain built-in costs, like bargaining costs, the costs to gather and interpret information, and the costs to protect trade secrets. These transaction costs interfere with market activity and provide an incentive for entrepreneurs to produce goods and services in-house by hiring workers and forming a company. Creating a hierarchy inside a firm can lower transaction costs, but only to a certain degree. Coase also noted that as a company gets larger, it becomes more difficult to manage, a problem called diseconomies of scale. Because of this, there is a limit to the size to which companies can grow (contrary to what Karl Marx believed). Rather, according to Coase, firms will begin to make contracts with individuals and smaller companies to do the work that is inefficient for the firm to do itself.

Coase's second groundbreaking article, "The Problem of Social Cost," came in 1960, 23 years after "The Nature of the Firm." In it, Coase attacked a generally held theory about how people interact in society, first posited by Arthur Pigou in 1920. Externalities (spillover costs) are the costs and consequences of one decision imposed upon third parties external to the transaction. According to Pigou, the government can tax the entity creating the externality (such as pollution) to make it stop the behavior or at least reduce it. The government could then use the tax money to deal with the effects of the behavior: in this case, to clean up the pollution.

Coase's insight into externalities was that the situation could be solved by simply assigning clear property rights, or if that is not possible, by making one of the parties legally liable for the spillover costs incurred. The surprising conclusion is that the final amount of spillover will be the same regardless of who is liable for it. If the two parties involved are free to negotiate and trade with one another, they will make a deal to get the end result they both desire.

For example, if a factory is made liable for polluting the nearby neighborhood, the factory will pay the neighbors for the right to pollute. Conversely, if the neighbors are held liable, they will pay the factory to pollute less. If there are no transaction costs (and this is a big "if"), the same amount of pollution will be produced either way, though the wealth of the parties involved may be different. This became known as the "Coase theorem," and it has had a definite real-world impact. Because of Coase's theorem, legislators and judges are now encouraged to define ownership (property rights) before issuing taxes or injunctions.

Primarily for his work on social costs and the Coase theorem, Ronald Coase was awarded the Nobel Prize in Economics in 1991. Coase spent much of the rest of his professional career editing the University of Chicago's *Journal of Law and Economics*.

At the age of 100, Coase was busy analyzing the growth of the Chinese economy and advising Chinese economists through the Coase China Society while coauthoring a book entitled *How China Became Capitalist*. Coase died at the age of 102 on September 2, 2013, in Chicago, Illinois.

COASE THEOREM

The Coase theorem is a nonmathematical description of the conditions under which two (or more) parties can bargain their way to a socially efficient allocation of disputed resources. In his 1960 article in the *Journal of Law and Economics*, "The Problem of Social Cost," Nobel Prize–winning economist Ronald Coase lays the foundation for this oft-discussed and oft-misinterpreted theorem. Because Coase himself did not set out to define a mathematical theorem, there are multiple ways to think about the Coase theorem and its implications for how economists think about property rights and markets and their role in the socially efficient allocation of environmental and natural resources.

While perhaps far from Coase's original intent in outlining the role of property rights in bargaining situations over a local externality (think a local factory polluting a small community), the starting-point version of the Coase theorem in economics usually addresses the role of free markets in solving a local property rights dispute. A firm pollutes because it feels like it has the right to produce, with emissions as a natural by-product of production. The victims feel they have the right to clean air. At issue is both parties believe they have the property right situation ill suited to bargaining. If I believe I am in the right, and you believe that you are in the right, neither party has the incentive to give up anything to get what he or she wants. Without a resolution of the property rights dispute, there will be no bargaining or market transactions, and there will always be a socially inefficient amount of pollution produced. If property rights are well established, regardless of to whom they are assigned, both parties will have incentives to bargain to the socially desirable outcome.

This free-market version of the Coase theorem goes something like this: As long as both parties are free to bargain, the final amount of pollution will be independent of the initial allocation of property rights.

The problem is not that the polluter is polluting. Pollution has its benefits to the producer and to the consumer of the produced product. The problem is that both the polluter and the third-party victim think they have ownership (the property right), and no legal authority has stepped in to clearly define the property rights. Markets operate efficiently only when ownership is clearly defined. So who owns the clean air? In the free-market version of the Coase theorem, the role of the legal system is to decide who gets the property rights and then get out of the way; bargaining between the two parties will achieve the socially optimal outcome.

To put it simply, if the polluter is assigned the property right, the victim of the pollution has the incentive to pay the polluter to not pollute. The polluter will accept payment to not pollute until the cost of preventing additional pollution exceeds the victim's willingness to pay for additional pollution reductions. Likewise, if the victim is assigned the legal property right to clean air, the polluter has an incentive to pay the victim to allow it to pollute, and the victim will accept payment as long as the payment exceeds the damages caused by additional pollution. In either case, the final amount of pollution is the same, and only the distribution of wealth is different. Because bargaining is assumed to be free, it does not matter to whom the property rights are assigned, just assign them to either the polluter or the victim and let bargaining (or the market) work. The result will be an efficient solution.

The free-market version of the Coase theorem fits nicely with other market-based solutions to externality problems, like Pigouvian taxes and subsidies. A properly set Pigouvian tax on emissions, or a properly set Pigouvian subsidy on pollution abatement, will result in the same final amount of pollution; the tax or the subsidy acts as a social price for pollution. The free-market Coasian bargaining solution does the same thing, only it allows bargaining to set the price for pollution. The market solves the problem. This version of the Coase theorem serves as a foundation for emissions trading schemes in which tradable pollution permits serve as a proxy for the property right to pollute.

There are a lot of assumptions embedded in the simple free-market version of the Coase theorem that render the theorem unrealistic in its simple form. In "The Problem of Social Cost," Coase's intent was to clarify the conditions under which bargaining might or might not efficiently resolve a property rights dispute. A more realistic fair-market version of the Coase theorem makes explicit one of the conditions that might keep the free market from efficiently solving the pollution problem: transaction costs or any other impediment to bargaining.

The fair-market version of the Coase theorem is this: In the presence of transaction costs, the final amount of pollution depends on the initial allocation of property rights.

The focus here is on the transaction costs. If the victim is assigned the property right, the free-market version of the Coase theorem says that the victim will be willing to sell that right up until the point that the monetary damage from one more unit of pollution exactly equals the amount the polluter is willing to pay for it. With transaction costs, the victim must also recoup the transaction costs in addition to the damages. The result is less pollution than we would get without the bargaining (transaction) cost. But, if the polluter has the property right, the transaction costs cause more pollution relative to the free-market version. The result is a different amount of pollution depending on who gets the initial property rights.

The legal system now has a bigger impact. The outcome ends up tilted toward the side with the initial property right. In this case, the free-market version of the Coase theorem is a corollary created by assuming away transaction costs.

These are probably the two most common versions of the Coase theorem. They focus attention on property rights and transaction costs, and the debate usually turns on whether we can assume away transaction costs in a bargaining situation. But the debate should not stop there. The Coase theorem serves to focus attention on a number of assumptions that need to be looked at before we declare a victory for the free market. Here's a brief discussion of two.

The two versions of the Coase theorem presented earlier ignore the possibility that the bargaining outcome creates wealth for the owner of the property right. If I have the right to clean air, any income I receive from selling that right might increase my demand for clean air. Just like getting a raise at work increases my demand for eating out; getting more money from selling my right to clean air might increase my demand for clean air. Likewise, increased profits to the polluter from selling pollution rights might increase the demand for emissions. Similar to the transaction cost case, the final emissions outcome depends on the initial allocation of property rights.

Further, the increase in profits from selling the property right might lead others to want to take advantage. If firms are free to enter the market, the assignment of property rights to the firms and the resulting profits from the sale of those rights creates an incentive for other polluting firms to enter the market. Similarly, assigning property rights to the victim, and creating wealth through bargaining, creates incentives for new victims to enter the market; for example, more people might move into a polluted neighborhood as a result of the increased wealth from the sale of property rights. The simple versions of the Coase theorem assume away entry by both new firms and new victims.

The Coase theorem is usually presented separately from other incentive-based solutions to environmental problems. However, the real beauty of the Coase theorem is that it focuses attention on the assumptions needed to make incentive-based solutions work or fail. Wealth effects are not unique to bargaining solutions: taxes and subsidies have the same problem. Taxes on pollution create potential wealth for the victim, and abatement subsidies create wealth for the polluter. If victims are compensated proportionately to their damages, they will have the incentive to incur more damages. Similarly, subsidies create a potential incentive for new firms to enter a polluting industry.

The conditions highlighted by the Coase theorem are not unique to bargaining solutions, and that is the real benefit of talking about Coase. Instead of trying to figure out the right amount of pollution, we now focus our attention on the set of conditions that help or hinder market-based solutions to environmental problems.

COASE THEOREM, PROPERTY RIGHTS, AND ENDOWMENT EFFECT

The Coase theorem consists of a theoretical construction proposing a solution to the inefficient allocation of resources in society when competitive markets fail. In place of efficient competitive markets, the Coase theorem requires well-defined and enforced property rights and sufficiently low transaction costs. In such an environment, individuals can negotiate to a socially efficient allocation of resources in which the outcome of negotiations is mutually beneficial (Coase 1960). In this context, well-defined property rights imply that (1) the resources in question are exclusively owned by one party, either private or collective, who accrues all the privileges and obligations of the resource; (2) the owner can exchange these rights voluntarily; and (3) involuntary seizure by other parties, including the government, is prevented altogether (Hanley, Shogren, and White 2007).

The characteristics of rivalry and excludability in consumption determine whether a resource is referred to as private, public, or common pool. Resources being rival/excludable and nonrival/nonexcludable correspond to the private and public goods categories, respectively. Common-pool resources are rival and nonexcludable; the latter determines that, in the absence of effective property-right regimes, the property conditions for the Coase theorem are violated and the resources are overexploited, as in the case of open-access resources (Ostrom 1994), known as the tragedy of the commons. Experimental studies on the efficient management of common-pool resources are abundant and generally consistent with the principles proposed by Ostrom (1994) that success depends on the information and transaction costs of achieving a credible commitment among users, the existence of collective rules for self-monitoring, violators' sanctioning, resource appropriation and exclusion, and the institutional scheme being designed locally, not by an external authority. Reciprocity, reputation, and trust among resource users are behavioral traits that contribute to overcome the open-access problem (Ostrom 1998).

Under neoclassical rational choice theory and when income effects are small, willingness to accept (WTA) for selling a good and willingness to pay (WTP) for acquiring the same good are the same. This is a fundamental assumption for the validity of the principle of the Coase theorem. That is, the efficiency of the negotiated allocation depends on the existence and enforcement of property rights, not on the identity of the owner. However, evidence from experiments in laboratories and the field consistently support the existence of a gap between WTA and WTP. The difference between these two measures is known as the *endowment effect* and implies that people value a good more once it is in their possession.

Kahneman, Knetsch, and Thaler (1990) provide a series of experiments that clarify the causes and implications of the endowment effect. Strategic mistakes by bargaining parties (sellers rewarded by increasing WTA and buyers by reducing their WTP), considerations of the illegitimacy of the transaction that increase WTA, and subjects' misunderstandings are ruled out as determinants of endowment effect. Instead, reference positions on preferences, status quo biases that emerge from previous transactions or expectations, and loss aversion explain the existence of the endowment effect. As a consequence, the set of mutually acceptable trades in a bargaining situation shrinks and the efficient solution becomes more difficult to achieve.

Evidence suggests that the endowment effect is persistent even when income effects are small; it is persistent in the short and long term; it cannot be eliminated by training, experience, or market discipline; and it plays no role when perfect substitutes at lower prices are available. Kahneman, Knetsch, and Thaler (1990) find that the endowment effect plays no role with induced-value tokens, but it makes a great difference in valuation when goods are traded (e.g., coffee mugs).

Therefore, although the implementation of the Coase solution can survive the existence of transaction costs (up to a point) and the need for enforcement of property rights, the experimental evidence weakens the robustness of the Coase theorem in the presence of behavioral phenomena.

COLLATERALIZED DEBT OBLIGATIONS

Collateralized debt obligations (CDOs) were created in the late 1980s and played a prominent role in the financial crisis of 2008. A CDO is a security whose value is collateralized (i.e., “backed”) by a pool of underlying fixed-income assets. Meant to reduce the risk of nonpayment, the CDO compartmentalizes prepayment risk by distributing cash flow over a series of classes, called *tranches*, that pay investors at different times and at different rates. About 40 percent of CDOs consisted of residential mortgage-backed securities (RMBS), and three-quarters of those were subprime loans and home-equity loans with a higher risk and a lower lien status. Much of the subprime trouble was caused by mortgage fraud and falsifications of credit reports, which helped to fuel the increase in home prices. As a result, credit scores, loan-to-value ratios, and ownership status became less reliable as indicators of actual creditworthiness. As more and more homeowners faced foreclosure, defaults skyrocketed and the value of many CDOs plunged. In the wake of the financial crisis, many investors claimed they were unaware the mortgages upon which their debt vehicles were based were at such a high risk of default.

CDOs are divided into tranches containing securities with varying degrees of risk. When homeowners make payments on their mortgages, the money is directed to the investors of each tranche. The “senior” tranche contains the safest securities (lowest risk). Payments are made in order of seniority, so the most junior tranche (otherwise known as the equity tranche or “toxic waste”) is at greatest risk

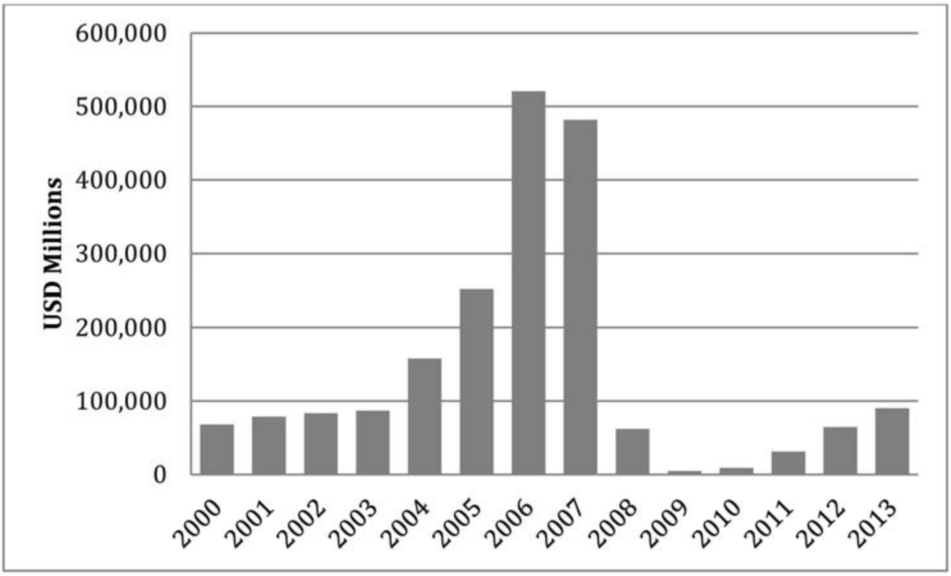

Figure 1. Global CDO issuance (SIFMA)

of not receiving a payment; it also offers the highest coupon payments to offset the increased risk of such a default.

For decades the government has made easy lending to low-income homebuyers a policy priority. The George H. W. Bush administration, the Clinton administration, the George W. Bush administration, Congress, and the U.S. Department of Housing and Urban Development all pushed government-sponsored mortgage companies Fannie Mae and Freddie Mac to encourage more and more subprime loans to low-income homebuyers. In the late 1990s, Fannie and Freddie rapidly increased their purchases of mortgages and securitized mortgages (also known as mortgage-backed securities) from the private-sector banks and mortgage companies.

The housing market first showed signs of weakness in 2006. With the housing bubble pushing inflation higher, the Federal Reserve raised interest rates in an effort to contain it. The cost of borrowing rose, and borrowers found they were no longer able to meet their mortgage payments; many people were forced to walk away from their homes and default on their mortgages. Lenders then sold these houses (the underlying security), but a declining housing market reduced the value of the securities. At this point, traders of CDOs looked for new ways to package the risk and generate additional business, making the financial crisis of 2008 far deeper and more devastating than it would otherwise have been. The CDO trading desks of Merrill Lynch, Citibank, and UBS have been cited as the biggest culprits of increasing trades of CDOs well into 2007. In spite of their high default rate during the financial crisis, global use of CDOs has been making a comeback over the past few years.

COMMODITIES

Historically, precious metals have been a primary form of value storage. After fiat money was introduced, it became common practice to exchange excess funds for gold, silver, and even diamonds. While it is less prevalent in the United States, this practice is still common in developing countries, especially those that have emerged from wars and other conflicts that devastated their economies. So, utilization of commodities is typically associated with instability.

Commodities do not generate additional value or cash flows in the future. People buy commodities today in the hope that in the future they can sell them for the same price or higher. This, in essence, is more speculation than investment. I will use the term *speculation* rather than *investment* to separate these two activities.

Commodity speculation has become increasingly common and involves more commodities than precious metals such as gold and silver, which have been used throughout history. The advances in the futures market allows many different classes of assets to be used for speculative purposes by individuals who are not directly involved in their production or use. Agriculture futures such as in coffee, wheat, corn, soybeans, lean hogs, and feeder cattle are some of the more commonly used futures contracts. The frozen orange juice market was the background for the cult-classic movie *Trading Places*, starring Dan Aykroyd and Eddie Murphy. A lesser-known commodity is also available in the futures market: mung beans. Many people don't know what a mung bean looks like, but it is a very popular agriculture commodity in China and the United States is one of its largest producers. You have most likely encountered mung beans without realizing it; the bean sprouts you see in the supermarket are from mung beans!

The precious metals market for gold and silver is very well developed. Not only can you hold the physical metals, you can also participate in the futures markets. As the world's economy becomes more industrialized, the needs for various metals also increases. This has been the driving force behind the growth in other precious metals markets, such as copper, aluminum, and rare metals. These commodities are essential for many industrial products, and price fluctuations significantly affect their material cost.

If you're not a true user of a particular commodity, you are a speculator. Imagine that you want to participate in corn futures because you think the price of corn will go up. If you are a corn user, buying corn futures allows you to lock in the price today. Likewise, if you're a corn producer, you can lock in a selling price for your products today. But if you're neither a producer nor a user, the only way you can profit is if the other side is wrong about future price fluctuations. By buying corn futures (establishing a long position), you're betting that the producers are wrong about the future price, and you're essentially providing an insurance policy for the price of corn for the producers. Likewise, if you established a short position in corn futures, you can only make money if the corn price turns out to be lower in the future. So, if you make money, it is either because the users are wrong about the price in the future or the other speculators are wrong. Either way, by participating in the commodity market, you essentially become an insurance underwriter for the commodity price.

The traditional argument for including commodities in an investment portfolio is that they typically have low correlation with the stock and bond markets. But using past correlation relationships as a guide to asset allocation is dangerous because this can change drastically as more and more people participate in these markets. And since most of these markets are relatively small, additional small outflows and inflows of funds can have a large effect on price movements. Furthermore, the historical return for commodities is poor by any standard. Even with its recent surge in price, gold's historical return is no better than inflation. Other more recent commodities provide not much higher return than medium-term treasury bonds.

The reasons for the low return over the long run are many. But the main reason is that most investors are led into buying commodities when their prices have risen drastically. When more funds are put into these markets, the price for the related commodities might rise in the short to intermediate term, but that could be driven by increases in demand from funds and not changes in fundamentals. As the fundamental conditions eventually return, the price will reflect the real demand and price momentum could reverse.

Participation in the commodities market is also incredibly risky. The risk comes from two sources: leverage and ease of market manipulations. To participate in the commodity futures market, you do not have to put up 100 percent of the fund for any specific contracts. Each commodity futures contract has its own requirement, set by the future exchange it is traded in. The typical requirement is less than 20 percent (a much lower margin requirement than for gold). So, your position will have at least 400 percent leverage. That means if the price declines by less than 20 percent, your initial investment could be completely wiped out.

Market manipulations, while less common due to increases in market regulations and enforcement, are nonetheless a real danger for small investors who choose to participate in commodity futures. The movie *Trading Places* tells the story of a futures broker that manipulates frozen orange juice futures by issuing false weather reports after it has established a strong position in the market. The

Brazilian government cornered the coffee market in the 1910s. The Hunt brothers (the Lamar Hunt Trophy, awarded to the winner of the NFL's AFC division, was funded by one of the brothers involved) were found guilty of cornering the silver market in the 1970s. More recently, the Vitol Group, a large hedge fund in the commodity market, was sued by the U.S. Commodity Futures Trading Commission for manipulating the oil futures market.

Furthermore, commodity markets typically generate a higher degree of interest after a large price surge. Since the oil price surge in 2006, most commodities have reached historic price levels. What is the chance of the price continuing to grow at such a high rate? Not likely. So, the chance of a negative return is also high.

Contrary to traditional finance theory, the commodities market is not an ideal market for individual investors due to the high degree of risk and low return. There are more and more mutual funds and exchange traded funds that specialize in the commodity market. These funds typically have lower risk than investing in the actual commodity or the futures markets. Still, the level of risk in these funds is very high. Some of these funds are also leveraged (they can do so due to regulatory loopholes) and present significantly higher risk.

COMMODITY EXCHANGE ACT OF 1936

Initially passed in 1936, the Commodity Exchange Act established federal regulation on all future trading activities and served as the successor to an earlier legislation that had proved to be ineffective in stopping the manipulation of commodity prices. Although the Commodity Exchange Act has been amended several times, and in its original form was found to be a flawed mechanism for regulating commodity markets, it has played an important role in history.

Prior to the enactment of the law in 1936, Congress adopted the Future Trading Act of 1921, which required all commodity futures trading to be conducted on an exchange licensed as a market by the federal government. This requirement was designed to allow federal regulation of trading commodity futures and to stop the speculation in commodity pricing.

In refute to the 1921 act, the Commodity Exchange Act prohibited the manipulation of commodity future prices while also maintaining that commodity futures be traded strictly on licensed contract markets. Fraud was prohibited, and brokerage firms handled customer orders; these were known in the industry as future commission merchants and were required to be registered with the federal government. The Commodity Exchange Commission was in charge of administering the Commodity Exchange Act and was composed of the attorney general and the secretaries of agriculture and commerce.

Moreover, daily regulatory responsibilities were delegated to the Grain Futures Administration, a bureau within the Department of Agriculture. Contrary to previous legislation adopted in the securities industry, no authority was given to the government to control the level of margins in the futures industry. Instead, the government was given the authority to limit the size of speculative positions of individual traders. The Commodity Exchange Act also sought to stop commodity options trading on regulated commodities, seeing such practices as highly speculative.

The Commodity Exchange Act proved to be ineffective in stopping manipulations or speculative abuses. One flaw in particular allowed the trading of options and futures on unregulated commodities, or those not listed in the Commodity Exchange Act. It was not possible for the act to be amended fast enough to keep up with the expansion of trading in options and futures on those unregulated commodities. In the early 1970s, this led to a large loss when unregulated commodity option firms collapsed, causing losses to many unsophisticated customers.

The large increase in commodity prices during that time raised concern in Congress and resulted in the Commodity Futures Trading Commission (CFTC). The CFTC is an independent federal agency that is meant to function much like the Securities and Exchange Commission (SEC).

The CFTC took over the powers of the Commodity Exchange Commission and was given additional powers, including the authority to impose civil penalties for each violation of the CFTC rules.

COMMON PROPERTY AND COMMON-POOL RESOURCES

Goods and services can be classified based on their degree of excludability and subtractability. Excludability refers to an agent's ability to exclude others from consuming a good or service. For instance, upon purchasing a new vehicle one can exclude others from driving one's car via the legal rights conveyed with the purchase and the enforcement of those laws by the government. Subtractability refers to the degree to which one's consumption of a good reduces the ability of others to consume the good as well. For instance, if you have a pack of gum and you consume a piece, it reduces the amount available to either you or others by the unit consumed.

Goods and services that are excludable and subtractable are defined as private goods and services; ones that are excludable but nonsubtractable are deemed to be toll goods or services; ones that are nonexcludable and nonsubtractable are public goods and services; and those that are nonexcludable and subtractable are common-pool resources. In environmental economics, common-pool resources play a central role in the management of the environment. Examples of resources that are conventionally viewed to be common-pool resources are fisheries, oil reserves, and the atmosphere; these have all received considerable attention with regard to their efficient utilization.

The idea of the commons was popularized by Garrett Hardin's "Tragedy of the Commons" in which he outlined the incentive structure that results in the dissipation of resource rents within the commons: "Ruin is the destination toward which all men rush, each pursuing his own best interest in a society that believes in the freedom of the commons" (Hardin 1968, 1244). As an example of the incentive problem, he described a common grazing area in which agents are free to let graze as many cattle as they wish. He outlined that there are two components to the decision to add another head of cattle to the grazing area: (1) the utility gain of having another head of cattle to sell after grazing in the commons and (2) the disutility of overgrazing resulting from adding an additional head of cattle to the commons. Given that the disutility of adding an additional head of cattle is shared by all, whereas the utility gains of selling the head of cattle are private and borne solely by the decision agent, a rational decision-maker will add another head of cattle to the commons. Given this incentive structure, Hardin envisioned a commons area becoming overgrazed to the point at which it is no longer a viable grazing area for cattle; the rents would be completely dissipated.

Hanley, Shogren, and White point out an important distinction that needs to be made between common-pool resources and open-access resources. The commons, as referenced in Hardin's work, represents an environmental asset. A common-pool resource refers to the governance structure that endeavors to exclude some agents from the commons. On the other hand, open access implies a lack of governance that allows agents access to the commons. In Hardin's discussion, the rent dissipation is a result of open access to the commons; however, in a number of situations, governance structures and rights regimes have arisen that limit the dissipation of the resource rents in common-pool resources. Central to the development of these governance structures is an effort to create some degree of excludability in the commons because it transforms the commons to a private good.

A resource that well illustrates the tragedy of the commons as well as the problems that arise from open-access and common-pool resource governance is fisheries. H. Scott Gordon's seminal contribution to the fisheries literature analyzed the incentive structures present in the commons when fishermen have open access to the resource. Gordon illustrated that in the commons, the objective of fishermen is to equate total revenues with total cost versus maximizing the difference between the two. He furthermore outlined that in a spatial context, the fishermen's primary concern is the average productivity on a fishing ground versus the marginal productivity relative to the other fishing grounds they can fish. In equilibrium, the average productivity is equal across fishing grounds and fishermen may actually fish some grounds even when marginal productivity is negative. The incentives problem is well illustrated in his statement, "the fish in the sea are valueless to the fisherman, because there is no assurance that they will be there for him tomorrow if they are left behind today" (Gordon 1954, 135). This incentive problem is generated because the resource is not excludable; in the absence of a governance structure, a fishery is an open-access resource.

Gordon further discussed that the most efficient utilization of a fishery will occur when there is a sole owner of the resource. This is because the resource becomes excludable and the traditional marginal analysis, that which maximizes the rents derived from the resource, may be achieved. Expanding on the notion of sole ownership, Anthony Scott argued that sole ownership was not the only requirement to ensure the efficient use of the fishery and that the tenure of the rights need to be over the long run. If the rights were only for the short run, the sole owner would have a similar incentive to overexploit the resource, whereas in the long run the benefits of conservation and dynamic resource management could be ensured. The dynamically optimal use of a fishery was later theoretically illustrated in the seminal work of Colin Clark and Gordon Munro.

Sole ownership does not necessarily imply that only one agent has exclusive control of the resource. The efficient utilization of the resource can be similarly obtained by privatizing the resource using property rights. However, privatization is not the only governance structure that can be used to efficiently govern the commons. Other institutions are Pigouvian taxation and collective governance. The central theme of these governance structures is that they try to invoke some degree of excludability that is enforced via a formal or informal governance structure. The central benefit of privatization is that the owners of the resource can trade among themselves in a Coasian manner in an effort to ensure that the most efficient use of the resource is achieved. On the other hand, Pigouvian taxation seeks to internalize the costs imposed onto others via a tax that aligns the private incentives of an agent in the commons with the incentives generated under sole ownership. Lastly, collective governance has been well illustrated in the work of Elinor Ostrom; it relies on local communities to establish small-scale governance structures to identify the users and management of a resource.

An excellent real-world example of the role that privatization has played in the efficient use of the commons is the recent Bering Sea Crab Rationalization Program (BCRP). The BCRP was enacted in 2005 and allocated rights (defined as limited access privileges) to those fishermen operating within the federally managed crab fisheries of Alaska. Prior to the creation of this policy, there were approximately 250 vessels in the red king crab fishery and nearly 180 vessels in the snow crab fishery and the fishing season was only a few days long. These statistics are indicative of the rampant overcapacity in the race to fish generated by having open access to the commons. Following the creation of the BCRP, the number of vessels participating in the red king crab and snow crab fisheries contracted by approximately 65 and 53 percent, respectively, and their respective season lengths began to be measured in terms of months, all generating a more efficient use of the resource (Schnier and Felthoven 2013).

The ability of collective governance to manage the commons has been well illustrated in the work of Elinor Ostrom. She defined a number of key components that are central to the ability of a common-pool resource institution to effectively manage the commons. Bergstrom consolidated these factors into eight features that he defined as: (1) clearly defined resource boundaries; (2) appropriation rules defined for the specific community; (3) rules for collective choice; (4) the existence of monitoring and compliance; (5) penalties for noncompliance that vary depending on the gravity of the infraction; (6) access to conflict resolution mechanisms; (7) minimal recognition by national or regional government; and (8) multiple layers of governance for complex commons. Evidence of the effective utilization of collective governance is well illustrated in numerous case studies with contexts ranging from common grazing areas and water allocation regimes to small-scale fisheries.

CONSUMER CREDIT AND DEBT

Consumer debt is defined as money borrowed to purchase goods or services. Consumer debt is incurred using a credit card or a store payment plan. When one buys anything with a credit card, such as clothes, electronics, or a dinner out, one incurs consumer debt until the balance due on the credit card is repaid. The terms *consumer debt* and *consumer credit* are sometimes used interchangeably, although they have slightly different meanings. Specifically, debt is an obligation incurred by the consumer. Consumer credit is offered so the borrower can buy now and pay later. Both terms involve buying consumer goods today with the obligation to pay for the items in the future.

Consumer credit is easily identified as money borrowed to purchase consumer goods with a credit card or payment plan. For example, a credit card gives the holder credit to buy goods and services up to a certain amount. This credit is actually a loan or debt. Consumer credit does not include borrowing money to buy a home but does include the big-screen television in the home's family room. In general, consumer credit is used with purchases that depreciate (decline) in value, such as cars, personal goods such as clothing, restaurant meals, and vacations.

Problems with Consumer Credit and Debt

It is quite easy to obtain a credit card to purchase goods and services on credit. The problem arises when the bill arrives. Payments are due every month for charges made on a credit card or payment plan. If the charges incurred during the month are not paid in full at the end of the month, the consumer is required to pay a portion of the total amount due, called a minimum payment. Any amount that is left unpaid incurs a charge that is carried over to the following month. The credit card company adds additional interest to the total charges. The cycle continues, and every subsequent month the bill is not paid in full, additional interest is incurred. Consumers who choose to pay the minimum on a credit card or payment plan and continue to accumulate additional consumer debt may ultimately pay double or more than the cost of the original charge.

There is a nationwide epidemic of failure to pay credit card bills in full. Many citizens continue to add to their consumer debt/credit over time and end up owing a lot of money to the credit card companies. The Federal Reserve Bank keeps track of consumers' debt as compared to their disposable (after-tax) income. This household debt service ratio (DSR) is considered an estimate of what percentage of a homeowner's or renter's after-tax income goes toward consumer debt repayment. For example, homeowners' consumer debt as a percentage of total disposable income ranged from 4.81 percent in 1982 to 6.39 in 2005. Renters had much higher consumer debt levels according to the Federal Reserve Board's *Household Debt Service and Financial Obligations Ratios* (2013). According to the New York Federal Reserve Bank, in the first quarter of 2013, aggregate consumer debt was $2.7 trillion. In 2013, the consumer debt level was $.58 trillion above its trough of $2.12 trillion in the first quarter of 2004. These debt levels include student loans, credit card debt, auto loans, and delinquencies.

Consumer credit and debt are integrated into societal consumption patterns in the modern world.

COOPERATIVE ORGANIZATIONS

"A cooperative is an autonomous association of persons united voluntarily to meet their common economic, social, and cultural needs and aspirations through a jointly-owned and democratically-controlled enterprise" (International Cooperative Alliance, 1995).

Cooperative firms are business enterprises exercising collective governance, ownership, and decision-making. Cooperative members typically actualize their membership and control rights based on the user relationship with the cooperative. Cooperatives take many forms depending on their members and purpose. They exist as agricultural cooperatives, consumer cooperatives, housing cooperatives, worker cooperatives, financial or insurance cooperatives, service cooperatives, as well as multistakeholder cooperatives that encompass more than one type of member. A cooperative may be formed to coordinate activities and achieve favorable prices for its members' products or purchases, as is often the case in agricultural and consumer cooperatives. Worker cooperatives, on the other hand, are about creation of meaningful employment at a "living wage," and, often, about social justice.

The nature of cooperative organization and function is both social and economic. As collective problem-solvers, co-ops are known to possess a dual character: on the one hand, they are businesses driven by economic incentives and competition, while on the other they are associations with a social purpose and character. Cooperatives have often been portrayed by their members as businesses that combine a social mission with their economic goals, placing them in the category of enterprises operating in the social and solidarity economy. Connections to the social economy stem from the cooperative's purpose, its *modus operandi*, or both. When they deliver a product with a social purpose, such as public goods or services, they are more readily understood as social enterprises. In other cases, they fill the gap left by market or government failure to deliver a product or a service to a particular constituency.

Regardless of their purpose, cooperatives hold a special place in the economy as the only type of enterprise with well-defined ethical values and principles and a global social movement behind it. Seven International Cooperative Alliance principles of cooperation guide the international cooperative movement: (1) voluntary and open membership; (2) democratic member control; (3) member economic participation; (4) autonomy and independence; (5) education, training, and information; (6) cooperation among cooperatives; and (7) concern for community. Cooperative principles and values can be viewed as the crux of competitive advantage for cooperative enterprises and a source of cooperative business strategy.

Cooperative objectives are as varied as their membership bases, but more often than not they are rooted in social justice issues, ranging from job security and solidarity, through a "fair" price for their products in imperfect markets, or fair trade in international supply chains. A worker cooperative is a social network in which solidarity, equity, equality, and democratic governance are some of the guiding principles. In this case, and contrary to the dominant views in neoclassical economics, nonpecuniary incentives for a worker-member often offset the importance of the monetary gain. Trusting relationships, reciprocity, and values of equity and liberty play key roles in cooperatives and their networks (Zamagni and Zamagni 2010, 28). The strength of the cooperative is determined in the amount of social capital created, which is essential for effective collective entrepreneurship and collective governance. Cooperatives rely on participatory decision-making and on democracy as associations but also on upholding the subordinate role of capital as people-centered businesses. The user-control component separates them from investor-owned and -controlled enterprises as cooperative capital is a means to realize member-defined objectives and is typically not traded in the secondary capital market. A part of cooperative capital is also nondivisible, ensuring their longevity and adaptability as well as maintaining their collective character.

In the institutional-economic context, cooperatives are hybrid organizations lying on the continuum between markets and hierarchies, forming networks to reach scale economies and reap the benefits of cooperation in imperfectly competitive markets. Network governance is key to cooperation, but it also poses a challenge. Self-defined rules together with their self-enforcement are critical components of cooperative success.

CORNING GLASS WORKS V. BRENNAN

Traditionally, women have struggled to gain equality with men in the workplace. The wage gap has been lessening since the Fair Labor Standards Act of 1938, but despite such federal legislation, pay disparities have continued between female and male workers and in various demographic groups. *Corning Glass Works v. Brennan,* 417 U.S. 188 (1974), was the first time the Supreme Court considered an Equal Pay Act claim based on an employer paying women less than men for the same work. While some wage discrepancies are due to differences in occupation, experience, skills, and other legitimate factors, there is still a considerable gap between men and women that exists without explanation. This case is a milestone in the long journey to remedy this market phenomenon. It determined that wage differences between female and male workers for the same work violated the Equal Pay Act of 1963.

Case Summary

Adam Smith expressed in *The Wealth of Nations* (1776) that the compensation of workers was the encouragement of production. Historically, women have struggled with enormous wage disparities. This unfair discrimination throughout the 19th century was exceptionally difficult for women. However, during the 20th century, much was accomplished. The Industrial Revolution ushered in manufacturing and commercial industries and moved women into the labor force in unprecedented numbers. The sweatshops and factories where women earned their wages were not always safe and secure environments. Work for women varied, but their pay remained unequal to that of men.

Corning Glass Works was a glass company started by Amory Houghton Sr. in the 1800s. Houghton helped Thomas Edison make the electric light a business success by producing the first glass light bulbs. Ever since, the company has invented and built an assortment of items, from baking dishes to missile nose cones. Corning's home office is in Corning, New York. In addition, Corning opened a plant in Wellsboro, Pennsylvania. In 1925, Corning plants operated production during the day and hired women to inspect the finished products. By 1930, Corning upgraded its manufacturing process and needed to hire night-shift inspectors to keep pace with the increased productivity. This included an additional night shift. However, New York and Pennsylvania state laws did not allow women to work at night. Furthermore, inspecting finished products had been the main job held by women and was labeled by male coworkers as "women's work." Men expressed the attitude that night-shift inspection work was demeaning, and they did not want to take a job that earned a woman's pay. Corning signed up men to work the night shift by agreeing to pay them more than their daytime female counterparts. In 1944, unionization of Corning Glass Works brought collective bargaining agreements that took the pay disparity away from day-shift workers but did not end the higher pay for night-shift inspection workers due to prohibitions still in place pertaining to women working between the hours of midnight and six in the morning.

In 1963, President John F. Kennedy signed the Federal Employees and Labor Laws Equal Pay Act of 1963 (EPA) as part of his New Frontier program. In passing the act, Congress added to the Fair Labor Standards Act of 1938. The act stipulated that companies were to pay men and women equally for similar work. By 1953, laws prohibiting women working at night had been rescinded in both states. After midyear of 1964, the Equal Pay Act was in effect, and the better-paying night inspection jobs opened up to women through process and replacement. In 1969, Corning agreed to pay day-shift and night-shift inspectors the same wage. However, there was an exception made for workers who were hired before 1969, most of whom were men, which still allowed them to earn wages higher than the day-shift inspectors. In the view of Secretary of Labor Peter Brennan, this clearly constituted a violation of the Equal Pay Act. Brennan filed two lawsuits, one in New York and one in Pennsylvania, claiming in each that Corning had violated the act. The New York plant cases were heard in the Court of Appeals for the Second Circuit and found that Corning was in violation of the EPA for paying different wages to men and women doing the same job for no other reason except gender. However, the Court of Appeals for the Third Circuit heard the Pennsylvania plant cases and reached the opposite conclusion. There was no violation, in its opinion, because night work was different from day work; time of day thereby created a pay differential, not gender.

In *Corning Glass Works v. Brennan*, the Supreme Court was asked to reconcile the conflict between two federal circuit courts, both involving cases against the Corning Glass Works plants in regard to wage inequities. The Supreme Court granted certiorari (a request by the Supreme Court to the lower court for the files of the case to be sent up for review). Corning Glass Works argued that the Equal Pay Act said companies could pay employees different wages if they worked under different conditions. The company claimed that working the night shift was less desirable and therefore constituted different conditions. The attorney for the labor secretary argued that “condition” referred to manufacturing facility and environment, not the time of day one worked. Furthermore, this was, in the opinion of the Department of Labor, a blatant case of gender discrimination, and short of equalizing pay, there was no other remedy.

In question was what the Equal Pay Act included as working conditions. In this case, it was incumbent upon Corning Glass Works to show that the facts of the case fit within one of four exceptions that did not constitute discrimination of pay. Those included a seniority system; a merit system; a system based on the amount or quality of production; and some other factor besides gender. Corning chose to emphasize the last exemption. It claimed that working at night was a different condition than working during the day. In addition, it claimed that the men were also paid more due to seniority. The burden was too much. In a 5–3 vote, the Supreme Court ruled that different times of day did not fit the exemption status. The Court stated that the act was clear in stating that working conditions included physical surroundings and hazards. The seniority system only served to perpetuate past discrimination. Justice Thurgood Marshall delivered the majority opinion, stating that the Equal Pay Act was constructed to end the idea that men could get paid more for doing the same work as women because of their role in society.

However, Chief Justice Burger joined with Justice Blackmun and Justice Rehnquist to write the dissenting opinion. He argued that the laws of New York and Pennsylvania had established barriers that did not allow Corning to hire women for the night shift. After these night prohibitions were lifted, there were transportation barriers that did not permit women to travel to and from evening work facilities without meeting particular guidelines. These barriers were not completely lifted until July 1965. Therefore, it was necessary to hire men for those positions due to exogenous legal circumstances. The only competitive hourly wage at which to hire a male was higher than any female wage at that time, and therefore Corning was adapting to the dictates of the market. The intention was not to violate the Equal Pay Act but to adapt to state mandates and bring the factories into compliance as soon as possible. Justice Stewart abstained from the case.

Women have worked alongside their male counterparts in many segments of American industry and have all too often been the victims of serious and endemic wage discrimination. The solution—to pass a law that requires equal work to be rewarded with equal wages—is simple in principle but has been just the opposite in practice. This landmark case lifted up the rule of law to the practices of ancient outmoded beliefs, contributing to the evolution of equality in the workplace.

CORPORATE AVERAGE FUEL ECONOMY

Following the energy crisis of 1973, the U.S. Congress established Corporate Average Fuel Efficiency (CAFE) standards via the U.S. Energy Policy and Conservation Act of 1975 (PL94-163). The National Highway Traffic Safety Administration (NHTSA) was given the authority to determine the average standards for fuel efficiency that U.S. car and light-duty truck (pickup trucks, minivans, sport utility vehicles up to 8,500-pound gross vehicle weight) manufacturers must meet based on four statutory criteria: (1) technological feasibility; (2) economic practicability;

(3) the effect of other federal standards upon fuel economy; and (4) the need for the nation to conserve energy. The intent was to reduce fossil fuel (petroleum) consumption of cars and light trucks by increasing their fuel efficiency.

The CAFE regulations have been updated in response to new congressional laws that broaden the U.S. Environmental Protection Agency's (EPA) authority to regulate greenhouse gases (GHGs). EPA was given authority to regulate GHG emissions after the Supreme Court's 2007 *Massachusetts et al. v. EPA* decision that GHGs are air pollutants covered by the Clean Air Act (549 US 497). Following this decision, in 2009, the EPA administrator signed two findings: (1) the endangerment finding, stating that the administrator had determined that the current and projected concentrations of GHGs threaten public health and welfare, and (2) the combined emissions of these GHGs from new motor vehicles and new motor vehicle engines contribute to the GHG pollution. Because the primary method to reduce GHGs from vehicles is through improvements in fuel economy, EPA's authority to regulate GHGs is closely related to NHTSA's regulation of vehicle fuel economy. The transportation sector, as a whole, was responsible for 27 percent of U.S. GHG (31 percent CO_2) emissions in 2010. The on-road sector (cars, motorcycles, trucks, and buses) makes up 84 percent of this total.

The EPA and NHTSA now develop harmonized fuel economy and GHG standards. Thus, CAFE regulations, which had an initial justification and focus on energy security and fuel savings, are coordinated with standards for nonfuel economy GHG emissions from such additional factors as air-conditioning coolants (hydrofluorocarbons) and efficiency factors.

CAFE standards apply to all vehicle manufacturers based on their sales-weighted harmonic average fuel economy, measured in miles per gallon (mpg). There are separate standards for cars and light trucks, and imported and domestic fleets of cars are tracked separately. The effectiveness of CAFE standards in raising the light-duty vehicle fleet's fuel efficiency, and other effects of CAFE regulations, has been discussed in a large body of literature. Some debated whether the improvements in average fuel efficiency realized from 1978 (the first year that the CAFE standards went into effect) through 1987 were attained at a reasonable economic cost and whether the CAFE regulations induced undesirable changes in vehicles that could lower their safety. In addition, the CAFE standards themselves, by being less restrictive for trucks than for cars, likely had the effect of encouraging the shift in market share from cars to light-duty trucks. Higher vehicle fuel economy also lowers the cost per mile of driving, which induces additional driving (i.e., the rebound effect). While estimates of this additional driving differ, the EPA and NHTSA have most recently used a 10 percent rebound rate, which implies an increase of 5 percent in vehicle miles traveled when costs of driving are cut in half.

The concerns over safety and changes to vehicle fleets induced by CAFE regulations as well as a continued national interest in energy security and transportation GHG emissions have led to a number of reforms and expansions of CAFE regulations.

The Energy Independence and Security Act (EISA) of 2007 required an attribute standard that allowed NHTSA to change from a uniform standard to one based on the sales-weighted footprint (wheel base times track width) starting with model year (MY) 2011. The rationale for moving to this standard is that it reduces the incentive to change the size of vehicles for regulatory compliance. The footprint standard diminishes the incentive to reduce the size of a vehicle since doing so increases the stringency of its fuel economy target. There are separate footprint-based standards for cars and light trucks. Also, EISA broadened CAFE regulations to cover large sport utility vehicles from 8,500 to 10,000 pounds gross vehicle weight that were previously exempt from CAFE requirements.

The rules for MY 2012–2016 vehicles require that fleet-averaged fuel economy reach an equivalent of the estimated combined average emissions level of 250 grams/mile of CO_2 or 35.4 mpg by MY 2016 (using air-conditioning GHG credits by the EPA). Since CAFE standards as measured by NHTSA cannot take into account air-conditioning credits, this is equivalent to 34.1 mpg as calculated by NHTSA. In 2012, the agencies finalized rules for MY 2017–2025. The final standards are projected to result in an average fleet-wide level of 163 grams/mile of carbon dioxide (CO_2) in MY 2025, equivalent to 54.5 mpg if achieved only through fuel economy improvements and equal to 48–49 mpg using air-conditioning improvement credits. Compared to the standards in place through MY 2016, the EPA and NHSTA estimate that these CAFE standards provide significant savings for consumers in terms of expenditures on fuel. Higher costs for new vehicles will add, on average, about $1,800 for consumers who buy a new vehicle in MY 2025. Those consumers who drive their MY 2025 vehicle for its entire lifetime will save, on average, $5,700 to $7,400 (7 percent and 3 percent discount rates) in fuel compared to a vehicle meeting the MY 2016 standard.

Technically not part of CAFE regulations is the closely related Heavy-Duty National Program, which, for the first time, reduces GHG emissions and improves the fuel efficiency of medium- and heavy-duty vehicles. The EPA and NHTSA estimate that the standards will reduce CO_2 emissions by 270 million metric tons and save about 530 million barrels of oil over the life of vehicles built from 2014 to 2018, providing $49 billion in net benefits.

The details on specific rules have changed over time and differ between the light- and heavy-duty sector. Nonetheless, for compliance, manufacturers are generally allowed to carry back and carry forward CAFE credits in a three- or five-year window around each model year. Thus, the CAFE regulations are one of the first major U.S. regulations to allow for credit borrowing and banking. Other flexibility mechanisms also allow CAFE credit averaging between separate standards for cars and light trucks or within the same regulatory category (heavy-duty) for the same manufacturer and limited trading across manufactures of credits for the same vehicle category.

If a vehicle manufacturer's average mpg for a given compliance category (e.g., domestic passenger car) falls below the applicable standard, and the manufacturer cannot make up the difference by using credits, the manufacturer is subject to civil penalties of $5.50 for each tenth of a MPG that a manufacturer's average fuel economy falls short of the standard for a given model year, multiplied by the total volume of those vehicles in the compliance category. For some manufacturers (predominantly foreign manufacturers of performance vehicles), paying this civil fine is a cheaper alternative than compliance with the fuel economy regulations. NHTSA has collected $844 million from 1983 through 2011 (cumulative, nominal dollars) in CAFE penalties (NHTSA n.d.).

CORPORATE ENVIRONMENTALISM

Corporate environmentalism, or voluntary pollution control by businesses, has become an integral part of U.S. environmental policy, along with the traditional legislative approach of directly regulating emissions, better known as command and control, and market-oriented instruments such as tradable permits. While command-and-control regulation remains the main pillar of U.S. environmental policy, the regulatory landscape has changed since the early 1990s with the increased recourse by federal and state agencies to voluntary pollution control mechanisms to improve environmental protection. These government-sponsored programs encourage businesses to take a comprehensive approach to pollution prevention so as to achieve reductions in pollutants that are not directly regulated and/or lower emissions beyond their targets for regulated pollutants.

In 1990, the Pollution Prevention Act (PPA) was passed to promote widespread adoption by businesses of voluntary pollution prevention (P2) activities. A P2 practice can occur by two different means. One, the practice reduces the amount of a pollutant or substance entering a stream or into the air. Secondly, the practice can reduce the hazards to either public health or the environment. Examples of P2 activities include equipment and material modifications such as substituting less toxic solvents for hazardous solvents, and procedural changes such as self-inspection and monitoring programs to discover spills or leak sources. The U.S. Environmental Protection Agency (EPA) has identified 43 P2 practices that firms can choose to implement voluntarily in order to reduce waste generation.

With the enactment of the PPA, the government hopes to induce voluntary corporate environmental investments and infuse a pollution prevention ethic within corporate management that will stimulate substantial pollutant source reductions across the board. To encourage the adoption of P2 practices and other voluntary environmental investments, the EPA provides matching grants, technical assistance, and access to valuable P2 information exchanges. The EPA has also embedded in its enforcement settlement process the option of reducing penalties against violators who perform P2 activities above and beyond the mandatory actions required to correct the violation.

In 1991, the EPA created the 33/50 program to reduce emissions of 17 high-priority toxic chemicals, including two ozone-depleting compounds, by a third by 1992 and by half by 1995 through voluntary action by firms. In early 1991, the EPA invited the 509 companies emitting the largest volume of 33/50 pollutants to participate in the program; these companies were responsible for over three-quarters of the targeted toxic releases. In July 1991, 4,534 other companies were invited to participate as well. With additions through 1995, the EPA invited a total of 10,167 firms to join the 33/50 program, and 1,294 firms accepted. The 33/50 program was purely voluntary, and its pollution reduction targets were not enforceable. Yet, the EPA cites some aggregate statistics as indicators of the program's success. Among reporting firms, total 33/50 chemical releases declined by over 52 percent between 1990 and 1996 compared to a 25.3 percent reduction in non-33/50 toxic emissions over the same period.

In 1992, the EPA introduced Energy Star, a voluntary labeling program designed to identify and promote energy-efficient products to reduce carbon dioxide emissions. To date, more than 20,000 organizations have chosen to participate in the Energy Star program. In the same vein, the EPA partnered with the U.S. Department of Agriculture in 1994 to create AgStar in order to induce voluntary reductions of methane emissions and protect water quality in concentrated animal feeding operations. AgStar promotes the use of anaerobic digesters to capture and combust methane so as to generate electricity.

The number of similar partnership programs between the EPA and businesses has grown rapidly to more than 50 today (www.epa.gov/partners); these programs are designed to address a wide variety of environmental issues related to air and water quality, climate change, energy efficiency, and product labeling. Furthermore, several state agencies have followed the EPA's lead to initiate their own voluntary programs. For example, over 160 businesses joined Ohio Prevention First in 1993, a voluntary program sponsored by the Ohio Environmental Protection Agency (Ohio EPA) to halve emissions generated throughout Ohio by the year 2000. More recently, in 2007, Ohio EPA launched the Tox-Minus Initiative, another partnership program with Ohio businesses to achieve meaningful reductions in toxic releases within five years.

In addition to government-sponsored voluntary pollution control mechanisms, many businesses and industries are taking unilateral steps to proactively improve their environmental management by adopting ISO 14001 standards and related environmental management systems, such as Total Quality Environmental Management (TQEM), that enable them to identify the environmental impacts of their products and internalize those impacts in their operational decisions.

Many leading firms have shifted away from a regulatory-driven approach to a more proactive and beyond-compliance strategy toward environmental management. For example, in the wake of a tragic gas leak that killed thousands in Bhopal in India, the chemical manufacturing industry responded by creating, on its own volition, the Responsible Care program to enhance environmental performance and occupational safety above and beyond member firms' legal obligations. The apparent success of Responsible Care led the BP Oil Spill Commission to recommend the creation of a like-minded program for the oil and gas industry. Notable examples of firm-led initiatives to rein in waste generation include the multinational conglomerate 3M's Pollution Prevention Pays (3P) program and Chevron's Save Money and Reduce Toxics (SMART) program. More recently, in 2006, DuPont announced that it will increase its spending on research and development of environmentally smart technologies by $400 million, while Walmart, McDonald's, and Coca-Cola have all received awards for voluntary efforts to reduce their environmental footprint.

The rise of corporate environmentalism has ignited an ongoing academic debate regarding profit-driven business motives to self-select into costly voluntary programs. Economists have advanced a number of theories to explain this seemingly puzzling behavior. First, firms' overcompliance with environmental norms may be driven by a differentiation strategy designed to attract a growing chorus of green consumers willing to pay a premium for environmentally friendly goods. Alternately, voluntary pollution reductions may shield firms from green political activism, that is, lobbying by environmental interest groups such as the Sierra Club, the Environmental Defense Fund, and the League of Conservation Voters to enact tighter regulatory standards that could significantly raise costs of doing business. In the same realm, corporate environmentalism may deter boycott campaigns by environmental interest groups. Furthermore, a research-intensive firm may engage in voluntary environmentalism as a strategy to hasten legislative or regulatory action that would ratchet up pollution standards to the detriment of its rivals. A less-talked-about potential motive is the desire to lessen the scrutiny of environmental authorities, reducing the frequency of costly environmental inspections and enforcement actions. Such rewards, whether promised implicitly or officially, may represent an optimal government policy to promote participation in a voluntary pollution reduction program.

Businesses in developing countries with notoriously weak and/or corrupt environmental enforcement agencies may embrace corporate environmentalism not necessarily to seek green premiums but to reassure upstream customers about their commitment to environmental quality; this is more likely to be the case for businesses in export-oriented developing countries. Indeed, anecdotal evidence indicates that many suppliers have faced pressure from their customers in developed countries to seek ISO certification. China, for example, has by far the highest number of ISO 14001-certified businesses in the world.

Researchers have sought to test the empirical validity of the theories listed earlier mostly using data on the EPA's 33/50 program, the Green Lights program, the WasteWise program, the Climate Challenge program, the Energy Star program, and firms' adoption of P2 practices and environmental management systems. Yet, after more than two decades of experience with voluntary pollution control programs and an intense empirical scrutiny, a good deal of controversy remains on how effective these programs have been at curbing pollutant emissions from levels that would otherwise have been produced.

CORPORATE SOCIAL RESPONSIBILITY

Corporate social responsibility refers to the responsibilities that corporations, including transnational corporations (TNCs), have to workers and their families, consumers, investors, host governments, and indigenous peoples. At the heart of corporate social responsibility (CSR) is the understanding that harmonious relations among businesses, workers, governments, and other stakeholders are in everyone's best interests. Implied in the concept of CSR is that governments in advanced and developing countries create a positive business environment in which companies, including TNCs, can profitably operate. Good governance, the provision of a sound infrastructure, and macroeconomic stability help cement the working relationship between TNCs and the host country.

The concept of CSR has changed over time. During the early years of the Industrial Revolution in Europe and the United States, major corporations had a narrow view of CSR. That is, corporations existed to earn profits, a portion of which were reinvested in the firm and the remainder distributed in the form of dividends to the company's stockholders. During the 20th century, however, corporations were obliged to expand their view of good corporate citizenship. In part, the concept of CSR was broadened to accommodate a flurry of new laws and regulations designed to protect workers, consumers, investors, and the environment. The growth of civil society organizations (CSOs), including international nongovernmental organizations (INGOs), also caused corporations to reexamine their internal policies and act in more socially responsible ways. By the 1970s and 1980s, corporations and a number of international organizations devised voluntary "codes" to guide business conduct in domestic and global markets. Over time, these codes defined what it meant to be a socially responsible corporation.

One type of code is the "corporate code of conduct," which is written and implemented by individual corporations. Under a corporate code of conduct, the firm establishes standards to govern its treatment of workers, its dealings with indigenous peoples, and its use of the natural environment. Nearly all corporations today have adopted a corporate code of conduct. Nike, for example, strengthened its code of conduct after the firm suffered the ill effects of a global consumer boycott in the late 1990s. Nike responded to criticisms of sweatshop working conditions in the overseas plants of its subcontractors by pledging to strictly enforce its code. The Nike code promises a safe and healthy workplace, fair compensation, freedom of association, and limits on required work hours.

A second type of code is the "code of conduct for multinationals." Individuals or organizations outside of the corporate structure devise this type of code. The standards of behavior outlined in these codes resemble the corporate codes penned by the corporations themselves. One of the most recognized codes is the Guidelines for Multinational Enterprises, which was produced by the Organisation for Economic Co-operation and Development (OECD). Thirty-seven governments endorsed this code, including the 30 OECD countries and seven non-OECD countries. Its recommendations represent best practice for companies in the global economy. For example, the guidelines oppose business practices that result in environmental degradation, child and forced labor, workplace discrimination, and bribery and other forms of corruption. The guidelines support human rights, transparency, honesty in advertising and marketing, consumer safety and privacy, technology transfers, functional worker associations, and respect for local laws and cultures. The guidelines are widely supported by businesses and labor groups.

Other important corporate codes have surfaced in the global economy. The Tripartite Declaration of Principles Concerning Multinational Enterprises and Social Policy, a document produced by the International Labour Organization (ILO), stresses partnerships among businesses, labor, and government. Key principles in this declaration are the promotion of human rights and sustainable development; full employment in a secure and nondiscriminatory environment; human capital development for workers and management; workplace reforms, including improved wages and benefits, working conditions, and abolition of child labor; and freedom of association, including the right to form unions, bargain collectively, and resolve disputes with management.

The United Nations' Global Compact, which was introduced in 1999 by UN secretary-general Kofi Annan, identified nine core principles to promote CSR. Since this time, 1,200 companies have signed the compact. The first category of principles, human rights, asks corporations to respect human rights and avoid any complicity in business activity that involves human rights abuses. The second category, labor rights, supports workers' right to unionize and calls for the abolition of compulsory labor, child labor, and workplace discrimination. The third category, environmental protection, calls on business to use the natural environment wisely and to develop and employ environmentally friendly technologies. In 2004, a 10th principle, anticorruption, was added to the original list. In 1999, the Reverend Leon H. Sullivan introduced the Global Sullivan Principles of Corporate Social Responsibility. This document promoted human rights, equal opportunity, freedom of association, fair pay, a safe workplace, fair competition, and an improved quality of life for all peoples in the global economy.

Corporate social responsibility has been a hot topic in the modern era of globalization. INGOs and other elements of civil society openly confront TNCs for not living up to their civic responsibilities. There is still considerable debate over the success of voluntary codes on business behaviors. Supporters of voluntary codes argue that effective monitoring of TNCs ensures compliance with international standards. Intense surveillance, by INGOs and CSOs, the International Organization for Standardization (ISO), and other groups, reinforces laws and regulations approved by national legislatures. Critics counter that voluntary codes are toothless and cannot prevent the abuse of the marginalized, voiceless element in the world's poorest economies. Critics note that low-skilled workers in the global supply chain continue to languish in sweatshops as TNCs implement cost-cutting strategies to pad corporate profits.

COSTS

In economic terms, costs are the trade-offs of choosing one alternative over another. The costs incurred in economic decisions can be monetary or nonmonetary. There are many types of economic costs.

Fixed Costs

Fixed costs (FCs) are short-run costs independent of the output produced. Examples of fixed costs include rent on property, rental agreements on equipment with a time restriction, and labor costs as part of a labor contract. In the long run, fixed costs do not exist because the terms of agreements and contracts eventually expire.

Variable Costs

While fixed costs may be defined as short-run costs that do not vary with output, the level of variable costs (VCs) are dependent on total output. Examples of variable costs include a company's cost for commodities, raw materials used in the production process, and possibly some labor costs not determined by a union or other form of labor contract. In the long run, all costs are variable costs.

Total Cost

Total cost (TC) for a company is the sum of total variable costs and total fixed costs (TC = TFC + TVC). In the short run, a company could have both short-run fixed costs and short-run variable costs. In the long run, all of a company's costs are variable (TC = TFC + TVC where TFC = 0).

Average Fixed Costs

Average fixed costs (AFCs) are those costs found by dividing total fixed cost by output. AFC is represented by a continually downward-sloping curve. The downward slope represents the fact that as output increases, the total fixed cost is divided by the larger output; TFC divided by total output (Q).

For example, if output is 1 and total fixed cost is $100, average fixed cost is TFC / Q = $100 / 1 = $100 = AFC. If output is 10, total fixed cost remains $100 so TFC / Q = $100 / 10 = $50 = AFC. Average fixed cost continues to decrease per unit as quantity produced continues to increase.

Average Variable Costs

Average variable costs (AVCs) are those costs found by dividing total variable cost by output. AVC is represented by a downward-sloping curve until diminishing marginal input sets in, at which time AVC begins to increase per total output (see Figure 1).

For example, if output is 1 and total variable cost is $10, average variable cost is TVC / Q = $10 / 1 = $10 = AVC. If output is 10, total variable cost is $100 and TVC / Q = $100 / 10 = $50 = AVC. Average variable costs continue to increase per unit as quantity produced continues to increase.

CREDIT CARDS

A credit card is a small plastic card issued by a bank, financial institution, or merchant that enables the cardholder to purchase goods and services with borrowed funds.

Interest on the unpaid balance begins one month after purchase. If the card user pays the amount owed within the first billing cycle, there are no interest charges.

Credit cards have higher interest rates (around 19 percent per year) than most consumer loans.

Credit cards have become prevalent across all realms of both U.S. and international developed markets. Unfortunately, their overuse can lead one to accumulate excess debt and can cause financial problems.

History

Lending money with a card began in the 1800s when store owners and agricultural enterprises offered credit in conjunction with financial institutions. By the beginning of the 1900s, hotels and large department stores created paper "charge" cards for their important customers. These designated "creditworthy" customers used the cards in the issuing merchant's store in the same way consumers use credit cards today, and they had a predetermined upper credit limit.

Sears was one of the first companies to use a credit card to increase sales, and the strategy worked very well. Long before the Internet, Americans received a Sears catalog, which contained pictures of toys, tools, tractors, and every kind of household product sold in the Sears stores. With the innovation of credit cards, people could buy anything they wanted from Sears immediately—and pay for it later, with interest.

General purpose, as opposed to store-based, credit cards began in 1949 when Diners Club created its nationwide network card. Cardholders could charge goods and services from network members. Diners Club cards were initially designed for wealthy individuals to pay for entertainment and travel expenses. Merchants also appreciated the card, despite the 7 percent fee they paid to Diners Club, because card users tended to spend more than those who paid with cash.

As with most successful concepts, Diners Club inspired many competitors. By the late 1950s, Bank of America jumped into the credit card business with a national card. At that time, interstate banking laws prohibited banks from operating outside of state borders. Creatively, Bank of America circumvented the interstate banking laws with the credit card and reached a large national customer network. As the national network grew more complex, Bank of America separated its credit card business into what is now known as the Visa network.

In 1966, the MasterCard network emerged to compete with Visa. The credit card industry continues to grow with extensive competition for consumers. According to Douglas et al. (2005) in 2001, approximately 76 percent of American families own at least one credit card. Today, 92 percent of families with incomes over $30,000 have at least one credit card. The average number of credit cards for all households is 6.3 cards.

How Do Credit Cards Work?

To obtain a credit card, the consumer completes an application and the issuing company does a quick credit check to determine the applicant's ability to make the credit card payments. If the credit card company believes the applicant can repay the borrowed funds, it will issue a credit card with an upper spending limit.

The credit card is a plastic card with the customer's name and account number on the front. The account number, specific to each cardholder, applies to the credit card's network, bank, and account. On the back is a signature box, partial account number, and a three- or four-digit card identification security number along with a magnetic code strip.

This is how a college student might get his first credit card. Joachim completes a credit card application and the issuing company checks his credit and possibly his work history. If Joachim has a part-time job and is attending college, the bank will likely approve him for a credit card. Since his income is low, the card might have an upper limit of $800. That means Joachim can make purchases up to $800. Those with higher incomes and greater credit histories usually receive higher credit limits.

Every month, the cardholder receives a statement in the mail or online with the list of purchases, fees, and the amount owed along with the due date for payment. If the full balance of the card is paid off every month, no interest fees are charged. If a partial payment is made on the bill, interest begins to accrue or build up. If the consumer continues to pay only part of the total bill, more interest accrues and eventually the individual ends up owing a lot more money than he or she initially charged.

Advantages and Disadvantages of Credit Cards

Credit cards are convenient because they eliminate the need to carry cash. Using a credit card responsibly can help consumers build credit history. A good credit history is important if one wants to borrow money to buy a home or car. Some credit card companies protect the cardholder from false charges in case the card is stolen and do not hold the cardholder responsible for most of the charges made by the thief. Many credit cards also offer rewards such as cash back, airline miles, or gift cards. Using a credit card is also a method to keep track of expenses.

Credit cards allow consumers the opportunity to buy more than they can pay off in one month. This is both an advantage and a disadvantage. The advantage is that it boosts consumers' spending power and can help during times of unexpected expenses. The disadvantage of buying more than one can pay off in a month is that the consumer pays a very high interest rate on the unpaid credit card balance.

Credit cards make it easy to incur large amounts of debt, a major disadvantage. Some consumers charge a lot over the holiday season and end up paying the bills months after the holiday festivities are over.

Many merchants, such as hotels and rental car companies, require consumers to have a credit card on file in order to rent a car or stay at a hotel. This is a disadvantage if the consumer doesn't have a credit card.

In short, credit cards can be convenient when they are used responsibly by paying off the balance every month. Let the balance build up for many months and the convenience is converted into a serious financial disadvantage.

CREDIT CYCLE

Cycles in bank lending had been treated in economic research even before the study of business cycles became a central research topic. Clemént Juglar (1962) and John Mills (1867) published early analyses. In order to understand credit cycles, it is helpful to consider various propositions concerning this prototypical financial cycle. The first and weakest proposition states that lending moves with the overall course of the economy. Hence, during expansions bank lending grows strongly, and in recessions credit grows slowly or even declines. This is uncontroversial since financing needs—that is, credit demand by firms and households—move with the economic tide. A second proposition holds that lending is not only cyclical but that it is excessively so. According to this notion of the credit cycle, banks tend to lend too much in the upswing—and with this lending finance inefficient projects—while curbing lending in recessions too much so that even efficient projects fail to find financing.

Behavioral propensities of borrowers who tend to be overly optimistic in boom times and overly pessimistic in recessions can make the inefficient wave of credit even stronger. The furthest-reaching proposition regarding the credit cycle is the notion that excesses in lending during economic upswings eventually bring about a financial crisis and a downturn in economic activity when investment projects go sour and creditors default. Summing up the possible effects of lending excesses, we note at the minimum an inefficient allocation of capital and possibly a role in the recurrence of economic recessions.

Research studies have elaborated various explanations as to why credit booms take place and why they are often followed by so-called “credit crunches.” One major effect draws on the connection between lending and the value of loan collateral. Lending booms often occur together with asset price booms because collateral values and bank lending drive each other up (Kiyotaki and Moore 1997). Other explanations turn on various frictions in the credit market concerning the effort that lenders put into gathering information regarding the creditworthiness of borrowers (Gorton and He 2008). Yet another mechanism that favors the emergence of inefficient cycles of bank lending concerns the dynamics of bankers’ expectations. Bankers with a limited experience span tend to behave in a boundedly rational manner. During boom times they are inclined to underestimate the occurrence of a recession and become overly optimistic, whereas in recessions they tend to become overly pessimistic (Rötheli 2012).

This mechanism leads to an underpricing of credit risk during long booms and an overpricing of credit risk in recessions. This means that in the period of upswing banks have a tendency to lend at excessively low interest rates, whereas in downswing periods they are liable to charge excessively high interest rates. Overall, the credit cycle must be reckoned as a major factor contributing to macroeconomic fluctuations.

CREDIT OR BOND RATING AGENCY

In the finance world, it's important for investors to trust institutions that issue bonds and fixed-income debt. After all, if an individual or institutional investor purchases a 30-year bond for $1,000 that promises to pay a 5 percent coupon or interest rate, the investor must be certain that the issuer will be solvent and available to make the interest payments for the next 30 years.

Credit ratings, also called debt or bond ratings, give fixed-income debt issuers a score determined by their financial strength. This rating helps investors understand the likelihood of receiving their interest payments for the duration of the bond, with high credit ratings indicating financially stronger companies and low credit ratings denoting weaker corporations.

Credit Ratings Overview

Ratings agencies perform in-depth analysis of the creditworthiness of all major debt issuers, from companies to city and state governments to sovereign countries who issue bonds, and assign a credit grade or score. The raters investigate the economic conditions of a country when deriving the rating for a sovereign nation. A rating agency might also examine the political condition of a country. War-torn and economically unstable countries would receive lower credit ratings on their debt than would a more stable country such as the United States.

Corporations; city, state, and municipal governments; and countries all borrow money from the public and large institutions by selling bonds. Bonds function similarly to a loan, only the lenders are the individuals who buy the bonds.

For fixed-income investors to feel confident in purchasing the debt, they must understand what they are buying. That is where the rating agencies come in. These agencies review the entities that issue corporate bonds, municipal bonds, government bonds, and a stock–bond hybrid, called preferred stock.

There is an inverse relationship between ratings grade and possibility of default. Higher-rated securities have a lower risk of default. For example, Standard & Poor's credit rating scale begins with AAA, the highest available grade (AA+ is next highest) on down to C and D ratings. Those debt securities with ratings below BBB– are considered to be the riskiest and are called speculative or junk bonds. Only the most risk-tolerant investors should invest in the lower-grade debt.

History of Credit Rating Agencies

In 1913, John Knowles Fitch founded the Fitch Publishing Company, which published *The Fitch Stock and Bond Manual* and *The Fitch Bond Book*, compilations of financial statistics used by the investment industry. In 1924, Fitch introduced the AAA through D rating system. These grades laid the groundwork for modern investment product ratings.

Other players in the ratings industry include Moody's Investors Service, who published *Moody's Manual* in 1900, which included statistics and information about stocks and bonds. The modern iteration of this early organization was initiated in 1914 with the creation of Moody's Investor's Service. In the 1970s, Moody's began rating all types of debt instruments, including short-term government bonds, called commercial paper, and bank deposits. Moody's continues today as one of the premier rating agencies.

Henry Varnum Poor began his financial career compiling and detailing the financial information of the railroad industry. He first published *History of Railroads and Canals in the United States* in 1860. He continued publishing updated annual financial reports under the company he began with his son, the H.V. and H.W. Poor Company. In 1906, Standard Statistics published corporate bond, sovereign debt, and municipal bond ratings. In 1941, the two companies merged and formed the well-known Standard & Poor's Corporation. Although retaining the "Standard & Poor's" name, in 1966, the company was bought by The McGraw-Hill Companies, Incorporated. In addition to ratings, Standard & Poor's (S&P) creates many tools for securities analysis, including the gold standard of major stock market indexes.

Ratings Drill Down

The three prominent bond rating agencies—Standard & Poor's, Moody's, and Fitch—each use their own letter-based rating system. Although similar, with A ratings being higher than D ratings, the specific grades for each company vary.

Bonds are rated at issue and subsequently reviewed periodically to determine whether a rating change is warranted (based on changes in the issuing entity).

Ratings are very important to issuers as well as bond buyers. If a bond is expected to receive a high rating, the interest paid by the organization to the bond buyers is lower than a comparable entity with a lower credit rating. The lower the interest rate payments, the lower the cost of borrowing for the company. Clearly, an entity prefers to pay less in interest than more.

For example, if Company XYZ receives a credit rating of AAA, it might pay 3 percent interest on a 10-year bond, whereas if Company LMN receives a credit rating of C, it might have to pay 4.5 percent interest on a 10-year bond in order to entice investors to purchase its debt. The reason for this discrepancy is that investors must be compensated with higher interest payments for buying riskier bonds.

CREDIT REPORT

A credit report is a tool used by lending institutions such as banks to determine if you are a good credit risk and will pay back the loan you are applying for. The credit report contains information on your past and current financial transactions that involve debt, such as credit cards and loans, as well as information on judgments and past credit inquiries from credit rating institutions.

The credit reporting agencies are the companies that compile the data for your credit report and provide the information to banks and other institutions for a fee.

You are allowed to get one free credit report a year from each of the reporting agencies. You may also request a report when you are denied credit.

What Is on a Credit Report?

A credit report contains information related to your ability to pay back money that you borrow. It includes the following items:

- Personal identification information—this includes your name, address, social security number, and phone number. It may also contain information from your past, such as former names, addresses, employers, or possible people that you have a credit relationship with, such as your spouse.
- Outstanding debts—these are debts that you have not paid off in full. Examples are mortgages, car loans, student loans, and credit cards.
- Past debts—any debts that you have finished paying off will continue to show on your credit reports. As an example, once you have paid off a car loan, it will remain on your credit report as a debt paid in full. If you do not pay it in full and instead use a settlement, it will indicate that the debt was settled and closed.
- Payment history—your credit report will show if you made your payments on time or late. Typically, it will show on time, 30 days late, 60 days late, and 90 days or more late. After that point, the debt will typically be moved to a collection status, such as "referred to collection," repossession, or charged off. These last classifications indicate that you have not paid the debt as you had agreed to originally.
  Your positive information on your payment history will typically stay on your report indefinitely, and your negative information will go away after seven years. Bankruptcy will stay on your report for 10 years.
- Available credit (utilization)—your report will show how much you have available on revolving credit. Available credit is considered the available credit line minus your outstanding balance. Thus if your credit line is $20,000 and your balance is $5,000, you have available credit of $15,000.
  The lower your utilization the better it is for your credit score, and lenders look upon this favorably. If you are maxed out on your credit cards and are applying for more, it is not a good sign.
- Public records—your credit report will also include any items that are on the public record, such as tax liens, court judgments, and bankruptcies.
- Credit inquiries—anytime someone checks your credit it will show up on your credit report.
- Dispute statements—if you have an item that you disagree with on your report, you can file a dispute statement, and this will show up on your credit report. The credit-granting company you have the dispute with may also include its statement of what happened on the credit report.

Types of Debt

There are three types of credit that will appear on your credit report:

1. Revolving credit—This is when you don't have a final end date for paying of the debt; you are allowed to continually use the credit, pay it off, and then take out more. Examples of revolving credit are credit cards and home equity loans.
2. Installment loan—This type of loan has a fixed loan amount, a fixed payment, and a fixed payoff date. Examples are auto loans and mortgages.
3. Open debt—This is the least common among the types of debts and includes debts that must be paid in full every month. American Express offers credit cards like this. There is no credit limit, but you have to pay in full every month.

Purpose of a Credit Report

The purpose of the credit report is to help companies determine if you are a good credit risk. It is also used by insurance companies, employers, landlords, and when granting military security clearance. These companies and institutions typically use credit reports to determine if you are responsible and pay your debts.

For some jobs, such as in the banking industry, they want to ensure that you are able to handle the constant interaction with money and are responsible enough to manage money for others. In the military, it has been shown that most unethical or illegal acts are committed in order to gain money to pay off debts.

Credit Score

The credit report itself does not say you are a good or a bad risk. It is up to the lending institution to take the information from the report and make its own decision on your creditworthiness.

In an attempt to make this easier, a credit score was created to summarize your ability to pay. This is also known as your FICO score. This score is not part of your credit report. Companies pay extra to have this score given to them in addition to your credit report.

When you get your annual free report, it will not include your credit score unless you pay an additional fee to access it.

Reporting Agencies

Your credit report is compiled by a credit reporting agency, also known as a credit bureau. There are three major agencies: Experian, Equifax, and TransUnion.

Each one gathers information from lending agencies and public records to compile your report and score. While each company typically has very similar information on you, there may be small differences between each of the agencies' reports and the scores that they report to lending institutions.

These agencies are for-profit companies and make money by selling reports to lending institutions and others that want the information. You do have to grant the company requesting the credit report permission to access your report; the company cannot simply request it. For example, if your landlord wants to run a credit report, you must first sign an authorization form allowing it.

Lending institutions are not required to report any information on your debts but do so voluntarily to help create a complete picture of individuals' credit.

The reporting agencies are monitored by the Federal Trade Commission (FTC).

Disputing Information on a Credit Report

If you pull your credit report and determine that information is false, you can request that the reporting agencies remove it from your report. In order to do this, you must submit a request. Then the agency has 30 days to verify or remove the information.

However, it is possible the information may show up at a later time. This occurs when the bank or lending institution has the wrong information in its files. After the agency has removed the information, the bank will re-report the data and it will show up again on your report.

In order to guarantee that the debt will not show up again, you must work with the lending institution to remove the bad information from its files.

CREDIT UNIONS

Credit unions are a type of financial institution that allows you to deposit your money and take loans, similar to a bank. However, unlike banks, their organizational structure is nonprofit and member owned. The focus of a credit union is to provide a low-cost source of loans and banking services while promoting community and education among its members. Credit unions are regulated by the government entity that grants them a charter. A charter is a license to operate as a financial institution. Charters are issued by the state government that the credit union is located in or from the federal government.

History

The first credit union was started in the 1850s in Germany by Franz Hermann Schulze-Delitzsch as a way for city shopkeepers, traders, and artisans to pool money for mutual benefit.

The idea behind pooling money is that a group of people could put their money together and those who needed to borrow could do so, while those who had extra could make additional money by loaning it out to the others. Thus the businesses that were in the middle of a slowdown could borrow for a reasonable cost from those that were doing well.

In the 1860s, another German, Friedrich Wilhelm Raiffeisen, took the concept to the rural areas and started credit unions for the poorer common workers who were not able to use traditional banks. These unions had special structures that allowed seasonal employees to make payments on loans when income was coming in and not when there was no income. In the early days, all positions were volunteer except for the cashier.

By the end of the 19th century, credit unions had spread throughout Europe. The first official credit union in the United States started in November of 1908 in Manchester, New Hampshire.

Today there are more than 6,900 credit unions throughout the United States and more than 55,000 worldwide.

How Credit Unions Are Different from Banks

While banks and credit unions offer many of the same products and services, credit unions have a different structure, purpose, and other features. Following are the main differences:

- Profit—Banks are for-profit institutions with the money going to the bank's owners or shareholders. Credit unions, on the other hand, are nonprofit. Once the costs of running the credit union and excess capital requirements are reached, the profits are returned to the members.

  Profits are typically returned in the form of higher interest rates (which they call dividends), lower fees for products, and lower interest rates on loans. Some credit unions even use the overage to offer additional services and benefits, such as scholarships and member appreciation days with giveaways.
- Management structure—Credit unions are governed by their members, who are the owners. Every member gets one vote to elect the board of directors, no matter how much money is in his or her account.

  For day-to-day operations, credit unions hire traditional banking employees to hold positions such as tellers, managers, and loan officers. However, top-level management is done by the members of the credit union on the board of directors.

  This board steers the strategy and decision-making of the credit union. They review interest rates, set policies, approve budgets, and hire the CEO or president, who runs the credit union on a daily basis.

  Board members are typically volunteers. The board of directors is elected by the entire membership, and committees are typically appointed by the board of directors. Typical committees include a credit committee and a supervisory committee.

Banks are governed by employees, shareholders, and outside directors. The board is elected by the shareholders, where the number of shares you own determines how many votes you get. Not everyone that is on a management board or committee is an actual customer of the bank, whereas all members of management in a credit union are account holders in the credit union.

- Insured and governed—Banks and credit unions are overseen and backed by different government entities. Federally chartered banks are under the control of the Federal Deposit Insurance Corporation (FDIC), and credit unions fall under the National Credit Union Administration (NCUA).

  Just as customers of banks have insurance against the banks closing from the government, credit unions also get that benefit. They are insured by the National Credit Union Share Insurance Fund, which is run by the NCUA.
- Who can join—With a bank, anyone can open an account as long as he or she meets the financial requirements set forth by the bank. Conversely, credit unions have nonfinancial requirements that are instead focused on where you work and live.

  For example, you might be required to live, go to school, or work in a specific county or city. Or if it is a company credit union, you must work for that company. After you meet those requirements, the opening deposits are much cheaper than a traditional bank; instead of $100 as with a traditional bank, one can typically open a credit union account with around $5.

  Once you are a member, you have lifetime membership even if you move or change jobs. Once you have membership, your immediate family members may also join even if they do not meet the requirements on their own.

Products

Like a bank, credit unions offer checking and savings accounts, loans, certificates of deposit, ATMs, and more. There are some minor differences in the names used for these items, although this is changing to make it easier for members to understand.

For example, here are some of the naming variations of credit unions:

- A checking account is a share draft account.
- A savings account is a share account.
- Certificates of deposit are share term certificates.

Additionally, some credit unions have begun adding outside services such as insurance and investment management.

The biggest difference between credit unions and traditional banks are the fees that you pay for services. In credit unions, most deposit accounts do not have any monthly fees, unless they have special benefits to them. Additional services such as wire transfers, cashier checks, and statement research are offered at a fraction of the price of traditional banks. For example, a wire transfer at a credit union runs around $10, whereas the banks charge about $30.

Credit unions are a competitive alternative to traditional banks for great cost savings. Plus, they serve an often-ignored segment of the population that has less money. By offering low fees and smaller account opening requirements, credit unions are better able to serve their members.

D

DEBT COLLECTION

A debt is an obligation of a consumer to repay to a lender or vendor money that was borrowed. A debt collector is anyone whose job it is to obtain debt repayments. When people fail to pay their bills, they may be subject to debt collection. Initially, the lender attempts to collect the amount due from the borrower. A lender could be a credit card company for a retail store or national company, a bank, a vendor of services such as a cable company, a medical provider, a mortgage company, or any business with whom you have conducted a business transaction on credit. In sum, a lender is any type of organization that issues credit cards, sells goods or services on credit, or makes loans.

This entry groups lenders and businesses together and calls the creditor a lender. If the lender is unsuccessful in receiving the monies owed, he or she may transfer the debt to a debt collection agency or attorney whose job is to collect or recover all or part of the money owed.

When a consumer fails to pay his or her department store credit card bill, after a few months, the bill is transferred to a debt collector who attempts to collect the debt. This process occurs when an individual has financial problems and stops making payments or underpays the amount owed to the lender.

The Fair Debt Collection Practices Act

The federal Fair Debt Collection Practices Act (FDCPA) governs how debt is collected. This law was enacted to eliminate abusive debt collection practices. In the past, debt collectors engaged in abusive practices that led to personal bankruptcies, marital instability, loss of jobs, and invasions of individual privacy.

This law requires debt collectors, within five days of initial contact, to provide the consumer in writing with the amount of the debt, the name of the creditor to whom the debt is owed, and a statement that the debt is valid. If the consumer does not dispute the debt within 30 days, the debt is assumed to be valid.

If the consumer disputes the debt, it must be done in writing within 30 days of first contact. At that point, the debt collector is required by law to obtain verification of the debt in writing and mail it to the consumer. The verification must include the amount of the debt and the name of the original creditor to whom the debt is owed.

Debt Collectors May Not Engage in Abusive Practice

FDCPA clearly prohibits debt collectors from harassing, oppressing, or abusing anyone while attempting to collect a debt. Debt collectors can't lie in their attempts to collect debts. For example, collectors cannot misrepresent themselves as attorneys or officers of the U.S. government, nor can they falsely claim that the debtor will go to prison. Debt collectors may not call you at work, or early in the morning, or late at night. Nor can debt collectors levy additional interest, fees, or charges on top of the debt unless permitted to do so by state law or under the terms of the original credit contract.

Unless the debt collector sues the individual and wins a judgment, the collector may not garnish the creditor's wages. If the borrower believes the collector violated the law, the borrower has one year in which to sue a debt collector in state or federal court. The debt collector may also be reported to the state attorney general's office for abusive practices.

Debt collection is used when a borrower fails to pay money owed. This practice is regulated by the government and must be practiced in accordance with the law.

DEBT AND CREDIT COUNSELING

Credit counseling (sometimes referred to as debt counseling) is designed to help people experiencing financial difficulty. Credit counseling assists those who are behind in their credit card payments, living paycheck to paycheck, having difficulty saving money, receiving calls from collection agencies, facing bankruptcy, or experiencing other financial hardships. Credit counselors advise consumers on managing money, budgeting, saving, debt, and assist in creating a money management plan. There are both for-profit and nonprofit agencies to help with financial problems.

Credit cards, payday loans, and a variety of other loans are widely available today. This ready credit encourages individuals to borrow in order to buy items they cannot afford. Additionally, emergency expenses, such as unexpected medical bills, create financial hardship. When an individual's bills become delinquent and expenses surpass income, credit counseling can help. Additionally, those facing bankruptcy are required to seek credit counseling.

For example, credit (debt) counseling may be needed in the following situation. If an individual charges a large amount on a credit card and does not pay the total amount due at the end of the month, interest is applied to the unpaid balance. If the bill is not paid in full in subsequent months and more charges are added, additional interest accrues. When this debt, combined with other debts, increases each month without the likelihood of paying the complete debt due, credit counseling services can instruct the consumer in how to manage debt and finances.

How to Locate a Credit Counselor

A reputable credit counseling agency will send free information about itself and its services without requiring any information from the consumer. Credit counselors can be found at universities, military bases, credit unions, housing authorities, Consumer Financial Protection Bureau (CFPB), and branches of the U.S. Cooperative Extension Service (for those located in rural locations).

It is usually preferable to choose a nonprofit credit counseling service; although nonprofit does not mean free. Additionally, it is important to understand that there are unscrupulous business people posing as credit counselors at both for- and nonprofit credit counseling organizations.

After locating a credit counselor, check the state attorney general and local consumer protection agency to determine whether complaints have been filed against the agency. The U.S. Department of Justice maintains a list of approved credit counseling agencies by state. Even if an agency is included on the Department of Justice's approved list, it is important to review fees and services to ensure it is appropriate.

The consumer must ask questions of the credit counselor to understand his or her services:

- What services do you offer?
- Do you offer a plan to help with both current and future financial problems?
- What are the fees, and what if I cannot afford the fees?
- Are you licensed?
- What are the qualifications of the counselors?
- How are the counselors paid? (Beware if counselors are paid more if the consumer signs up for special services or requests special contributions to the firm.)

Typical Credit Counseling Services

Basic services include budgeting, designing a financial management plan, and teaching basic money management skills. The agency may recommend a debt management plan (DMP) if the consumer has excess debt. The credit counselor works with creditors to arrange a payment plan and possibly lower interest rates and fees. With a DMP, the consumer deposits a predetermined amount of money with the credit counseling organization. The agency pays the unsecured debts, such as credit card bills, student loans, and medical bills, with the deposits. Consumers must follow up with creditors to confirm that the debt payment arrangement described by the credit counselor is valid.

On occasion, the credit counselor may recommend bankruptcy. Although non-profit credit counselors usually do not offer debt settlement, it is an alternative. This occurs when a for-profit credit counselor negotiates with creditors for a lump-sum payoff of the debt. This payment is usually lower than the full amount owed. Debt settlement can be risky for the consumer because of high fees, lack of transparency, and unscrupulous counselors.

Credit counselors are useful for consumers with significant financial problems, but consumers may also handle their financial situation on their own. Consumers may call creditors directly and attempt to negotiate their own repayment plan.

There is a wealth of free online resources to help those experiencing financial problems, such as the National Foundation for Credit Counseling (NFCC) and the mymoney.gov website.

DEMAND

Of all the concepts in the world of economics, demand (along with its partner, supply) is arguably the most famous and most used concept. Demand (and supply) is used to describe current, and predict future, prices and actions of consumers. All other things being equal, demand describes the behavior of consumers and how they respond to changes in prices.

Law of Demand

The law of demand describes the relationship between price and quantity demanded by consumers. It states that price and quantity demanded have an inverse relationship, all other things being equal. As the price of a good or service increases, consumers' willingness and ability to purchase the good or service decreases. Conversely, as the price decreases, consumers are more willing to purchase the product.

Demand Schedule

For each product or service there is a relationship between price and quantity demanded (aka, the law of demand). The relationship is determined through surveying the willingness and ability of consumers to purchase a product at various prices. The results of the survey create a data set of the quantities consumers are willing and able to demand at each price. The law of demand states that this relationship will be inverse. As price rises, quantity demanded will fall, and vice versa, all other things being equal. The data set is the demand schedule. For an analogy, consider the demand schedule to be a product's "story."

Demand Curve

The relationship between a set of prices and the quantities consumers are willing to produce at each price, the demand schedule, allows one to graphically depict the price/quantity demanded relationship. The graphical depiction is called the demand curve. From the law of demand, to the demand schedule, the graphical demand curve will illustrate this relationship by being downward sloping to the right. To extend the analogy, if the demand schedule is the "story," the demand curve is the "picture." The story/picture analogy is useful in determining whether a change is a change in quantity demanded or a change in demand. To do this, it is necessary to identify whether the "story" changes or just the price.

Determinants of Demand

Determinants of demand are those elements that change a consumer's willingness and ability to purchase a product at all prices. These determinants change the "story."

Examples of these determinants include:

- expectations of future price changes
- changes in income level
- effective marketing
- government policies, such as price ceilings or price floors
- price of a substitute or complementary good (A substitute good is a good that a consumer could be satisfied with in place of the original product. Complementary goods are goods that work together or affect each other. Peanut butter and jelly could be considered complementary goods. If the price of peanut butter changes, it could potentially change consumers' preference for jelly.)
- tastes and preferences, lifestyles, customs, common habits, changes in fashion, standards of living, religious values, age, and gender

Demand versus Quantity Demanded

One confusing aspect of demand is the difference between demand and quantity demanded. To determine whether a change is in demand or quantity demanded, think in terms of the earlier analogy. If the change is only the price, consumers' willingness did not change. The story remains the same. Since the story did not change, the picture did not change. When the picture does not change, it reflects a movement of price and quantity demanded along the original demand curve.

However, if one of the determinants identified earlier creates the change, consumers' willingness and ability at each price changes and we have a new story. The new story creates a new picture, that is, a change in demand and a new demand curve.

DEMAND DEPOSITS

A demand deposit is a type of transaction account held at banks and financial institutions from which funds may be accessed on demand. Demand deposits data are used by the Federal Reserve System to measure the size of the money supply in the U.S. economy and to formulate monetary policy. The amount of demand deposits is also a primary determinate of reserve requirements for financial institutions.

Accounts that are classified by the Federal Reserve as demand deposits are those that have no maturity period or an original maturity period of less than seven days and are payable on demand or within less than seven days' notice. Accounts may also be interest bearing. Demand deposits have no eligibility requirements, and there is no limit on the number of withdrawals the account holder may make.

Demand deposits are considered money because they serve the three functions of money: as a medium of exchange, as a store of value, and as a unit of account. When bank deposits can be traded without being converted into actual currency, the deposits are considered money, which is anything considered a medium of exchange. If the bank deposit has the same value as physical currency in relation to the goods and services it can purchase, it is considered a store of value. Demand deposits also share the six characteristics of money: they are durable, portable, divisible, scarce, uniform, and acceptable.

Demand deposits are included in the money aggregate M1, which is money primarily used in transactions or as a medium of exchange. M1 is the narrowest definition and measure of the money supply and includes currency and coin held by the public, demand deposits, and other checkable deposits and traveler's checks.

The Federal Reserve System (commonly known as the Fed) is the central bank for the United States and holds regulatory authority over financial institutions that hold demand deposits. The Federal Reserve controls the money supply in its goal to achieve full employment, price stability, and economic growth. The three tools the Federal Reserve uses to expand or contract the money supply include open market operations, the federal funds rate, and the required reserve ratio.

Depository institutions report the value of demand deposits to the Federal Reserve Board of Governors, which uses the data to calculate required reserves, the dollar amount of deposits banks are required to hold as cash in their vault or as deposits at the District Federal Reserve Bank in relation to the amount of checkable deposits. The amount of reserves required changes as the amount of deposits increases. The banks' goal is to keep the amount held in reserves to a minimum, since they cannot earn interest on this money by loaning it out. Because these funds are not in circulation, they are not counted as part of the money supply. Any deposits that the bank holds in excess of the required reserves are called excess reserves and can be used to make loans or purchase government securities.

The Federal Reserve can change the reserve requirements to increase or decrease the supply of money in the economy. By lowering the required reserve, the Fed increases the money supply, allowing banks to loan out a higher portion of their deposits. Increasing the required reserve reduces the money supply by requiring banks to keep a higher ratio of deposits as reserves, which leaves less to circulate in the economy. The Fed may increase the supply of money in order to reduce interest rates. Lower interest rates stimulate consumption and investment. Consumers save less and borrow more. Consumers do not have an incentive to save money at a lower interest rate; instead, they will borrow at lower rates to purchase goods. Businesses will borrow money to invest in capital goods. Aggregate demand increases, which increases real GDP. The Federal Reserve can also change the money supply through open market operations, by buying or selling treasury securities, and by raising or lowering the discount rate, the rate at which banks can borrow funds from the Federal Reserve.

DEREGULATION

Deregulation is the act of limiting the government's involvement in monitoring and controlling private companies and how much companies can charge customers. Deregulation favors a free-market approach, encouraging competition and eliminating the protection often offered to weaker businesses in a regulated market.

In the long run, this is considered healthy for the economy, but it can be hard on workers in the short run.

Effects of Deregulation

The results of deregulation depend on which side of the affected business you are on. In most cases, when new firms enter an industry, consumers receive lower prices, typically a better quality product, and more choices. Competition certainly increased in the airline, trucking, and banking industries when they were deregulated. With such rapid growth, the competition went wild, which in the short run is beneficial for consumers but not for current business owners. Deregulation causes current industries to compete with new firms, which usually means improving quality or lowering prices.

Deregulation often means new firms and thus new jobs are created; however, in the long run, the weaker firms will be weeded out of the industry and those jobs will be lost, thus balancing out employment.

History of Deregulation

From the turn of the century through the 1960s, the trend was for the government to become more involved with private companies. By setting minimum wage laws, child labor laws, and antitrust regulations, the government controlled some aspect of all businesses.

During the Progressive Era (1890s–1920s) most regulations were on big business and industry. Some of the most aggressive reforms were on trusts, breaking up monopolies, creating laws to protect consumers, the creation of the Federal Reserve system, the progressive tax structure, and helping American workers. Laws that shortened the work day; mandated higher wages, better living conditions, and safer working conditions; and protected labor unions created a nation that felt more socialist than free market.

From 1921 to the early 1930s, the government and presidents generally pursued a laissez-faire approach to the economy. However, after the Great Depression, President Roosevelt implemented major changes, and government involvement in the economy soared. The National Industrial Recovery Act placed drastic regulations on the trucking, airline, and communications industries.

Deregulation began to gain momentum in the 1970s, and transportation was the first major industry to feel its effects. The proposed legislation affected both railroad and trucking transportation, but not air. With the passage of the Railroad Revitalization and Regulatory Reform Act of 1976, the momentum for deregulation had begun.

In the 1970s and 1980s, Congress continued to pass laws to deregulate industries including airline, television broadcasting, banking, and natural gas. In the 1990s, several states deregulated their electricity companies to produce and sell energy to homeowners.

Depending on the degree of deregulation, the government's action allowed firms in these industries to compete more freely in the markets by eliminating many entry barriers and price controls. The ultimate goal of these acts was to promote competition within the market.

Results of Deregulation

In most cases, after deregulation many new firms immediately entered the marketplace. Competition increased dramatically in the airline, trucking, and banking industries. Usually, with the influx of completion, years of rapid growth were followed by the elimination of some of the weaker firms. This process is considered healthy for the economy and consumers but can be difficult to handle as a worker in the industry.

When airlines were deregulated in the late 1970s, large airline companies competed aggressively for the busiest routes and began to buy out the smaller airline companies. For most travelers, the increased competition created lower prices. However, in many busy airports, one airline company gained dominance, which in some instances caused fares to rise higher than before deregulation.

In the 1980s, when cable television was deregulated by the FCC, cable rates skyrocketed and service became even worse in certain parts of the country. This resulted in a move in the 1990s to regulate the cable industry once again. In 1992, with the passage of the Cable Television Consumer Protection Act, competition was again allowed in hopes of stabilizing rates and bringing improved service.

When several states deregulated their electricity companies in the 1990s, energy prices did fall in many areas, but elsewhere customers paid more. California experienced a massive energy crisis in 2000 that forced the government to pay extremely high rates for electricity.

The financial deregulation of the 1980s was designed to benefit depository institutions, especially the thrift industry. The removal of interest rate ceilings on deposits and more relaxed accounting practices that allowed thrifts to spread out losses over a 10-year time span gave the financial world a lot more freedom. Bank regulators were urged to avoid intervention in the private market, which was the norm during "Reaganomics." Between 1982 and 1985, deposits in the savings and loan industry flourished. Investors saw potential profits in the new investment powers granted to thrifts, and they invested in condominiums and other commercial real estate. This meant that investment portfolios of savings and loans began to shift from more secure traditional home loans into higher-risk loans. Unfortunately, by the mid-1980s, the real estate market went bust and so did thrifts' investments. Hundreds of institutions failed, and the federal government had to contribute $10.8 billion in one year to bail out the savings and loan industry. Unfortunately, the industry continued to fail over time, requiring more drastic measures from the federal government.

The deregulation movement of the late 20th century had substantial economic effects. It relied heavily on the market forces closely related to the growth of economic globalization. With the economy reliant on global competition, regulations within one nation can cause industries to seek other less regulated locations to open their businesses. The 21st century has seen rapid growth in outsourcing of labor, globalization of industries, and global competition.

DERIVATIVES

Derivatives are a unique financial instrument. In fact, these investments receive their value from an underlying asset, typically stocks, bonds, or loans. The derivative itself is actually a contract between two individuals. An investor in a derivative does not own the underlying asset but profits (or loses) from the movement up or down in the price of the underlying asset.

This is a complicated financial product with benefits for individual investors, professional investors, corporations, and speculators. The derivative products, with their frequent media mentions, are important additions to the modern personal finance glossary.

Derivative Example

The payoff of a derivative investment depends on the value of other assets. For example, a call option gives the holder the right to purchase an asset such as a stock at a prespecified price, on or before a certain date. The profit comes from the sales price of that option on the expiration date of the derivative contract. If the sales price on the expiration date is higher than the call option exercise price, the call holder can buy the asset at the lower (option exercise) price and sell it for a profit at the higher market price.

Assume Facebook (FB) stock is selling for $68 per share in March and you believe the stock is going to rise in price. You don't want to shell out $6,800 to purchase 100 shares. You decide to buy a call option. The call option will give you the option to buy FB shares at a predetermined price before a specific date. According to the call option chart, you can buy the $67.50 May 14 call for $6.20. What this means is that for $6.20 x 100 or $620, you have the right to purchase

100 shares of FB stock for the strike price of $67.50 any time between March and May 14.

If the price of FB is $75 on May 13, you can decide to exercise the option and purchase the shares for $67.50 per share or $6,750. You can then turn around and sell the shares for the market price of $75 per share or $7,500. This yields a profit of $7,500–$6,750 or $750. But you must also subtract the $620 cost of the call options. Thus your net profit for these transactions is $750–$620 or $130.

This scenario suggests you would have made more money had you purchased the stock outright. Well, in this situation that is true. But what if you purchased the stock outright and it fell in price from $68 per share to $60 per share? In that case, you would have lost $6,800–$6,000, or $800.

There are many different types of derivative transactions from buying and selling (or writing) calls to buying and writing puts. Puts give the option holder the right to sell a stock at a predetermined price during a specific time period. Buying a put is sometimes considered insurance for investors who believe the market is going to decline in value but don't want to sell their shares.

Who Invests in Derivatives?

Derivatives are used by corporations to hedge financial risks arising from variations in foreign exchange, interest rates, and commodity prices. Depending on the type of contract, derivatives can trade on regulated exchanges (like stocks) or over the counter (OTC) in unregulated exchanges.

Individuals and corporations use derivatives as insurance to protect their investment portfolio from a downward shift in prices or to speculate for future profits.

Forward and Futures Contracts

Forward or futures contracts are contracts between two counterparties wherein one party agrees to buy an asset/commodity at a predetermined price at a future date and the other party agrees to sell it. This helps investors to hedge the prices of their assets.

For example, a corn chips manufacturing company enters into a forward contract to buy a bushel of corn for $100 in two months from a corn farmer. At the end of two months, if the market price of a bushel of corn is $105, the farmer loses and the company gains $5. If the market price is $95, the farmer gains and the company loses $5. In either case, the price of $100 determined two months earlier helps the company lessen the impact of fluctuating corn prices on its bottom line. This transaction also helps the farmer put a floor under the price of corn he or she will sell in the future, protecting a specific profit level.

Though the underlying contract structure is the same for forwards and futures, they differ in the following way: Forward contracts are customized contracts between two parties that have a counterparty risk (risk of default on payment) and trade over the counter between private parties. Future contracts are liquid, trade on exchange, and have very low counterparty risk (counterparty is the exchange on which the future contract is traded, not another investor).

Option Contracts

Options are an extension of future contracts with an embedded exercise option. An option contract gives the buyer the option to buy or sell a security at a predetermined price (strike price) at a predetermined date (maturity). The cost of entering this contract is called the option premium.

Option contracts fall into two categories: puts and calls. A call option is the option to buy at a predetermined price, and a put option is the option to sell at a predetermined price. For an investor who wants to take a bet on the directionality in the price of a certain security, options are a cheap way of speculating instead of buying the underlying security.

An investor who believes that IBM (trading at $175) will trade above $180 in two months will buy a call option and is said to be long call. An investor who believes that the IBM stock will trade below $180 will sell the option and is said to short or write the call. The seller of the call gets the option premium, which is also the price of the option. The price of an option is dependent on the strike price, fluctuations in the price of the security, time to maturity, risk-free rate, and dividends paid.

For an investor who wants to limit his or her downside risk on a security, buying a put option acts as insurance. If a current holder of IBM stock (trading at $175) believes that IBM might trade down to $165 in two months, he or she will buy a put option at $165 with expiration in two months and will pay an option premium (the value of put option) to the seller (or writer of the option contract). If IBM goes down to $160 in two months, the put option buyer will sell the stock for $165 and make a gain of $5 (less the option premium paid). If the stock trades up to $180, the put option buyer's loss equals the premium paid and the option expires worthless.

The put option buyer is said to be long put and the put option seller or writer is said to be short put. Thus, a long put is equivalent to buying insurance to limit downside price movements, while a long call is equivalent to buying a stock with unlimited upside potential.

Options are widely used by portfolio managers to hedge portfolio exposure, to bet on the direction of certain securities, to generate income (from premiums), and to create complex option structures that provide a return profile in line with their hedging needs.

Swaps

Swaps are derivative instruments that allow for transfer of an asset or liability between two counterparties. The most common types of swaps are interest rate swaps and currency swaps. Interest rate swaps allow for swapping of interest rate payments between two parties, including fixed to floating swap, floating to fixed swap, and floating to floating swap.

A company that has floating rate loans (loans on which the interest rate may go up or down) on its balance sheet would want to swap them for a fixed payment schedule if interest rates are expected to increase. This helps lessen the company's interest expense. Similarly, a company with fixed rate liabilities would want to swap them for a floating rate payment schedule in case of falling interest rates.

Currency swaps are used by companies that derive their revenue from multiple countries (i.e., multiple currencies) and would like to hedge (or protect) their exposure to various currency fluctuations. For example, a multinational company with business branches in Germany and Mexico will enter into currency swaps in euros (to hedge revenues coming from Germany) and pesos (to hedge revenues coming from Mexico). This provides the company with more certainty on its revenues and helps the company keep track of future earnings.

Derivatives are financial instruments that help the financial community smooth out risk and increase potential profit (or losses) for the speculator. Many parties in the financial community benefit from using derivatives. Unfortunately, these complex financial instruments are occasionally misused.

DERIVED DEMAND

Derived demand is a demand for a resource used in the production of a good or service; the demand is "derived" from the demand for the good or service it was used to produce.

We make economic choices every day. When consumers demand a good or service, an intermediary is also demanded. Customer preferences increase or decrease, which is linked to derived demand. Beginning with consumer demand, derived demand establishes a value chain. Through this value chain, derived demand creates a ripple effect in local communities. In manufacturing, the derived demand for raw materials creates additional derived value chains. In most cases, the manufacturing is the intermediary used in this kind of demand. The demand for a good or service in one industry can create a derived demand in another industry.

The transportation industry is an interesting example of derived demand. As a resource, trucking is a transaction cost in the production of goods and services; its demand is derived from the production of a final good or service. In contrast, taxicab and bus transportation are themselves final services where demand is positioned against the supply in a product marketplace. The airline industry's product demand derives the demand for other airline services such as terminal space, baggage handlers, reservation personnel, and air personnel such as pilots and flight attendants.

Economists use derived demand predictions and metrics to calculate the derived demand of resources as a leading indicator of future economic activity. Understanding how an economy's resources are being utilized allows economists to identify future demands of goods and services by consumers.

Derived demand is a key component to understanding the demand of our economy and being able to predict future economic activity.

DIAMOND, PETER

Born: April 29, 1940, in New York City; Nationality: American; Professional Interests: public finance theory economics, public policy analysis, welfare economics, Nobel Prize (2010); Major Works: *Saving Social Security: A Balanced Approach* (with Peter R. Orszag, 2003); *Saving Social Security: A Balanced Approach* (2005); *Reforming Pensions: Principles and Policy Choices* (2008).

Peter Diamond is an American economist known for his analysis of pensions and specifically the U.S. Social Security system. He was awarded the Nobel Prize in Economics in 2010 with Dale Mortensen and Christopher Pissarides. He served as an adviser on the Advisory Council on the Social Security to the U.S. Senate. In 2010 and 2011, he was nominated by President Barack Obama on three different occasions to serve on the Board of Governors for the Federal Reserve System. Even though chairman of the Federal Reserve Ben Bernanke had once been one of Diamond's students, each time opposition by Senate Republicans prevented Diamond's confirmation. Eventually, he withdrew his nomination.

Peter Arthur Diamond was born on April 29, 1940, in New York City. After attending public schools in the Bronx and Long Island, Diamond entered Yale University for his undergraduate studies. Even though he was studying math as a major, young Diamond was greatly influenced by not-yet Nobel laureate Gérard Debreu, from whom Diamond took several classes. Diamond received a BA from Yale summa cum laude in 1960, and despite his interest in economics, he accepted an offer to study math at MIT for his graduate studies. Yet once at MIT, it was suggested his fellowship be transferred to the economics department, and Robert Solow became his adviser. Diamond graduated from MIT with a PhD in 1963 with a strong interest in public finance, general equilibrium, and taxation.

In 1960, Diamond began his career in economics as a research assistant to Nobel laureate-to-be Tjalling Koopmans (1975). Diamond's contributions to Koopmans's research led Koopmans to redesign his own plan. This led Diamond to be a coauthor with Koopmans and to Diamond's first publication in 1964. Diamond considered Koopmans one of his major influences and a role model in his career.

Upon graduation from MIT in 1963, Diamond accepted a position at the University of California, Berkeley. After one year at UC Berkeley, Diamond returned permanently to MIT as a member of the faculty, rising through the ranks from associate professor to institute professor. From 1992 to 1997, Diamond was the first Paul Samuelson Professor at MIT, relinquishing it in 1997 to become an institute professor. As a professor, Diamond found invigorating the combination and supportive nature of teaching and research.

As an overseas fellow at Churchill College in Cambridge in 1964–1965, Diamond's research in public finance took a major leap forward while delivering a seminar on optimal taxation. At this time, he met future Nobel laureate James Mirrlees (1996), who recommended expanding Diamond's model from a one-consumer economy to a many-person economy. This meeting began a project that resulted in a paper on optimal taxation, not published until 1971, and the Diamond-Mirrlees efficiency theorem. Their theorem suggests that taxes should not be imposed on intermediate goods and imports. The Diamond-Mirrlees collaborative partnership led to many additional papers throughout Diamond's career.

At the recommendation of Paul Samuelson, Diamond was invited to join the Panel on Social Security Financing, a consultant to the U.S. Senate Finance Committee. This invitation began Diamond's study of pensions and social security. A proponent of basis research and public policy analysis being supportive of each other, Diamond's professional interest in these areas made him well suited for this appointment.

Diamond wrote many articles and books in his career with many collaborators and coauthors. Topics in his articles ranged from analyses of different social welfare programs to the U.S. Social Security system and Social Security Administration. In 2003, Diamond coauthored with Peter Orszag *Saving Social Security: A Balanced Approach*.

As a public finance economist, Diamond was focused on both the financial viability of social programs as well as their social benefits. This was reflected in his many writings on the Social Security system. Several of his recommendations included adjustments in the taxation of Social Security income as well as adjusting contribution amounts as life expectancy patterns change.

His career in public finance and work on Social Security did not go unnoticed by either his colleagues or the public. In 1978, Diamond was named a fellow of the American Academy of Arts and Sciences and of the National Academy of Sciences in 1984. He was elected a fellow and served as president of the Econometric Society in 1968, and in 2003 held the prestigious office of American Economic

Association president. In 2008, he was honored as the recipient of the Robert M. Ball Award for Outstanding Achievements in Social Insurance. In 2010, Peter Diamond received the ultimate honor, being awarded the Nobel Prize in Economic Sciences along with Dale T. Mortensen (Northwestern University) and Christopher A. Pissarides (London School of Economics). The focus of his prize-winning work was to determine equilibrium in labor markets.

DISABILITY INSURANCE

Disability insurance protects a worker's current and future earnings. There is both government and private insurance to assist disabled workers.

Workers' earnings are their most valuable asset. Any injury, illness, or medical condition, be it a mental disorder or physical incapacity, leading to a permanent or temporary disability can be more disastrous to income earners and their financial dependents than death. Family breadwinners, the self-employed, and those with substantial debts are particularly exposed.

Disability insurance protects people who are disabled to the extent they can no longer perform the main functions of their work and must forego their income. The proceeds from disability insurance replaces disabled workers' income and pays for their daily living expenses and significant medical and rehabilitation expenses.

A disability occurs when the worker is physically or mentally disabled, has been in a debilitating accident, or has suffered an injury and/or serious illness.

United States Social Security Disability Insurance

The government offers Social Security Disability Insurance, which pays benefits to insured workers who become disabled. To become insured under the Social Security program, workers must have worked in jobs covered by Social Security and have a medical condition that meets the Social Security definition of disability. Additionally, workers must have been unable to work for at least one year because of a disability. These benefits usually continue until the worker can return to the workforce.

Private Disability Insurance

Many companies offer disability insurance, which generally offers more lenient coverage rules and the opportunity for the policyholder to receive benefits earlier than with Social Security Disability Insurance.

The most important feature of any disability insurance policy is how the policy defines *disability*. This definition can vary from insurer to insurer. Consumers should avoid policies where the definition and types of benefits offered are not easily understood. As a general rule, the more ambiguous the definition of *disability*, the more open the definition is to interpretation by the insurance company. Unclear and ambiguous policy language may lead to difficulty collecting compensation.

Disability insurance benefits include paid sick leave, short-term disability benefits, and long-term disability benefits. After an individual is deemed disabled and unable to complete his or her job duties, the insurance company pays a percentage of the claimant's income as a monthly benefit. Periodic payments begin after the waiting period (14 days is common) and over a benefit period (varies in duration for each policy).

The waiting or elimination period ranges from 30 to 90 days. During the waiting period, claimants require other sources of income, such as an emergency fund, sick leave, or annual leave benefits to support themselves while they wait for their benefit to be paid. The longer the waiting period a claimant has opted for when purchasing the insurance, the lower the premiums.

The maximum benefit amount payable can vary between 50 and 80 percent of the insured's gross earnings prior to the disability event.

Types of Disability Insurance

The different types of disability insurance available are short-term disability (STD) insurance, long-term disability (LTD) insurance, and critical illness insurance. These insurances consist of regular payments to someone who suffers a disability and cannot work.

Short-Term Disability and Long-Term Disability

Short-term disability coverage pays for disabilities of up to two years. In actuality, most short-term policies pay for six months of coverage.

Short-term disability policies have a waiting period of between zero and 14 days before the benefit becomes available to the claimant, with a maximum benefit period of between two and five years.

Long-term disability policies have a waiting period that may range from 30 to 360 days with a maximum benefit period ranging from a few years to usually age 65, after which Social Security income benefits become available. Long-term disability insurance generally covers injuries and treatments lasting at least 30 days.

Some policies have residual (additional/rider) benefits, such as guaranteed renewable or noncancelable policies. The guaranteed renewable feature gives consumers the right to renew the policy with the same benefits and not have the policy canceled by the insurer. The insurer has the right to increase the premiums as long as it does so for all other policyholders. Noncancelable means the policy cannot be canceled by the insurer, except for nonpayment of premiums. A cost-of-living rider will ensure the benefit payments keep up with inflation. All disability policies waive premiums during the disability.

Not all employers offer disability insurance. Even if an employer offers disability insurance, the coverage may be insufficient. In these cases, individuals may choose to insure themselves with an individual disability insurance policy. Professional associations frequently offer group disability insurance policies to their members.

Critical Illness

Over one's lifetime, a person is more likely to suffer from a serious illness for a short duration and survive than to die prematurely. In this scenario, the individual and his or her family may suffer severe financial consequences while the disabled person is recuperating and unable to work.

Critical illness or trauma insurance policies pay a lump sum rather than regular income payments in the event a person is disabled as a result of a dreaded disease. A dreaded disease is defined as heart attack, stroke, bypass surgery, and cancer. This type of disability insurance pays a benefit upon the occurrence of the dreaded disease event, provided the definition of the disability is satisfied.

This insurance is distinct from short- and long-term disability insurance. Critical illness disability insurance provides protection for those who are temporarily disabled and cannot make a claim for illness or injury under their medical, short-term, or long-term disability insurances.

The critical illness lump sum payout can be used for many expenses, such as paying off the mortgage, covering daily living expenses, funding future income needs, and contributing to retirement savings while the person is ill and not able to work. Critical illness disability payments do not just cover medical costs (Gjertsen 1998).

Disability Insurance Cautions

Buyers beware, because some insurance policies define people as disabled if they are unable to perform the duties of "any occupation," justifying charging low premiums.

For example, if a university engineering professor becomes disabled and holds a policy that only applies if he is unable to work in "any occupation," here's what might occur. Assume the professor has a very mild stroke that doesn't impact him physically but leaves his memory and mind minimally impaired. Due to the mental incapacity, the professor is not competent to teach engineering coursework. But, since he returns to physical competence, he is able to perform physical work, such as a checker in a grocery store.

The grocery store clerk job is not similar to his former job as an engineering professor.

His disability would not pay out because although he is unable to teach engineering courses, he can still work in another field. His policy states that in order to receive benefits he must be unable to work in any role.

The superior insurance policies are usually more expensive in terms of premiums because they pay benefits if someone is unable to do the usual duties of their "own occupation," which is the role they performed prior to the disability.

Consumers must carefully compare the various disability insurance options available on the market, especially if the insurer is offering lower premiums compared to its competitors.

Workers Who May Be Ineligible for Disability Insurance

Those individuals in hazardous occupations, such as pilots and flying and diving instructors, may be uninsurable for disability insurance. High-income earners are subject to payment ceilings for disability benefits.

DUAL MOTIVE THEORY AND DUAL INTEREST THEORY

The notion of dual motive theory (DMT) grew out of the collaboration of several individuals, as summarized in a series of papers published in the *Journal of Socio-Economics* (see Cory 2006a and related papers in that issue). The core idea drew on the notion of the triune brain, proposed by MacLean (1990) as a result, DMT is closely associated with the understanding in neuroscience as interpreted by MacLean. He proposed the brain had evolved in an interconnected and modular three-level structure, involving the reptilian complex at the core, overlain by the mammalian complex, with both complexes overlain by the neocortex neomammalian complex.

Cory (1999) elaborated this theme, positing that the reptilian core led to the egoistic tendency to self(ish) interest only, while the mammalian complex led to the empathetic tendency to shared interest with others. So, individuals have evolved with both egoistic and empathetic tendencies, with said tendencies resolved through a rational, "executive" control in the third part of the brain tasked with cognition.

This notion of dual tendencies in turn leads to the proposition that individuals have dual motives, with the egoistic tendency leading to mainly self-interested motives and choices and the empathetic tendency leading to better shared outcomes with others. For example, an individual may purchase a mask and gear to explore a coral reef mainly in self-interest while joining with others to help preserve coral reefs, the latter reflecting a shared interest in longer-term sustainability.

Dual interest theory reflects the proposition that individuals have evolved with not only the egoistic-hedonistic tendency to self-interest, as standard microeconomics presumes, but also with an empathetic-sympathetic tendency to other-interest (shared with others, yet internal to own self). This is still about one's own interest and not about regarding others' preferences and interests. These two interests are viewed as joint, nonseparable, and intertwined. Every economic choice gives payoff in both domains of interest. Dual interest theory (DIT) is closely related to dual motive theory, and, in fact, grew out of the same core ideas (Lynne 2006a, 2006b). DIT, however, reflects a broader attempt at an overall metaeconomics framework that ties closely with standard, neoclassical economic theory, the "meta" referring to going beyond and transcending that theory while keeping its core ideas.

Meta framing reintroduces and makes explicit the moral dimension and the ethical system underlying economic choice. The empirical side of meta framing and DIT is then represented in a dual motive model (DMM), which refers to particular behaviors like purchasing a mask and gear to explore a coral reef (reflecting self-interest), with the other-interest (shared) in sustaining said coral reef posited as tempering and restraining the self-interest. DIT posits that the final choice of the amount of gear purchased and coral reef sustained usually requires a bit of own-sacrifice, altruism, in each domain of interest, with the potential for a greater-than-the-sum-of-the-parts outcomes.

Empathy-sympathy serves a major role in tempering and restraining self-interest. DIT as an integrative theory is evolving based on growing evidence on actual human nature as it pertains to economic choice. This is reflected in economic psychology (Kahneman 2011), evolutionary biology (DeWaal 2009), neuroscience (Damasio 1994), and neuroeconomics (Singer 2009).

DUPUIT, JULES

Born: May 18, 1804, in Fossano, France; Died: September 5, 1866, in Paris, France; Nationality: French; Professional Interests: political economy, marginal utility; Major Work: *On the Measurement of the Utility of Public Works (Annales des ponts et chausses*, vol. 8, 2nd series) (1844).

Jules Dupuit was the first economist to describe marginal utility. Using his definition of marginal utility, he was also the first to provide evidence for the demand curve. Dupuit used the term *relative utility* to describe the area above the price, and Alfred Marshall later built on this idea when he introduced the idea of consumer surplus, which describes the area above the demand curve (marginal utility curve). Dupuit has been considered economics' first public works economist. Dupuit died in 1866.

Jules Dupuit was born in 1804 in Fossano, Italy. His family imigrated to France when he was 10 years old. As a young man, he studied in Versailles. He went to study civil engineering at the École Polytechnique. As a civil engineer, Dupuit received the Legion d'honneur for his work on France's system of roads. He continued his career in Paris, supervising Paris's construction of a new sewer system. As Dupuit continued his studies in civil engineering, he developed an interest in economics. He studied economics on his own, apart from his civil engineering career, so he was a self-taught economist.

In 1844, Dupuit published his classic "On the Measurement of the Utility of Public Works," wherein he addressed the relationships between value, utility, price, and consumption. Dupuit examined utility as related to building and maintenance costs for public works such as roads, canals, railways, and bridges. In this article, Dupuit first introduced the idea of a diminishing marginal utility curve. He showed that as the quantity of a good consumed rises, the user's marginal utility of the good declines. For example, as road tolls lower, more people will use the toll road or bridge. And conversely, as the usage increases, the willingness of the person to pay declines. The concept proposed by Dupuit converts into a downward-sloping demand function, leading him to describe the demand curve as a marginal utility curve.

Dupuit was the first economist to define the demand curve by using the definition of marginal utility. He was also the first to provide a convincing explanation of why the demand curve is downward sloping. Many questioned Dupuit's reasoning, however, with some critics complaining about his use of marginal utility to define the demand curve. The concept of marginal utility is a microeconomic concept used to describe the action of an individual. However, Dupuit uses marginal utility to define an aggregate concept, market demand.

Dupuit also contributed to the development of economics by defining the term *relative utility*. Relative utility is the area under the demand curve (the marginal utility curve) and above the price. He used the idea to measure the public welfare on his bridge toll. He concluded that the public welfare would be maximized when the bridge toll was priced at zero. Dupuit's definition of relative utility is the same area that Alfred Marshall later called *consumer surplus*. Dupuit's writings also included articles on monopoly and price discrimination.

Dupuit was a unique economic thinker in part because he was able to combine his economics background with his civil engineering training. His interdisciplinary research in many areas of public works is clearly evident. His research included, for example, an evaluation of the net economic benefit of Paris's public services.

He analyzed functions for economic development and once attempted to develop a paradigm for utility theory to measure the benefits of public works.

Dupuit researched other areas of public works, including the development of tools for measuring groundwater flow. He simplified an equation to derive analytical solutions for groundwater flow, known today as the Dupuit assumption.

Jules Dupuit died in Paris, France, on September 5, 1866.

ECONOMIC COSTS AND PROFITS

Economic costs and profits are essential concepts to businesses or firms since their goal is to maximize profits while minimizing costs. A firm may also base its level of production on its costs and profits and may seek to maximize short-run or long-run profits. In the short run, all costs are fixed costs, while in the long run, all costs are variable costs.

Fixed costs are costs that cannot be altered in the short run and exist no matter what quantity of goods or services the firm is producing. They include rent (or payment for leasing a building), insurance, and utilities. Businesses should examine their fixed costs to determine how expensive it is to operate their facilities and if they are doing so efficiently.

Variable costs are costs that vary as the production or level of output changes and include labor (or workers) and materials. Businesses should closely examine their variable costs in order to ensure that they are utilizing resources efficiently. Since these costs are very responsive to the amount of goods or services a business produces, they tend to be examined more carefully when compared to fixed costs. Total cost is the sum of variable costs and fixed costs.

Marginal cost is the increase in total cost when output increases by one unit. It can be calculated by dividing the change in total cost by the change in quantity.

Economists must also consider sunk costs, or costs that are incurred but are not important to current decision-making. This may include the costs of the machinery or equipment necessary to start a business. Sunk costs may also be considered a barrier to entry into a particular market as they may be very high.

Costs can also be further broken down into average fixed cost, average variable cost, and average total cost. Average fixed costs are calculated by dividing fixed costs by the quantity being produced. Average variable costs are calculated by dividing variable costs by the quantity being produced. Average total cost is calculated by summing the average fixed costs and the average variable costs or by dividing total cost by the quantity being produced. All of these cost curves can be displayed in a graphical format and are commonly used in microeconomics.

It is also important to note that economists and accountants measure profit differently. Economists examine both explicit and implicit costs and revenues, which takes the opportunity cost into consideration. They look at what was given up by choosing to produce the current good or service.

An accountant examines only explicit costs and revenues. This means an accountant takes the total revenue and subtracts all expenses to determine the level of profit. Therefore, there is a difference in accounting profit and economic profit, and it is possible to earn an accounting profit but no economic profit.

One form of economic profit is a normal profit, where the economic profit is zero. This type of profit is common in both a perfectly competitive market as well as a monopolistically competitive market in the long run.

Economic costs and profits should be taken into consideration when one is looking to start a business. Firms always seek to minimize costs while maximizing profit.

ECONOMIC RENT

Economic rent is the value received for the use of a resource (input) above the next best alternative use. Economist Henry George spoke of economic rent as the value of the land on which buildings sit.

The classical idea of economic rent was fairly straightforward. Economic rent was the income landowners received from the use of their land or other natural resources. The key thought behind this definition was that the supply of natural resources, including land, is fixed at any one time. Alfred Marshall is credited with this early definition of economic rent. In the 18th and 19th centuries, classical economists devised theories to define income distribution. Economic rent gave classical economists a base to measure the income received by the landowners. The other income categories (wages of laborers and profits of businessmen) were much easier to identify.

The concept of economic rent came into play especially in regards to the fertility of land. Infertile land was considered to have no economic rent since it had no value. But as more land was used for cultivation, even the marginal land began to be cultivated. The classical view asserted that if the value of the output exceeded the costs of the planting, even marginally fertile land generated an economic rent. Economists called this a differential rent. As cultivation procedures improved and crop yields per acre increased, even fertile land experienced an increase in economic rent. Since land has a fixed supply and can be effectively "used up," it is considered to generate scarcity rent; in today's terms, this would be considered "perfectly inelastic."

It was theorized that any input resource could similarly generate a scarcity rent. But the classical economists submitted that land was a special case because of its fixed supply. It is claimed that many years later Will Rogers promoted land as a good investment because there was not any more being produced. Being a fixed input, the supply price of land was zero, regardless of its market price. Quantities of the other inputs (labor and capital) could be supplied based on their price in the market. Land had a special characteristic among inputs. The classical view later changed so economic rent became any return to any input over its supply price.

The inability to duplicate an input over the long run became the key characteristic to classical economists in accruing an economic rent. LeBron James has an athletic talent that cannot be duplicated. Meryl Streep has an acting talent that is hers alone. When inventions are first implemented, initially they all earn an economic rent. Economic rent is present as long as the supply of these unique inputs cannot be duplicated. These are called quasi-rents as they will earn economic rent until such time as supply catches up with the demand. Obviously James or Streep cannot be cloned, so their rents may go on for quite a while. Eventually the new invention will be produced to such a quantity that economic rent will disappear.

A second key characteristic to earn economic rents of labor was the value above the person's opportunity cost. The economic rent of land is all of its return, since the starting point for land was a price of zero. Regarding labor such is not the case; a person has options. LeBron James does not have to play basketball, nor Meryl Streep act. But their value in their chosen profession far outweighs the opportunity costs of their next best alternative. *Forbes* listed James's 2015 total income at $65 million. The question is, how much of that $65 million would be considered economic rent? To answer that question, we must know James's next best alternative for earning an income; in other words, we must know James's supply price. Only James can answer this question, but any observer of economic rent can surmise it would not earn him $65 million a year. It is safe to say James's economic rent for labor is quite high.

A more modern idea of economic rent focuses on the return of an input relative to its supply price. Even in modern times, land is still fixed so its supply price is still zero, making all of its return economic rent. Labor and capital inputs are different. Their economic rent is based on the difference between their supply price and the income they generate. These input incomes can change. Referring to LeBron James again, how much could his $65 million income be reduced before he would stop playing basketball? At some income point, his incentive to play basketball would disappear and he would choose to do something else, his next best alternative. Fortunately for fans, the market for basketball players supplies James an economic rent, so he is willing to sell his services to be a basketball player and fans can enjoy his talents.

EDGEWORTH, FRANCIS YSIDRO

Born: February 8, 1845, in Edgeworthstown County, Longford, Ireland; Died: February 13, 1926, in Oxford, England; Nationality: Irish; Professional Interests: political economy; Major Work: *Mathematical Psychics: An Essay on the Application of Mathematics to the Moral Sciences* (1881).

Francis Ysidro Edgeworth was an Irish-born political economist most noted for his work in economics and statistics. A prolific author, he was considered one of the best economists of his day. The original editor of *The Economic Journal*, his first and most important contribution to economics was the publication of the book *Mathematical Psychics: An Essay on the Application of Mathematics to the Moral Sciences* (1881). In his book, Edgeworth introduces the economic ideas of indifference curves and the Edgeworth Box. The Edgeworth Box is a way to model how general equilibrium (quantity demand equals quantity supplied) might be reached in a simplified economy comprising two goods and two individuals. Edgeworth died in 1926.

Ysidro Francis Edgeworth was born on February 8, 1845, to a Spanish mother and Irish father. He later transposed his two first names and was called Francis or Frank by his family and friends. Home-schooled by tutors, Edgeworth later studied at Trinity College in Dublin and Balliol College in Oxford, graduating in 1869 and qualifying as an English barrister in 1877.

In his life and career, he made many contributions to the field of economics and statistics during the time when these sciences were coming into their own as fields of study. Edgeworth is remembered as a prolific author even if at times his striking originality is difficult to interpret. In his career, he held the Drummond chair at Oxford University and was considered among the best economists of his day.

He maintained extensive correspondence with his contemporary academic colleagues around the world and was the first editor of *The Economic Journal*, published by the Royal Economic Society. In the field of statistics, his work was recognized with a gold medal of the Royal Statistical Society in 1907, and he subsequently became president of the society in 1912–1914.

His most important contribution to economics came in the publication of the book *Mathematical Psychics: An Essay on the Application of Mathematics to the Moral Sciences* (1881). He uses interesting and distinct metaphors in order to explain the problems he sets out to understand, if not solve. Specifically, he used electromagnetism as a metaphor to explain how energy arises with pleasure in humans and proceeds with a conception of man as a pleasure machine. Edgeworth envisioned society as a great aggregate of such machines, with collisions and compacts between them resembling electricity and magnetism fields.

Edgeworth attempted to determine the distribution of productive factors (land, labor, capital) that would be conducive to the highest aggregate of well-being. The conclusion of his philosophy here tends to support a hierarchical society of social rank rather than one of equality. He reasoned that the distribution of labor between those equally capable of work is equality, and generally those most capable of work will do more work and therefore suffer more fatigue. Understood this way, he considers that the highest and most capable of labor, with education and improvement, should advance the most. In practice, this conclusion of Edgeworth's would result in a society where the average issue of goods would be as large as possible for all segments of society above a determinate level of capacity but zero for all sections below that degree.

Mathematical Psychics is also characterized by a style that has been called obscure, terse, and implicit, so that the reader is left to puzzle out every important sentence like an enigma. The book's ideas were only slowly adopted into the standard economic textbooks. *Mathematical Psychics* has nevertheless been influential in the history of economic thought.

One important concept widely used in economic analysis and first described and used in *Mathematical Psychics* is known as the indifference curve. This is a way to model the preferences of an individual or household when some combination of different goods results in the same utility. The indifference curve models how different combinations of goods are preferred by a particular individual while keeping the same level of satisfaction in all the combinations represented along the curve. This concept is applicable in many economic models and has been used widely in economic analysis. The indifference curve is equated with the marginal rate of substitution, which shows how much of one good a consumer is willing to give up for another good. This concept is relevant in microeconomic consumer theory and also plays a role in another key concept that was developed by Edgeworth, the "Edgeworth Box."

The Edgeworth Box models how general equilibrium might be reached in a simplified economy with two goods and two individuals. Edgeworth laid the theoretical groundwork for this analysis in his *Mathematical Psychics*. It has been further developed over the years by his successors, most notably Vilfredo Pareto.

The Edgeworth Box has proportions equal to the productive resources (land, labor, capital) of a country. The box shows all of the ways those resources can be allocated to two industries that are producing two different goods, A and B. The lower-left origin on the box is the origin for measuring allocations of factors for industry A. The upper-right corner origin on the box is for industry B. Thus every point on the four sides of the box denotes an allocation of the resources to the production of the two goods, A and B.

Indifference curves are drawn inside the box for each good, convex to their origin (lower left or upper right). The places where the indifference curves intersect represent where each individual could trade without feeling any worse off. Essentially, the model shows how general equilibrium is reached and predicts trade behavior based on the supposed indifference curves of two individuals.

Edgeworth's contributions to the field of economics cannot be understated. He helped shape the science into what it is today.

Francis Ysidro Edgeworth died on February 13, 1926, in Oxford, England.

EFFICIENCY WAGE HYPOTHESIS

In the 1920s, Alfred Marshall first introduced the concept of efficiency wages in his *Principles of Economics*. The efficiency wage hypothesis contends that wages, in certain markets, are determined by more than the forces of supply and demand. In order to increase the productivity and efficiency of workers, managers have an incentive to pay their employees more than the market-clearing wage. Several theories exist that explain why managers have an incentive to pay efficiency wages: to minimize turnover, to reduce shirking, to combat adverse selection, and to encourage a spirit of fairness and high morale.

In order to minimize turnover, an employer may pay a worker a wage above the market-clearing level to entice the worker to stay at the job and stop looking for a job elsewhere. Employee turnover is costly to firms as they must hire and train new workers. Therefore, paying an efficiency wage is justified to the extent that it minimizes turnover and offsets the cost of hiring and training new workers.

Another theory for efficiency wages is that they reduce shirking by employees. Complete contracts rarely exist that stipulate exactly what the worker needs to produce in a given amount of time. As a result of incomplete contracts, workers have an incentive to shirk rather than work. The effort that a worker displays is a function of the real wage rate. Workers will provide more effort if they are paid more; this higher pay has both a "carrot" effect and a "stick" effect. The "carrot" effect is that the higher pay increases morale and loyalty. The "stick" effect is that the opportunity cost of being fired increases. As a result of a real wage rate that is higher than the market-clearing level, shirking is deterred; this provides a justification of the efficiency wage.

An employee's job performance depends on his or her ability level, and each employee differs in terms of ability. In order to combat adverse selection, employers may pay an efficiency wage such that high-ability job seekers apply for their jobs. This efficiency wage implies that the employer can choose among applicants to get the best possible worker.

Matthew Rabin suggests three stylized facts about how norms affect behavior: people are prepared to sacrifice their own material well-being to help those who are being kind; people will also sacrifice their well-being in order to punish others who are being unkind; and as the material cost of sacrificing becomes smaller, the incentive for fairness becomes larger. This sociological notion of fairness provides another reason for why efficiency wages exist. If workers feel that their actual wage is lower than what they perceive as a "fair wage," they may withdraw effort to compensate for the disparity in perceived fair compensation. Therefore, encouraging a spirit of fairness and high morale is essential to obtain maximum employee effort and provides another justification for paying efficiency wages.

Efficiency wages also provide a market failure explanation of involuntary unemployment. Involuntary unemployment is caused when, at a given real wage, people are willing and able to work at the same real wage as an employed person with the same ability but are unable to find work. As a result of firms paying employees efficiency wages, firms are not willing to accept underbidding by unemployed workers. Thus, involuntary unemployment may arise as a by-product of firms' efforts to keep real wages high to entice workers to be more productive.

ELASTICITY

British economist Alfred Marshall is considered the creator of the microeconomic concept of elasticity. Elasticity shows how sensitive (or responsive) a change in quantity demanded or quantity supplied is to a change in price.

A good's elasticity can be described as relatively elastic, relatively inelastic, or unitary elastic. A good is relatively elastic if there is a greater change in quantity demanded with a small change in price. Generally, demand for luxury goods is considered to be relatively elastic. A good is relatively inelastic if there is a small change in quantity demanded with a greater change in price. The demand for basic goods, such as pencils, is considered to be relatively inelastic.

Demand can also be perfectly elastic, which means that quantity responds heavily to any change in price. Demand can also be perfectly inelastic, which means quantity demanded is insensitive to a change in price. Although the concepts of perfectly elastic and perfectly inelastic exist in economics, there are no true examples of them in the real world.

Income elasticity of demand measures the responsiveness of demand to changes in income. When consumers' income increases, they demand more normal economic goods. Economists consider economic goods normal when their use (or demand) increases as income increases or decrease as income decreases. Normal goods can be divided into necessities and luxuries. When income increases and demand decreases, economists define the good as an inferior good. One will demand fewer inferior goods and elasticity is less than zero, or a negative number.

Cross-price elasticity measures the responsiveness of demand to changes in prices of other goods. Positive cross-price elasticity indicates that a good is a substitute, and a negative cross-price elasticity indicates a good is a complement. Goods are substitutes if the price of good X would increase and consumers would as a result demand more of good Y. If the price of good A increases and the quantity demanded of good B decreases (the demand curve shifts to the left) the goods are complements and there is a negative cross-price elasticity.

One way to measure elasticity is to determine the elasticity coefficient. To do so, one must use the following equation:

$$\frac{\%\Delta Q_{(d)}}{\%\Delta P} = e_{(p)}$$

If $e>1$, demand is elastic; if $e<1$, demand is inelastic; and if $e=1$, demand is unit elastic.

Goods that are elastic generally have many substitutes and take up a larger portion of a consumer's income. Generally, the demand for necessities is inelastic, and goods with fewer substitutes are also inelastic. Elasticity of demand is a measurement of how responsive consumers are to a change in price. It is the percentage change in demand divided by the percentage change in price. Price elasticity of demand is expressed as a positive number, where $e>1$.

A second measure for calculating price elasticity of demand is the total revenue test. Demand is elastic if an increase in price causes total revenue to decrease or if a decrease in price causes total revenue to increase. Demand is inelastic if an increase in price causes total revenue to increase or if a decrease in price causes total revenue to decrease. Demand is unit elastic if a change in price leaves total revenue unchanged.

Elasticity of supply shows how sensitive producers are to a change in price. Price elasticity of supply is the percentage change in quantity supplied divided by the percentage change in price.

$$\frac{\%\Delta Q_{(s)}}{\%\Delta P} = e_{(p)}$$

If $e>1$, supply is elastic, and if $e<1$, supply is inelastic, and if $e=1$, supply is unit elastic.

Supply is also affected by the substitution effect since the more substitutes a good has the more elastic its supply is. If the price of a good rises, consumers will shift their consumption to substitute goods.

The concept of elasticity can be especially relevant to taxes, regarding who bears the burden of a given tax. Taxes may be paid by the consumer and/or the producer of the good depending on the tax burden. The more inelastic one's relative demand and supply, the larger the tax burden the producer will bear. If demand is more inelastic than supply, consumers will pay the higher share. If supply is more inelastic than demand, suppliers will pay the higher share.

Elasticity may vary from one market structure to the next, and businesses seek to gather data to examine consumer behavior when it comes to a change in the price of a particular good. Businesses pay close attention to which brands of a good are selling and use this to manipulate the price of a particular good.

ELY, RICHARD

Born: April 13, 1854, in Ripley, New York; Died: October 4, 1943, in Old Lyme, Connecticut; Nationality: American; Professional Interests: economics, socialism, Christian socialism; Major Works: *French and German Socialism in Modern Times* (1883), *The Labor Movement in America* (1886), *Social Aspects of Christianity* (1888), *Hard Times: The Way In and the Way Out* (with Thomas William Lamont et al., 1931).

Richard Ely was an economist and social reformer. He is credited as an intellectual guide for the Social Gospel movement, which is an attempt to apply Christian principles to social issues. His activities and writings also attracted furious condemnation from a leading public official, which led to a trial over the question of academic freedom in universities. Ely died in 1943.

Richard Theodore Ely was born in Ripley, New York, in April 13, 1854. He was brought up in a strict Presbyterian household, though he transferred to the Episcopal Church at Columbia University. He earned his PhD in economics at Heidelberg University in Germany, where he came under the influence of German Historical economics. This school of thought emphasized an empirical, data-driven approach to economic questions and criticized the Austrian and American tendencies toward abstract reasoning. The Historical School also led Ely to an evolutionary view of social development, in which communities and nations improve slowly over time through the efforts of individuals and organizations. Ely's writings emphasized progress; things were never good enough, nor were timeless laissez-faire policies sufficient for the governance of a nation.

After receiving his PhD, Ely joined the faculty at Johns Hopkins University in Maryland. He was constantly active in public life, seeking ways to apply economic reasoning to the problems the world faced. He helped organize the American Economic Association in 1885, was a member of the tax commissions of the city of Baltimore and the state of Maryland, became secretary of the Christian Social Union in 1889, and cofounded the American Institute for Christian Sociology in 1893. In 1892, he was hired by the University of Wisconsin.

Ely's writings are filled with calls for professors and other researchers to get involved in public life. Because he thought that the study of economics should use real data instead of abstract theories, he thought that professors should always be busy collecting information and processing it for the public interest. Furthermore, in order for such information to be useful, he thought that professors must work with government officials to put their studies into action. The theory that universities should be in close partnership with local, state, and national governments became known as the Wisconsin Idea.

Ely received a terrible shock in 1894 when the state superintendent of Wisconsin, Oliver E. Wells, wrote a letter to a national newspaper accusing Ely of teaching utopian, impracticable, and pernicious doctrines. His caustic remarks accused Ely of being a socialist who encouraged murderous anarchy. Thereafter followed a furious debate concerning (1) whether Ely was indeed a purveyor of dangerous ideas and (2) what were the limits of academic freedom in a state university. To take command of the situation, the board of regents of the University of Wisconsin called a trial for Richard Ely. They created a commission that was to investigate and pass judgment on the situation and on Ely himself.

The resulting investigation cast light onto important aspects of Ely's life and thought. First, the accusers had some of the facts of the case flatly wrong (they had mistaken one of Ely's students for Ely himself when the student went to meet with a union leader, and they had misinterpreted some gossip about Ely's relationship with a local printer's union that printed his books). Second, Ely's philosophy could be characterized as progressive conservatism, a view that was quite conservative in its conception of most property rights and politics but was not closed to socialist demands concerning major industries that tended to be monopolistic. Indeed, while socialism at the time often referred to thoroughgoing Marxism, the socialism of Ely's mind corresponded more to the modern European policy in health care and national industries—but with a Christian twist. Ely was a lifelong believer that the teachings of Jesus could be used to guide government policy as it related to social welfare programs. He also thought, however, that society evolved in a sort of Darwinistic fashion and that citizens should constantly try to find new ways to improve upon old traditions.

Ely was judged innocent of all charges by the commission. The commission released a ringing statement defending academic freedom in universities. Even if Ely did have radical views, they wrote, professors nevertheless ought to seek truth as best they could, even if what they found was not to society's liking.

Ely wrote many works on economic applications to social problems. He worked hard all throughout the Great Depression to find practical and theoretical solutions to what he called "Hard Times." He guided the social ministry of liberal Protestant churches. Ely was confident that mankind could create a better future, and there was no idea he would not sanction in order to achieve it.

Richard Ely died in Old Lyme, Connecticut, on October 4, 1943.

EMPLOYEE STOCK OWNERSHIP PLANS

There are two types of employee stock ownership plans (ESOPs) and they are commonly confused: employee stock option plans and employee stock ownership plans. An employee stock ownership plan is an employee benefit plan, similar to a profit-sharing plan with defined contributions, designed for employees to invest in the stock of their supporting employer. Companies often use employee stock option plans as a benefit to retain and attract employees with a specialized compensation program.

Employee stock option plans give the employee the option to buy company stock at a given price. Employees can benefit from stock options by employing their option when the stock price is higher compared to when they purchased the stock.

Suppose a company offers a stock option plan to its employees. The employee is granted the option to purchase 250 shares of the company's stock at the current market price of $7 per share. Plans generally require employees to wait a certain amount of time before they're permitted to exercise their stock options. In contrast to the time requirement, companies may require the stock to reach a certain price before employees are permitted to exercise their option. If the price of the stock increases to $10 per share, for example, employees may exercise their option to buy 250 shares at the $7 price and then sell the stock at the current market price of $10.

With an employee stock ownership plan, the parties involved, including the sponsoring company, the shareholder, and other participants, receive tax benefits. These tax benefits allow ESOPs to be recognized by the Internal Revenue Service as "qualified." Tax benefits include tax-deductible contributions, tax-deductible dividends, tax deferrals, and exemption from federal income tax, among others.

Corporations use ESOPs for various reasons, including as a finance strategy and as a way to align the interests of employees with the interests of company shareholders. ESOPs provide a market for the shares of departing employees. They can be used to motivate and reward employees for obtaining company objectives. ESOPs are usually a contribution to the employee, not a benefit that the employee purchases.

The company establishes a trust fund and then contributes cash or new shares of its own stock to buy existing shares of stock. Contributions to the plan are tax deductible. Employees receive special accounts in which their shares of the trust are allocated. The longer employees are with the company, or the more seniority they accrue, the more vested they are into their account. In other words, the longer employees are employed with the company, the more right to the shares in their account they acquire. Depending on the vesting structure, employees must be 100 percent vested within three to six years.

The company buys back the stock from employees when they leave the company. If the company is publicly traded, employees are owed the market price of the stock. If the company is privately owned, employees are owed fair market value. Private companies must hire outside evaluators to determine the value of the shares.

EMPLOYMENT ACT OF 1946

Enacted by Congress under President Harry Truman as a result of high unemployment in the 1930s, the Employment Act of 1946 held the government responsible for maintaining high employment levels and price stability. Additionally, this act resulted in the creation of the Council of Economic Advisers, which was established to assist the president in preparing the annual economics report, to collect economic data and report economic growth and trends within the U.S. economy, and to advise the president on certain policies.

Initially, the act was sought to strengthen the economic gains to the U.S. economy that had resulted from massive government spending during World War II. Following the theory of British economist John Maynard Keynes, who believed that intense government spending was necessary to end economic depression, President Truman proposed a program in 1945 to boost the U.S. economy. The program required full employment legislation, an increase to the minimum wage, and better unemployment and social security benefits. President Truman believed the bill would protect the country from reverting back into depression because it enabled remedial action, such as tax cuts and spending programs, if economic indicators took a downward shift.

In addition, the Employment Act of 1946 created the Council of Economic Advisers to report to the president but failed to authorize intervention from the government in order to maintain full employment when indicators signaled a recession. Instead of giving the government the strong role that Truman intended, the act allowed only modest governmental involvement in regards to economic planning.

ENDANGERED SPECIES

Protecting endangered species (and thus their habitats) provides economic value. Value consists of recreational use of endangered species (e.g., wildlife viewing, ecotourism, photography) and nonuse values or passive use values (existence and bequest values) that nonusers have for the knowledge that the species continues to exist in the wild and will be available to future generations. These values are measured by economists as the maximum amount of money a person would pay to protect the species and its habitat to provide that particular benefit. For example, the amount a visitor would pay for the opportunity to view sea otters in their natural habitat is a measure of the value to the visitor. The same is true of passive use value. This value is the maximum amount a person would pay to simply know that the species exists in its natural habitat. Likewise, bequest value is the maximum amount a person would pay to know that preservation today will provide the species to future generations.

Currently, one of the accepted methods used to quantify these benefits is the contingent valuation method (CVM), which employs surveys outlining a hypothetical market or referendum in order to elicit people's willingness to pay (WTP) for the preservation of a particular species. It has been found that people are willing to pay a small portion of their income toward the protection of endangered or rare species for the reasons given earlier (e.g., existence value).

A number of studies have estimated WTP to protect different types of endangered species. Households in the United States are willing to pay, on average, $17 annually to preserve land mammals, whereas the rest of the world is willing to pay $50 annually per household. Similarly, U.S. residents are willing to pay $40 annually to protect marine mammals, whereas households in the rest of the world are willing to pay $72 annually. When it comes to birds, the willingness to pay for preservation numbers are very similar between the United States ($42 annually) and the rest of the world ($44 annually). While U.S. households are willing to pay somewhat less annually to preserve endangered species, they are willing to pay more than the rest of the world if they are asked to pay a one-time lump-sum payment for species preservation. For land and mammals, U.S. households are willing to make a one-time payment of $61, while the rest of the world is only willing to pay $9. For marine mammals, the corresponding one-time WTP payment is $203 for the United States and $23 for the rest of the world.

Rather than looking at broad categories, examining the WTP of individual species derived from studies conducted in different countries allows a comparison of values for the same, or very similar, species. For example, U.S. households are willing to pay $20 to $40 for the preservation of wolves, while residents of Sweden are willing to pay $123. Likewise, residents of Greece are willing to pay $72 for the preservation of seals, but U.S. residents are only willing to pay $35. A similar pattern emerges for other species, like sea otters and sea turtles. Citizens of other developed countries generally have higher values for the majority of these species than U.S. citizens.

The annual economic value per household of endangered species protection is plausible, representing about one-tenth of 1 percent of annual household income in the United States. However, since the economic benefits from preservation of endangered species are freely available to all households in the United States (and for that matter the world), the aggregate national benefits are in the range of $2–$20 billion per species. One must be careful to recognize that multiplying these per-species values by the number of endangered species would greatly overestimate the collective value of all endangered species. This is true for several reasons. First, the contingent valuation surveys asked respondents to value just one species in isolation, not all species at the same time. As such, these values do not take into account substitution effects between species (e.g., for some people, seals, sea otters, and sea turtles might have some substitutability). While the WTP for each species may be less than one-tenth of 1 percent of income, the sum of WTP for the more than 400 endangered animals in the United States and more than 1,200 in the world in the aggregate would be a sizeable fraction of income. This illustrates the real-world trade-offs that even well-off developed countries, let alone poor developing countries, face in determining how much of their scarce resources to devote to protecting endangered species.

ENERGY EFFICIENCY

Energy efficiency is achieved by reducing energy use until the costs of further reductions would exceed the benefits. There are several paths toward energy efficiency. Energy consumers can substitute practices that require less energy, such as drying clothes on a clothesline, for practices that require more energy, such as drying clothes in a drying machine. Technological advances such as light-emitting diode (LED) light bulbs can reduce the amount of energy needed for a particular task. The increased use of existing products, such as insulation, can achieve the same goal. And policies such as fuel economy standards and peak-load pricing can reallocate energy use to more beneficial purposes or to less costly times.

Savings on fuel and electricity bills are the primary incentives for private conservation efforts. For sizable energy conservation projects, a common metric for assessing cost effectiveness is the payback period. The payback period is the time it takes to save enough money to cover the full cost of the project. The simple payback formula is:

$$\text{Payback Period}\left(\text{in years}\right)=\text{Cost of Project / Annual Savings}$$

This formula does not account for complicating factors such as inflation, risk associated with the project, alternative investment opportunities, or the discounting of future costs and benefits. Many energy-saving projects continue to provide savings for years after the payback period is reached.

Solar water-heating systems are among many examples of cost-effective products. The payback period for a solar water heater can be as short as two years. Specific payback periods depend on the level of usage, installation costs, local energy prices, and the efficiency of the existing equipment. Other products with a relatively short payback period include high-efficiency windows, geothermal heating systems, fluorescent lighting, and various types of insulation. Successful energy conservation projects come in all sizes. A $13 million energy-saving project at the Empire State Building completed in 2011 paid for itself in three years.

There are also failures in energy conservation. Decisions to conserve energy can be confounded by imperfect information or improper discounting of future values. Information problems arise when decision-makers lack specifics on the costs or benefits of conservation projects or are poorly informed about goods and services that would facilitate energy conservation. For instance, some people are unaware that solar energy is collected even on cloudy days in winter, or that battery storage allows people with solar systems to use energy all night long. As an example of conservation missteps on a larger scale, there have been great efforts in the United States to reduce gasoline consumption by substituting ethanol made with corn. Unfortunately, it takes almost as much energy to produce ethanol from corn as the ethanol itself provides. Initiatives to produce ethanol from sugarcane, plant stalks, wood by-products, switchgrass, and municipal waste have met with relative success.

The second issue that confounds private conservation decisions, discounting, stems from the timing of costs and benefits. Whether insulating a building, installing a geothermal heat pump, purchasing a hybrid car, or insulating a hot water heater, the major costs are upfront and the benefits come slowly over many years. In order to weigh the benefits against the costs, potential adopters must therefore decide what value to place on future benefits. Essentially, this comes down to choosing a discount rate for future periods. This discount rate is used to determine the value today, or present value, of a future benefit.

The selection of a discount rate depends on the decision-maker's preferences, patience, alternative investment opportunities, and feelings for others who might share future benefits. Studies find that individuals apply discount rates that range from extremely altruistic negative values that prioritize future benefits over immediate benefits to infinite values that treat the present as the only time that matters.

The administrations of the past four U.S. presidents applied discount rates between 2 and 10 percent. The U.S. Government Accountability Office, the Environmental Protection Agency, and the Congressional Budget Office currently use discount rates in the 2 to 3 percent range.

Even with full information and proper discounting, private incentives typically lead to inefficient levels of energy conservation from a societal standpoint. Society receives benefits from conservation beyond cost savings, only a fraction of which are enjoyed by those who conserve. Fossil-fuel-based energy production is a major source of carbon dioxide, sulfur dioxide, nitrous oxide, and other pollutants that contribute to disease, the loss of wildlife, and global climate change. The extraction of fossil fuels also involves spills, fracking (the injection of water, sand, and chemicals into the ground to release fossil fuels), mountaintop removal, and other potentially dangerous or environmentally destructive activities.

Consider the decision to purchase a $7,000 solar thermal system that heats water using energy from the sun. Because the household does not receive all the benefits of reduced reliance on fossil fuels, the cost of this system may be more than the private benefit but less than the social benefit. If the private benefit is $6,750 but the total benefit to society is $7,500, the household will decide against purchasing the system. To encourage decisions that provide net gains for society, many countries, including the United States, subsidize solar systems and other products that promote energy efficiency. In the solar thermal system example, a government subsidy of $250 or more would lead the household to purchase the new system. The social benefit not internalized by the household is $7,500 – $6,750 = $750. The government would not want to offer a subsidy in excess of $750, because that could lead to the purchase of systems that cost more than the $7,500 total benefit to society. An alternative way to correctly incentivize private decision-making would be to place a tax on energy consumption or production. There is currently a tax on gasoline in the United States. Broader taxes on energy use have been proposed.

Decisions about energy efficiency can be misguided by inadequate information about costs and benefits. It is appropriate to discount any benefits or costs that come in the future at a rate that reflects the preferences of those involved. Additional factors that may warrant consideration include inflation, the risk of project failure, and the availability of alternative investments.

Because energy efficiency provides benefits to society, the environment, and future generations, private expenditures on energy efficiency may fall short of the socially optimal level. Subsidies for conservation projects and taxes on energy consumption are among the approaches that, when properly executed, can bring private decisions in line with the best interests of society.

ENRON, THE FAILURE OF CORPORATE FINANCE AND GOVERNANCE

Enron was formed in 1985 following a merger between Houston Natural Gas and Omaha-based InterNorth. Kenneth Lay became Enron's CEO and chairman, and he decided to rebrand Enron into an energy trader and supplier. Enron was poised to take advantage of the deregulation of the energy markets that allowed companies to place bets on future prices. Several years later, Kenneth Lay was succeeded as CEO by Jeffrey Skilling. Skilling developed a staff of executives who were able to hide billions of dollars in debt from failed deals and projects with the help of accounting loopholes, special purpose entities, and poor financial reporting.

Sell-Off and Bankruptcy

Shortly after the company achieved $100 billion in revenues in August 2001, Jeff Skilling unexpectedly resigned, prompting many to question the health of the company. Kenneth Lay once again became the CEO. Lay, Skilling, and other Enron executives started selling large amounts of Enron stock as prices continued to drop—from a high of about $90 per share earlier in the year to less than a dollar. The U.S. Securities and Exchange Commission (SEC) opened an investigation.

Less than a week after a takeover bid from Dynegy was called off, Enron filed for bankruptcy protection. The company had more than $38 billion in outstanding debts. The U.S. Justice Department initiated a criminal investigation into Enron's bankruptcy. Many executives at Enron were indicted for a variety of charges and were later sentenced to prison. Enron's auditor, Arthur Andersen, was found guilty in a U.S. district court. Employees and shareholders received limited returns in lawsuits, despite losing billions in pensions and stock prices.

Mark-to-Market Accounting

In its natural gas business, Enron followed straightforward accounting standards. The company listed actual costs of supplying the gas and actual revenues received from selling it in each time period. However, when Jeff Skilling joined the company, he decided to change that practice and made sure that the trading business adopted mark-to-market accounting. Mark-to-market accounting requires that once a long-term contract is signed, income is estimated as the present value of net future cash flow. Often, the viability of these contracts and their related costs were difficult to estimate. Thus, investors were typically given false or misleading reports.

Special Purpose Entities

Enron also used special purpose entities to fund or manage risks associated with specific assets. Special purpose entities are limited partnerships or companies created to fulfill a temporary or specific purpose. The company disclosed very few details on its use of special purpose entities. Enron had used hundreds of special purpose entities to hide its debt. As a result, Enron's balance sheet understated its liabilities and overstated its equity and earnings. Prominent examples of special purpose entities that Enron employed were JEDI, Chewco, Whitewing, and LJM.

Corporate Governance and Risk Management

Enron seemed to have a model board of directors comprised predominantly of outsiders with significant ownership stakes and a talented audit committee. In its 2000 review of corporate boards, *Chief Executive* included Enron among its five best.

Before its scandal, Enron was also praised for its sophisticated financial risk management tools. Enron established long-term fixed commitments that needed to be hedged to prepare for the inevitable fluctuation of future energy prices. Many critics attribute Enron's bankruptcy downfall to its reckless use of derivatives and special purpose entities. By hedging its risks with special purpose entities it owned, Enron retained the risks associated with the transactions.

The board of directors was aware of Enron's aggressive accounting practices. Although not all of Enron's widespread improper accounting practices were revealed to the board, the practices were dependent on board decisions. Even though Enron relied extensively on derivatives for its business, the company's finance committee and board did not have enough experience with derivatives to understand what they were being told.

Ethical, Political, and Other Accounting Issues

Many observers believe that executive greed and a lack of corporate social responsibility were the reasons behind Enron's fall. Others blame post-1970s deregulation and inadequate staffing and funding for regulatory oversight. Some others believe that Enron's collapse resulted from its reliance on political lobbying, rent-seeking, and the gaming of regulations.

Enron regularly recorded costs of canceled projects as assets, with the rationale that no official letter had stated that the project was canceled. This method was known as "the snowball." It was initially decided that such practices would be used only for projects worth less than $90 million. However, it was later increased to $200 million.

Whenever analysts would tour the Enron Energy Services office, Skilling would order employees from other departments to move to that office to create the appearance that the division was larger than it was. This trick was used several times to fool analysts about the progress of different areas of Enron and to help improve the stock price.

Increased Regulation and Oversight

At the time of Enron's collapse, it was the biggest corporate bankruptcy ever to hit the financial world. The Enron scandal drew attention to accounting and corporate fraud, as its shareholders lost $74 billion in the four years leading up to its bankruptcy, and its employees lost billions in pension benefits.

Increased regulation and oversight have been enacted to help prevent or eliminate corporate scandals of Enron's magnitude. As a consequence of the scandal, new regulations and legislation were enacted to expand the accuracy of financial reporting for public companies. One piece of legislation, the Sarbanes-Oxley Act, increased penalties for destroying, altering, or fabricating records in federal investigations or for attempting to defraud shareholders. The act also increased the accountability of auditing firms to remain unbiased and independent of their clients.

EXXON VALDEZ OIL SPILL

The 1989 *Exxon Valdez* oil spill (EVOS) represented a watershed moment in environmental economics. The spill commanded considerable attention from the public and policymakers as oil traveled long distances from the reef hit by the Exxon-owned tanker, causing large-scale harm to a wildlife-rich, pristine environment. From an economic vantage point, the disaster triggered a rethinking of the value of changes to pure public goods where there is no requirement that people directly use the resource in order for there to be a monetary loss. It also focused attention on the survey-based technique, contingent valuation (CV), developed by economists for measuring the monetized value of such changes.

The governmental trustees for injured natural resources, the State of Alaska, and the United States undertook a large-scale CV study of the American public's willingness to pay (WTP) to avoid a future oil spill similar to the EVOS. The government trustees presented the results of the study to Exxon and, subsequently, Exxon settled out of court for the roughly $2 billion spent on response and restoration activities plus an additional $1 billion in natural resource damages. The government's CV study had estimated that the American public's WTP to prevent an EVOS-like spill was approximately $3 billion, and regulations require that money received for injuries to natural resources go either to restoration activities or to acquire similar resources to those injured. After the settlement, a council of trustee agencies was set up to spend the money received for this second purpose.

There were a number of unsettled issues facing the EVOS case if it had gone to trial, including whether traditional admiralty law took precedence over newer pollution statutes (which would have greatly reduced Exxon's liability), which expenditures constituted response that did not count toward liability for natural resource damages and which constituted restoration, and how much weight the court would put on the government's EVOS CV study.

The U.S. Oil Pollution Act of 1990, passed in response to the EVOS, codified the positions adopted by government in the EVOS case. From an economic vantage point, these positions largely followed practices of government agencies in conducting benefit-cost analysis, which placed considerable weight on monetizing all benefits and costs of a policy and utilized CV to do this. Violation of the U.S. Clean Water Act was a key component of the government's EVOS case, and CV had been used to comprehensively measure the benefits of that act. The last impediment to a government trustee including passive use considerations in a natural resource damage assessment was removed in a major 1989 U.S. appellate court case: *Ohio v. Department of Interior* (880 F.2d 432, D.C. Cir. 1989). In that case, the court ruled that lost passive use value associated with injuries to natural resources was compensable under U.S. law.

The ability to include passive use values illustrates a striking difference between the EVOS and the Santa Barbara oil spill of 1969, which was one of the key events that influenced major U.S. federal environmental legislation enacted over the next several years. The Santa Barbara spill was the largest in U.S. coastal waters until the *Exxon Valdez* and resulted in compensation to government agencies of roughly $15 million. In the EVOS case, the compensation might have been even less than this without the inclusion of passive use considerations, as Exxon's estimate of the lost nonmarket value was $4 million for the reduction in outdoor recreation in Alaska.

The EVOS CV study used a large in-person survey of a national sample of U.S. households. Surveyors presented a detailed description of Prince William Sound, where the spill occurred, focusing on the landscape and impacted wildlife and using photographs and show cards. A plan for preventing a future spill similar to the EVOS was put forward that utilized escort ships to prevent a tanker from going off course and which had the ability to quickly lay down a containment boom. The payment mechanism was a one-time federal tax. Respondents were offered a discrete choice between the status quo and paying the specified higher tax to obtain the prevention plan.

Following the settlement with Exxon, the U.S. Coast Guard mandated a prevention plan similar to one put forward in the EVOS CV study. Soon after, a supertanker going down the narrow Straits of Valdez lost power and drifted toward a reef near the one hit by the *Exxon Valdez*; fortunately, its escort tugs pushed it away and towed it out for repairs. Subsequently, escort ships have been called upon on several occasions to prevent another potential large oil spill.

Exxon put on a conference after the EVOS settlement in which a set of papers highly critical of CV were presented. In response, the U.S. government sponsored a Blue Ribbon Panel, co-chaired by Kenneth Arrow and Robert Solow, to assess the use of CV for natural resource damage assessment. The panel concluded that "well conducted CVM studies can produce estimates reliable enough to be the starting point of a judicial process of damage assessment, including lost passive values" and set out guidelines for conducting CV studies for litigation purposes. These guidelines largely followed the procedures used in the EVOS CV study with the exception of requiring a test of whether WTP was sensitive to a change in the scope of the good described. The conflicting views of the Hausman volume and the Arrow et al. report stimulated a substantial amount of research related to CV and nonmarket valuation.

FEDERAL HOME LOAN BANK

In 1932, Congress chartered the Federal Home Loan Banks, also known as the FHLBanks or FHLBank Systems. The Federal Home Loan Banks are a system of regional banks from which local lending institutions in the United States borrow funds to finance housing, jobs, economic development, and infrastructure. The banks help institutions, not individuals. There are 11 United States government–sponsored banks, located in Atlanta, Boston, Chicago, Cincinnati, Dallas, Des Moines, Indianapolis, New York, Pittsburgh, San Francisco, and Topeka. Including all of the Federal Home Loan Banks' members, the bank represents the largest collective source of home community credit and mortgage in the United States.

The Federal Home Loan Banks support several efforts of their member lending institutions. These efforts include helping families realize their dream of owning a home, improving the local business environment, and building affordable housing.

Members of the Federal Home Loan Banks

The Federal Home Loan Banks have nearly 7,300 members. In order to become a member, the applying entity must meet the following requirements:

- be duly organized under the laws of any state of the United States
- be subject to inspection under the banking laws or similar federal and state laws
- make a long-term home mortgage loans
- have at least 10 percent of its total assets in residential mortgage loans
- be financially stable enough to safely make Federal Home Loan Bank advances
- have a character of management and a home financing policy that is consistent with economical home financing

The members include banks, credit unions, insurance companies, and thrifts. Shares of the regional federal banks are distributed among their members. Each regional bank is an individual corporate existence that must meet strict management and capitalization criteria to remain a government-sponsored enterprise. In order to ensure that each regional bank remains well managed and capitalized, the regional banks are watched over by the government and are subject to normal bank regulations and shareholder vigilance. Each Federal Home Loan Bank reflects a public purpose; however, they are capitalized privately and do not receive money from taxpayers.

Mission of the Federal Home Loan Banks

A key mission of the Federal Home Loan Banks is to ensure that the housing enterprises sponsored by the government operate in a safe and sound manner so that they can serve as a dependable source of funding and liquidity for housing community investments and finances. In order to prosper, the Federal Home Loan Banks set values that each of the 11 U.S. government–sponsored banks must follow. The values of each bank include respect, excellence, integrity, and diversity. For decades the Federal Home Loan Banks have helped to improve the lives of U.S. families.

FEDERAL HOME LOAN MORTGAGE CORPORATION (FREDDIE MAC)

The Federal Home Loan Mortgage Corporation (FHLMC), also known as Freddie Mac, has a public mission to stabilize the nation's residential mortgage markets and expand opportunities for home ownership and affordable rental housing. Congress chartered Freddie Mac, located in Tysons Corner, Virginia, as a stockholder-owned, government-sponsored enterprise (GSE) through the Emergency Home Finance Act of 1970. Freddie Mac purchases loans from lenders to allow them to make more mortgage loans to other borrowers. They then guarantee and securitize these mortgages to form mortgage-backed securities. These securities are very liquid and carry a credit rating close to that of U.S. Treasury notes, bills, and bonds. Freddie Mac does not make loans directly to homebuyers, nor does it pay state and local income tax. The FHLMC also works to educate home buyers and homeowners through financial education programs like their "Considering a Home" and "CreditSmart" curricula.

In 1989, the Financial Institutions Reform, Recovery and Enforcement Act revised and standardized the regulation of Freddie Mac and the Federal National Mortgage Association, known as Fannie Mae. The U.S. Department of Housing and Urban Development (HUD) then oversaw Freddie Mac and created an 18-member board of directors.

In the early 1990s, Congress encouraged Freddie Mac and Fannie Mae to increase their purchases of mortgages for low- and moderate-income borrowers. These factors, along with Freddie Mac's implicit guarantee of government support, left it attractive to investors and vulnerable to the impending housing bubble.

During the financial crisis of 2008, Treasury Department officials and leading industry experts concluded that neither Freddie Mac nor Fannie Mae had enough money to sustain the crisis. Then Treasury Secretary Henry M. Paulson Jr. created a plan of "conservatorship" under the Federal Housing Finance Agency (FHFA). Boards and chief executives were fired and new chief executives were appointed. As both agencies had funded about 70 percent of home loans at the time, many saw this as a crucial step necessary for the recovery of the housing market. The government changed them from commercial entities with a goal of making money for stockholders into quasi-public service companies intended to help the housing mortgage market function.

Criticism of Freddie Mac stems from the fact that the U.S. government allows it to borrow money at interest rates lower than those available to other financial institutions. It can issue a large amount of debt and purchase and hold a large portfolio of mortgages, known as its retained portfolio. Due to the size of the retained portfolio relative to the size of the total housing market, many believe it poses a systemic risk to the U.S. economy.

Freddie Mac has strengthened its credit and eligibility standards to produce better-quality loans that foster sustainable home ownership.

FEDERAL NATIONAL MORTGAGE ASSOCIATION (FANNIE MAE)

President Franklin D. Roosevelt and Congress chartered the Federal National Mortgage Association, also known as Fannie Mae, in 1938 as part of the New Deal. Prior to this time, the private sector issued home loans with large down payments (about half the home's purchase price) and short time frames for payment, thus limiting home ownership. These lending institutions—banks, thrifts, credit unions, and savings and loans—held the mortgages themselves. After the Great Depression, private lenders did not want to invest in risky home loans. The National Housing Act of 1934 offered federally backed insurance for home mortgages from Federal Housing Administration–approved lenders. The Federal National Mortgage Association was established as an amendment to the National Housing Act.

Fannie Mae's purpose is to buy mortgages from banks so that they may then loan capital to other borrowers. This works to keep the mortgage market liquid and keep lenders providing mortgages. This strategy has allowed many lower- and middle-class Americans to borrow money from banks and improve the level of home ownership and the availability of affordable housing. Fannie Mae saw much growth with the advent of the Servicemen's Readjustment Act (GI Bill), and specifically the Veterans Administration mortgage insurance program, in 1944.

In 1954, the Federal National Mortgage Association and Charter Act of 1954 changed Fannie Mae from a government agency to a public-private corporation. Facing the financial pressures of Vietnam, Lyndon B. Johnson also reorganized Fannie Mae to eliminate its debt portfolio from the balance sheet through the Housing and Urban Development (HUD) Act of 1968. Congress split Fannie Mae into two companies. One was Fannie Mae. The second, new company was named the Government National Mortgage Association, or Ginnie Mae. Ginnie Mae continued to buy government-issued loans and remained a government entity.

The new Fannie Mae was converted into a publicly traded investor-owned company with federal government support, or a government-sponsored enterprise (GSE). This designation directed Fannie Mae to maximize shareholder profits for its private owners and support home ownership via its congressional or public mandate. Fannie Mae was now allowed to buy conventional mortgages in addition to those issued by the government from the Veterans Administration and the Federal Housing Administration. Fannie Mae also still had access to a line of credit from the U.S. Treasury and was exempt from state and local income taxes and SEC oversight. The president was authorized to appoint 5 out of 18 members of Fannie Mae's board of directors. HUD also had the authority to require Fannie Mae to direct a larger portion of its business to low- and moderate-income housing. In 1970, Congress correspondingly created the Federal Home Loan Mortgage Corporation, Freddie Mac, to compete with Fannie Mae.

The unique identity of Fannie Mae as a private corporation and a government entity created an implicit belief that the U.S. government guarantees loans backed by Fannie Mae and Freddie Mac. Fannie Mae has been criticized for its close government ties that might lead to an unfair advantage within the industry. It has been able to borrow money from foreign investors at low interest rates because of this U.S. government support. This gives Fannie Mae a funding advantage and the ability to earn large profits. Congress passed the Federal Housing Enterprises Financial Safety and Soundness Act in 1992 to conduct routine examinations of Fannie Mae and Freddie Mac.

In 1995, the Department of Housing and Urban Development began to specify mortgage purchase goals for both Fannie Mae and Freddie Mac in response to an inclusion of affordable housing as part of its mission. Both Fannie Mae and Freddie

Mac turned to subprime securities with lax underwriting standards to meet these goals. This also helped to maximize their profits for shareholders.

Fannie Mae weathered several accounting scandals in 2003 and 2004, ultimately paying a $400 million civil penalty for overstating reported income and capital by $10.6 billion. The Securities and Exchange Commission directed Fannie Mae to restate its financial results for 2002 through 2004 and replace both its chief executive officer and chief financial officer.

In addition, the ultimate default and collapse of the subprime mortgage market forced Fannie Mae and Freddie Mac toward a government bailout. The Federal Housing Financing Agency placed Fannie Mae and Freddie Mac into conservatorships in July 2008, dismissing their chief executive officers and boards of directors and issuing new senior preferred stock and common stock warrants.

FEDERAL TRADE COMMISSION

The Federal Trade Commission (FTC) is an independent agency within the U.S. government that regulates competition between businesses and protects consumers from unethical business transactions by preventing industries from forming anticompetitive trusts. When President Woodrow Wilson signed the Federal Trade

Commission Act on September 26, 1914, business trusts were still very active in the U.S. business environment. One objective of the FTC was to continue to pursue and break up the business trusts as they were structured at that time. The Federal Trade Commission Act was considered by some as a follow-up to the 1890 Sherman Antitrust Act as consumer protection.

The forerunner to the FTC was the Bureau of Corporations, created on February 14, 1903, by then-president Theodore Roosevelt as a promise under his Square Deal. The Bureau of Corporations was created as an investigatory agency under the Department of Commerce and Labor. The bureau examined industries' business practices, specifically those businesses that engaged in interstate commerce. The reports the bureau created were useful when examining antitrust cases. Up until this time, trusts had become a major problem in the United States. Trusts are companies or organizations that work together to limit competition from other similar companies or organizations. In 1890, Congress passed the Sherman Antitrust Act, which made these trusts illegal. With the Sherman Antitrust Act, if the federal government felt a company was limiting competition, it would launch an investigation. The act was not fully enforced until the creation of the Bureau of Corporations. The Federal Trade Commission replaced the Bureau of Corporations with the signing of the Federal Trade Commission Act in 1914.

The FTC's mission is to prevent business practices that are deceptive, unfair, or anticompetitive, and to enhance informed consumer choice and public understanding of the competitive process without burdening legitimate business activity. It has three main goals: (1) to protect consumers by preventing unfair business practices and deception in the marketplace; (2) to maintain competition by preventing trusts from forming, creating a lack of competition; and (3) to advance its performance through maintaining organizational, individual, and management excellence.

In order to fulfill its mission and meet its goals, the FTC has created a variety of agencies and bureaus to oversee specific components of the organization. This list includes the Office of Public Affairs, Office of Congressional Relations, Office of the Executive Director, Office of the General Counsel, Office of Equal Employment Opportunity, Office of International Affairs, Office of the Secretary, Office of Administrative Law Judges, Office of Policy Planning, Office of the Inspector General, Bureau of Competition, Bureau of Economics, and Bureau of Consumer Protection.

The Bureau of Consumer Protection enforces a variety of consumer protection laws enacted by Congress as well as trade regulation rules issued by the FTC. Its actions include individual company and industry-wide investigations, administrative and federal court litigation, rule-making proceedings, and consumer and business education. In addition, the bureau contributes to the commission's ongoing efforts to inform Congress and other government entities of the impact that proposed actions could have on consumers.

The Office of Congressional Relations works with members of Congress. The office informs FTC staff of Capitol Hill issues and policies and provides information on legislation of interest to the commission. It also coordinates the preparation of both congressional testimony and responses to congressional inquiries concerning FTC policies and programs.

The Office of Equal Employment Opportunity investigates complaints of discrimination based on race, color, national origin, religion, disability, sex, reprisal, sexual orientation, genetic information, and parental status.

The Office of International Affairs's main role with the FTC is to work with competition and consumer protection agencies around the world to promote cooperation and convergence toward best practices.

The Bureau of Competition is considered the antitrust arm of the FTC. Its job is to prevent anticompetitive business practices and mergers. By doing this, the FTC promotes consumers' freedom to choose goods and services in an open marketplace at a price and quality that fits their needs. This is also good for other, similar businesses, as it guarantees opportunity for businesses by ensuring a level playing field among competitors.

The Bureau of Economics helps the FTC by providing economic analysis and support to consumer protection and antitrust investigations and rules. It also analyzes the impact of government regulation on competition and consumers and provides the government with economic analysis of market processes related to antitrust, consumer protection, and regulation.

In addition, the FTC has regional offices that cover seven geographic areas. The regional offices work with the Bureaus of Competition and Consumer Protection to conduct investigations and litigation; provide advice to state and local officials on the competitive implications of proposed actions; recommend cases; provide local outreach services to consumers and businesspeople; and coordinate activities with local, state, and regional authorities.

FISHERIES ECONOMICS ASSOCIATIONS

The International Institute of Fisheries Economics and Trade (IIFET) and the North American Association of Fisheries Economists (NAAFE) are two organizations for individuals interested in fisheries economics, which can be broadly defined to include marine resource economics, fisheries management, seafood trade and markets, aquaculture economics, and fisheries development. Membership of both organizations includes individuals from industry, government, and academia with disciplinary interests ranging beyond economics into other social and biological sciences.

IIFET was founded in 1982 under the leadership of Richard Johnston of Oregon State University and, as its name suggests, was organized as an international organization. It holds a biennial meeting in even years in locations throughout North and South America, Europe, Asia, New Zealand, and Africa, which hosted the most recent meeting. IIFET recently instituted a fellows award. The main criterion for selection of fellows is substantial, long-term, ongoing contributions to the advancement and development of economic theory and analysis in the areas of fisheries, aquaculture, and/or seafood trade. Achievements may be evidenced by research, teaching, academic service, and/or policy impact. Anthony Scott of the University of British Columbia and James Wilen of the University of California, Riverside, are the first two IIFET fellows.

NAAFE is an independent organization formed in 2000 primarily under the leadership of Gunnar Knapp of the University of Alaska Anchorage and Walter Keithly of Louisiana State University. It was something of an offshoot of IIFET, and much of the impetus for forming the new organization was to focus attention on more local issues and to hold meetings at sites with relatively lower travel costs to allow for more attendance. Meetings are held in odd years, and many of the experts in the field attend both meetings. Both meetings span three or four days with many concurrent sessions with academic and policy relevance. *Marine Resource Economics* is the affiliated journal of both organizations.

While the two groups are now fully independent with separate bylaws and officers, the day-to-day business for both is carried out by secretariats hosted by Oregon State University's Department of Agricultural and Resource Economics under the leadership of Ann Shriver. IIFET membership varies between 600 and 800 individuals from approximately 65 countries, and attendance at meetings averages about 300. NAAFE's membership is about 150, and attendance at meetings averages about 100. Both are membership organizations open to any interested individual.

FISHERIES MANAGEMENT

Economists have long understood that the cause of fisheries problems is the inability to exclude users. A resource is open access if users cannot be excluded (or exclusion is costly) and the resource is rival in consumption (also referred to as subtractable), meaning that a fish caught by one individual cannot be caught by another. Under open access, no one owns the fish in the sea. Fishermen thus lack incentives to restrain themselves in order to sustain the biological health of the resource and ultimately the long-term economic health of the fishing industry. Each fisherman races to catch the fish before the other person. Dynamic resource models, and bioeconomic modeling in particular, demonstrate that open access leads to biological overexploitation (overfishing) and economic losses (rent dissipation).

The degree of excludability is on a continuum. Resources on this continuum are generally referred to as common pool resources, a phrase that sometimes substitutes directly for the phrase *open access*, and difficulties in solving the exclusion problem are generally referred to as the *commons problem*. When access is completely nonexcludable and the resource is completely rival, we refer to this extreme case as *pure open access*. As a practical matter, few fisheries are pure open access because there is often some degree of exclusion. For example, one country may keep other countries from fishing in its territorial waters but fail to exert any control over its domestic fishing fleet. At the other end of the spectrum is complete exclusion, under which the resource effectively becomes private property. By definition, a private good is excludable and rival.

In between open access and private property are various institutional arrangements that partially exclude users. Some of these cases are regulatory attempts to limit access. For example, under limited entry, a form of regulated restricted access, the number of participants in a fishery is limited but the level of exploitation of each participant typically is not controlled. Another institutional arrangement between open access and private property is common property resource management, whereby communities of resource users self-organize to limit access and sometimes control other aspects of the fishery. Although fisheries contribute significantly to protein consumption, employment, and export earnings in developing countries, many developing countries lack the institutional capacity to manage fisheries with strong government regulations, and common property resource management is seen as a possible alternative. A third option is a hybrid of regulation and common property resource management called co-management, where self-organized resource governance and government regulation reinforce each other; the regulator lacks the capacity to manage the fishery entirely on its own, but communities are unable to exclude users (typically users from outside the community) without assistance from the regulator. As globalization of the seafood trade generates more market opportunities for fishery resources, co-management may be necessary to bolster otherwise successful common property resource management.

Rivalry is also a characteristic of open access that is on a continuum. For example, some recreational fishermen like to catch and release fish for sport. Some of the released fish survive and can be caught again. When survival rates are high, the resource is less rivalrous. Combined with nonexcludability, nonrivalry of catch-and-release fish makes the resource more like a public good.

The history of fisheries management is a history of successes and failures in addressing the open access problem. There was a time when even many scientists believed that fishery resources were effectively limitless. Well into the 20th century, fisheries management was aimed primarily at promoting and developing fisheries without recognition of the capacity of humans to affect the availability of fish in the future and with little regard for the problem of open access. By the 1950s, scientific awareness of the finite nature of fishery resources had grown, and the problem of open access was well understood by economists. But the most significant breakthrough in solving the exclusion problem did not come until 1976, when nations agreed to define 200-mile exclusive economic zones (EEZs), which were formally adopted by the UN Convention on the Law of the Sea in 1982. Because the majority of fishery resources exist above continental shelves and in other near-shore environments, the 200-mile EEZ creates the potential for nations to exclude users and manage their fishery resources to sustain the biological resource and generate economic rents. However, to date there is considerable variation in the extent to which nations have addressed excludability within their EEZs. For resources outside of EEZs (ones that are only on the high seas or highly migratory fish that move through the high seas), excludability is limited because it requires an international agreement. For resources that span multiple EEZs (known as straddling stocks), bilateral or multilateral agreements are necessary to address open access.

In the United States, the centerpiece of fisheries law is the Magnuson-Stevens Fishery Conservation and Management Act. At its core it is a mandate to end overfishing by setting catch limits in federally managed fisheries. Historically, this mandate has focused on the symptom of the problem, namely biological overfishing, without addressing the cause. By setting catch limits without addressing the exclusion problem, managers began to control biological overfishing but inadvertently worsened the race to fish. This regulatory approach is known as regulated open access: aggregate catch limits can maintain a biologically healthy stock; fishermen have incentives to build more and bigger vessels to catch fish before their competitors; and managers respond by shortening season lengths, forcing unsafe fishing conditions, gluts of product onto the market, and the need to sell fish frozen rather than fresh. Because the stock of fish is maintained at a healthy level, regulated open access can lead to even more excess fishing capacity and associated economic waste than pure open access. Most notoriously, an economically wasteful derby in the Pacific halibut fishery of Alaska shrunk the season length to less than three days by 1994.

In 1995, a solution to address the cause of this problem was introduced: an individually transferable quota program that set the total catch based on biological assessment and divided the catch between resource users into shares that could be traded. Individually transferable quotas were used in only a handful of other U.S. fisheries but appeared to be successful in managing larger numbers of fisheries in Iceland and New Zealand. With the new policy, the Pacific halibut fishery was transformed overnight from a source of tremendous economic waste to one of the great success stories in fisheries management, with a season lasting 245 days and a steady flow of fresh, high-value product to the market.

The 2006 reauthorization of the Magnuson-Stevens Act provided a means to use new tools like the halibut program in federal fisheries management. These tools are broadly defined as limited access privilege programs (LAPPs) and include individual fishing quotas (both tradable, like in halibut, and nontradable) and territorial use rights in fisheries (TURFs). In policy circles, individual fishing quotas have now been renamed *catch shares*. LAPPs address the cause of overfishing and not just the symptoms by solving the exclusion problem, thus aligning the incentives of individual fishermen with the objectives of fisheries management.

Economists have shown that that problem of open access applies to a broader definition of marine resources than just a single targeted fish stock. A number of innovations have examined spatial heterogeneity of fish stocks and fishing fleets and the potential for closing fishing grounds to increase yields and profits. Here the issue is whether to exclude access to a spatially delineated portion of the stock rather than to the stock as a whole. To some extent, regulators are repeating their mistakes of regulated open access in attempts to control bycatch, the unintentional catch of nontarget species. By setting industry-wide caps rather than individual vessel quotas, regulations create the potential for a race to bycatch. Similar issues arise in the protection of critical habitat and other marine ecosystem services. Proposed solutions to these problems require aligning incentives of individuals with the objectives of management, including spatially delineated management, individual bycatch quotas, and individual habitat quotas.

FLEXIBLE SAVING ACCOUNT

A flexible saving account, also called a flexible spending account (FSA), is a workplace-provided account into which employees contribute money before federal income taxes and the employee portion of Social Security tax (pre tax) are calculated. Once a worker sets up an FSA, the employer then deducts the predetermined amount in installments from the employee's pay each pay period and deposits the money into the worker's FSA. Account owners can use the pretax dollars to pay specific out-of-pocket costs.

Companies are allowed, but not required, to offer employees both medical expense FSAs and dependent or childcare FSAs. An employee can enroll in one account, both, or neither. When carefully established and managed, the accounts can save individuals tax dollars and cover costs, such as uninsured expenses, that they would normally pay out of pocket.

Medical FSA Rules

By opting to open a medical FSA, workers can set aside up to $5,000 to help pay health care costs that are not covered by insurance. Medical FSA owners either present covered cost receipts to the account administrator and are reimbursed for the expenses or pay for the eligible expenses using a plan-issued debit card. Even if a debit card is used, workers should retain receipts in case the employer or tax officials have questions about a reimbursement's eligibility.

Qualified medical expenses that are eligible for FSA reimbursement or payment via debit card are generally those costs listed in the FSA's plan description. Most employers use the medical costs listed in IRS Publication 502, Medical and Dental Expenses.

Common eligible health care expenses detailed over more than 12 pages in the publication include insurance co-payments made with after-tax income, treatment co-payments, deductibles, eye surgeries (such as Lasik), extra pairs of prescription eyeglasses and contact lenses, chiropractor treatments, travel costs for treatment, birth control pills, and pregnancy test kits.

In addition, prescription drugs and over-the-counter (OTC) drugs may be reimbursed from or paid for directly with FSA funds. However, a tax law change effective with the 2013 tax year requires that an FSA owner get a prescription from a doctor for OTC medicines before the account money will cover those costs.

The IRS periodically updates the qualifying medical expenses list. FSA account owners should check the IRS website and double check with their FSA administrator before making questionable medical purchases or receiving services to ensure they will be covered.

Childcare FSA Rules

By opting to open a dependent-care FSA, workers can set aside up to $5,000 to help pay some of the costs of placing children in day care while the parent or parents are at work. If both married spouses work and each has access to a childcare FSA, the $5,000 limit applies to them as a couple; one spouse can open a $5,000 FSA or they can split the limit between themselves.

A childcare FSA operates like a medical FSA. Once an employee decides what amount to contribute to the account, up to the limit, the employer deducts that amount in installments from the employee's gross pay each pay period before taxes are calculated and sends it to the FSA. The money is then used to pay the childcare provider or reimburse the parents for their out-of-pocket expenses.

Free Money from FSAs

Another advantage of FSAs is that a reimbursement request can be fulfilled before the account has enough money to cover the cost. For example, a medical FSA owner breaks his wrist in February and requires surgery. The injured employee's workplace health insurance covers most of the surgical costs, but because the injury was incurred early in the benefits year, he had to pay a $2,000 deductible. Also, because of the timing, the worker had only contributed to his medical FSA for two months, or $833 toward his eventual $5,000 annual total. Tax law, however, allows for the worker to be reimbursed for the full $2,000 deductible costs because he is enrolled for a $5,000 FSA total contribution. Even if the worker leaves his job before he contributes the amount already paid by the FSA, he won't have to repay the money.

Use or Lose FSA Money

FSAs, however, do have a major downside. If an account holder ends a benefits year with excess money in the account, the money is forfeited to the employer. This is known as the "use it or lose it" rule. It is also why many workers undercontribute to their FSAs.

Employers are allowed to offer FSA owners a grace period of two and a half months, or until March 15 for benefits plans that operate on a calendar year, to ensure eligible medical expenses use the prior year's excess funds. But this is an employer option, not a requirement of its employee benefits offerings.

Workers should make sure they understand when their FSAs must be used so that they don't inadvertently lose some of their contributions.

Life Changes Allow for FSA Changes

Once an employee chooses an amount for an FSA, no changes are allowed unless the employee experiences a major life change.

Valid life changes for both medical and childcare FSAs are:

- a change in marital status (e.g., marriage, divorce, death of spouse, legal separation, or annulment)
- dependents added or lost via birth, adoption, placement for adoption, or death
- employment status change on the part of the employee, a spouse, or dependents (e.g., change in work site, switching from part-time to full-time work or vice versa, or job loss)
- residency change
- a dependent's eligibility changes (e.g., reaches a birthday beyond the eligibility age or is no longer a full-time student)

In these cases, an FSA owner can and should adjust the contribution amount to the saving plan to ensure that it has enough funds to cover expected costs but not so much as to lose unused money.

FOOD SAFETY

There are thousands of types of bacteria found naturally in our environment. Some of these are pathogenic microorganisms (pathogens) that enter the food supply and can cause food-borne illnesses to consumers. In recent years, outbreaks of *E. coli* 0157:H7, Salmonella, Listeria, and *Vibrio vulnificus* have caused well-documented incidences of human illness and death associated with consuming everyday products such as tomatoes, eggs, spinach, peanuts, milk, beef, poultry, and oysters. In the United States alone, Centers for Disease Control and Prevention (CDC) data indicate that around 76 million cases of food-borne diseases, resulting in 325,000 hospitalizations and 5,000 deaths, are estimated to occur each year. Further, it is expected that the risks of food-borne illness are likely to increase over time due to factors such as climate (e.g., rising ocean temperatures increase the presence of naturally occurring bacteria that may contaminate the seafood supply chain), continued urbanization of traditionally rural areas (creating runoff that can exacerbate harmful algal blooms in coastal waters), or demographic conditions (rising population levels will continue to place additional pressure on mass production methods of food production that may pose problems in effectively tracing a contamination incident to its source).

As media attention directed at these events has increased public awareness of the risks associated with eating contaminated food, policymakers have attempted to address individuals' risk perceptions by creating new policies designed to reduce the incidence of food-borne illness. These policies come in various forms and at different levels of governance. At the industry level, firms, either voluntarily or mandated by government regulation, may provide safety assurances to consumers. At the federal level, some government agencies attempt to directly control the supply of food products. For example, the U.S. Department of Agriculture's Food Safety and Inspection Service (FSIS) is the public health agency responsible for ensuring that the nation's commercial supply of meat, poultry, and egg products is safe, wholesome, and correctly labeled and packaged. The U.S. Food and Drug Administration (FDA) and Interstate Shellfish Sanitation Conference (ISSC) control the National Shellfish Sanitation Program (NSSP), which is a federal/state cooperative program to promote and improve the sanitation of shellfish produced and sold for human consumption. However, the most significant piece of legislation relating to food safety in the United States for decades came in the form of the 2011 Food Safety Modernization Act (FSMA). While there are several components to the new law, essentially the FSMA shifts the food safety focus from reaction and response to prevention. Under the new law, there are, among others, provisions to provide more frequent and targeted inspections of domestic food production facilities; to make importers accountable for verifying that the required controls are in place in foreign food facilities that export to the United States; to grant the FDA authority to issue a mandatory product recall if a company fails to voluntarily recall unsafe food; and to enhance federal, state, and local surveillance systems for food-borne illness so that outbreaks can be identified and controlled more quickly while also gaining the scientific knowledge to prevent future outbreaks.

Since the late 1970s, a significant body of research in the food safety arena has examined the impact of food safety information conveyance on consumer risk perceptions and behavior in the marketplace for a variety of products. Using both market-based techniques on actual sales data and nonmarket valuation techniques, such as choice experiments, averting and contingent behavior, and field experiments, researchers have shown that media coverage of a food-related health scare or contamination event can alter risk perceptions and cause consumers to react defensively, reducing demand for the product even when there is no scientifically supported health risk from normal consumption. Consequently, consumers accrue welfare losses or avoidance costs. Researchers interested in examining potential policy implications have also considered the effect of positive counterinformation treatments, designed to reassure consumers about the product's safety following a scare event, on risk perceptions and consumer behavior. Generally, studies find an asymmetry in consumer responses to negative and positive product news as consumers place greater weight on negative news concerning a product contamination or health scare event. As such, counterinformation treatments have a negligible effect on consumer demand, so welfare losses persist.

Since the 1990s, the rising incidence of food-borne illness has also supported a growing area of research examining how consumers value food-borne risk, their preferences for the use of technology in reducing risk, and the role of information in altering risk perceptions. Results from these studies generally indicate that individuals tend to underestimate objective risk of food-borne pathogens, but after receiving information regarding the likelihood of illness or death from consumption, they will pay a premium for safer food. Experimental auction methods have been used to investigate consumers' preferences for food safety technologies, such as freezing, irradiating, or pasteurizing food to reduce food-borne risk. Use of technology in food production presents an interesting trade-off for the consumer. While processing food reduces risk, it can also alter the esthetics (taste, smell, texture) of the product. As such, consumers' valuation for a new processed food product over a traditional variety is a composite measure of their valuations for actual and/or perceived differences in the individual characteristics of the food.

Also, as consumers gain information, either through experience or from external sources, preferences and the resulting valuations are subject to change, so information is likely to be an important determinant of consumers' valuation of processed foods. Research has shown that, in general, consumers will pay a premium for processed foods, but premiums vary across treatment types. However, it has also been shown that processing technologies may degrade the taste of the altered product to the extent that the benefits of risk reduction are overwhelmed by the change in taste, and willingness to pay for the processed good declines significantly.

GAMBLER'S FALLACY

The gambler's fallacy refers to an incorrect belief about a sequence of independent random events. Someone falling prey to the fallacy believes that if a sequence of observed random events deviates from expected behavior, subsequent events will be biased in the opposite direction in order to move the observed sample toward a known population mean. A commonly overheard example is the expectation that something is "due": a roulette ball is "due" to fall on a red number after a long series of black numbers.

Estes (1964) demonstrated these beliefs experimentally by asking subjects to observe a sequence of coin flips and predict outcomes. Subjects behave as if every segment of the sequence must reflect the true proportion of 50 percent, and they expect corrective biases in the opposite direction of the observed sequence. This can also be seen by asking experimental subjects to generate a random sequence of hypothetical coin flips. Tune (1964) showed that subjects maintain the proportion in any short segment at much closer to 50 percent than the laws of chance would predict.

Tversky and Kahneman (1971) suggest that the gambler's fallacy is driven by belief in the law of small numbers (the law of large numbers applied to small samples). This can be described as the belief that a sample randomly drawn from a population is highly representative; thus each sample must be similar to each other sample and to the population. In surveys of professional psychology researchers, they demonstrate fundamental misunderstandings of interpreting replication studies. This includes overestimating the likelihood of replicating study findings and underestimating the significance of successful replication with differing magnitudes. They suggest that across naïve subjects and trained scientists alike there exist strong intuitions about random sampling that are fundamentally wrong. They argue that belief in the law of small numbers (and thus the gambler's fallacy) is a result of the representativeness heuristic, a cognitive bias that operates regardless of motivational factors. This has been replicated in field experiments by Croson and Sundali (2005).

A related fallacy is known as the hot-hand fallacy, where future outcomes are believed to be biased in the *same* direction as a previous sequence (this is sometimes also called the gambler's fallacy, as both fall into a general category of inference from previous independent results). There may be some validity to such beliefs in a human-generated outcome like the shot of a basketball, but it is just as misguided as the gambler's fallacy with respect to independent, randomly generated outcomes.

Correcting or avoiding the gambler's fallacy has proven to be difficult, as education about the nature of random events has been ineffective at reducing the prevalence of picking "with" the fallacy. Beach and Swensson (1967) tested how people predict draws of reshuffled cards with and without prior education about the gambler's fallacy and found both groups made similar predictions that relied on the fallacy.

Roney and Trick (2003) have demonstrated that the effect of the gambler's fallacy can be reduced by "grouping" observations to make the next outcome appear as though it were the beginning of a sequence. Participants were shown the results of a sequence of six coin flips, with the last three all coming up heads. Those who were asked to predict the outcome of the seventh coin flip relied more heavily on the gambler's fallacy (by choosing tails) than those who were asked to predict the first flip for the next sequence of six. They thus argue for encouraging people to view each event as a beginning and not a continuation of events.

GAMBLING BEHAVIOR

Gambling refers to staking money on an outcome with a random element. Gambling takes many forms: betting on races or sports events, card games, roulette, lotto, slot machines, scratch tickets, or online casinos. The acceptance of gambling has varied in history and across societies, but current surveys in Western nations suggest that a large majority of adults gamble on a regular basis. From a profit-maximizing perspective, gambling represents a puzzle. For the individual, the expected value of gambling is often considerably less than the cost. This comes from the usual small probabilities of winning in combination with payout ratios being reduced by profit made by bookmakers, casinos, or lotto agencies. Different explanations have been suggested to explain why people gamble nevertheless, focusing on the subjective interpretations of probabilities, risk seeking, self-deception, affect, and social factors.

Subjective interpretations of probabilities often differ from objective probabilities. People overweight low probabilities, as described by the weighting function of *prospect theory*. They use *heuristics* to judge probabilities, like the availability heuristic, which is based on the ease of retrieval from memory. People often have a limited understanding of random processes, which in turn influences subjective probabilities. They often expect the outcome of a random process also to look random (representativeness heuristic) and therefore prefer to bet on seemingly unordered sequences. In the gambler's fallacy, random processes are misunderstood as self-correcting over time, and independent probabilities are perceived as depending on previous outcomes. For example, after the roulette wheel has shown red five or more times in a row, people expect black to be more likely and bet accordingly. Observing a "near miss," only one symbol missing to win the jackpot on a slot machine, leads to continued gambling by reinforcing the gambler's fallacy.

Risk seeking explains why the decision to engage in gambling can differ even when the same probabilities are involved. Individuals who are more risk seeking are more likely to gamble, but situational factors are also important. The "house money effect" describes that people are more careless about windfall gains (such as money won in the casino). But also losses can induce riskier behavior in line with the value function of prospect theory, particularly when there is a chance to "break even" and to recover the losses. This can result in "chasing," placing higher bets after losing, in the hope of making up for previous losses.

Self-deception describes how gamblers may have self-serving views related to gambling. Gamblers may show unrealistic optimism in the sense that they see themselves as more likely to win than other people. They may also be prone to illusions of control—they believe they have more influence on outcomes than is the case. Some gamblers hold superstitious beliefs and use rituals or lucky charms, bet on significant numbers such as birthdays, or believe that a ticket they owned but gave up is more likely to win. For games that involve some skill elements, overconfidence in their skills can be a driving factor for gamblers.

Affect, mood, and emotions can influence how people perceive probabilities and their risk aversion. Gambling in itself is often arousing and exciting, and casinos and other gambling sites are often designed to add to the experience. Seeking positive emotions and avoiding negative emotions contributes to gambling beyond considerations of probabilities and outcomes. For example, people anticipate regret when not participating in a lottery designed to provide clear feedback (e.g., Dutch postcode lottery) and therefore are more likely to buy tickets.

Social factors can take various forms. Gambling is often heavily advertised and part of mainstream television, and some forms of gambling are seen more as a leisure activity than as betting money. On the level of social networks, gambling among peers and family members has been found to be related to gambling behavior. Finally, some forms of gambling are specifically done in groups or syndicates and provide a valued group membership.

In some cases, gambling develops a pattern similar to addiction. Pathological gambling is characterized by the need to bet higher amounts for excitement, by chasing losses, and by unsuccessful attempts to quit gambling. Pathological gambling can have severe economic, social, and psychological consequences, like bankruptcy, criminal behavior, relationship conflicts, or depression.

GAME THEORY (BEHAVIORAL/COOPERATIVE)

Game theory is an interdisciplinary study of rational strategic behavior. The 2005 Nobel laureates in Economics, Robert Aumann and Thomas Schelling, have both observed that game theory would be better described as interactive decision theory. As such, most of the literature of game theory is about "absolutely rational decision makers whose capabilities of reasoning and memorizing are unlimited" in the words of Reinhard Selten. Within game theory there are two major streams of thought, cooperative and noncooperative game theory, which can be thought of as corresponding to two different concepts of (equally perfect) rationality.

For cooperative game theory, which stems from the foundational book of von Neumann and Morgenstern, whenever rational agents can realize a mutual benefit from coordinating their strategies, they will find a way to do so. For noncooperative game theory, which originates from the work of John Nash, strategy choices are stable only if each individual chooses his or her best (or least bad) option at every stage of the game. Because of this limitation, mutually beneficial strategy choices may not be realized. Of the two, noncooperative game theory has been the more widely influential. In noncooperative game theory, there is a fairly extensive literature that substitutes bounded rationality for the more common assumption of perfect rationality, and there is also an extensive literature of experimental studies. Some experimental studies of cooperative game theory have also been done.

Noncooperative game theory is often illustrated by an example called the prisoner's dilemma, one of a broader category of social dilemmas. Another widely studied social dilemma arises in price strategies for a duopoly. This is illustrated in Table 1. Each of the two firms can choose between two strategies: maintain a monopoly price or cut the price to a more competitive level. These strategies are shown in the table as the bottom two rows, representing the two strategies for Firm 1, and the rightmost two columns, representing the two strategies for Firm 2.

Table 1. A Pricing Dilemma

First payoff to Firm 1, second to Firm 2.		
	maintain price	**cut**
Firm 1	5,5	8,0
Firm 2	0,8	1,1

In each of the lower-right four cells, two payoffs are shown: the profits to Firm 1 and Firm 2, respectively, in millions or tens of millions or on another appropriate scale.

The payoffs in the table reflect the idea that if one firm chooses a lower price than the other, the firm with the lower price will attract most of the customers; but if they both cut their prices, they will continue to split the market at the lower price. Assuming that each chooses his or her best response to the strategy chosen by the other, each will choose to cut the price, which is the dominant strategy for each firm. Thus, they will price competitively, even though both would do better charging the monopoly price. This is an example of Nash equilibrium.

The monopoly price would be the cooperative solution to this game. We should observe that the customers, who would benefit from lower prices, are not considered players in the game.

This is not quite conclusive, though, since the pricing game is likely to be played again and again. If, in each year, there is some probability that the game will be played again in the following year, it is quite possible that the cooperative monopoly price will be realized. For example, if each firm chooses its strategy according to a tit-for-tat rule, cooperation may be realized. The tit-for-tat rule is to play cooperatively unless and until the other player plays noncooperatively, and at that point retaliate by playing noncooperatively in the next round. This rule may be a Nash equilibrium in some games. On the other hand, perfectly rational players will never cooperate if both players know that their play will be terminated after a certain number of plays.

This will serve to illustrate both experimental studies and the implications of bounded rationality. From quite early in the history of game theory, researchers have experimented with repeated games (e.g., Poundstone). Typical results are that some cooperation is realized in early repetitions of the game. That is, it appears that real human beings are rational enough to recognize the possibility of some mutual gain but not rational enough to reason back from the last repetition and understand that cooperation is never the best response. In all, game theory has applications in any field in which outcomes depend simultaneously on the decisions of two or more persons.

GATES, BILL

Born: October 28, 1955, in Seattle, Washington; Nationality: American; Professional Interests: attended Harvard College; founder, Microsoft Corporation.

Bill Gates and his business partner Paul Allen founded Microsoft in 1975. Along with Apple, Microsoft's Windows software program created a new frontier in the world of personal computing software. Bill Gates became one of the first successful opponents of pirated software programs when Microsoft's first product, BASIC, was being pirated by early computer enthusiasts. Microsoft became the world's largest software business.

William Henry "Bill" Gates III was born on October 28, 1955, in Seattle, Washington, in an upper-middle-class family, the second of three children. He has two sisters, Kristianne and Libby. A voracious reader, Bill spent many hours as a child going over reference books such as the encyclopedia. When Bill turned 13, his parents enrolled him at Seattle's Lakeside School, an exclusive preparatory school. He excelled in nearly all of his subjects, especially in math and science. He also did very well in drama and English. Gates graduated from Lakeside in 1973 and scored 1590 out of 1600 on the college SAT test. Originally thinking of a career in law, Gates enrolled at Harvard University.

Early on, Gates was fully absorbed with the power of computers, spending as much time as possible learning all he could. One of his first programs was a tic-tac-toe game using BASIC language. Computer users could play tic-tac-toe with the computer as their opponent. At the age of 15, he joined Paul Allen in business and developed Traf-o-Data. Traf-o-Data was a computer program for monitoring Seattle's traffic patterns. Traf-o-Data earned them $20,000, and their business careers had begun.

While Gates attended Harvard, Paul Allen moved to Boston to work for Honeywell. In the summer of 1974, Gates joined Allen at Honeywell, where Allen showed Gates an edition of *Popular Electronics* magazine featuring an article on the Altair 8800 mini-computer kit. A small company in Albuquerque, New Mexico, called Micro Instrumentation and Telemetry Systems (MITS) made the Altair. Gates and Allen wrote to Altair, saying they were developing a BASIC software program to run their computer. The only catch was they did not have an Altair or its code. Ed Roberts, president of MITS, requested a demonstration of their work. They spent the next two months preparing for the big demonstration. Allen went to Albuquerque to conduct a test trial of their software on the Altair computer. The test was flawless and Allen was hired at MITS. Gates soon followed, leaving Harvard. The Gates/Allen partnership was officially formed in 1975 with their new company, Micro-soft. The company name combined the *micro* from micro-computer with the *soft* from software.

Their first business challenge was getting paid for their BASIC software. During the very early days, the computing world was mostly hobbyists and enthusiasts who were not in it for the money. Yet, many had been able to obtain copies of their Microsoft BASIC software, either as a premarket copy or a pirated reproduced copy. In either case, Allen and Gates were not getting paid for their efforts. They figured that approximately only 10 percent of BASIC's use was from paid copies.

In February 1976, Gates wrote an open letter to computer hobbyists saying that continued distribution and use of software without paying for it would prevent the development of better software. Gates implied that pirating software would discourage developers from investing time and money into creating more quality software. He would later use this same argument when Microsoft was accused of unfair business practices. Microsoft continued its growth with its software now in various formats. In 1978, Gates moved the company to Bellevue, Washington.

At 23, Gates placed himself as the head of Microsoft, which grossed $2.5 million in 1978. From 1978 to 1981, Microsoft's staff increased to 128 and revenue topped $16 million. Microsoft was incorporated with Gates as president and chairman of the board with Allen executive vice president. In 1983, Microsoft opened offices in Great Britain and Japan. Thirty percent of the world's computers were now using Microsoft software.

Windows was launched in November 1985 and was immediately compared to the Apple's Macintosh system, which had been introduced two years earlier. The two programs were very similar in appearance. Earlier, while Microsoft was working on making Apple-compatible products, Apple had given Microsoft full entrée to its technology. Apple ignored advice to license its software. Now a similar, but different, product was ready for non-Apple computers.

Apple threatened a lawsuit against Microsoft. Microsoft retaliated by threatening not to sell its Macintosh-compatible products. A software war was averted, but not a court case. Microsoft won in the courts, proving its products, while similar, were also quite different.

In 1986, Gates took Microsoft public with an initial public offering (IPO) of $21 per share. At 31, Gates's worth was valued at $234 million, and he became an instant millionaire. With company profitability and several stock splits, he became a billionaire in 1987. By 1999, his wealth topped $100 billion.

In 1989, Microsoft introduced Microsoft Office. This left Microsoft with a virtual monopoly on operating systems for PCs. Soon the Federal Trade Commission began to investigate the company for unfair marketing practices. Microsoft faced a string of Federal Trade Commission and Justice Department investigations throughout the 1990s. Microsoft defended itself, harking back to Gates's earlier battles with software piracy and proclaiming that such restrictions were a threat to innovation. Eventually Microsoft was able to come to a settlement with the federal government to avoid a breakup. Gates continued to run the company and go through the federal investigations through the 1990s.

On January 1, 1994, Gates married Melinda French in Hawaii. Only a few months later, Gates's mother was diagnosed with breast cancer. She died in June 1994. In 1996, Bill and Melinda's first daughter, Jennifer, was born. In 1994, Gates and his wife established the William H. Gates Foundation dedicated to supporting education, world health, and investment in low-income communities. In 2000, the couple combined several family foundations to form the Bill and Melinda Gates Foundation. They started out by making a $28 billion contribution to set up the foundation.

In 2000, the leadership of Microsoft changed hands. Bill Gates removed himself as CEO and handed the leadership to his college friend, Steve Ballmer, who had joined Microsoft in 1980. Gates stayed on as chief software architect. He remained chairman of the board, and his time steadily drifted to more and more work for the Bill and Melinda Gates Foundation. Gates said he was removing himself from work at Microsoft to spend time on the foundation.

Time magazine named Gates one of the most influential people of the 20th century. The magazine also named Gates and his wife, Melinda, as the 2005 Person of the Year. Gates holds several honorary doctorates from universities throughout the world and an honorary Knight Commander of the Order of the British Empire by Queen Elizabeth II. In 2006, Gates and his wife were awarded the Order of the Aztec Eagle by the Mexican government for their philanthropic work throughout the world in the areas of health and education.

In February 2014, Gates announced he would be stepping down as chairman of Microsoft in order to move into a new position as technology adviser. In addition to his transition, it was reported that 46-year-old Satya Nadella would replace longtime Microsoft CEO Steve Ballmer.

GENERAL MOTORS BANKRUPTCY, 2009

The unlikely bankruptcy of General Motors (GM) was one of the largest (and the largest of an industrial company) in American history and one of the largest in the world. Officially, it ranks as number four after Lehman Brothers, Washington Mutual, and WorldCom because GM had been shrinking for two decades before its bankruptcy. GM and Chrysler's decline to bankruptcy had deep roots, starting with the flood of imports in the 1970s, which steadily eroded the market share of the automotive giants. The bankruptcy filing by GM confirmed that America's deindustrialization had reached the top of the food chain.

GM had negotiated long-term reductions in wages with the United Auto Workers, but nothing helped in their struggle with imports. The company had not made a profit since 2004. The 2008 Great Recession and financial crisis caught the company in a cash-short position, which forced its bankruptcy filing on June 1, 2009. In the filing, GM reported $172 billion in debt and $82 billion in assets. The bankruptcy would be far from normal as the deal was prepackaged, that is, controlled by the federal government and financed by taxpayers. The American taxpayers ended up with about a 60 percent ownership in GM.

The real root of the problem was typical of the deindustrialization of American industry. GM lost market share while its pension and health care costs for employees soared. In 2005, such costs were estimated at $1,600 per car. GM had struggled through the 1990s with some major setbacks and a few successes. The 1990s actually ended on a high note; both GM and Ford gained market share and profitability with sales of light trucks and sport-utility vehicles. GM's stock price soared to $80 a share on huge profits.

The recession of the early 2000s, however, exposed a basic weakness in GM that had been growing for years. The rise in U.S. interest rates, the stock market drop, and increasing costs for its retirees put GM into a pension fund crisis. The pension fund was underfunded by $15 billion in 2003; GM responded by fully funding the pensions to avoid bond creditors downgrading its rating. Losses started to mount in the mid-2000s. GM had been selling units of the company, such as General Dynamics, Hughes Electronics, and Delphi, for cash to help keep GM solvent.

Still in 2005, GM was a huge company with sales of $193 billion and a payroll near $8 billion. But it was spending almost $5 billion a year on health care for retirees, which was part of a major structural problem below the surface. By 2006, the company was short of cash, and the unthinkable rumors of bankruptcy began. GM was able to raise $14 billion in 2006 by selling 51 percent of its highly profitable financing arm, GMAC, to Cerberus Capital Management. GM, whose stock had fallen to $19 a share, managed to improve in 2006, and the company remained afloat. In 2007, GM sold Allison Transmission for $5.6 billion.

A fluctuating stock market changed the funding ratio of GM's pension funds while market share declines continued to rack up losses for the company. GM continued to sell assets, close plants, and restructure. Its bond ratings declined, making it more difficult to raise cash. The 650,000 retirees continued to be a problem, while competitors like Toyota and Honda had few legacy costs. Regardless, Toyota and Honda opened nonunion plants in the United States with lower wages and minimal employee benefits. The Japanese plants in America purchased political capital in Washington for these Japanese companies as well.

Finally, the rise in gas prices to $4 a gallon in 2008 caused GM truck sales to plummet. Chrysler was experiencing similar problems by 2007 and had been taken over by Cerberus Capital Management. In October 2008, Cerberus proposed a merger of GM and Chrysler, but the deal fell through. GM was now losing $3 billion a month as the economy came to a standstill. The Senate refused to give the company a bailout loan in early December 2008. The Bush administration managed to give GM the money from the Troubled Asset Relief Program, but the relief was too late for GM, as its burn rates were now $5 billion a month.

Under the incoming Obama administration in late January 2009, efforts to save GM accelerated. The financial crisis had eroded GM sales to the point that it was hopeless to generate the cash needed to operate. In late March, the U.S. Treasury committed money to a fund to allow the government to guarantee GM's warranty liabilities. GM entered bankruptcy in June 2009 with the government in full charge of the details.

The government-managed GM bankruptcy would overturn 200 years of bankruptcy law. It devalued the assets of bondholders, who, under settled U.S. bankruptcy law, should have had first claims on GM's assets. At the same time, because of the large stock ownership position of the automaker's union, stockholders were given preferred treatment. Bondholders received pennies on the dollar, and lawsuits are still pending over the arrangement, most of them from government unions whose pension funds had large amounts of GM bonds. Both the United States and Canada infused money into the bankruptcy restructuring. The United Auto Workers held on to most of their wages and benefits in the deal. Under normal bankruptcy, the union contract would have been voided and the parties required to negotiate a new contract. The government was spared a takeover of the pension fund, which would have happened under normal bankruptcy.

To date, the results of the GM bankruptcy have been mixed, but jobs were saved as well as most of the American auto industry. Money the taxpayers loaned to GM has been paid back, although the real amount is in question. GM is now much leaner, and the union remains a major stockholder in GM. In fairness, the United Auto Workers proved much more flexible than did other heavy-industry unions, such as the United States Steel Workers in the decades of deindustrialization. GM was scaled down to its core brands of Chevrolet, Cadillac, Buick, and GMC. Worldwide, it has once again become competitive with Toyota, which suffered from quality problems and recalls shortly after the GM bankruptcy. GM has developed a strong base in the Chinese market. It has also moved aggressively into electric and hybrid cars and plans to move into the subcompact market.

GEORGE, HENRY

Born: September 2, 1839, in Philadelphia, Pennsylvania; Died: October 29, 1897, in New York City; Nationality: American; Professional Interests: political economy, editor, publisher, social reformer; Major Work: *Progress and Poverty: An Inquiry into the Cause of Industrial Depressions, and of Increase of Want with Increase of Wealth: The Remedy* (1886).

Henry George was a political economist who promoted the reforms of taxation and trade to benefit society as a whole. He developed his philosophy from his life experience without formal education or class privilege. His ideas were embraced by vast numbers of followers worldwide and are taught in "Georgist" schools of economics today. George argued that taxes and the government banking system favored the few at the expense of the masses and demanded social justice for citizens without regard to race and sex. He believed he had found a method of spreading wealth and dedicated his life to sharing it with the world. George died in 1897.

Henry George was born on September 2, 1839, to Richard S. H. George and Catherine Pratt Valliance George in Philadelphia, Pennsylvania. The second of 10 children, he quit school at age 15 to work in an office and aboard a ship bound for India and Australia. He later wrote about seeing small numbers of wealthy Indians compared to the majority of poor citizens. Upon his return home, George learned to set type. When the printing business declined, he was hired to work aboard a ship sailing to California. When he arrived on the West Coast, he worked as a typesetter before joining his cousin's mining store in British Columbia on the Fraser River.

In 1858, his enthusiasm for gold prospecting waned and he returned to San Francisco. After a time of struggling financially, he found a job as a newspaper printer and writer. A speaker he heard on the topic of protectionism challenged his thinking about the negative impact of protectionism on individual prosperity. The editor of two small newspapers, George began to promote the benefits of free trade. The tariffs supported by protectionists kept prices for goods high, enriching a few at the expense of the majority. George found growing support for his viewpoint and was encouraged to run for a state office. Although he lost his first election, he was gaining a following for his ideas.

Soon another idea stirred his conscience: land use reform. The common folks, barely eking out a living, outnumbered the few land speculators who were enriched by railroad and other developments. The seed of his best-known work, *Progress and Poverty*, began with a magazine article, published on September 18, 1877.

A year and a half later, George completed his first book and self-published the first 500 copies. The thesis of the book was that it was immoral to charge and collect rents on raw land that individuals had not created. George submitted that what nature provided could not be owned by individuals. People would own only what they themselves produced. George concluded that poverty was caused by the private ownership of land, which resulted in wealth for a small minority. He observed that land values depended on someone's need for the land and believed that this policy threatened democracy.

A single tax on land, not on improvements to land, was the only tax morally justified in George's view. He believed that all other taxes should be abolished and that since landowners did nothing to create the value of the land they owned, they should not extract increasingly higher rent from laborers. He concluded that the land's value was created by the need of someone to use it.

Common working men found a hero in Henry George, and they rallied around him. Additional volumes of his book were printed and eventually sales surpassed all other volumes except for the Bible. At 42 years old, George became world famous and a popular public speaker on the topic of political economy. Europeans and Australians invited him to speak.

Renowned European economist Alfred Marshall debated George, who was considered a leader inspiring great societal changes beyond the United States. Proponents of land reform arose, empowered by the Henry George movement. He was warmly welcomed by the British and the Irish working class and social reformers. The well-known scientist Alfred Russell Wallace touted the significance of *Progress and Poverty*. George's public policy influences were popular as far away as Australia and New Zealand.

Politicians and union leaders desired his affiliation. The United Labor Party, a sector of Democrats who opposed the Tammany Hall political machine, supported his candidacy for mayor of New York City in 1886. They presented a petition signed by over 30,000 New Yorkers that helped convince George to run. He lost to Democrat Abram Stevens Hewitt and beat Republican Theodore Roosevelt.

Although George was maligned as a socialist and a communist, he participated in political campaigns to spread his message and appeal for broadened support of his ideology. As editor of the New York–based paper *The Standard*, George continued to educate the populace about the morality of his brand of economics. He published *The Condition of Labor*, *The Science of Political Economy*, and *Protection or Free Trade*, which became a part of the Congressional Record of 1890. He used every opportunity to spread his message, traveling and debating.

In George's final campaign for mayor of New York, in 1897, he represented his former affiliation, renamed the Party of Thomas Jefferson. He was in poor health but decided to press on. The campaign would allow him to influence more people to consider his views on economic practices that he was convinced would alleviate the suffering of the impoverished.

Henry George's ideas are still discussed and debated today. In many cities, Schools of Henry George exist to continue teaching his philosophy of economics. Because he was one of the common folk, with no formal education and no influential family, and because of his moral basis to fight for equality, justice, and fairness, the appeal of his policies endures.

Henry George died days before the election on October 29, 1897, in New York City.

GREAT NATIONAL RAILROAD STRIKE, 1877

In 1877, the nation was still recovering from the panic of 1873, and the national unemployment rate was higher than 20 percent throughout the United States. The two biggest employers in the nation were the railroad industry and the steel industry. The depression of the 1870s had squeezed the profits of the nation's railroad companies. The Pennsylvania and the Baltimore & Ohio railroads decided to lay off thousands and asked the remaining brakemen and firemen to take a 10 percent pay cut while doubling their workload with "double-headers" in which two trains and two engines (two locomotives and 34 cars instead of one locomotive and 17 cars) were combined but manned by a single crew. These actions by the railroad led the workers of the Pennsylvania Railroad to call for a strike on July 14, 1877, that spread from Maryland and West Virginia to Chicago and farther west to California.

The railroads thought they had the upper hand in this dispute because railroad wages were the highest in the nation, and the nation was in a depression. Nonetheless, the workers were able to unite, and the nation experienced its first national strike, which shut down most of the country for weeks. The railroad workers were making \$5 to \$6 a week; in comparison, steelworkers averaged \$3 a week. Most railroad workers, however, were only getting work six months of the year. A major source of the conflict was the poor economy, which was hurting the companies, their investors, and workers. Yet the wage cuts for rail workers arrived along with the news that the railroad companies were increasing dividends for investors. This, more than anything, angered the workers. The idea that investors were being paid increased dividends while thousands were unemployed or getting pay cuts would gain the workers public support. In addition, the public blamed the railroads and associated corruption for the nation's depression.

The rail strike started on July 14 at Martinsburg, West Virginia. On July 16, the strike spread to Camden Yards outside Baltimore, where workers demanded that wages be reinstated. The strike moved quickly along the line to West Virginia and farther west. At Cumberland, Maryland, the strike turned violent. In Baltimore, 10 strikers were killed as they faced off against federal troops. On July 19, workers on the Pennsylvania Railroad joined the strike and took control of the Pittsburgh station and the switches. On the morning of July 20, no trains were moving in Maryland, Pennsylvania, West Virginia, Ohio, and Illinois, completely shutting down East Coast commerce.

During the peak of the riots in Baltimore, gangs, socialists, and the unemployed joined the strikers. In major cities, the unemployed flooded the ranks of the strikers, raiding railroad cars for food and goods. Pittsburgh became the center of violence because of its railroads and depressed industries. The strike soon spread to another center of unemployment, Chicago, but its epicenter was Pittsburgh.

The riot in Pittsburgh started on July 21, 1877, as the first double-headers arrived at the Pittsburgh station. Rioters overturned locomotives, pulled up tracks, and set the Union Depot on fire. Pittsburgh erupted in violence, and the state militia arrived. Tracks were torn up and cars burned. The unemployed and street gangs joined in the riot, the looting of stores started, and shooting broke out on both sides.

By the end of the day, 20 people had been killed, including the sheriff, and hundreds of wounded were lying on the sidewalks. Pittsburgh's Catholic bishop walked the streets, giving last rites to the wounded; another nine would die in the streets. The Pittsburgh Station was torched, and more than 1,000 freight cars of products were looted as other citizens joined the riot. In all, 1,383 freight cars, 104 locomotives, and 66 passenger cars were destroyed in Pittsburgh, and 39 buildings were burned to the ground.

President Rutherford Hayes rushed in federal troops to help the overwhelmed state militia. Fear seized the city. Pittsburgh's damage came to more than $5 million. The strike moved west into Ohio, where the governor encouraged the formation of private police forces to protect property and put militia and heavy machine guns on the trains.

Chicago also had significant riots and property damage, and the death count reached 20. A mob of more than 20,000 terrorized Chicago, and the city was totally closed down. Rich neighborhoods hired police to secure their homes and gardens. It was the perfect storm as the recession, a heat wave, the unemployed, and strikers came together on July 21, 22, and 23. The strike went on for 45 days before total peace was restored. Eventually the federal and state militia prevailed.

With the tracks torn up between Baltimore and Pittsburgh and Chicago, the nation's industry came to a standstill. Other disgruntled workers joined the strike: coal miners in Illinois and steelworkers in Pittsburgh. The riots had spread to the West Coast by July 24, and violence erupted in San Francisco when unemployed Chinese immigrants joined in the strike. The country had never known such violence except in war and would never see such civil unrest again until the civil rights riots in the summer of 1967.

Initially, the railroad workers had widespread public sympathy and support. As violence increased and the riots evolved, however, the workers lost that support as well as the support of the press, which had initially supported the strikers, because of the increasing violence and the inclusion of socialists and communists in the movement.

Still, there was little sympathy for the railroads. They had won the wage battle but at a great cost to equipment and property. The nation realized that the strike had a lot to do with the high unemployment rate. Many cities started funds to employ the unemployed for service work to take people off the streets and keep them from joining such riots.

The Great National Railroad Strike would change the course of American unionization. Unions learned the importance of better organization. They also learned the importance of public opinion. The public wanted no part of the socialist movement that was spreading violence across Europe. The railroad companies changed their strong-arm approach to employee grievances, realizing that the property cost of such strikes far outweighed the wage concessions. Within five years, the major railroads had injury insurance, unemployment insurance, and pensions for their workers. The railroad companies also added air-brake technology to eliminate brakemen (one brakeman was previously needed per two cars) and to allow for double-headers. Mayors and capitalists learned to pool money to help ease the pain of unemployment in cities. The violence of the strike also slowed a rising popular movement toward European-style socialism.

GULF OF MEXICO OIL SPILL, 2010

The 2010 Gulf of Mexico oil spill is often called the BP (British Petroleum) oil spill or *Deepwater Horizon* oil spill. The spill started on April 20, 2010, with the blowout of a drilling rig in the Gulf of Mexico. Of the 126 crew members on the platform, 11 were killed and 17 injured. It would take until July 15 to cap the leak. The total spill was estimated at nearly 5 million barrels, making it the largest oil spill on record. It covered more than 85,000 square miles of ocean, and oil washed up on around 500 miles of coast in Louisiana, Mississippi, Alabama, and Florida. The impact on the overall U.S. economy was massive. The costs to BP to date are around $43 billion, which includes direct costs such as spill response, containment, economic loss claims, and penalties.

In 2010, in response to the spill, President Obama enforced a moratorium on Gulf oil drilling, but it was overruled in federal court in October of that year. The moratorium forced thousands out of work in the oil industry. The fishing industry was also hit hard by the spill because contamination of the ocean forced closures. More than 36 percent of the Gulf was closed to commercial fishing at a cost to the industry exceeding $2.5 billion. Estimates of lost tourism dollars ranged from $20 to $30 billion. The loss of 400,000 tourism jobs also represents a revenue loss of more than $30 billion.

The leaking well was located 41 miles off Louisiana. It was estimated that oil was spilling into the Gulf at a rate of 62,000 barrels a day. The rig itself was lost at a cost of $600 million in the first four days. The leak would continue as several efforts to cap the well with robots failed. Another dome cap would also fail. Capping the leak soon created a difficult technical problem. Many efforts for containment proved unworkable, and efforts to place booms in the water to protect the coast were also ineffective. Burning the oil was restricted because of environmental concerns. The cleanup required some burning (flaring) and skimming of oil, but most of the cleanup required dispersants, which created health and environmental problems of their own. Louisiana even proposed building its own barrier reefs. At its peak in July, 47,000 people and 7,000 vessels were involved in the cleanup. On June 16, 2010, President Obama and BP Oil announced the formation of the Gulf Coast Claim Facility, a $20 billion fund set up by BP to address natural resource costs, response costs, and individual compensation. By July 15, the well was successfully capped. Still, criticism of the federal government continued as the oil drilling and fishing industries were still under moratoriums. By the end of July, BP's stock had dropped 40 percent, and the company reported a quarterly loss of $19 billion. BP's CEO, Tony Hayward, was forced to resign after making remarks deemed insensitive.

The government moratorium on offshore drilling had a heavy impact on 58,000 oil and 250,000 oil-related jobs in Louisiana, which accounted for more than 15 percent of Louisiana jobs. Many foreign-owned oil rigs left the Gulf for good. Oil prices and gasoline prices skyrocketed. Gasoline prices went up $1 a gallon, breaking the $3 a gallon mark throughout the United States. One year after the spill, gasoline prices were averaging $3.83 a gallon. Prices had been $2.73 a gallon when President Obama ordered the moratorium on oil drilling in the Gulf.

The fishing industry of the Gulf was hit hard in the short term. Shrimp, crab, and oyster fishing was restricted for fear of contamination. Estimates of reductions in fishing range from a 15 to a 40 percent decline in the year of and the year after the spill. Although volume was off, prices skyrocketed, making revenues actually higher for the fishing industry, so in hindsight the estimated $2.5 billion loss to the fishing industry seems high. The losses to tourism exceeded $15 billion, but much of the damage was caused by overreaction. Many prime beach areas never saw the predicted heavy oil and tar cover; however, tourists clearly avoided the area for several years. As was the case with most recent disasters, the spill became a major media event, which created its own set of problems and public expectations.

BP and related companies faced further liabilities via civil litigation. The major lawsuits involved the rig owner Transocean, cement maker and builder Halliburton, and blowout manufacturer Cameron International. These individual lawsuits included a wide range of charges that totaled in excess of $40 billion by the end of 2011. BP was able to settle with the plaintiffs for around $8 billion. Later in 2012, the Justice Department sued BP for gross negligence. Under the Clean Water Act alone, the federal government could impose fines of $1,100 to $4,300 per barrel spilled. BP would settle this suit for $4.5 billion, which was the largest settlement of its kind in U.S. history. BP was also found guilty of criminal charges and paid a $4 billion fine. Transocean was also sued by the Justice Department and settled for $1.4 billion in fines. Halliburton would pay a fine of $200,000. Thus far, BP's still-evolving bill consists of $19 billion for cleanup, $20 billion in claims to individuals and businesses, $4.5 billion in fines, and a possible $5 billion in state suits. The overall costs to BP reduced it from the world's second-largest oil company to the fourth position and pushed it to the brink of bankruptcy.

HARDIN, GARRETT

Born: April 21, 1915, in Dallas, Texas; Died: September 14, 2003, in Santa Barbara, California; Nationality: American; Major Work: "The Tragedy of the Commons" (1968).

Garrett James Hardin was a prominent ecologist who enjoyed a long and distinguished academic career at the University of California, Santa Barbara. He is best known for his 1968 essay, "The Tragedy of the Commons," which called attention to the dangers associated with population growth and environmental degradation.

Hardin was born in Dallas, Texas, on April 21, 1915. He was afflicted by polio at an early age, which left him with a shortened right leg and the need to use crutches and then a wheelchair later in life. Physical limitations no doubt played an important role in his desire to achieve success through academic pursuits. Hardin's father was a sales representative for the Illinois Central Railroad, an occupation that forced the family to relocate periodically. His grandfather's 160-acre farm in Missouri was a source of stability and a place where he spent many summers during his formative years. It has been suggested that Hardin's observations of the farm's cat population influenced his views on the need for human population control.

Hardin received a bachelor's degree in zoology from the University of Chicago, where he was mentored by ecologist W. C. Allee, who warned about the perils of overpopulation. Hardin went on to earn a doctorate in microbiology from Stanford. At Stanford he met and married Jane Swanson in 1941. He joined the faculty of the University of California at Santa Barbara in 1946, where he was known as a passionate and thought-provoking teacher. Hardin retired in 1978 after 32 years of service to the university.

Hardin published over 300 scholarly articles and more than 20 books in his lifetime, the last when he was in his eighties. Many universities used his introductory biology textbook, *Biology: Its Human Implications* (subsequently retitled *Biology: Its Principles and Implications*). Hardin's continued productivity well into retirement earned him the Constantine Panunzio Distinguished Emeriti Award from the University of California system in 1997.

Hardin's ecological training and insight led him to believe that unchecked population growth will lead to environmental devastation. Economists recognize the dilemma Hardin presents as the conflict between what is in an individual's self-interest and what is best for society as a whole. Self-interested individuals will use common pool resources (like the environment) as long as they individually benefit from that use, ignoring the damage that their use imposes on the sustainability of the resource.

His writings and lectures addressed the themes of morality and sustainability and influenced policy debate concerning many controversial topics, including population control, immigration, foreign aid, and abortion.

HAZARDOUS WASTE

Modern societies are pretty wasteful. According to recent estimates, on average Americans generate about five pounds of waste each day per person for a total of around 300 million tons a year. While all waste can cause environmental problems, some waste, known as hazardous or toxic waste, has been singled out for its potential to cause significant environmental damage. If left unregulated, hazardous waste can pollute groundwater, rivers, and lakes; contaminate soil; and kill people, livestock, and wildlife.

While the legal definition of hazardous waste varies across countries, hazardous waste generally includes any discarded material that is toxic, reactive, or flammable and poses a hazard to the health of humans, other living organisms, or the environment. As you might imagine, this definition covers a wide range of materials that are generated by a lot of different companies and processes. This means that big chemical-intensive companies such as DuPont or Exxon are not the only companies that generate hazardous waste. Much smaller, local companies, such as the neighborhood service station, dry cleaner, or even your dentist, also generate hazardous waste. In fact, you have probably generated hazardous waste yourself, since leftover paint, some discarded cleaning products, and used batteries all qualify as hazardous waste.

Because waste has no intrinsic value (if it did, we would not waste it), people who generate it want to get rid of it as cheaply as possible. Before hazardous waste was regulated in the United States, most industrial generators just dumped it on unused land. Since many hazardous constituents are persistently toxic, unregulated waste dumps have resulted in damages long after the material has been dumped. Have you ever heard of Love Canal? Probably the most famous unregulated hazardous waste dump, Love Canal was used as a chemical waste dump for a decade before being redeveloped as a neighborhood school site. Twenty years after the dump was closed, unusually heavy rains caused parts of the dump to sink, making the contamination of surrounding groundwater, surface water, and soil apparent. While the full effects of the contamination cannot be easily measured, residents of the area had unusually high rates of cancers, miscarriages, and birth defects. Eventually over 1,000 families were relocated from the area; the cleanup of the Love Canal site cost over $60 million.

Hazardous waste presents a classic case of negative externalities. Unless prohibited by regulation, a generator will decide how and where to dispose of hazardous waste based on private cost, ignoring the effect of that decision on human health and the environment. Economic theory provides three primary solutions to such negative externalities: command-and-control regulation, Pigouvian taxes, and the assignment of property rights. All of these solutions are currently used to minimize the social costs of hazardous waste.

Command-and-control regulation is used in many countries to minimize the externalities associated with hazardous waste disposal by imposing standards for the safe management of hazardous waste. Both the United States and the European Union regulate hazardous waste from the cradle to the grave, that is, from the point of generation until final disposition. Their regulations require facilities that have the potential to generate hazardous waste to test any likely waste streams and if the waste is determined to be hazardous, track, store, and manage it according to particular standards. Such requirements are designed to decrease the potential harm that hazardous waste can cause and thus the external costs imposed by hazardous waste. Additionally, complying with regulatory requirements significantly increases the private cost of hazardous waste generation and provides incentives for companies to reduce the amount of waste they generate in the first place. Of course, by increasing the cost of legal waste management, command-and-control regulation may indirectly encourage illegal disposal. Thus the enforcement of hazardous waste regulations plays a critical role in their practical effect.

One shortcoming of command-and-control regulation of hazardous waste (and command-and-control regulation in general) is that the regulations are standardized rather than tailored to particular waste streams or generators even though the potential for harm will vary significantly based both on the characteristics of the waste stream and the location in which it is managed and disposed. In some cases, command-and-control regulations may be too stringent from the perspective of maximizing social welfare, while in other cases the regulations may be too lenient.

An alternative solution to the negative externalities associated with hazardous waste is to impose Pigouvian taxes on hazardous waste. In theory, such taxes can internalize the costs of hazardous waste disposal and thus provide incentives for generators to reduce the quantity of hazardous waste they produce in the first place. When the costs associated with hazardous waste increase, generators may find it cost-effective to change their production processes, use less toxic inputs, or find ways to recycle by-products. Of course, imposing taxes on waste generation or disposal might also lead generators to conceal the amount of waste generated through illegal disposal or dumping.

A final solution to the negative externalities imposed by hazardous waste is the assigning of property rights by imposing legal liability for any damages caused by hazardous waste on the generator of that waste. In theory, assigning legal liability to generators forces them to fully internalize the costs of their waste. This should lead to more careful management of the hazardous waste as well as a reduction in the amount of waste generated in the first place. Additionally, imposing legal liability helps to compensate the victims of pollution, something that neither of the other two solutions accomplishes.

One concern with using legal liability to control for externalities is that generators facing large damage payments might go bankrupt rather than pay a large settlement. If a generator's liability is capped at some level, the generator will not fully internalize the costs associated with its waste and thus legal liability may provide only a partial solution. However, governments can strengthen the liability system by requiring generators to either carry insurance or have the ability to pay reasonable damage awards. For example, in the United States, hazardous waste management facilities are subject to financial responsibility requirements.

While it is difficult to determine the effect of individual hazardous waste regulations as most countries use a number of different policy approaches simultaneously, it is clear that the regulations have made a difference. For example, in 1980, in the United States, there were over 50,000 hazardous waste generators, approximately 300 million tons of waste generated annually, and 30,000 unregulated facilities that managed that hazardous waste in some manner. By 2000, only about 20,000 businesses generated approximately 40 million tons of hazardous waste and the 2,000 hazardous waste management facilities were all regulated by the Environmental Protection Agency.

HEALTH AND THE ENVIRONMENT

The link between human health and the environment is important for at least two reasons. First, environmental pollution is a significant contributor to the global burden of disease. The exact numbers are uncertain, but environmental contaminants and exposures are known to cause a wide range of adverse health effects, including many respiratory, diarrheal, and cardiovascular illnesses and cancers. Second, health concerns are one of the main reasons people care about environmental quality. The public certainly has other environmental concerns, such as protecting natural areas and avoiding the extinction of plant and animal species, but health threats are often a main source of worry.

For these reasons, understanding how the environment affects human health and how these threats can be best managed has been a priority for many researchers and policymakers. Environmental economics contributes to this understanding by addressing the following types of questions: How large are the costs and burden of illness from environmental exposures? What are the benefits and monetary value of preventing illness through policies that improve environmental quality? How are these costs, benefits, and the effectiveness of environmental policies affected by human behaviors?

Answering these questions requires models that integrate environmental science and economics. For example, estimating the loss in human well-being due to health effects from air pollution involves two main parts. The first part is estimating the relationship between elevated air-borne contaminant levels and the increased number (or severity) of illnesses. This concentration-response relationship is typically based on results from environmental epidemiology or toxicology studies; however, it may also require an understanding of how humans change their behaviors in the face of higher pollution levels. The second part is estimating the monetary equivalent of the loss in human well-being due to illness. As with other areas of nonmarket valuation, economists typically rely on willingness to pay measures as the best representation of this monetary equivalent. To answer the questions posed earlier, environmental economists often rely on a household production framework. This framework recognizes that households use their own resources to produce better health outcomes for themselves. First, they engage in averting or defensive behaviors to protect themselves against external harms, such as environmental pollution. For example, if groundwater monitoring indicates higher than usual contaminant levels, households with private wells may purchase bottled water or filtration systems. Second, they engage in mitigating behaviors to reduce the harm and discomfort from illness, for example by buying medicines or staying at home from work. Despite these two types of self-protective behaviors, households may still experience disutility (i.e., pain and suffering) from illness.

Based on this framework, there are four main components for valuing (in monetary terms) the relationship between health and the environment. For a given change in environmental conditions, they involve changes in averting/defensive expenditures, mitigating (e.g., medical) expenditures, productivity losses (e.g., lost income/wages due to illness), and disutility from pain and suffering.

Health and environmental economists have developed a number of valuation approaches that can be used to estimate one or more of these components. Cost-of-illness methods focus on direct medical and other treatment costs (mitigating expenditures) and, in many cases, on indirect costs (productivity losses). They have been widely applied, largely due to data availability, but their main limitation is an inability to capture values associated with changes in pain and suffering. Averting behavior methods focus on the first component. If they only measure changes in averting expenditures, then, like the cost-of-illness method, they are also limited in scope. However, if they are used with mitigating expenditures to estimate a health production function, they are capable of incorporating all four components of value. Unfortunately, this combined approach has rarely been used due to its relatively difficult data and technical requirements.

Another approach is to use survey-based stated preference approaches, such as contingent valuation or choice experiments. In health value applications, these methods present survey respondents with hypothetical scenarios involving trade-offs between money and health. Responses are then used to estimate respondents' willingness to pay for better health-related conditions. One of the main advantages of these methods is that they can be used, in principle, to capture all four components of value. However, as with other stated preference applications, one of their main drawbacks is the hypothetical nature of the trade-offs and the resulting difficulty in validating responses.

Economic analysis methods can also be designed to address other unique features of environmental health. One such feature is the large variety of health outcomes associated with environmental exposures. These outcomes vary in several dimensions, including the duration, frequency, latency, and severity of illness. Environmental illnesses include a wide range of acute and chronic conditions, both of which can vary in severity from low consequence to high severity and even fatal conditions. Some conditions, such as cancer, can also involve long latency periods between the time of exposure and the development of disease. Using stated preference surveys, in particular, different levels and combinations of these illness attributes can be communicated to respondents and then separately valued.

A second feature is that environmental exposures often result in a risk of illness, rather than a certainty of illness, for exposed individuals. Moreover, policies that reduce environmental contaminants tend to reduce these risks for individuals, rather than to reduce the severity, duration, or other attributes of illness. For this reason, it is important to understand how individuals value reductions in the probability of adverse health outcomes, including death. In addition to using stated preference methods, a variety of revealed preference methods have also been used to explore individuals' trade-offs between money and health risks. Hedonic wage-risk studies, for example, use evidence from labor markets to determine the amount of additional compensation individuals require for taking jobs with higher risks of death. Other studies have examined purchases of safety goods, such as bicycle helmets and fire detectors.

A third, and final, feature is that, when faced with lower levels of contaminants in the environment, individuals may respond by reducing their averting behaviors. For example, after improvements in outdoor air quality, individuals may spend less time indoors where the air may still be cleaner. In these cases, the health improvements or risk reductions are less than they would be without the change in behavior. As previously discussed, accounting for changes in averting behaviors is important for fully valuing improvements in environmental quality. It is also essential for understanding the net effect of policies on environmental health.

HEALTH INSURANCE

Health insurance helps consumers pay for medical costs. As former Minnesota governor Jesse Ventura stated, "Health insurance should be a given for every citizen." Historically, health insurance in the United States has been optional, with no requirement or law to purchase a health insurance policy. With the passage of the Patient Protection and Affordable Care Act (ACA) (2010), the goal was for all citizens to have health insurance access.

Health insurance covers the insured for medicine, visits to the doctor and emergency room, hospital stays, and other medical expenses. The amount and type of coverage, the co-pay charges (portion paid by the insured), the deductible (how much the insured must pay before the insurance contributes), and cost are determined by the health insurance policy.

Understanding Health Insurance

Health insurance makes paying for health care costs more affordable. With a health insurance policy, consumers pay a portion of their total health care costs. Consumers sign up for a policy, either on their own, through the U.S. government or state marketplace, or through their employer. This policy is similar to other types of insurance. It describes in detail the medical coverage provided as well as the co-pays the consumer must pay for treatment. Policies vary from high-deductible plans to more extensive ones that cover vision and prescription drugs. The policy costs and co-pays also depend on the policy details.

After purchasing the health insurance policy, the individual joins other members in the same plan. All health insurance plan members belong to a risk pool. Individuals in the risk pool consist of those higher-risk participants who are in poor health (likely to need a lot of medical care) and lower-risk individuals with good health. The insurer takes into account the risk profiles of its members and calculates how much it will cost to pay for the expected medical expenses of the plan participants. Those calculations are used to determine the per-member monthly rate or premium charge.

Health insurance provides a shared-cost format. The plan member pays a monthly premium—sometimes the employer pays all or part of the premium on behalf of the employee—and the member also pays additional out-of-pocket costs for service received. The plan member's out-of-pocket fees may be a co-pay, deductible, and/or coinsurance.

A co-pay is a predetermined amount the consumer pays for doctor and emergency room visits and for prescription medicines. This is different from coinsurance, where the insured pays a percentage of the cost of the medical care. An annual deductible is a predetermined out-of-pocket amount the insured is required to pay before the insurance company pays for any medical claims.

Types of Health Insurance Plans

There are hundreds of different health insurance plans. This section will discuss the three most common types of health plans.

Health maintenance organizations (HMOs) frequently charge lower monthly premiums and out-of-pocket costs in exchange for allegiance to a predetermined group of medical providers. Normally, HMO participants have a primary care physician. Any referrals and treatment needed from specialists must go through the gatekeeper primary care physician.

Preferred provider organizations (PPOs) offer more flexibility than HMOs, along with higher costs. A PPO offers a network of member doctors, specialists, and hospitals. PPOs do not require the member to go through the primary care physician for a referral to a specialist. The plan member may see in-network providers for a lower cost than out-of-network medical professionals.

Consumer-directed health plan (CDHPs), often called high-deductible plans, usually require greater initial out-of-pocket expenses than the HMO or PPO with lower monthly premiums. For example, the high-deductible plan may require consumers to pay up to $2,500 or $5,000 out of pocket before the health plan payments kick in.

Health savings accounts (HASs) are tax-advantaged accounts (with special tax benefits regulated by the Treasury Department) available to participants with CDHP plans. These accounts allow users to pay for medical care with pretax dollars. This type of plan may be offered in conjunction with an HMO or PPO.

Government Health Insurance Programs

The government offers public insurance for the elderly and lower-income members of the population. Medicare is the federal government health insurance program for citizens age 65 and older as well as the disabled. Medicaid, jointly funded by the federal and state governments, is the health insurance program for the poor. The State Children's Health Insurance Program (SCHIP) is a special type of health insurance for children. Even if parents do not meet income thresholds for Medicaid, SCHIP ensures that children's medical needs are covered. See Medicare and Medicaid entries for more detailed coverage.

HEDGE FUND

Hedge funds are private pooled funds that make investments in equities, bonds, and derivatives. They are similar to mutual funds in that they are pools of capital collected from investors and the capital is invested by a dedicated investment team, consisting of portfolio managers and analysts, on behalf of the investors. Hedge funds are less regulated than mutual funds and do not have to disclose their NAV (net asset value = sum of value of all investments in the fund less expenses) on a daily basis. They are also not traded on a stock exchange like stocks and ETFs. Investors can invest in hedge funds by directly getting in touch with the fund team.

In order to invest in a hedge fund, high net worth investors have to meet certain income and assets criteria. Before investing in a hedge fund, prospective investors complete a worksheet detailing all of their assets, including stocks, real estate, physical commodities (such as gold), commodity contracts, and derivatives.

There are two categories of private investors: accredited investors need a net worth of at least $1 million; qualified purchasers need $5 million in investments excluding a business and primary residence. There may be other requirements to invest, such as a commitment to leave funds in the fund for an allotted time period.

These guidelines have been put in place to discourage small investors from putting all their savings into hedge funds. Ordinary investors could lose all their savings if they invested in a hedge fund strategy that they do not fully understand or are not able to liquidate from when they need to. Hedge funds are riskier than mutual funds given their lack of liquidity (not traded on an exchange) and their lack of transparency (hedge funds do not have to report their asset values or the underlying holdings on a daily or weekly basis). All of these requirements are enacted by the SEC to protect the investor as these funds are loosely regulated.

Hedge Fund Fees

The fee charged by hedge funds to manage the money is made up of two components: management fees and incentive fees.

Management fees are fixed annual fees charged as a percentage of an investor's investment with the fund. For example, if an investor invested $1 million with a hedge fund that charges a 2 percent management fee, the management fee paid by the investor for the year is $20,000. Most hedge fund managers charge management fees between 1 and 2 percent.

Incentive fees are the performance-based fees charged as a percentage of the hedge fund's profit. If the above hedge fund charges a 20 percent incentive fee and generates a 10 percent return in a year, the profit for the investor is $100,000 and the incentive fees paid by the investor to the fund is $20,000. Most hedge funds charge incentive fees between 10 and 20 percent.

Some hedge funds charge an incentive fee beyond a hurdle rate. Say the above hedge fund has a hurdle rate of 6 percent. The incentive fee is calculated on the profit generated above this hurdle rate. The excess profit in this case is 4 percent or $40,000 and the incentive fee paid by the investor to the hedge fund is $8,000.

Another common feature of hedge funds is charging incentive fees with a high-water mark, meaning that in case of negative returns in a particular year, the fund cannot charge incentive fees the next year until it recoups the loss from the previous year. For example, if a fund generated a 5 percent loss in year one and a 12 percent profit in year two, the fund can charge incentive fees only on profit equaling 7 percent of returns generated in year two. This 7 percent incentive fee is the difference between the 5 percent loss in year one and the 12 percent gain in year two. The fund is said to have reached the high-water mark in year two when it recoups the losses generated in year one.

Hedge Fund Strategies

The strategies used by hedge funds vary in complexity and by the types of assets the funds invest in. The aim of hedge funds is to generate absolute returns—that is, returns that are independent of market movements. They aim to make profit even when stock or bond market returns are negative. They achieve this by creating strategies that are less, or not at all, correlated with the markets.

Hedge funds trade in derivatives (futures, options) and by short selling. Derivatives are a type of financial security contract between two individuals who receive a payoff by the movements of an underlying asset. This topic is further discussed in the derivatives section.

Short selling is a strategy whereby a short-selling investor believes that the price of a security will go down. That short seller will borrow the security and sell it at its current price. The investment company finds a stock to borrow either from its own inventory or a client account.

When the price falls, the short seller buys back the security in the market; the difference between the higher selling price and lower buyback price is the short seller's profit.

Short selling has received bad press due to the structure of the investment contract. A short seller benefits when stock prices decline. The press suggests that the short seller may be benefitting from others' misery (i.e., loss in security value).

Some of the common strategies include long/short equity (buying and short selling equities), market neutral equity (buying and short selling securities such that the total market exposure equals zero, i.e., for every dollar of security bought there is a dollar of security sold short), distressed credit (buying bonds that are near or in bankruptcy), and global macro (buying and selling across equities, bonds, futures, and options to take advantage of global trends like a rise in consumerism in emerging markets, rebound in the European economy, etc.).

Hedge funds, with their high fees and risks, are investments for wealthy and sophisticated investors. Although reported about in the news, these investments are only a small component of the overall investment world.

HOMEOWNERS AND RENTERS INSURANCE

Protecting one's assets is a pillar of modern personal finance. Whether one lives in a home or apartment, renters and homeowners need financial protection against unexpected perils, including theft, fire, or potential for litigation occurring over accidents or mishaps in or around the home.

In the United States, there are seven forms of homeowners insurance that range in name from HO-1 through HO-8. Each of these levels offers a different package of protection. For example, HO-1 is the most basic homeowners policy and covers fire but not damage due to frozen pipes.

If there is a mortgage on the property, the mortgage company will require a minimum level of coverage in order to protect its investment in the property. Homeowners and rental insurance offer that necessary protection. Homeowners' insurance policies differ from renters' insurance policies in that they may cover different perils with different amounts of insurance coverage. Additionally, a homeowner must protect the building structure, whereas a renter only needs to protect the apartment's contents, not the building itself.

Homeowners Insurance

The likely perils that may damage a property are hail, wind, lightning, falling trees, tornadoes, water, theft, fire, explosion, vandalism, riot, and perhaps even a falling aircraft. Most homeowners purchase an insurance policy to cover insurable events that may occur in or around their home that would culminate in a financial loss.

Although the homeowner's insurance policy will normally reimburse the homeowner for rebuilding expenses, there are other costs to consider as well.

After a catastrophic event, while the home is being rebuilt or repaired, the occupants of that home incur living expenses that are over and above their usual costs. In this circumstance, homeowners may be temporarily unable to live in their home and be forced to pay for alternative accommodation, such as hotel expenses, clothes, and meals at restaurants (Norton 2009). For these reasons, homeowners insurance helps them recuperate some of these additional unforeseen expenses.

A standard homeowners insurance policy is often a package deal. Not only is the home itself insured but also structures on the property, such as garages, barns, sheds, gazebos, and fencing. Trees, plants, and shrubs may also be covered under standard homeowners insurance.

Items that are covered in the homeowner's policy may include personal possessions that occupants may keep in and around the home. So if an occupant's furniture, electronics, clothing, sports equipment, and other personal items are stolen or destroyed by fire, hurricane, or other insurable disaster, the insurance company will pay out a sum of money as specified in the policy document so that the policyholder may replace or repair the lost or damaged belongings. Ideally the insurer places the claimant in the same position financially as he or she was before the calamitous event.

Homeowners insurance also covers liability in the unforeseen event that visitors to the property suffer bodily injuries or property damage. Homeowners insurance policies may also insure them for any legal liability to third parties. The personal liability portion of the homeowners insurance policy covers homeowners against lawsuits or legal judgments in favor of members of their family or other third-party individuals who are not the occupants of the property.

The homeowner's policy pays to defend the homeowner in court and covers any court awards. In most cases, there is an agreed limit the insurer will pay out (Teale 2008).

If a friend or neighbor is injured in an insured homeowner's home, medical expenses can be paid to the injured party without a liability claim being filed against the homeowners.

If a homeowner's children or dog accidentally ruins the neighbor's expensive rug, the homeowner's policy will cover it, but not if they destroy the rug within the homeowner's own home.

If the policy allows for off-premises coverage, the insurance will cover property such as binoculars stolen during a vacation away.

Casual and occasional workers such as babysitters or neighborhood children mowing the homeowner's lawn are generally covered by the standard homeowners policy. Permanent full- or part-time domestic employees or contractors such as plumbers, electricians, home health carers, or gardeners are not covered by a homeowner's policy.

It is very important that homeowners not underinsure their property. This means insuring it for less than replacement value or for less than the amount sufficient to rebuild the home in the event of a disaster, even though it may only need to be repaired. A home is never insured for its market value.

There are some disasters that may cause damage to a home that are not covered by private insurers. Federal and state governments are left to make provisions for these events, and other natural perils such as earthquakes, tornadoes, hurricanes, and of course flooding, whether caused by bursting levies, overflowing rivers, or a spring thaw.

Poor maintenance or general wear and tear of a home is not covered, because the homeowner is responsible for any maintenance-related damage to the house. If the toilet backs up or the sump pump fails, no homeowners insurance will cover it. Instead coverage against these natural perils and problems of poor maintenance are purchased as two additional distinct policies rather than covered under a homeowners policy.

Expensive antique furniture, furs, jewelry, silverware, artworks, and other valuables, such as coin and stamp collections or baseball memorabilia, will not be covered by homeowners insurance. Owners of these things need to purchase a special personal property endorsement or "floater" to cover their full appraised value up to a dollar limit in the event they're lost, stolen, or destroyed.

Renters Insurance

Renters insurance is frequently overlooked, yet it is just as important as homeowners insurance. Renters, or tenants, insurance provides the same coverage as homeowners insurance, with the exception of the structure of the home itself (Johnson and Sykes 2005).

Renters insurance costs correspondingly less than homeowners policies, since only the personal property items are insured and not the real estate.

Although landlords buy insurance to protect the structure of rental units against loss, homeowners policies do not protect tenants' personal property (Foong 2012).

Standard renters insurance typically protects renters against loss of personal property to theft and other perils, such as liability, fire, vandalism, lightning, and water damage caused by overflowing bathtubs and unreported water leaks that have caused substantial damage. The personal possessions component will reimburse tenants for loss of personal property, and the external living expenses cover will pay residents for living expenses and accommodation costs if they should be evacuated temporarily as a result of a fire or some other disaster. The liability component of renters insurance protects the residents of the rental against damages caused to third parties that may lead to a lawsuit.

Renters insurance does not cover property losses due to floods, earthquakes, sewer backups, and hurricanes. So additional specific policies or endorsements to protect property from damage or loss caused by those threats should be purchased, especially if the renter does not have the means to replace or pay for insured items.

Some landlords, as part of the lease or rental agreement, may force residents to purchase rental insurance and provide proof of a certificate of insurance prior to the resident moving in (Nelson 2007).

The greatest benefit of tenant insurance to landlords is the ability to recover costs of repairs and replacement for damages from the resident's insurance company should the resident cause destruction to the rental property.

Deductible

Both homeowners and renters insurance require the policyholder to pay a deductible before the insurance company pays for a claim. The deductible is set at the time the policy is purchased and ranges from a low of $250 to $1,000. The higher the deductible, the lower the cost of the policy. That is because with a high deductible, the insurer assumes that small claims will be paid by the homeowner, meaning lower overall financial outlays for the insurance company.

HOUSEHOLD DECISIONS

Household decisions are made in a community of two or more persons living together in a close relationship. Most empirical studies on decisions under "the common roof" focus on married couples or on partners with children. Researchers often distinguish between financial/economic decisions (monetary management, expenditures, saving, investment, credit use) and nonfinancial decisions (housework, leisure activities), with expenditures having received more attention. Economic typologies of purchase decisions are based on the frequency of the usage of goods (durable goods) or on the types of expenses (products, services). Psychological classifications concentrate on aspects of the decision process, on cognitive scripts (event schemata), the financial commitment, the social visibility of the good, and the effects on family members. Depending on the partners' satisfaction with their relationship and their relative power, their behavior ranges from profit-seeking exchange to spontaneous altruistic behavior.

Interaction dynamics in household decisions differ depending on the involved actors (spouse, children), their relative knowledge and interest in the topic at stake, their communication skills, and the decision history. Spouses' influence patterns were frequently found to depend on partners' relative expertise and relative interest in a decision outcome. In everyday life, economic and noneconomic decisions are interrelated, constituting a decision history that determines future interaction patterns. If a partner decided in favor of the other, or if one partner profited less from a purchase than the other and had lower influence on decision outcomes in the past, she or he is privileged, or more influential, in forthcoming decisions. Traditionally, the relative influence of partners in purchase decisions also depended on the type of good and its characteristics. Women were often responsible for kitchen utensils and health care products and the style of the product, whereas men were responsible and dominant in decisions about technical items (e.g., cars), financial products, and the payment mode. Although this gender-role pattern has been expected to have changed dramatically over the years, studies applying conventional surveys and interview techniques indicate no major shift. The comprehensive Vienna diary study (Kirchler, Rodler, Hölzl, and Meier 2001) revealed, however, that controversial decisions where either the wife or the husband decided solely on her or his own are rare and that the influence of the wife or husband on economic and noneconomic decisions is about equal. Traditional role segmentation is disappearing and the "breadwinner hypothesis" is also rarely confirmed: in the past, the partner who was higher educated, had learned an occupation of more prestige, had a better paid job, and possessed more material goods had, in general, more influence; however, this seems to be less the case at present.

Communication tactics settle conflicting interests and disagreements: tactics to avoid conflicts, to solve problems, to persuade the partner, or to negotiate. The type of tactic used depends on the quality of the relationship, the spouses' relative power, and gender, with women admitting using emotional tactics more often than men.

Children also influence purchase decisions. For specific goods, such as toys, ice cream, trainers, books, sweets, and lemonade, they have a vote. Children's influence depends on their age, whereby older children are more influential than younger ones. Additionally, their position within their siblings seems to be crucial: firstborns have more influence than younger siblings. Also, children of single parents are more influential than children living in families with both parents.

As decisions in the private household are highly interrelated and in general are made behind closed doors, they are difficult to investigate, and the selection of appropriate research instruments is crucial (for an overview, see Bolger, Davis, and Rafaeli 2003). Observations and questionnaire studies often produce biased results of dynamics in close relationships. Researchers sometimes use diary techniques to more adequately investigate interaction processes between intimate partners. If both partners complete a structured diary independently from each other over a long period of time, researchers can derive a detailed picture of everyday life in the home. Participants fill in diaries for an extended period and not only journalize their decision processes but also other topics that characterize the shared life. This enables researchers to investigate economic decision-making as a relevant business embedded in multifaceted activities in which members of the household are engaged.

INCOME

Income is commonly understood to be money that is received in exchange for producing a product or providing a service that is valued by others. Another source of revenue involves acquiring money from various investments that perform well enough to create a flow of funds not tied to one's employment. This is known as unearned or passive income.

A major portion of income received by most individuals in this world is based on what they can produce or do that's of value to others. This reality has inspired philosophical debates for centuries. There are those who believe personal income should be based on one's needs and others who believe one's income should be based on the market for one's activity and what the market will bear. Compounding this contention is the reality of unearned income, a revenue flow that is not the result of actual daily current labor.

Whether someone designs mobile phone apps for a Fortune 500 multinational corporation, waits on tables in a small family restaurant, or mows lawns locally during the summer months, money received for these tasks is considered earned income. This tends to be the predominant way in which people pay for goods and services produced by others in an economy.

Harvard's N. Gregory Mankiw suggests a "life cycle" in terms of income: "Income rises as the worker gains maturity and experience, peaks around age 50 and then falls sharply when the worker retires around age 65" (Mankiw 2008, 421).

Certain societal realities dictate income prospects for some individuals more than other factors. A frequently cited reality in recent years has been how education, or the lack of it, can impact one's income potential over a lifetime. Human capital is a factor over which some people have considerable control, including educational credentials or professional qualifications. Human capital and its impact on income may also include a special talent or skill that an individual possesses that can be offered in exchange for income. Examples of an individual's human capital are as wide-ranging as an athlete's ability to hit a ball, an engineer's degree, the ability to speak several languages, or a model's physical appearance.

Unearned or passive income is revenue received from an established mechanism, such as a financial investment, royalties, Social Security and retirement income, or rental real estate. It is income received without the recipient actually toiling on a daily basis to create it. Income from investments such as stock takes the form of dividends, or profits when the value of a company's shares increases. An individual or institution may take these dividends in the form of regular income.

Not all income is documented. In the service industries, tips and gratuities as those paid to waiters and taxi drivers and cash payments for services are considered undocumented income. Income from certain informal transactions, such as yard sales, is also commonly not documented. Income received from certain so-called black market transactions, such as sales of unofficial video or audio recordings, often escape being documented, as do revenues from sales of illegal drugs.

Undocumented income can have several consequences. One, endeavoring to avoid taxes on income can have consequences not only for an individual or institution but also for the government seeking to do the business of governing. A good example of this issue is the nation of Greece in the early 21st century; it found itself unable to either meet its debt obligations or pay for the public services its citizens expected. A major source of this problem was a successful effort of Greek citizens to avoid paying taxes on their income. As is the case in many developing countries, when a large proportion of a nation's income is undocumented, it becomes exceedingly difficult to get a true measure of a nation's economic activity and the standard of living of its people.

The income of enterprises and individuals can also be classified differently depending on its nature. A person's expected or normal income is often referred to as permanent income. A salaried worker in a secure position would likely be able to state this amount with some accuracy. Other earners are subject to events that can impact income for better or worse. In the United States, Maine and Idaho are both major producers of potatoes. If an agricultural fungus such as what struck Ireland in the 1840s befell Idaho, potato farmers there would see a temporary drop in their incomes. This disaster in Idaho would cause potato prices to rise, which would benefit the incomes of the farmers in Maine. These fluctuations create what is known as transitory income, which results from random or irregular events.

All of the income received in an economy, without regard to whether it is taxed, is referred to as aggregate income. This term can also refer to the total income within one household.

Increasingly, the matter of income inequality within nations and globally has been raised as an issue requiring societal and political action where it exists. Since the latter half of the 20th century, considerable literature and political rhetoric has focused on income inequality both within an economy and between economies. Theoretically, centrally planned economies would produce a smaller range between the highest and the lowest income earners. The historical record suggests a higher quality of life politically and socially for the majority of people in free-market economies such that even lower-income earners enjoy the freedom of choice to pursue opportunities to increase their income possibilities.

INCOME ELASTICITY

Income elasticity is a measure of how consumer demand responds to changes in consumer income. A normal good or service experiences an increase in demand when consumer incomes increase, while an inferior good or service experiences a decrease in demand when consumer income increases. Goods that have high positive income elasticity are often luxury goods such as vacations, gourmet meals, computers, automobiles, and many others; these are referred to as normal goods. Goods that have negative income elasticity are often substitutes for normal goods, such as a "staycation" (staying home on vacation rather than traveling), Ramen noodles or Spam (instead of a gourmet meal), going to the library (using the library computer rather than buying one), and bus tickets (instead of buying a car) are referred to as inferior goods. Goods that have a positive income elasticity less than one are necessities such as toilet paper, tap water, and basic food items, such as milk. This means that when consumer income increases, demand also increases, but at a slower rate than income.

When consumer incomes decrease, demand for normal goods decreases and demand for inferior goods increases. Conversely, when consumer incomes increase, the demand for normal goods increase and the demand for inferior goods decrease. It is important to note that the classification of normal goods, necessities, and inferior goods are not true for everyone in society. It is very possible for one person to view a good as a normal good and another person to view the same good as an inferior good. However, goods can be classified as normal and inferior goods based on the observed behavior of consumers when incomes increase and decrease.

Income elasticity can be calculated by dividing the percentage change in quantity demand by the percentage change in consumer income (percent change QD / percent change in income). If the quotient is positive, the good is a normal good; the larger the quotient, the more luxurious the good. If the quotient is negative, the good is an inferior good; the larger the negative quotient, the stronger the good is as a substitute for a normal good.

The consumer demand for normal and inferior goods can be observed during economic expansions and contractions. It should be no surprise that during contractions the demand for normal goods decreases and the demand for inferior goods increases. Conversely, during expansions the demand for normal goods increases and the demand for inferior goods decreases. Additionally, during income tax return season, many consumers use their income tax refunds to purchase luxury goods. The demand for normal goods and luxury goods almost always increases when there is an increase in consumer income.

Producers and retailers use the identity of a good as a luxury, necessity, or inferior good during the advertising process. There seems to be very little advertising for necessities because consumers purchase these goods regardless of their income. Advertisements for luxury goods are most often targeted to audiences with substantial disposable incomes. It is almost comical to imagine an advertisement for an expensive car or other luxury item in an impoverished area. Impoverished communities would most likely be exposed to advertisements for inferior goods such as Ramen noodles, bus tickets, or canned food. Likewise, it would be rare to see these items advertised in wealthy communities.

There is extensive research on the income elasticity of most broadly defined goods and services. A quick Internet search will reveal multiple interesting topics, such as the income elasticity of health care, environmental protection, antipoverty policies, and essential nutrients. Perhaps the most interesting is the income elasticity of environmental protection, which suggests that only relatively wealthy countries are willing to pay the cost of protecting the environment while relatively poor countries are not. Income elasticity is a fascinating topic that often reveals the behaviors of consumers as a group.

INCOME VERSUS SUBSTITUTION EFFECTS

When studying demand and the causes that affect demand, we need to take into consideration both the income and substitution effects on the law of demand. The two patterns of behavior overlap when studying why consumers demand the goods and services that they consume. Both the substitution and income effects can modify consumers' spending patterns. Together they explain why an increase in price decreases the quantity purchased.

Income Effect

When the price of an item changes, but a consumer's income remains the same, this will affect the quantity of a given good (for example, candy bars) purchased by that consumer. As the price of a candy bar rises (or falls) and the consumer's income holds steady, the amount of candy bars consumed will fall (or rise). This is known as the income effect reinforcing the law of demand.

This effect has to do with consumers' feeling of wealth and the purchasing power of their income. Another element to the income effect relating to this behavior is whether the good or service is considered to be a normal good or an inferior good. This distinction does not refer to the quality of the good. Normal goods are goods for which an increase in income leads to an increase in the demand for the goods. Inferior goods are goods for which demand decreases when income increases. So as income falls, the demand for inferior goods will rise, while the demand for normal goods will fall. When income rises, the demand for normal goods rises, while the demand for inferior goods falls.

Substitution Effect

Another behavior that reinforces the law of demand is the substitution effect. As the price of a good rises in comparison to alternative goods, the demand for the original good will fall while the demand for alternative goods will rise. As long as there are comparable alternatives, most people will substitute a more expensive good for an alternative less expensive good. The inverse is also true. If the price of a frozen yogurt rises in comparison to its substitutes (ice cream) the demand for the frozen yogurt will fall while the demand for ice cream will rise.

INDEX MUTUAL FUNDS

According to the U.S. Securities and Exchange Commission (SEC), an index fund is a type of mutual fund or unit investment trust (UIT) whose investment objective typically is to achieve approximately the same return as a particular market index, such as the S&P 500 Composite Stock Price Index, the Russell 2000 Index, or the Wilshire 5000 Total Market Index. Index funds achieve this objective primarily by investing in the securities (stocks or bonds) of companies that are included in a selected index.

History of the Index Fund

The index fund originated in the early 1970s when Wells Fargo implemented the first models of index account for the pension fund of Samsonite Corporation. Wells Fargo's strategy, which was based on an equal-weighted index of New York Stock Exchange equities, was not successful; it was abandoned in 1976 and replaced with a market-weighted strategy using the Standard & Poor's 500 Composite Stock Price Index (Bogle 2006).

In 1973, Burton S. Malkiel, a Princeton University professor, released a book entitled *A Random Walk Down Wall Street*. In his book, Dr. Malkiel suggested the creation of a new type of investment instrument, a mutual fund that was no-load and with a minimum management fee. Dr. Malkiel's book led to calls by many financial observers for index funds to be formed. Dr. Samuelson, a professor of finance at MIT, wrote "Challenge to Judgment," an article that appeared in the *Journal of Portfolio Management* in the fall of 1974. Charles D. Ellis, president of Greenwich Associates, wrote a seminal article entitled "The Loser's Game" in *The Financial Analysts Journal* for July/August 1975. Both articles issued an implicit challenge for someone to start an index fund.

In 1975, boosted by Dr. Malkiel's book and the articles from Dr. Samuelson, Ellis, and others, John Bogle, founder of the Vanguard Group Inc., launched the first broad-market index fund for retail investors.

How an Index Fund Is Structured

When an investor purchases a share of an index fund, he or she is purchasing a share of a portfolio that contains the securities in an underlying index. The index fund holds the securities in the same proportion as they occur in the actual index, and when the index decreases in value, the fund's shares decrease as well, and vice versa. The only time an index buys or sells a stock is when the index itself changes (either in weighting or in composition). Index funds have ticker symbols and are traded on all major exchanges.

Index funds are available for most indexes. Some index funds replicate broad market indexes, and some replicate indexes that only contain securities with special characteristics, including minimum financial ratios, participation in a certain industry, geography, or other distinctions. The Standard & Poor's (S&P) 500 includes 500 of the most important U.S. company stocks. It is frequently referred to as the benchmark of the U.S. stock market. There are thousands of other indexes tracking various regions and industries.

The performance of an index fund usually does not exactly match the actual index's performance. This is because index funds charge management fees, which reduce returns, and because the fund's weighting in particular securities may not perfectly match the weighting of the securities in the actual index. The degree to which the fund and the index returns differ is called tracking error.

Although the first index funds tracked stock investments, today there are index funds composed of bonds, commodities, real estate, and most financial asset classes.

Advantages of Index Funds

Index funds are a popular way to participate in the stock market and diversify a portfolio. Index funds have several major advantages over direct ownership of the underlying securities.

Index funds provide the investor with broad diversification. Each index fund represents an interest in an underlying basket of securities. This allows investors to easily gain broad exposure to a large group of companies. This diversification also makes index funds much less volatile than individual securities. Foreign index funds in particular make diversifying abroad less difficult and expensive; they also offer exposure to entire foreign markets and market segments.

Index funds have lower fees than actively managed funds. Buying and selling shares of an index fund is far less expensive than separately buying and selling a basket of underlying shares. Also, the decision of which securities to invest in is determined by the index rather than by active management. This is why index funds usually have minimal expense ratios and are often more affordable than other diversified investment vehicles. However, many have minimum investment requirements and front- or back-end loads (or commissions), making them impractical for some investors.

Other benefits of index funds include liquidity and the opportunity to compound growth or increase cash flow from the dividend payments. Index fund shares are bought and sold on major exchanges every day, and many funds trade hundreds of thousands (and in some cases millions) of shares per day. Buying and selling shares of an index fund can be faster and more convenient than buying and selling the underlying shares. Many index funds pass through the accumulated dividends paid by their underlying stocks. Over time, these dividends can add up to a significant sum.

Some index funds track broad U.S. equity market indexes. Others track specific sectors or industry groups. Still others represent an interest in baskets of foreign stocks. And finally, others invest exclusively in the bond market. The index fund varieties make it easy to implement a particular investment strategy.

Index funds have tax benefits over actively managed mutual funds. Since shares are bought or sold only when the underlying index adjusts, these funds don't incur as many taxable gains as their actively managed counterparts might.

Studies have proven that over time, the average mutual fund typically fails to beat the broad indexes. With this in mind, index funds are a great way to capture broader-market returns. For adherents to the efficient market hypothesis, which states that it is impossible to outperform the broad stock market over the long haul, index funds can be a way to optimize portfolio returns. In his article "Behavioral Perspectives on Index Funds," Keith Redhead states that the average actively managed fund underperforms index funds. Redhead also states that the use of index funds could help to avoid the perception of loss, unrealistic expectations, inappropriate choice criteria, loss of dividend income, and emotional attachment to investments.

Disadvantages of Index Funds

An investment in an index fund could lose money over short or even long periods. The share price and total return may fluctuate within a wide range, like the fluctuations of the underlying assets. As with all investments, tax liabilities are incurred on dividends. Additional risks may also impact fund performance.

Newer Varieties of Index Funds

The first modern index funds were market capitalization weighted. The percentage of each company in the index fund was determined by the company's size or market capitalization within the index. Today, newer varieties of index funds offer equal weight where each company is owned in the same amount. Specialized index funds use specific factors to create index funds as well.

In addition to index mutual funds, a newer variety of index funds are called exchange traded funds (ETFs). *Index funds* may also refer to ETFs in addition to mutual funds. Like mutual funds, ETF index funds are comprised of a basket of underlying securities representing an index. Unlike a mutual fund, they trade on a stock exchange throughout the day and can even be bought on margin.

The last century's newly designed index funds have become the cornerstone of modern investing strategy today.

INDUSTRIAL POLICY

Industrial policy is a governmental approach aimed at promoting and implementing initiatives that will result in better production and outcomes for various sectors of the economy. The most common example of this has been when nations have undertaken major manufacturing initiatives in the heavy industry sectors of their economies to mobilize for war. During World War II, with the compliance and support of business owners, the automobile and aircraft industries in combatant nations converted their factories to also produce vehicles and planes for military purposes.

In the U.K., until the 1980s, the nation's energy needs were considered important enough that the coal mining industry was nationally owned. Contention over how overt and involved a government's industrial policy should be reflects similar debates over public efforts to promote and regulate private business concerns. Advocates of a strong, proactive industrial policy suggest that as a government should serve the interests of workers, the environment, and the economy in general and promote a healthy balance of trade, it is in the best position to oversee and enforce policies that will promote improvements with regard to all of these interests. Harvard economist John Kenneth Galbraith, whom President Franklin D. Roosevelt put in charge of price controls during World War II, maintained that left to their own devices, industrial interests will not serve society's complete or even most pressing interests.

Galbraith foresaw an eventual fusion of interests between government and industry, citing, for example, how industry depends on government to educate its eventual workforce (Gilbraith 1967).

The postwar economic resurgence of Japan can be traced to a strong industrial policy by its government, which in 1949 created the Ministry for International Trade and Industry (MITI), which was designed to promote economic growth by coordinating domestic production with trade policy (FAS 2001). One criticism of such an approach is that it can involve government-imposed tariffs on imports, closing markets to foreign competitors. Following World War II, the British government nationalized all coal mines in its realm, and while production soared, there was much rancor on the part of labor when the government began to close unprofitable mines in the 1980s and 1990s.

Opponents of strong industrial policy argue that private industry (rather than public officials) is best equipped to make business and economic decisions. Writing for the Federal Reserve Bank of St. Louis in 1993, economist Michelle Clark Neely articulated a number of flaws with a strong industrial policy, concluded that the number of American workers involved in the manufacturing sector shrank after World War II from three out of every five to one in five. However, manufacturing's total output share had not changed from its approximately 20-percent share that reflected manufacturing's productivity growth.

Few would dispute the merit of government safeguarding the environment and well-being of workers, but the extent to which any government's industrial policy should assert control over commercial interests in a free-market economy is a debate that is frequently waged according to political and philosophical lines.

INFLATION-PROTECTED INVESTMENTS

Inflation is the rate at which prices of goods and services increase. When prices rise, consumers' purchasing power declines. In other words, as inflation increases and prices increase, the same dollar amount purchases fewer goods. Inflation touches the entire society. This is a problem for savers attempting to amass funds for retirement and future consumption.

Anyone who needs to divert current income into savings for a future expense may be hurt by inflation. For example, if you are saving money for college expenses 10 years in the future and your bank pays interest of 3 percent, you assume that at the end of 10 years that 3 percent interest rate would grow your initial funds at 3 percent per year. If inflation during that period was 4 percent per year, at the end of the savings period, your money would purchase less than when you started. Although you receive a 3 percent return on your funds, subtract 4 percent per year inflation and your actual purchasing power declines approximately 1 percent (3% return less 4% inflation rate = –1%).

Inflation-protected investments were created by the U.S. government to provide savers with investment products that protect savings from a decline in real value and purchasing power.

There are two types of inflation-protected investments: Treasury inflation-protected securities (TIPS) and government I savings bonds (inflation adjusted). By investing in these secure government products, the consumer is promised a return that keeps pace with the government-calculated inflation rates until the predetermined date when the purchaser receives the full amount due (principal). TIPS principal or face value changes with inflation and deflation as calculated by the nonseasonally adjusted Consumer Price Index (CPI-U). For example, if inflation increases, the principal value of the TIPS increases by the same amount. So with increases in inflation, you are assured that the value of your TIPS bond also increases in value.

There is a second part to the return on a TIPS investment. When purchased, the TIPS have an interest rate that remains fixed for the entire period of ownership. This interest rate is paid semiannually on the adjusted principal amount. For example, purchase a five-year TIPS bond for $1,000 with an interest rate of 1 percent. If inflation increases, the 1 percent interest is paid semiannually on the increased principal amount. In the event of deflation, the 1 percent interest is paid on the reduced principal amount. At maturity, which in this case is five years, the TIPS owner receives either the upwardly adjusted principal or the original principal amount in the case of zero inflation or deflation. Additionally, this protects the consumer against deflation as one never receives less than the original principal amount.

Federal tax is due on the semiannual interest payments and inflation adjustments in the year that they occur. Interest is subject to federal and exempt from state tax.

How to Buy TIPS; Denominations and Maturities

TIPS are sold in denominations starting at $100 on up to $5 million. Their maturities are 5, 10, and 30 years and they can be bought at auction through the treasurydirect.gov website or from a bank or investment broker. TIPS (previously issued) are also available in the secondary market. The secondary market means investors buy and sell the TIPS securities in much the same way that they buy and sell stocks and bonds. In other words, TIPS may be held until maturity or sold in the secondary market at any time prior to maturity.

I Savings Bonds

Similar to TIPS, I savings bonds are designed to provide a savings vehicle that protects consumers' funds from erosion due to inflation. Although I bonds' purpose is the same as for TIPS, the investment I bond is uniquely designed. I bonds combine two interest rates: a fixed rate of return assigned at the bond's creation and a second interest rate that is calculated semiannually and is based on changes in the nonseasonally adjusted Consumer Price Index (CPI-U). Interest is compounded semiannually and earned monthly. The published value of the bond does not show the previous three months of interest. Yet, the purchaser receives no semiannual interest payments, as TIPS holders do; instead, the final redemption value includes all of the previous interest payments.

The I bond's value changes each month as the interest is calculated and applied to the principal amount. Unlike TIPS, ownership is neither transferrable nor able to be traded on the secondary market. I bonds may be redeemed any time after 12 months at the treasurydirect.gov website or a bank. If I bonds are redeemed prior to five years, the seller loses the previous three months' interest accrued. The principal and all interest due are paid at redemption.

Taxes are not due on I bonds until they are redeemed, although the consumer may opt to pay taxes annually. Interest is subject to federal and exempt from state tax.

How to Buy I Savings Bonds; Denominations and Maturities

I bonds may be purchased electronically at the treasurydirect.gov website. They are offered in denominations of $50, $100, $200, $500, $1,000, and $5,000. There is a limit to the amount of I bonds an individual may buy each year. Investors may purchase up to $10,000 worth of I bonds annually and up to an additional $5,000 with a tax refund.

Education Considerations for I Savings Bonds

The Education Savings Bond Program stipulates that if the savings bond proceeds are used to pay qualified higher education expenses at an eligible institution in the same year that the bonds are redeemed, the savings bond interest is exempt from federal tax. Additional information regarding this provision is available in IRS Publication 970.

INTEREST RATES

Interest rates can be viewed as the cost of money and a tool that central banks use to control the money supply, inflation, unemployment, and economic activity. When individuals, firms, or governments want to borrow money, they must repay the lender the principal plus interest. When lenders loan money to borrowers, the lenders lose the liquidity of their money and are compensated for this through the interest rate that is paid by the borrower. Low-risk borrowers often pay a lower interest rate compared to high-risk borrowers. The risk levels of borrowers are often measured on the ability of the borrower to repay loans and the historical repayment of the borrower. Interest rates are also paid to individuals, firms, and governments who save their money in financial institutions. Financial institutions that provide rapid liquidity and insured accounts often pay lower interest rates on savings compared to financial institutions that provide little liquidity and some risk of losing principal. It is important to understand that interest rates act as an incentive for lenders, borrowers, and savers. For consumers, low interest rates encourage borrowing and discourage saving; high interest rates encourage saving and discourage borrowing.

Interest rates often dictate the economic behavior of individuals and firms. When interest rates increase, individuals and firms have an incentive to save rather than borrow funds for consumption and investment. In other words, as interest rates increase, the opportunity cost of borrowing funds for consumption and investment increases. If individuals and firms borrow funds when interest rates are relatively high, they forgo the increase in interest income. Conversely, when interest rates decrease, individuals and firms have an incentive to borrow funds for consumption and investment rather than to save due to the reduced opportunity cost of borrowing. There is a negative correlation between consumption and investment spending that is based on borrowing funds and interest rates.

Interest rates can be expressed in nominal and real terms. A nominal interest rate is the rate that borrowers pay lenders and financial institutions pay savers. For example, if you borrow money from a bank to purchase a car, the bank will charge you a nominal interest rate; if you save money in that same bank, the bank will pay you a nominal interest rate. However, the nominal interest rate does not take into account inflation, which is a decrease in the value of money. If the bank charged a nominal interest rate of 10 percent and inflation was 3 percent, the bank would only realize a 7 percent interest rate because the original amount loaned decreased in value by 3 percent due to the inflation. In the same fashion, if the bank paid a

3 percent interest rate on savings and the inflation rate was 3 percent, the savings account would realize a 0 percent inflation rate because the value of the money that was saved in the bank decreased by 3 percent. This realized adjustment of the nominal interest rate is the real interest rate, which is the nominal interest rate minus the expected inflation rate. The American economist Irving Fisher (1867–1947) developed the Fisher Equation. The Fisher Equation is the real interest rate equation, and it states that the real interest rate equals the nominal interest rate minus expected inflation. As long as inflation is predictable and expected, lenders, borrowers, and savers can all equally predict the real interest rate and set nominal interest rates to reflect their individual goals.

There are many interest rates that impact society, but perhaps the most important is the federal funds rate. The federal funds rate is the interest rate that depository institutions (banks) charge each other to borrow money from their cash reserves that are held at Federal Reserve banks. Depository institutions are required to keep a minimum amount of cash reserves determined by the Federal Open Market Committee of the Federal Reserve Board. If a depository institution fails to keep enough reserves, it must borrow money from another institution or from the Federal Reserve. The Federal Open Market Committee can effectively control the federal funds rate by buying and selling bonds in the open market. This is significant because many consumer-related interest rates rise and fall with the federal funds rate. This ability to control interest rates provides the Federal Reserve with the power to control inflation and unemployment to some extent.

During the contraction phase of the business cycle, the Federal Reserve can reduce the federal funds rate, which reduces other consumer interest rates and encourages consumer spending with the goal of increasing gross domestic product and recovering from the contraction. Likewise, during times of high inflation, the Federal Reserve can increase the federal funds rate, which increases other consumer interest rates and encourages saving rather than consumption with the goal of slowing inflation to acceptable levels. The spending and saving incentives that cause changes in interest rates provide the Federal Reserve with some control over economic activity.

Changes in interest rates also impact bond prices. A bond is an asset that earns a fixed interest rate for the term of the bond. When people purchase bonds from the government or a private firm, they are essentially loaning money to the government or the firm with the promise that it will repay the principal and a fixed interest rate at the end of the term of the bond. If interest rates increase during the term of the bond, because the bond's interest rate is fixed, it will not adjust and the bond will decrease in value if it is sold before the end of the term. The reason that the bond will decrease in value is that new bonds will be sold with a higher interest rate and in order to sell the current bond before term, the bond holder will be forced to lower the price of the bond to compensate the purchaser for the lower interest rate of the old bond compared to the interest rate of the new bond. Likewise, when interest rates decrease, bond prices increase because current bonds have a higher interest rate compared to newly issued bonds and are a more attractive asset than newly issued bonds.

The incentives that interest rates have on economic activity, unemployment, and inflation are profound. The ability of the Federal Reserve to have some control over them affords the Fed some control over the macro economy.

INTERSTATE COMMERCE ACT OF 1887

The Interstate Commerce Act of 1887 was originally designed to legislate and regulate the monopolistic behavior of the railroad industry. The Interstate Commerce Commission (ICC) was created to oversee and enforce the implementation of the act. The main purpose of the act was to force the railroads to offer "reasonable and just" rates to their customers and to publicize those rates. The act prohibited price discrimination, including differences between short- and long-haul rates, a common practice of the railroads at the time. It was the first federal law to regulate a private industry.

The Interstate Commerce Act of 1887 was a national reaction to concern over the increasing size and power of companies in the United States. No industry was gaining power as quickly as the railroads. At the end of the 19th century, the railroads had become the main form of transportation for both people and freight. As a result, the rates they charged for both had a significant impact on trade, commerce, and the movement of people.

Competition both within the railroad industry and from other modes of transportation was minimal. It was no secret that the railroad companies were forming cartels and colluding to control rates. It was also clear that this collusion was creating rates that were extraordinarily high relative to what market rates would be without the collusion. Another policy adopted by the railroads that moved the government to take action was the practice of charging a higher per-mile rate for short hauls versus long hauls. This put small businesses at a distinct disadvantage.

States attempted to limit these practices by the railroads by passing their own legislation, but the interstate aspect of the railroad industry made enforcement difficult. Then, in 1886, the Supreme Court ruled in *Wabash, St. Louis & Pacific Railway Company v. Illinois* that state laws were unconstitutional, as they violated the commerce clause of the Constitution, which gave the federal government the power to legislate commerce between states. The federal government, which had up to this point avoided getting involved, was now forced to act. So in 1887, the Interstate Commerce Act was passed by Congress and signed into law by President Grover Cleveland on February 4 the same year.

The act forced the railroads to publish their rates, thereby eliminating the practice of price discrimination, which helped to increase competition. The increase in competition changed the revenue stream of railroad companies, which diminished their financial allure to investors and stockholders.

The act established the Interstate Commerce Commission to oversee its enforcement. It was the first independent agency established by the federal government for the express purpose of regulating a private industry. The role of the ICC was to preside over complaints lodged against the railroad companies, issue cease-and-desist orders against practices that the ICC deemed unfair, and contest any unfair practices of the railroads. The ICC scope of enforcement was limited to railroads that operated across state lines.

Several amendments were made to the Interstate Commerce Act early in the 20th century. From 1903 through 1910, amendments increased the scope of the ICC to include bridges, ferries, oil pipelines, and cable, telephone, and telegraph companies. The Motor Carrier Act was passed by Congress in 1935 to include the trucking industry and bus lines.

Congress began to deregulate the railroad industry through the 1970s and 1980s. The Railroad Revitalization and Regulatory Reform Act of 1976 removed pricing barriers for the railroad industry. Through the 1980s, ICC authority was reduced further as the railroad and trucking industries were further deregulated. In 1995, the ICC was abolished by Congress and its functions moved to the new Surface Transportation Board.

INVESTMENT BANKS VERSUS COMMERCIAL BANKS

Commercial banks are financial institutions that provide services to individuals, businesses, and organizations. Commercial banks operate as "traditional" banks with the majority of their business being related to taking deposits and making loans. Commercial banks make their profits by taking small, short-term, liquid deposits, and loaning the money to individuals and companies through long-term loans. The services that commercial banks offer business and individual customers are familiar to most people, such as checking and savings accounts, certificates of deposit, credit and debit cards, and mortgages and loans.

Checking and savings accounts make up a large portion of the depository business and provide the base income for traditional commercial banks. These accounts are offered to both individuals and businesses and provide the bank with the majority of the income needed to make loans. These accounts are sometimes charged a monthly fee, and additional fees are charged for customers that overdraw their accounts.

Certificates of deposit (CDs) are another type of deposit offered to individuals and businesses at most banks. CDs are savings certificates that bear interest at a specified fixed interest rate with a maturity date and are offered as "small CDs," less than $100,000, or as "jumbo CDs," which are more than $100,000. These offer a safe and secure investment for individuals and businesses to earn higher interest than they would if the funds were left in checking and savings accounts.

Credit and debit cards have become another highly lucrative source of revenue for commercial banks and are offered to both individuals and businesses. Often these cards come with interest rates and fees that offer commercial banks an additional source of income.

Commercial banks provide loans for commercial and residential properties, automobiles and other machinery, and business expenses. While these can be a liability for the bank if the borrowers default or fail to pay back the loans, they are typically the best source of income for the bank. If loans are made wisely to borrowers with less risk, they can provide a secure source of income for the commercial banks. These loans are backed by collateral such as property, machinery, automobiles, or business assets. This creates a secure loan for the banks since the collateral backing the loans can be sold to pay back the outstanding balance of the loan if the borrower fails to pay.

Commercial and residential property loans are usually backed with the collateral of the house or property upon which the loan is made. These loans usually provide the least amount of risk for the bank since the properties that are backing the loan can be foreclosed if the borrower does not pay back the money. Loans for automobiles and other machinery are often made to individuals and businesses.

These loans are also collateral backed by the automobile or machinery. In the case of default, the bank can repossess the auto or machinery.

The last type of loan that commercial banks usually make is personal loans to businesses or individuals. These loans can be backed by collateral, or they can be made with nothing backing the loan but a personal guarantee by the borrower. Business loans are often made so the business can expand or improve. Personal loans to individuals are often made for people to purchase something or to pay off other debt at a lower rate. These types of personal loans with little guarantees are often made after the customers have set up other accounts with the bank. Commercial banks make unsecured loans to individuals through credit cards.

Investment banks are banks that perform a variety of services for companies and large investors. Instead of earning their money through depository services, investment banks offer services primarily related to investments, such as underwriting and advising on securities issues, mergers and acquisitions, trading on capital markets, and research.

One thing that distinguishes investment banks from commercial banks is that investment banks make trades with their own account while commercial banks are restricted from doing so. This practice has been altered since the passage of the "Volcker Rule" within the Dodd-Frank Act. If a private company would like to go public, generate working capital through the selling of stock, it will do so through the services of an investment bank. If a public company listed on a stock exchange would like to offer new stock, it will use the services of an investment bank to underwrite the new stock offerings. The investment banks will then resell the stock directly and through broker-dealers. Investment bankers also make trades on the stock market to provide profit for their customers and the company.

Investment bankers arrange mergers and acquisitions for their customers and charge for research and advice. This provides a source of both income and publicity for the company.

J

JEVONS, WILLIAM STANLEY

Born: September 1, 1835, in Liverpool, England; Died: August 13, 1882, in Hastings, England; Nationality: English; Professional Interests: economic statistician, marginal utility theory; Major Work: *The Theory of the Political Economy* (1871).

William Stanley Jevons was one of the foremost writers of economics and logic in the 19th century. His writings and theories on the political economy were original and prominent. Jevons is most noted for his introduction of the concepts of marginal utility theory of value and marginal analysis. Jevons may be considered one of the first environmental economists as he wrote about the British coal dependence in 1865 and introduced the Jevons paradox. Jevons was also later noted for his distinction between ordinal and cardinal utility. Jevons died in 1882.

William Stanley Jevons was born on September 1, 1835, in Liverpool, England. Jevons's father was a writer of legal and economic subjects, and his mother was the daughter of famous historian William Roscoe. At the age of 15, his father sent him to the University College School. Early in his education, Jevons actually preferred studying the sciences of chemistry and botany, and he excelled in both. After two years at University College School, he received an unexpected offer to take a position as an assayer in Australia. The thought of leaving England had never been in Jevons's mind, but financial problems in his father's firm in 1847 changed his thinking, and in June of 1854, he left for Sydney.

It was in Australia that Jevons's interest in political economy flourished. After five years in his post as an assayer, Jevons resigned and returned to the University College School in 1859. He obtained a BA degree, and not long after taking his MA, Jevons obtained a post to tutor at Owens College in Manchester, not far from Liverpool.

Jevons was one of the first political economists to value the use and application of mathematics to political economy. At Owens College, Jevons began publishing, beginning with the piece "A General Mathematical Theory of Political Economy" (1862), written for the British Association, which outlined the marginal utility theory of value. At the time, it was originally written as a letter and received little recognition, even after its full publication in the *Journal of the Statistical Society* four years later.

Jevons wrote his first complete work in 1871: *The Theory of Political Economy.* The theory of utility was the focal point of Jevons's thought on political economy. Jevons's main idea was that the degree of utility of a commodity is some continuous mathematical function of the quantity of the commodity available. His work was quickly developed by Austrian economist Carl Menger and Swiss economist Leon

Walras. Although it was Gossen who should be credited with the discovery of the connection between value in exchange and final (or marginal) utility, Jevons's contribution cannot be ignored.

Of special note regarding Jevons's writing is the distinction between ordinal and cardinal utility, which he fails to acknowledge but with good reason. At the time of his writing, this distinction did not exist. For a better understanding of his writing, it helps to know that his mathematics required the use of cardinal utility functions. Cardinal utility allowed Jevons to discuss the relative magnitude of utilities, unlike ordinal utility, which states that goods can be ranked and compared only according to which provides the most utility. Jevons strongly believed that his measurements of utility were relative, not a direct measure.

Although Jevons's work was essential in the development of such a key modern thought, his first recognition came through his writings on other practical economic questions. His next two books, *A Serious Fall in the Value of Gold* (1863) and *The Coal Question* (1865), placed Jevons on the face of applied economics and statistics. These works alone were sufficient to earn him a reputation as one of the greatest economists, even in the absence of his more famous work, *The Theory of Political Economy.*

The Coal Question focused on Britain's dependence on coal. His ideas have even been revisited in modern times. Jevons introduced the counterintuitive idea we use today to improve energy efficiency. He submitted that as energy efficiency measures are implemented, less energy is necessary for any one use; however, the rate of consumption will not fall, as might be expected, but rather rise due to increased demand. This counterintuitive idea is now known as the Jevons paradox. Jevons also raised the question of the sustainability of coal, which is a finite, nonrenewable resource. Other topics that were central to this idea of sustainability were resource peaking, limits to growth, overpopulation, post global relocalization, energy return on energy input, taxation of energy resources, and renewable energy alternatives. The book remains at the foundation of energy depletion theory.

Jevons had a great impact on political economy, but his work in logic was on equal footing. *Pure Logic: Or the Logic of Quality Apart from Quantity* (1864) was his first small volume in this field. He simplified the principle of substitution of similars by explaining that "whatever is true of a thing is true of its like." He published *The Substitution of Similars* in 1869. It worked on the basis that the conclusion derivable from any given set of premises could be mechanically obtained. This was symbolized through the presentation of his "Logic Piano," a mechanical computer he built and presented in the same year alongside his new thought.

His works on logic went further in 1874 with his theory of induction, which appeared under the title *The Principles of Science.* It was aimed to revive the theories of Whewell and address the criticisms made by John Stuart Mill. He developed the view that induction is simply an inverse employment of deduction. He also toyed with the general theory of probability and the relation between probability and induction. Jevons's work on this subject was different from the rest because of his knowledge of the various natural sciences. These enabled him to relieve the abstract character of logical doctrine by concrete scientific illustrations, often worked out in great detail.

William Stanley Jevons died from drowning on August 13, 1882, at Hastings, England.

JUNK FOOD

Junk foods are foods that are easy to make and quick to consume. They are rich in saturated fat and sugars but have limited nutritional value (e.g., pizzas, burgers, French fries, snacks, soft drinks). They are widely believed to be the major contributor to obesity, which more than doubled globally over the past three decades, with more than 1.9 billion adults overweight and at least 600 million clinically obese (WHO 2016). Obesity is a major risk factor for many chronic conditions, including hypertension, cardiovascular disease, type 2 diabetes, and certain types of cancer (Taylor 2011). It also generates significant costs to governments, employers, insurance companies, and the obese individuals themselves.

To combat the growing prevalence of obesity, economic instruments have been proposed to affect individuals' eating and physical activity choices. The most popular proposal is the "fat tax" program, which aims at raising the relative price of calorie-dense foods so as to create an incentive for switching to low-calorie alternatives. In particular, the program seeks to tax junk foods, the revenue from which could be used to finance a "thin subsidy" for healthy foods. While at the moment there is no fat tax operating in the world, the idea has been supported by the World Health Organization and is under active consideration by public health scholars and practitioners in several countries.

Yaniv, Rosin, and Tobol (2009) address the fat tax and thin subsidy within a food-intake rational-choice model. Assuming that healthy meals are cooked at home with purchased ingredients and time input, the paper examines the effects on obesity of a tax on junk-food meals and a subsidy to cooking ingredients, distinguishing between a weight-conscious and a non-weight-conscious individual, and between a weight-conscious individual who is physically active and physically inactive. For a non-weight-conscious individual, a fat tax will unambiguously reduce obesity, whereas a thin subsidy may increase obesity. However, for a weight-conscious individual, particularly one who is physically active, even a fat tax may increase obesity, as it may reduce not just the consumption of junk food but also the time devoted to physical activity. This is because the fat tax encourages the preparation of healthy meals, which necessitates time for cooking and healthy ingredient shopping, quite likely at the expense of physical activity. Since weight is gained when calorie intake exceeds calorie use through physical activity, obesity might rise in spite of the fall in junk-food consumption, exacerbating the problem the fat tax proposal intended to eliminate.

While the traditional justification for government intervention to reduce obesity is to correct the health outcomes resulting from individual choices that impose negative externalities on normal-weight individuals, a very different approach would be to respect consumer sovereignty, in particular the right to risk future health in order to consume foods that provide immediate pleasure. In this spirit, the main critique of the fat tax program has been that people should be free to make their own health/lifestyle choices without government paternalistic intervention.

However, O'Donoghue and Rabin (2003) suggest the notion of "optimal paternalism," arguing that paternalistic policies may be advantageous if they help rationally bounded agents make better choices without overly affecting those who are fully rational. That is, even if obesity did not impose externalities on others, so that by the conventional approach of welfare economics no intervention was the best policy, a light paternalistic policy is preferable to nonintervention if it improves the welfare of those who behave suboptimally (because they do not know what is best for them or know but have trouble doing it) without limiting the freedom of those who behave optimally.

Thaler and Sunstein (2008) introduce the notion of "libertarian paternalism," arguing that it is legitimate for the government to try to influence people's behavior by rearranging the choices they face in a way that would nudge them to opt for a healthier behavior without taking away their freedom of choice. This is particularly relevant to reducing child obesity rates, which have more than tripled since the 1970s. Because child obesity has been linked to junk foods, consumed every day by one-third of all American kids, a simple nudge would be placing healthy foods in school cafeterias at eye level, while putting less healthy junk food in harder-to-reach places. Children would not be prevented from eating whatever they want, but the arranging of the food choices in that way would have the effect of decreasing consumption of junk food and increasing consumption of healthier foods.

Another behavioral economic tactic, suggested by Just and Wansink (2009), is to require high school students to pay cash for desserts and soft drinks rather than mindlessly putting it on their debit card or pin account. Because they have to take out the dollar they might otherwise spend on an iTune, they are likely to ask themselves how bad they really want that cookie.

K

KAHNEMAN, DANIEL

Born: March 5, 1934, in Tel Aviv, Israel; Nationality: Israeli; Professional Interests: behavioral economics, Nobel Prize (2002); Major Works: "Prospect Theory: An Analysis of Decisions under Risk" (with A. Tversky, 1979), *Thinking, Fast and Slow* (2011).

Daniel Kahneman is a psychologist by profession, yet he won the 2002 Nobel Prize in Economics for his work in behavioral economics. Working with his longtime friend and colleague Amos Tversky, the two were honored for their research in economic decision-making. They focused specifically on how humans may think in terms of costs and benefits yet often make irrational decisions. Kahneman and Tversky blended psychology and economics to derive what became a basis for the field of behavioral economics.

Daniel Kahneman was born on March 5, 1934, in Tel Aviv, Israel. Even though he was born in Israel, his family resided in Paris. He was growing up in Paris when the Germans occupied the city. During World War II, his family moved several times throughout France to avoid the fate of so many other Jewish people. Young Kahneman's father, who had been temporarily interred by the Germans, died just weeks before VE Day. At the conclusion of World War II, young Kahneman, his mother, and his sister were able to leave France for Israel and begin a new life.

Following high school, as a young Jewish man in Israel, Kahneman had choices to make regarding his college education and his Israeli military obligation. He was able to defer his military obligation to attend Hebrew University, graduating in two years with a degree in psychology and mathematics.

After graduation he was drafted to fulfill his military obligation. After one year, he was assigned to the psychology section of the Defense Forces. Several assignments during this time in the military influenced his future career as a psychologist. During one assignment when he and his colleagues were asked to make predictions on the future performance of young soldiers, they found their predictions were not very accurate. This led Kahneman to coin the term "illusion of validity." Twenty years later, he was to introduce this term to the world of psychology. A second such experience was an exercise in which the psychologists made very broad predictions of future performance based on very limited knowledge of subjects' behavior. A third military experience that strongly influenced Kahneman's future was the challenge of designing an interview process for determining the fitness of combat recruits. The system was a combination of statistical analysis and clinical interviews. The results were impressive, achieving predictive success at a rate three times the past rate. These challenges were the seeds of Kahneman's and Tversky's future work on the psychology of intuitive prediction.

In 1958, Kahneman went to the United States to attend the University of California, Berkeley (UC Berkeley). Receiving his PhD in 1961 from UC Berkeley, Kahneman returned to Israel. He joined the faculty of the psychology department at the Hebrew University. Kahneman set himself the goal of becoming a better researcher. During his early years at Hebrew University, he established a research lab, developed several research models, and assisted in developing additional training models for the Israeli military. His published research career began with his 1965 sabbatical.

In 1965 while on sabbatical from the University of Michigan, Kahneman and a graduate student colleague, Jackson Beatty, began a series of experiments on mental effort. After several publishing successes with Beatty, Kahneman moved on, continuing his research on mental effort at Harvard. He returned to Hebrew University in 1967 a trained researcher.

During the 1967–1968 academic year, Kahneman met Amos Tversky. Tversky's field of judgment and decision-making intrigued Kahneman. Following a discussion on their personal experiences and the errors they each had made in prediction, the two decided to study the intuitions of experts, beginning what would become a lifelong professional duo. Kahneman and Tversky had a collaborative relationship that far transcended their professional lives. From 1971 to 1981, Kahneman and Tversky published eight journal articles. In 1971 and 1972 the "dynamic duo," as they became known to their colleagues, did considerable research and writing on judgment and decision-making at the Oregon Research Institute (ORI). In 1972, Kahneman published *Attention and Effort*, his single most significant contribution to psychology.

Following his research and work at ORI, Kahneman's career took another major turn in 1972 when he and Tversky published an article in *Science* journal. The article, read by a small group of economists and philosophers, was interpreted as a critique on the rationality model of human behavior. Surprisingly to Kahneman, the article became the standard critical response to the rational-agent model of decision-making. The *Science* article had many critics, yet the duo collaboratively pressed forward in their study of decision-making.

In 1975, they presented a paper on what they originally labeled *value theory*. In 1978, they published "Prospect Theory" in *Econometrica.* Interestingly, they did not publish in *Econometrica* to necessarily impact or influence the science of economics; their focus was on impacting the field of decision-making and *Econometrica* was the most respected and well-known professional journal for decision-making publishing. However, publishing the prospect theory in *Econometrica* did influence economics. Kahneman's entrance into the field of behavioral economics was about to be complete.

Kahneman and Tversky completed prospect theory while at Stanford University's Center for Advanced Studies in 1977–1978. While at Stanford, Kahneman met a young economist named Richard Thaler. The integration of the prospect theory into economic theory became the basis for Kahneman's collaborations with Thaler. Through collaborative efforts with Thaler, Kahneman's work now focused on the behavioral patterns of the economic human. Behavioral economics was born.

In 1984–1985, Kahneman, now at the University of British Columbia and working with economists Thaler and Jack Knetsch, expanded the field of behavioral economics. The focus of their work was on what they called *reference transactions*, or making a decision based on the perception that someone has an entitlement to a particular outcome and the only fair transactions are those that uphold the entitlement. They created a series of experiments, vignettes, and surveys to support their thesis.

In 2002, Daniel Kahneman was awarded the Nobel Prize in Economics for his valuable contributions in integrating psychology into economics and for his work on human judgment and irrational decision-making. Besides the Nobel Prize in Economics, Daniel Kahneman has been the recipient of many awards and prizes in psychology. In 1982, he received the Distinguished Scientific Contribution Award of the American Psychological Association and in 2002 the Grawemeyer Prize. Both awards were jointly awarded with Amos Tversky. He was also honored with the Lifetime Contribution Award of the American Psychological Association in 2007.

After returning to his alma mater in 1986, in 1993 Kahneman accepted a position to teach at Princeton in psychology and with the Woodrow Wilson School of Public Affairs and International Affairs. In 2011, Daniel Kahneman became known beyond the academic world to the general public with his best-seller exploration of how we think: *Thinking, Fast and Slow.*

KANTOROVICH, LEONID

Born: January 19, 1912, in St. Petersburg, Russia; Died: April 7, 1986, in Moscow, Russia; Nationality: Russian; Professional Interests: optimal resource allocation, linear programming, mathematical economics, Nobel Prize (1975); Major Works: *The Mathematical Method of Production Planning and Organization* (1939), *The Best Uses of Economic Resources* (1965).

Leonid Kantorovich was known in the field of mathematical economics for his work on linear programing and his theory and techniques for optimal allocation of resources, for which he won a Nobel Prize in 1975. He worked as a scholar in Soviet Russia and applied his theories in industry under Stalin as part of the movement to modernize the nation. Kantorovich died in 1986.

Leonid Vitaliyevich Kantorovich was born on January 19, 1912, in St. Petersburg, Russia, during the final years of the Russian Empire. During his formative years, he watched as his nation made the transition to communism, fighting a bloody civil war in the process. He obtained his PhD in mathematics from Leningrad State University at the age of 18. While his interest was initially in the pure field of mathematics, he went on to teach at Leningrad University and in the Institute of Industrial Construction Engineering, where he spent much of his time working on the development of functional analysis.

Kantorovich's first achievement involved the invention of a mathematical technique now known as linear programming. In 1938, he consulted as a professor at Leningrad for the Laboratory of the Plywood Trust, which was attempting to maximize its use of resources. As it turned out, this economic problem was not unique, and his mathematical solution involving linear functions was applicable across situations. For this work and for his research in *The Mathematical Method of Production Planning and Organization* and *The Best Uses of Economic Resources*, his first significant publications, Kantorovich was awarded the Stalin Prize in 1949. At a time when hybrid specialties such as mathematics and economics were slow to gain recognition in the scientific community, the government accolades he received legitimized his work and caused others to take notice.

During this time Kantorovich was also enlisted in the World War II effort for his mathematical ability. Kantorovich was awarded a medal for defense of Leningrad for his work ensuring that supplies reached survivors of the siege over a terrain of ice-covered lakes. This application of his work points to the value that the state placed on his work as a method of advancing the Soviet industrial state during an era of struggle for economic, military, and political power in the USSR.

The crowning achievement of Kantorovich's career was receiving the Nobel Prize in Economics for the work he pursued during the 1950s in improving theories on optimum allocation of resources. For this work, he was first awarded the Lenin Prize in 1965 and the Order of Lenin in 1967. International acclaim came years later in 1975 with his Nobel Award, which he shared with his peer in the field, Tjalling Koopmans. During the 1950s, Stalin's five-year plan and collectivization policies represented an increased interest in government control of economic operations. Increased efficiency became a priority. Out of Kantorovich's work came his book *The Best Use of Economic Resources*, wherein he tackled the central economic problems of industry and management and the optimal conceptualization of these problems as they occur within industry, regional, and national economies.

From 1961 until 1971, Kantorovich continued his earlier work at the Siberian branch of the USSR Academy of the Sciences. He directed research at Moscow's Institute of National Economic Planning from 1971 until 1976, wherein he developed further evidence for the necessity of price systems to most efficiently allocate resources. In his later career, Kantorovich turned his attention to computer architecture.

Leonid Kantorovich died in Moscow, Russia, on April 7, 1986, at the age of 74.

KELLOGG CO. V. NATIONAL BISCUIT CO.

Imitation may be the highest form of flattery, but in a competitive market it can rob innovators of their profit and stifle their motivation to create. Legal protections for property that someone has invented, thought of, discovered, or created are commonly known as intellectual property rights. Trademark and patent rights are included in this category. Although these rights do not ensure the profitable success of the inventor or originator, they do offer an incentive for entrepreneurs to keep innovating. Some might argue that Americans' ability to innovate and think creatively has been one of the key factors in the nation becoming an economic world leader. In *Kellogg Co. v. National Biscuit Co.,* 305 U.S. 111 (1938), the courts clarified judicial precedents for intellectual property rights in the United States. The rule of law as applied to intellectual property helps safeguard against unfair trade practices as well as motivating productivity.

Case Summary

The biscuit war in Battle Creek, Michigan, was more than just a pillow fight. At the turn of the 19th century, America was waking up to a new breakfast. Persuading people to leave bacon and eggs and start their day with what seemed more like chicken feed was not a simple task. Innovations in the process of manufacturing different cereals followed research concerning the healthiness of grain-based diets. Dr. John Harvey Kellogg was a physician and innovator in manufacturing of grains. Working with his brother W. K. Kellogg, they created a flake of wheat and repeated the process with corn. After much experimentation, wheat and corn flakes were boxed and marketed as the secret to a healthy diet.

Meanwhile, several other cereal entrepreneurs were adding their recipes to this new food industry. As early as 1877, Henry Seymour had applied for the first registered trademark for a breakfast cereal, using a traditionally dressed Quaker man as the company symbol and calling it Quaker Oats. W. C. Post was busy inventing Grape Nuts, a cereal named for the smell of grapes it put off during production and the nutlike texture of the finished product, though it contained neither grapes nor nuts. In 1893, Henry Perky and his partner William Henry Ford patented a machine that shredded wheat, resulting in a pillow-shaped biscuit predictably called *Shredded Wheat*. Link these trailblazers with the pasteurization of milk, and what was once in a trough was now in Americans' breakfast bowls. The nation transitioned to a cold, fast breakfast that came out of a cardboard advertising Mecca known as the cereal box. This set the stage for a competition that would see battle in the courts as well as on the grocery store shelves.

By definition, cereal is any edible grain. However, to get from edible to appetizing took innovation. To get from factories to breakfast tables took marketing. The process was fueled by cereal-industry competition and guided by the rule of law concerning fair trade practices, patents, and trademarks. In the *Kellogg Co. v. National Biscuit Co.* case, two major competitors and a pillow-shaped bundle of shredded wheat created case law that started with a skirmish and grew into an international brawl.

Henry Perky was a lawyer turned inventor who intended to sell machines. John Kellogg was a man of medicine. The two men knew each other, and both believed in the benefits of grains in the diet. However, John Kellogg turned toward religion and his brother, C. W. Kellogg, took the reins of the business and purchased the rights to Cornflakes, starting the Kellogg Toasted Corn Flakes Company in 1906. Meanwhile, Perky struggled with his mental health and eventually sold his patents and the Shredded Wheat Company in 1881 to the National Biscuit Company (the name was changed to Nabisco in 1971). However, the biscuit design patent was invalidated one year prior to its expiration date in 1908. The National Biscuit Co. and the Kellogg Company continued to parallel each other during the vertical climb toward the top of the cereal market, the former exclusively connected with Shredded Wheat biscuits and the latter with Corn Flakes. When the 20-year exclusivity to produce shredded wheat had expired due to patent time limits, the gloves came off.

Soon, Kellogg Co. began producing biscuit-shaped shredded wheat cereal under the Kellogg signature. In 1935, the National Biscuit Co. sued Kellogg, claiming that Kellogg had violated competition practices by deceiving the public into thinking that shredded wheat was a Kellogg product and by copying National Biscuit's product. Kellogg countered that the patent was in the public domain, as was the pillow shape.

National Biscuit Co. retorted that when Kellogg depicted the shredded wheat biscuits in a bowl with milk poured over them, it was too closely associated with National Biscuit Co.'s cereal box and consequently misled the consumer into purchasing a Kellogg product thinking it was a National Biscuit Co. product.

The federal district court in Delaware ruled in favor of Kellogg Co., stating that the term "shredded wheat" is free for all to use, and cereal bowls and milk flow naturally from that free domain. In 1937, National Biscuit Co. appealed its case to the federal circuit court of appeals, which reversed the decision of the district court and ordered Kellogg to stop using the term "shredded wheat," to stop selling its product in the shape of a pillow-shaped biscuit, and to pay damages in line with its subsequent fraud. A small percentage of the shredded wheat cereal sold by Kellogg to hotels and restaurants was not labeled sufficiently, and this influenced the court to believe that there was evidence to support deception. Kellogg Co. appealed to the U.S. Supreme Court, but certiorari (request for a lower court to send the records of the case to the Supreme Court) was denied.

At the same time, court battles were taking place between the Canadian-held sister companies of both parties. However, over the northern border, the decision was different. Canadian opinion held that there was no right to a patent that was public domain, as was the case with shredded wheat. Furthermore, the biscuit shape was a description of what happens when anyone bakes wheat that has been shredded. Hence, descriptions are not exclusive property. This international court mirrored the opinions of the U.S. Federal District Court; it handed down a ruling in favor of the Kellogg Company of Canada in May 1938.

Meanwhile, back in the United States, Kellogg continued to sell shredded wheat in a box with the biscuit image, clearly favoring a different interpretation of the U.S. Federal Appellate Court's opinion. National Biscuit Company requested clarification of the Supreme Court's orders to halt sales. Afterward, the decision from Canada became available and Kellogg resubmitted a request to the Supreme Court to hear its appeal again, taking into consideration the ruling of the British Privy Council (one of Canada's vestige appellate courts from British colonialism abolished in 1949) in *Canadian Shredded Wheat Co., Ltd., v. Kellogg Company of Canada, Ltd.*, 55 R.P.C. 125. The Supreme Court granted certiorari and heard *Kellogg Co. v. National Biscuit Co.* in October 1938.

National Biscuit Co. did not claim the exclusive right to produce shredded wheat, but it did claim the right to the trade name *Shredded Wheat* and the right to the biscuit design. Kellogg Company claimed that *shredded wheat* was a generic term used to describe the product that the company had the right to make. The court found no doctrine of secondary meaning (legal protection of an otherwise not protected trademark that arises when advertising and time make that mark signify a particular product). The National Biscuit Company needed to show that people thought of it alone when seeing the words or the shape. It failed to do so. Instead, it made clear that the words or shape brought to the mind of consumers a basic product that could have been made by any cereal company. Therefore, the only obligation Kellogg owed was to clearly identify itself to the consumer, which it made a point of doing by having W. K. Kellogg's own signature on every box as a trademark. On November 14, 1938, the Supreme Court ruled in favor of the Kellogg Company; Justice Brandeis wrote the opinion.

The framers of the Constitution knew how important it was to protect the intellectual property rights of authors and inventors in order to ensure innovation in science and the arts. Article I, Section 8 of the Constitution includes among the enumerated powers of Congress the power to secure, for limited times, the exclusive right of those who create. The significance of this power is evident in the myriad of patents, copyrights, and trademarks filed in the United States annually. In the *Kellogg* case, the courts established a point of reference for the laws for intellectual property rights in industrial America. The case helped define what was in the public domain and to what degree the functionality of a product could influence control over its economic use. Setting rules for intellectual property is one more weapon in the battle against unfair trade practices.

LABELS AND SIGNALING

In the real world of complex information—where information is asymmetric and misleading, can be incomplete and false, and is costly to obtain in terms of search and information-processing costs—the choices we make can be critically affected by product labels, quality ratings, information packages, and how the information is framed. Without appropriate information, individuals must make educated guesses as to what are the critical characteristics or attributes of a particular product. Given information gaps, errors in decision-making are highly probable. Individuals are likely to make choices that are in direct conflict with their preferences. Given their preferences, income, and relative prices, improved information would yield different choices, choices that would generate higher levels of utility or satisfaction.

There is here the possibility of market failure in the sense that market forces aren't allocating resources, given income and relative prices, in accordance with the preferences of individuals. Also, with inadequate information, our revealed preferences—that is to say our choices—tell us little about what our true preferences are. These choices generate no reliable information on what our choices would be had we been better informed.

Behavioral and institutional economists have long argued that trustworthy product labels, certification, and information packages are crucial to the efficiency of a market economy. They provide us with the information necessary to make informed decisions. And such information is most efficiently and effectively provided by government or through the auspices of government. Otherwise, there is an incentive for firms, organizations, and individuals to shirk on providing truthful information, relying on the uncertainty about reliability of labels to market substandard products as quality products. Although reputational effects of such behavior can partially contain this problem, this need not be the case and, empirically, it is often not the case. This has been most recently evident in financial markets where financial institutions and private rating agencies failed to deliver accurate product information and certification, resulting in individuals purchasing products that they might otherwise not have. For many individuals, in a world of complex and costly information, the economic benefits of being deceitful can often outweigh the costs.

For example, if you don't want to buy clothing made with nonunion labor or chickens that are not free range, you can't realize your preferences without proper product labels. If you are allergic to certain ingredients, you can't avoid these unless you're provided with the appropriate information. If you don't have appropriate information on the breakdown of the financial assets you are thinking of purchasing, you might end up buying assets that only appear to be consistent with your preferences. Without appropriate information, you most probably fail to realize your preferences. This can have disastrous consequences, especially in financial markets or if one suffers from severe allergies. Improved information does not impinge on the free choice of decision-makers. Rather, it makes free choice more effective and efficient, improving the quality of decision-making.

The provision of appropriate and trustworthy information is not a sufficient condition for individuals to realize their preferences. An assumption of conventional economics is that if product information is readily available or disclosed in terms of labels, info packages, and certification, rational individuals will locate, process, and assess this information to make a rational and optimal choice of what and how much to purchase and consume. But given information complexity and the costliness of acquiring, processing, and assessing information, this often does not take place. This is an important point made by behavioral economists. For this reason, it is argued, how the information is framed affects the decision-making process and, ultimately, the choices that individuals make. Framing is of critical consequence for decision-making even if it provides no additional information to the decision-maker. If the information is available but hard to locate and/or difficult to understand, if font size makes the material difficult to read or hints that the material is not important, if critical bits of information are buried in the information document, if certification is difficult to understand, people may be led to make poor and regrettable choices. The availability of adequate information alone will not suffice to produce choices consistent with the preferences of decision-makers.

LABOR ECONOMICS

All goods and services (outputs) are made from using productive resources of land, capital, and labor (inputs). Labor is the measure of human capital. Labor economics is the comprehensive study of wages, job markets, the demand for labor by employers, and the interconnections between income, wages, and employment.

Labor economics can be studied at the micro level of studying labor within a particular industry or firm in terms of job growth, skills, or wages. It can also be studied and measured at the macro level as measures of the overall economy, such as unemployment, overall wage growth, jobs market, or the relation between employment and the other economy goals of price stability (low inflation) and economic growth. At both the micro and macro levels, the demand for labor is also of interest, whether observing the demand for labor of an industry (micro) or the demand for labor as a measure of an economy's relative position in the business cycle (macro).

Measuring Labor and Unemployment

Measuring economic labor comes in many forms. One is measuring the labor force, or the number of people who are employed and unemployed. If they are unemployed, they must also be of working age, willing and able to work. A second important measure is the number of people in the labor force divided by the population, known as labor's participation rate.

The participation rate is very important because it reflects the accuracy of the most popular measure of labor, the unemployment rate. The unemployment rate is the number of people currently working divided by the labor force.

Another measure important to economists is the natural rate of unemployment. First suggested by Nobel laureate Milton Friedman, the natural rate of unemployment submits there is a level of unemployment inherent to an economy. A measure of the natural rate of unemployment is the sum of frictional and structural types of unemployment. Economists often discuss and debate this measure. Researchers also sometimes use a calculation as to how low unemployment can go before it impacts inflation, or the noninflation acceleration rate. This is often referred to as NAIRU, non-accelerating inflation rate of unemployment.

Types of Unemployment

There are four types of measured labor, or unemployment: frictional, structural, cyclical, and seasonal. Frictional unemployment refers to the unemployed who are between jobs. They never really left the labor force and were always willing and able to work. Structural unemployment refers to those who are usually the most harmed by unemployment. These are individuals who become unemployed because their industry or the economy is going through significant and permanent change. Structurally unemployed individuals' problem is that the newly changed industry will no longer require their skills. Plus, the new skills needed may be beyond the capability of the individual to acquire. Cyclical unemployment is the result of the business cycle and a downturn in the economy. Cyclical unemployment is in most cases temporary. Seasonal unemployment is as the label suggests. The seasonally unemployed are those individuals whose labor and work activity is determined by the seasons. This is obviously more significant in temperate climate zones and in outdoor labor.

One of the modern philosophies in labor economics is the neoclassical microeconomics model. This philosophy views the labor market mostly as any other market for goods or services. Neoclassicals essentially study the supply and demand of labor markets in the same way they study any other market, but with one major difference. The major distinction of the labor market is that the demand for labor is derived from the demand for the good or service that the labor produces. It is a derived demand and therefore dependent on the market forces of the product market.

Labor economists spend much of their time studying what is known as the labor-leisure trade-off. Individuals who work reflect a trade-off between the time they spend in labor and the time they spend in leisure. Economists measure the labor-leisure trade-off as a function of income and how the worker substitutes one for the other. A worker will substitute more labor for leisure as his or her wage rate (income) rises. The worker will accept the additional opportunity cost of less leisure in favor of the higher wage rate. This is also known as the income effect and the substitution effect of income. At times the income effect (impact of higher income) prevails, and other times the substitution effect (substituting more labor for less leisure) prevails.

LABOR MARKET REGULATION

Conventional economic theory predicts that introducing or increasing minimum wages or legalizing unions or enhancing union power or the capacity of workers to unionize will result in unemployment. The same could be said of any factor that increases the bargaining power of workers, such as market-based increases to the demand for labor. Based on the assumption that the economy is x-efficient, that workers and managers are working as smart and as hard as they can, it is argued that any increase in wages that follows from increasing productivity will reduce employment, thereby increasing the extent of unemployment. Because wages are one component of costs, it is assumed that increasing wages increases average or unit costs as well as marginal or additional costs of producing output, forcing firms to employ fewer workers. The classic argument is that the only people benefiting from minimum wages or unions are the relatively more productive workers who manage to hold on to their jobs.

Evidence does not support the conventional model's prediction that minimum wages or unions necessarily cause economic harm, increasing average costs and reducing employment. On average, there appears to be little or no negative impact of these two institutional interventions in the economy, given how minimum-wage legislation and unionization has been instituted. There is also no negative average statistical relationship between economies with higher minimum wages and higher rates of unionization and low levels of per capita income or lower rates of per capita economic growth. With regard to minimum wages, different levels of minimum wages for different age groups (one level for youth and another for the rest) is most consistent with little or no negative impact associated with minimum wages.

X-inefficiency theory (also referred to as x-efficiency theory) helps to explain this empirical regularity that's inconsistent with the conventional model. X-inefficiency theory assumes that effort per unit of input is neither fixed nor maximized irrespective of market forces given the overall work environment within the firm. Given x-inefficiency, increasing wages from minimum-wage legislation or through collective bargaining induces more effort on the part of workers, managers, and other firm members. Firms must increase their productivity to remain competitive, and one important means of doing so is through increasing the quality and quantity of effort inputs. Increasing productivity offsets the increased labor costs, and the predicted negative effects of minimum wages and unions need not transpire. Increasing effort effectively shifts outward the demand curve for labor. It is even possible that minimum wage and union-type shocks to the economy might increase productivity to such an extent that employment actually increases. The extent or size of the productivity offsets is an empirical question.

By way of illustration, if wages increase by 10 percent and labor is the only input, average costs increase by 10 percent (average cost = [wages/output per unit of labor]). This is what the conventional wisdom assumes. But if productivity increases as a consequence of the increase in wages, this diminishes the extent of the increase in average cost. And, if productivity increases by 10 percent or more, exogenously given increasing wages would have no negative effect on employment. In addition, making the economy more x-efficient increases the size of the economic pie, and workers are made better off without making anyone worse off. This is what economics refers to as Pareto optimality. This possibility is assumed away in the conventional model due to the assumption that effort is fixed. Moreover, higher wages or better work environments often result in lower labor turnover, which further reduces average costs, generating additional cost offsets. Finally, higher wages can induce technological change, further increasing productivity and shifting outward the demand curve for labor. As long as the increased output is absorbed on the demand side, increasing the level of x-efficiency and induced technological change can offset any negative effect that higher minimum wages and unions might otherwise have on the economy.

These more realistic behavioral assumptions allow for analytical predictions more consistent with the evidence. But there is no prediction here that minimum wages and unions can't negatively impact the economy. Rather, this model allows us to better explain why minimum wages and unions need not have the negative impacts predicted by conventional theory and why they might actually have a positive effect. This type of modeling is also more consistent with the facts as we know them.

LABOR THEORY OF VALUE

Late in the 18th century, during the period known as the Industrial Revolution, economist Adam Smith developed the labor theory of value. This theory states that the market price of a good is in proportion to the labor required for its production. Originally considered an idea of the classical economic view, the theory proposed that goods with the same labor value have the same price. The term *value* implies that the *value* of labor used in producing a product is equal to the *amount* of labor used in producing the product. In the mid-19th century, political economist Karl Marx, the most popular proponent of socialism, used the theory to suggest that prices of goods and services that were higher than the cost of the labor to produce them exploited workers.

When Adam Smith wrote the *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776), labor was the prime, and most mobile, resource in the production of virtually all goods and services. Smith's basis for the concepts of both division of labor and specialization was the labor theory of value. As Smith claimed in the *Wealth of Nations*, the value of a good or service was based on the value of the labor necessary to produce it. Smith used the theory to compare the relative worth of goods and to illustrate the value of voluntary exchange. If the owner of a good wanted to exchange it, he or she would use the value of the labor used to create it as the base of value for the exchange. The relative value would also help the owner decide if he or she was better off producing the desired object.

The labor theory of value does have its critics. They claim labor is not the determinate of a good or service's price. Labor is only one variable in the production of a good. The price of a good or service is determined by the relationship between supply and demand, not the value of the labor.

The effectiveness of the labor theory of value in modern economics is suspect on several levels. For one thing, the theory does not take into account the skills and experience level of the laborers. It also minimizes the use of capital and the costs of materials used in production. Finally, the theory does not take into account consumer demand of goods and services.

LAW OF DIMINISHING MARGINAL UTILITY (RETURNS)

The law of diminishing marginal utility states that the satisfaction a consumer receives from using an additional unit of a good declines as each additional unit is consumed. People generally make decisions on the margin by evaluating whether the satisfaction achieved by consuming an additional good is worth the costs. This law explains why price is more a function of demand and consumers' perception of value than it is of the costs of bringing a good to market.

Classical economist Alfred Marshall explained a consumer's utility as the extent to which a good or service satisfies a person's wants. The level of utility people receive from a good or service is determined by their most urgent desire for the good. The extra benefit received from an additional unit of a good or service is the unit's marginal utility. In addition, he further described *marginal* as the point where consumers are on the margin of doubt as to whether the additional unit of the good is worth the cost to obtain it. He concluded that eventually the utility of the additional units diminishes.

In making decisions about what to consume, people will estimate the benefit or pleasure they expect to receive in relation to what it costs to obtain it. They are much more willing to pay a higher price for the first unit of something than for subsequent units because the highest pleasure they will receive usually comes from that first unit and declines with each additional unit. Some products may provide increasing marginal utility at first, but every good and service will provide diminishing marginal utility at some point. For example, a person eating Thanksgiving dinner would likely perceive it as highly desirous and would very much enjoy the first several bites. As the meal progresses, however, the person's level of enjoyment will diminish. At some point, he or she will recognize that no further enjoyment can be obtained by eating more, and the meal will end. It can be extended further, however, into negative diminishing marginal returns where each additional unit actually provides pain or discomfort.

There are several conditions under which the law of diminishing marginal utility is constant. A single individual should want homogenous units of a single good. The utility of a good for one person cannot be measured against the utility of the same good by another person because they each have unique perceptions about the degree to which the good is important. Also, each of the goods must be the same weight and quality. A cup of water consumed from the ocean will not have the same value as a cup of water from a spring, regardless of a person's thirst. The preference, or taste, of a consumer must also remain constant. Any changes in tastes, habits, customs, fashion, or income changes the variables of measured utility.

There should be continuity in the consumption of a good. Units of a good should be used in concession in one particular unit of time. A person having 10 bottles of water at one meal will have a different measure of utility per bottle than a person having 10 bottles and only drinking one a day. Each unit of a good must also be of a suitable size. Giving someone who is thirsty a teaspoon of water will only increase marginal utility until a suitable amount has been consumed. Also, the unit value of the good compared with substitutes should remain the same.

A good should not be indivisible; it's not possible to measure the value of a durable good if its use is spread out over a period of time, such as a car or a refrigerator. Also, the law of diminishing marginal utility does not apply to commodities such as diamonds, or jewels, or collector's pieces. Consumers must be rational and act in their own interest. An impaired consumer may act against his or her best interest and derive satisfaction from a good that is actually harmful.

Money is also subject to the law of diminishing marginal utility. As people collect more and more money, each additional unit of wealth has a diminished marginal value. The $100 a 16-year-old earns at his or her first job has a far greater value than $100 earned by billionaire.

The law of diminishing marginal value can be used to explain the paradox of value: why people value diamonds more highly than they do water, which is necessary for survival, for example. The value of any item depends on the subjective value placed on it by an individual consumer. An additional bottle of water may have no value to a person who has a room full of bottled water to be consumed at will, but someone stranded in the desert may give every worldly possession they have, diamonds included, to obtain one. If the availability of water equaled the availability of diamonds, water would have a higher marginal utility and would therefore be more valuable. The perceived value of a good is reduced with an abundance of use.

The same principle can be applied to the stock of money in an economy. As the supply of money into the economy increases, the value of each unit and the price (interest) that consumers are willing to pay for it diminishes. Its value is reduced in relation to other goods and services (inflation). When the supply of money is restricted, consumers perceive scarcity and are willing to pay more for it. Money becomes more valuable in relation to other goods and services.

Organizations use this law to establish pricing; water companies charge higher rates for additional use so consumers' perceived value does not diminish with overuse. All-you-can-eat buffets charge one rate for unlimited utility, but consumers find less and less value with each additional serving, so businesses remain profitable. Progressive taxing policies increase tax rates as income increases because the marginal utility of money is much lower for the wealthy than it is for the poor.

LIABILITIES

The term *liability* has personal, business, and insurance connotations.

In personal and business uses, *liability* and *debt* both mean all obligations or amounts owed. On occasion, these terms may be used interchangeably. At other times, *debt* has a narrower definition and only includes funds borrowed and formalized with a written contract. In either case, the terms *liability* and *debt* are frequently used interchangeably.

Insurance liability refers to fault or legal responsibility. Liability insurance protects the policyholder from a variety of personal and business risks

Personal Liabilities

A personal liability is a financial obligation repaid out of one's personal assets. For example, the home mortgage is a personal liability the consumer has to repay to the lender for the amount borrowed to purchase a home. In this case, liability and debt mean the same thing.

Secured liabilities are loans guaranteed by collateral. If the loan is not repaid, the lender has the legal right to take possession of the asset. For example, a vehicle loan is secured by the car or truck. If the borrower doesn't make the loan payments, the lender has the right to repossess the vehicle.

An unsecured liability may be considered a promise to pay. Should the borrower default or fail to pay back the financial obligation, the lender has the right to sue the borrower for the unpaid balance. The lender may eventually be repaid from the borrower's other assets or future wages.

Business Liabilities

In general, a company's liabilities are the amounts owed to lenders as well as payments to vendors and suppliers. Simply, a company's liabilities are bills or payments due to others. In business, a liability might have the term *payable* in its title.

Liabilities and the Balance Sheet

In business and accounting, a balance sheet is an important financial statement used by business managers and accountants to describe the financial picture of a company at a specific point in time. The balance sheet includes three major categories: assets, liabilities, and equity.

A net worth statement is a document that shows an individual's assets less liabilities. The resultant figure shows the individual's financial worth. The business balance sheet is comparable to the net worth statement of a business. The balance sheet, like the net worth statement, includes a company's assets (any item of value owned by a corporation or individual that can be converted into cash) less its liabilities and net owner's or shareholder's equity or the economic value of the company.

The liabilities section of a balance sheet normally includes current and long-term liabilities or amounts owed. The current liabilities are short-term obligations due within one year, such as a short-term loan or note payable. Accounts payable, wages payable, and interest payable are also considered short-term liabilities. Long-term liabilities include long-term loans and other financial obligations due in more than one year.

On the balance sheet, after liabilities are subtracted from assets, the value of the company remains. Just as with personal liabilities, a corporation needs to keep liabilities within a certain range for the company to remain profitable.

Liabilities Example

This example shows how liabilities fit in with a family's financial picture and can be generalized to a company's financial balance sheet as well.

The assets owned by the Patels include a car, a home, and money and investments in savings and retirement accounts. These assets are worth $500,000.

Their liabilities include a home mortgage, a car loan, and a small amount of credit card debt. The total amount of their liabilities equals $275,000.

The Patels' net worth is $225,000. This figure is obtained by subtracting their liabilities ($275,000) from their assets ($500,000). The net worth is the sum of their financial worth, similar to a company's equity. This illustration shows how liabilities fit in an overall financial representation.

Insurance Liability

In business accounting and personal instances, *liability* means financial obligation. In insurance terms, *liability* refers to risk. Usually, liability insurance protects individuals from financial and legal risks.

A liability insurance policy protects the individual or business from the risk of a legal suit arising from malpractice, injury, or negligence claims. In most cases, this insurance pays for both legal costs and financial payouts for which the policyholder is legally responsible.

For example, most states require vehicle owners to purchase liability insurance. That way, when driver A's car hits driver B's car, injuring car B's driver and passenger, driver A's liability insurance will pay for the medical and vehicle repair bills.

Business liability insurance pays damages to customers injured on the business premises, such as if a customer falls, twists her ankle, and sues the company. Business liability insurance might also protect the business owners if an employee is injured while performing work duties.

Liability, in the broad sense, means responsibility. One might have financial responsibility to repay a debt or legal responsibility to pay for an injured person's medical charges (if the insured was the cause of the medical expense).

In modern money management, the well-informed consumer will understand this concept with relation to his or her personal finances as well as its business and insurance applications.

LIFE INSURANCE

Life insurance is a product created to protect family members from the loss of income when the family's primary earner (or earners, in the case of a two-income family) passes away. People protect their family financially in the event of death by purchasing life insurance. When the owner of the life insurance is the individual, the proceeds are paid to the policy's nominated beneficiaries or the insured's estate. In some cases, where the insured has been diagnosed with a terminal illness (confirmed by at least two medical practitioners), the insurer may also pay out the sum insured. Not only does life insurance coverage apply to breadwinners and individuals, there are many business owners who need a life insurance policy for the survival of their business in the event of a key employee's death.

Why It Is Important

Should the main income earner of a family die, the surviving family members may end up facing huge debts they cannot repay. Without an income or means of support, a death could leave the remaining family members destitute. Without life insurance, the surviving spouse and financial dependents could face a lowered standard of living, insurmountable bills and expenses, and even bankruptcy.

Life insurance, as with most other insurances, is purchased as protection for the beneficiaries. Similar to homeowners insurance, breadwinners should also be insured in the unfortunate and unforeseen event they die prematurely.

Life Insurance Terms

A life insurance policy will specify the policyholder (person who purchased the insurance cover), the insured (person whose life is covered), the insurer (insurance company who provides the cover), beneficiary (person who receives the proceeds of the insurance payout), the amount of the premium, and the face value (value of the policy in the case of the insured's death).

Premiums are the regular payments the policyholder agrees to pay to the insurer to transfer the risk of death of the insured to the insurer. Premium payments can remain the same for the duration of the policy, referred to as level premiums. Alternatively, premiums may increase periodically, usually annually, in a stepped fashion and are thus called stepped premiums. With permanent insurance, premiums may also decrease over time as cash value increases, or dividends from the policy may be used to decrease premiums.

In addition to basic life insurance coverage, options included in an insurance policy are called *riders*. Riders are the additional benefits that can be purchased and added to a standard life insurance policy. Riders can take the form of additional life insurance amounts or supplemental benefits, such as accidental death. An accidental death rider provides a supplemental payment if the insured dies as a result of an accident.

Types of Life Insurance Policies

There are three main types of life insurance policies or products that provide risk protection for individuals, families, or businesses (Life Insurance 2008; Sargent 2008; Zinkewicz 2002): permanent insurance (whole-of-life and endowment policies), term life (temporary) insurance, and universal life insurance.

Permanent Insurance

The face value of the policy provides the amount of death benefit. This type of policy also builds up equity in the form of cash value, which accumulates over the life of the policy. The policyholder receives the face value of the policy upon the insured's death. As the policy matures, the cash value increases. If no disaster befalls the insured, the policyholder has the option of borrowing cash value against the face value while keeping the face value benefit or canceling the policy and receiving the cash value accumulation. The policy lapses if the policyholder stops paying the premiums.

The investment component consists of premiums less expenses and less the cost of the insurance coverage. The cash value comprises the face value of the policy (amount of money the person is insured for) plus any bonuses. Bonuses are the return on the investment component of the policy that has accrued over the life of the policy.

There are two main types of traditional permanent insurance policies: whole life policies and endowment policies.

Whole Life Insurance

Whole life insurance offers permanent insurance for policyholders during their entire life. While premiums are higher than term life policies (discussed later in the article), whole life policies accumulate cash value available to policyholders during their lifetime. The contract detailing a whole life insurance policy may allow the policyholder to take out a cash value loan against the face value accumulated. These policies are for insurers who plan to keep the policy long term, so the policy includes a savings component of a guaranteed cash value with additional accumulations based on dividends and additions over the maturity of the policy. As long as the premiums are maintained, a whole life insurance policy offers a guaranteed payout to the beneficiaries of the policyholder, and the death benefit may increase over time as the policy builds cash value.

Endowment Insurance

Endowment insurance policies are similar to whole life policies with one exception: the two have different maturity periods. Endowment policies have short- to medium-term maturity dates and generally do not outlive the insured person.

The endowment policy pays the face value of the policy on a fixed date or upon the death of the insured, whichever comes first. The benefit may also be paid upon cancelation.

The endowment life insurance policy is used to meet certain future expenses, such as college tuition or buying a retirement home. The maturity dates can be set for a specific term (e.g., 10 years) or to mature when a beneficiary reaches a certain age (e.g., 21 or 65).

Term Life Insurance

Term life policies pay the beneficiary only in the event of the death of the insured within a specified term. Unlike permanent insurance, there is no cash accumulation (cash value) component to term life insurance. Term insurance policies often outlive the insured and are not initiated at the death of the insured.

The simple term life policy remains in effect for a specific period as the annual premiums are paid. The annual premium amount can be set at purchase for a specific length, such as 10, 15, or 20 years. This is called level term. This means the insured knows how much the annual fee will be for the specific amount of insurance purchased.

The premiums are fairly low cost, making them more affordable than many other types of life insurance policies. The insurance value is guaranteed to last for the specified term as long as the insured pays the annual premium. Unlike permanent life policies, term life contains no savings component. When the policy is canceled or lapses, there is no surrender value (cash value). A claim from these polices can only be made upon the death of the insured. Term policies only provide financial security to the surviving family of a breadwinner at death.

Universal Life Insurance

Universal life is a combination of low-cost insurance with a high-risk, high-potential-return side investment funded by additional premium payments from the insured. These policies are for insurers who plan to keep the policy long term with increased risk based on an investment instrument such as a mutual or stock fund. Universal life insurance policies need to be in force for at least 15 years to be eligible for any return on the investment.

By maintaining the policy for at least 15 years, the savings portion has enough time to accumulate into an investment. With a universal life insurance policy, the policyholder has some control over the investment decisions. The policyholder also has some latitude regarding the premium amount, how much cash value accumulates, and how much death benefit will be given to the beneficiary. Furthermore, the death benefit may increase over time as the policy builds value.

A variable universal life policy gives the insured the responsibility of choosing the types of investment products to accumulate a cash value. The underlying investments supporting a variable life policy increase the risk of loss of some or all of the value in the case the investment performance is less than expected.

Group Life Insurance

Group life insurance (group wholesale life insurance or institutional life insurance) is a type of term life insurance that covers a group of people, usually employees of a company or members of a union or association. Group life insurance is typically part of an overall employee benefits package. On occasion, a certain coverage level is paid for by the employer, with increased coverage available to individual employees.

Individual proof of insurability is not normally a consideration in the underwriting. Instead, the underwriter considers the size, turnover, and financial strength of the group. Contract provisions attempt to exclude the possibility of adverse selection.

Group life insurance often includes a provision for a member exiting the group to buy individual coverage.

LIQUIDITY

The liquidity concept traverses the personal and business finance categories. *Liquidity* refers to an individual or corporation's access to cash or assets that can be quickly converted into cash. For example, bank certificates of deposit and cash in a checking or savings account are liquid assets. Assets that can be easily bought or sold are considered liquid. Another term for liquidity is *marketability*.

Liquidity is important in daily life as consumers need ready access to cash to meet regularly scheduled bills and financial obligations as well as for unexpected expenses such as car repairs or medical bills.

Corporations need available liquid cash in order to meet ongoing expenses such as payroll and accounts payable. The company also needs a certain amount of liquidity available for other business uses.

Which Assets Are Considered Liquid?

Obviously, cash held in checking and savings accounts is liquid. Money market mutual funds and money market bank accounts are also used as cash substitutes. But there are other types of financial assets that are also easily converted into cash. These short-term financial obligations include a class of investments called short-term marketable securities. Short-term treasury bills and notes (types of government bonds) are liquid. Corporations also issue very short-term debt, maturing in less than six months. These types of financial assets, called commercial paper, are readily converted into cash.

Consumers and Liquidity

When consumers plan their spending, saving, and budgeting, liquidity is an important concern. While some expenses occur frequently, such as rent, utility, and grocery bills, others are less frequent. Individuals need to maintain sufficient liquidity to pay for emergency car repairs, medical bills, occasional insurance, and other periodic expenses.

When applying for a home mortgage, lenders examine the prospective borrowers' liquidity and access to capital. In general, lenders expect consumers' debt expenses, including mortgage, student loan, and consumer debt, to fall below approximately 40 percent of the borrower's gross income. This relationship between debt levels and liquidity is of concern to both lenders and borrowers. Lenders wish to ensure borrowers have enough liquidity to pay the loan payments. Borrowers are also concerned with their own cash availability and cash flow.

For example, the Martinez family is planning their monthly spending and saving and wish to calculate their liquid cash after all expenses. This illustration demonstrates how liquidity relates to personal finance and money management.

Mr. and Mrs. Martinez earn $7,500 per month, gross. They pay $2,000 per month in city, state, and federal taxes. This leaves them $5,500 to spend (or net spendable income). After paying rent, food, transportation, insurance, entertainment, miscellaneous expenses, and retirement account contributions, the Martinezes have no liquidity remaining. They spend all of their take-home pay.

This lack of liquidity is a problem as it leaves no cushion for unexpected expenses or extra savings into an emergency fund. When the Martinez family has unexpected expenses, they use their credit card as an emergency fund. The lack of liquidity causes the Martinezes to incur debt because of the excess interest charges on the unpaid balance of their credit card. The family has a very small savings account without sufficient liquidity to cover all of the unexpected or infrequent expenses. The Martinezes are not unlike many American working families. Consumers such as the Martinezes must understand their liquidity position and how to maintain sufficient accessible cash for living expenses.

Liquidity Related to Investing

Assets that can be easily bought and sold are considered liquid. This liquidity assumes there is a ready market of buyers and sellers. In general, stocks, mutual funds, and exchange traded funds (ETFs), which trade in the public markets such as the New York Stock Exchange, are liquid. If an investor owns shares of Apple stock and would like to sell them, there is a pool of investors ready to purchase the shares on the popular NASDAQ stock exchange. Most stocks are easily converted into cash.

In contrast, certain financial or investment assets are illiquid. These "thinly traded" stocks and bonds from smaller companies lack the interest that the larger companies enjoy. When an investor holds an "illiquid" security, it may take extra time to sell the asset and there may be a large "spread" (or difference) between the buy and sell prices.

Corporate Liquidity Ratios

When investors buy stock in public companies and the companies analyze their own financial condition, liquidity ratios help calculate whether a firm has enough ready cash. Companies use standard metrics or ratios to measure their ability to handle particular financial scenarios. The following liquidity ratios may have various acceptable levels based on the industry. Due to the differences in both cash coming in and the need for cash, a large retail store such as Target would have different liquidity needs than a utility company.

The current ratio or working capital position takes the company's current or short-term assets (cash, marketable securities, receivables, and inventory) and compares it to the current liabilities (notes payable, debt due within the year, accrued expenses, and taxes). This ratio shows whether the company's short-term cash is sufficient to cover short-term obligations. A higher ratio shows better financial strength.

The current ratio is one of the most widely used financial ratios, yet it can be misleading as it may not be easy to convert inventory into ready cash. Thus, the quick ratio can be a tighter ratio to better measure a company's financial solvency.

The quick ratio, sometimes called the acid test ratio, is an indicator that measures the relationship between a company's most liquid assets (such as cash, short-term investments, and accounts receivables) and its current liabilities. A higher ratio indicates that the firm is better able to handle financial obligations.

Why Liquidity Is Important

As the financial crisis of 2007 demonstrated, there are severe financial ramifications when both consumers and the banking industry lack liquidity. In the case of homeowners and banks, the financial crisis could also be considered a liquidity crisis. After the housing boom of 2005–2006, many homeowners' adjustable-rate mortgage payments increased, making it difficult for them to pay. This lack of liquidity led to mortgage delinquencies, foreclosures, and personal bankruptcies.

As previously mentioned, companies also need to maintain appropriate liquidity levels. If a company lacks sufficient liquidity to pay its short-term obligations, such as repaying loans, paying its employees, and paying bills, the company may experience a liquidity crisis. If this situation is not quickly resolved with cash, the company may need to file bankruptcy.

At the beginning of the 2007 financial crisis, banks improperly managed their liquidity and experienced great financial problems and stress. Banks need to lend money at higher interest rates than they pay depositors in order to make a profit. Yet banks also need to hold enough reserves to pay depositors under a variety of withdrawal scenarios.

In the middle of the first decade of this century, when many homeowners defaulted on their loans, subprime lenders (those who lent to less financially stable individuals) filed for bankruptcy due to a lack of liquidity.

Many larger banks, which had purchased mortgage loans from smaller banks that had originally granted the loans, later offered a form of the loans to investors as securities (called mortgage-backed securities). These larger banks also experienced financial problems because when the homeowners defaulted on their loans and stopped making payments, the large banks stopped receiving the expected mortgage payments. Thus, the banks didn't have enough money coming in to pay out to the owners of the mortgage-backed securities.

These liquidity issues were some of the major contributors to the 2007–2008 subprime housing crisis and subsequent mortgage meltdown.

Tools for Individuals to Manage Liquidity

The world of online personal finance has come up with many tools to help individuals monitor and manage their liquidity needs. Online companies now offer budgeting, saving, and financial monitoring. One of the most popular personal finance and liquidity management tools is Mint.com, an online version of the grandfather of personal finance tracking software, Quicken (published by Intuit). There are other online companies that help consumers track and manage their debt and credit score.

With easily accessible and free money management tools, consumers have access to assistance with all of their liquidity concerns.

LIQUIDITY TRAP AND LIQUIDITY PREFERENCE

In macroeconomics, *liquidity* refers to the ability of financial assets to be readily available in order to make market transactions without difficulty and with negligible loss of value. The degree of liquidity varies across financial assets. While a currency issued by a central bank has the highest liquidity, financial assets such as bank deposits in checking and savings accounts have a high degree of liquidity. These financial assets are therefore usually considered liquid. Although other financial assets, such as bonds and equities, yield interest and/or capital gains, liquid assets bear little or no interest. Despite this property, people refer to interest-bearing financial assets as being liquid to some degree. In reality, people have at least some portion of their total assets in the form of liquid assets. Keynes (1936) defines the demand for money as liquidity preference.

According to Keynes, liquidity preference is determined by three motives: the transactions motive, the precautionary motive, and the speculative motive. The transactions motive is based on the fact that we need money to buy and sell goods and services. In other words, people need liquidity for economic activities. Because the transactions increase with income, the demand for liquidity also increases with income. In addition, people usually have more than enough money for everyday use and for emergency needs. This constitutes the precautionary motive. Since emergency needs usually increase with income, the demand for money based on these two motives is an increasing function of income.

The third motive is speculative. This is based on the fact that people often use money as an important means for speculation. When the bond prices are high or the interest rate is low, people hold money to buy the bonds when they become cheaper or their interest rate becomes higher in the future. In other words, people hold money for portfolio purposes. When the nominal interest rate is low, people hold a lot of money although it earns little or no interest. The demand for money based on this motive is a decreasing function of the nominal interest rate because people prefer interest-bearing financial assets to liquidity when the interest rate is high.

According to the liquidity preference theory, the interest rate is determined by the supply and demand of money. Other things being equal, the demand for money is a decreasing function of the nominal interest rate. Hence, the nominal interest rate decreases with the money supply. Quite naturally, however, the nominal interest rate has a lower limit of zero because people surely prefer money when the bonds and other financial assets do not earn any interest. Even when the nominal interest rate is positive, if it is close enough to zero, people prefer riskless money to other risky financial assets. This is especially the case when their expectations of the future are dismal, when their animal spirits are depressed. This situation is called a *liquidity trap* because increased injections of money into an economy by a central bank cannot lower the nominal interest rate and therefore fail to stimulate the economy, and individuals with dreary expectations don't respond to low interest rates. Because, in a liquidity trap, the conventional monetary policies targeting the interest rate become impotent, fiscal stimulus such as government spending is believed to be the only remaining policy instrument able to boost the economy in traditional Keynesian economics.

The practical importance of the liquidity trap became evident in the early 1990s, when the Japanese economy fell into a prolonged and severe slump with near-zero interest rates and deflation following the bubble economy of the late 1980s. Krugman argued that the Japanese economy was in a liquidity trap and that many advanced and emerging economies have been similarly trapped since the subprime crisis of 2007 (1998).

Business and housing investment is a function not of the nominal interest rate but of the real (net of inflation rate) interest rate. Even when the nominal interest rate is trapped at a near-zero level, inflation can push down the real interest rate.

Because the conventional monetary policies try to control the nominal interest rate, they are unable to get an economy out of the trap. In contrast, according to Krugman (and others), since unconventional monetary policies such as a quantity-easing or inflation-targeting policies are consistent with some inflation, they can reduce the real interest rate and possibly stimulate the economy.

LOCHNER V. NEW YORK

The 14th Amendment to the U.S. Constitution, as interpreted in 1905 by the Fuller Court (1903–1905), prohibits states from interfering with most employment contracts. The right to buy and sell labor is a fundamental freedom that, in a federal system of governing, is protected from arbitrary statutes and acts of state legislatures. Unless there is a reasonable threat to public welfare or realistic concern for public health and safety, regulation of wages between employer and employee cannot be interfered with using the police power of the state. So whether you shoe horses or bake biscuits, your right to buy and sell your labor is exactly that: your right to be protected from arbitrary, unfair, and discriminatory treatment by state legislatures.

Case Summary

The case of *Lochner v. New York,* 198 U.S. 45 (1905), is about making "dough," figuratively and literally. How much "dough" could a baker make if a baker could make dough, without being limited? It sounds simple; however, the case is not just about bread and wages; it is also an important lesson in federalism and the labor movement, and it established a new era in constitutional law regarding the due process clause of the 5th and 14th Amendments, known as the Lochner era.

The United States was the first country to adopt a federal system of government. The framers of the Constitution designed the U.S. model of federalism wherein the national and state governments share power and derive all their authority from the people. The national government is sovereign over the states with defined powers as stated in Article I, Section 8 of the Constitution. Powers not specifically given to the federal government or denied to the states are reserved to the states (as per the 10th Amendment). However, many powers are shared, such as the power to regulate the health and safety of the people. Setting wage limits and working guidelines for industries are not powers mentioned in the Constitution, nor are they denied. Therefore, they are left for legislatures to act upon and courts to interpret. The *Lochner* case is an example of this interpretation.

The period between 1870 and the turn of the century in American history is known as the Gilded Age (a term coined by Mark Twain that captured the attitude of less-than-accurate expectations of immigrants toward America at that time). This era was marked by industrial growth, enormous poverty, and the rise of the labor movement. New York was flooded with immigrants from Europe, many believing in the promise of a better life. Conditions did not match these expectations; a few found prosperity, but the reality for the masses was long hours of labor for little pay and crowded, unsanitary living conditions. Thousands of workers searched for employment, saturating the labor market. During this era there were few regulations on hours, wages, age or gender of workers, working conditions, and so forth. Industries often employed fewer workers—frequently women and children because they did not agitate as much as men—at low wages for long hours in unsafe conditions. These circumstances gave rise to labor unions, which organized and pursued an agenda that they felt would improve the lives of the working poor.

In 1894, the New York Press published a series of "muckraking" (a term coined by Theodore Roosevelt to describe writers who exposed the weaknesses of the capitalist system during the Gilded Age) articles on the baking industry. The articles exposed an unhealthy state of affairs, unsafe working conditions, and filthy kitchens. Within months, the public outcry resulted in state officials crafting legislation that significantly changed the baking industry and gave the labor movement a victory. The Bakeshop Act of 1895 pertained specifically to biscuit, bread, and cake bakeries as well as confectionery establishments. The law restricted the maximum number of hours a person could work in a bakery to 10 hours per day and not to exceed 60 hours in a week. In addition, it made requirements of building conditions, employee lodging (many journeyman bakers lived in the kitchens where they worked), ventilation, and overall cleanliness. Within a decade of the state of New York enacting this law, the national government, under the leadership of President Theodore Roosevelt, passed the Pure Food and Drug Act of 1906 to deal with similar public health and safety issues.

Joseph Lochner owned a bakery in Utica, New York. In 1904, he was issued a citation for violating Section 110 of Article 8, Chapter 415, of the law, known as the labor law of the State of New York or the Bakeshop Act of 1895 because one of his workers had exceeded the 60-hour rule. He paid a $25 fine. Lochner was later given a second citation for the same violation. This time the fee was $50, or 50 days in jail. He asserted that he had been denied his due process, as was his right in the 14th Amendment to the Constitution. His misdemeanor was heard in the county court of Oneida County, where he demurred (made an objection or delay) on several grounds, mainly that what he had done was not a crime. The court disagreed and found him guilty. Lochner argued that people have liberty of contract with regard to carrying out their business. It was his general right to negotiate with persons to buy and sell their labor and to be free to exercise their right of contract. This right is protected by the due process clause of the Constitution and subject only to legitimate police power of the state. Lochner contended that in this case, there were no reasonable grounds for the state to deny him of this right.

Joseph Lochner appealed his case to the New York Appellate Court and ultimately to the New York Supreme Court, which upheld the ruling of the lower court, finding in favor of the state of New York. A writ of error (a writ issued by an appellate court directing the court of record to send a trial record to the appellate court to be looked at for potential errors) brought Lochner to the U.S. Supreme Court, which serves as the final word on policy matters that challenge the delicate balance between federal versus state power and individual rights.

The Supreme Court's responsibility in this case was to determine if the U.S. Constitution prohibited states from restricting the rights of individuals and businesses to negotiate labor and employment contracts. The court used judicial review to scrutinize the balance between the interests being served by the government statute and the infringement of individual rights. Justice Peckman, in writing the opinion of the court, held that there was no reasonable governmental interest that justified this encroachment on individual liberty. The court claimed the singling out of bakery workers was arbitrary and discriminatory. These workers were in no less peril for their health and well-being than were lawyers and others who toiled many hours in their occupations. In his dissent, Justice Harlan stated that it was the burden of the appellant (Lochner) to prove that the New York law was indeed beyond a question plainly not reasonable and was in excess of legislative authority, which he claimed Lochner did not do. In his separate dissent, Justice Holmes cited Sunday laws (laws designed to restrict or ban some or all Sunday shopping for religious standards) and usury laws (the practice of making unethical monetary loans with excessive interest rates) as early examples of state laws that may regulate life in such a way as to interfere with the liberty to contract but that nevertheless remained laws.

In March 1905, the Supreme Court voted to reverse the lower court's verdict. The Fuller Court determined the outcome in favor of individual freedom and against the power of the state to enact legislation restricting free enterprise. The Lochner era is characterized by this new interpretation of the due process clause to have a substantive content. Using this lens, the Constitution protected minorities and individuals from arbitrary control by government with regard to fundamental rights that are inherent within their personal freedom. However, this interpretation would end with *West Coast Hotel Co. v. Parrish* (1937).

The Lochner era was an outcome of the industrial revolution. Today, however, interpretation of substantive due process with an emphasis on minority rights and protection from government encroachment of private conduct remains well established, though still controversial.

M

MARGIN

Margin has several different meanings and applications related to personal finance. Business, accounting, economics, finance, investment, and banking all use the term *margin*. The meaning of the term varies along with the discipline in which it is used.

Business and Accounting

In business and accounting, *margin* refers to profit as a percentage of sales generated by a corporation. This is referred to as *profit margin* and shows how much money is left over after costs are subtracted. In this situation, a larger margin is better and means greater profit.

There are three basic classifications for margin depending on the profit calculation technique used. *Gross profit margin* refers to profitability after deducting only the costs of goods sold (COGS). COGS is an accounting term and usually refers to the cost of raw materials and labor expenses.

Operating profit margin measures profitability after excluding all overhead costs (these include rent, utilities, etc.) and administrative (such as salaries) and selling (vehicle, advertising, and other costs) expenses. Operating profit margin also excludes COGS.

Finally, *net profit margin* measures profitability after subtracting taxes and interest expenses resulting from debt incurred by a corporation as well as the exclusions from gross and operating profit margins. Net profit margin shows the true percentage of profit after deducting all expenses.

Higher profit margins are superior to lower and demonstrate how effective a company is at controlling costs. All other factors being equal, when comparing two companies in the same industry, if Company A has a profit margin of 15 percent and Company B has a profit margin of 19 percent, Company B would be considered to be more profitable than Company A. After all, a company prefers to keep a larger percentage of the sales revenue from the product or service.

Economics

In the context of economics, *margin* means extra. This can be illustrated by a simple example. The first sandwich you eat when you are extremely hungry will provide a certain level of satisfaction (this satisfaction is referred to as utility), but the second sandwich will likely achieve a lower level of satisfaction (this different level is what we mean by *marginal*). That concept can also be applied to money and the utility achieved from consumption. Additional consumption achieves a different utility or level of satisfaction and is referred to as *marginal utility*.

To generalize, margin is the excess benefit or cost that results from inducing a certain level of change. This concept has an important implication for one's personal finances. If you get a raise in allowance or salary, how much of that will you spend (consume) and how much will you save? Generally, if you get a small increase, you will spend most of it, but with a greater increase, you will tend to save more than you spend; that is referred to as the *marginal propensity to consume*.

Finance and Investment

In the context of finance and investment, margin is the deposit an investor needs to place with a broker when the investor borrows money in order to buy a security (such as a stock or bond). In this sense, margin is similar to collateral. If the value of the security drops significantly, the investor has to deposit more cash (i.e., increase the margin) or sell part of the securities purchased. In the United States, the Federal Reserve Board's Regulation T states that investors can borrow up to a maximum of 50 percent of the purchase price of the securities bought on margin.

The percentage provided by investors from their own money (equity) is called the *initial premium*. Self-regulatory organizations like the New York Stock Exchange require a minimum amount of equity to be maintained in the account. This is referred to as the *maintenance margin*. The maintenance margin required is equal to 25 percent of the security purchase price. If the security price drops, the broker will issue a margin call that requires additional funds to be deposited by the investor.

Investors choose margin trading because it provides a way to purchase more securities with less money. This is helpful when the market is moving up and a security purchased on margin increases in value. This allows investors to realize a higher return (given a smaller initial investment) than they would had they purchased the security totally with cash. But if the market drops, investors will suffer greater losses than with an all-cash purchase. The losses can force the broker to sell part or all of the security to meet the margin call requirements for the security that declined in price.

Banking

In the banking world, *margin* refers to the difference between the value of collateral pledged against a loan and the amount of the loan provided by the bank. This amount is sometimes called *haircut*. Collateral is an asset—a real asset like a building or a financial asset like a stock or bond. This asset secures one's borrowing in case of default. If a borrower defaults on the loan, the lender can sell this collateral to collect the value of the loan.

Usually a bank extends a loan for less than 100 percent of the collateral value. This requires market assessment of the volatility of the collateral value. The ratio is referred to as loan-to-value ratio. Different types of collateral require different margin levels. The larger the margin or "haircut," the more secure the loan. This concept is applied to protect against two types of risk: the risk of a decline in the value of the collateral and the risk of the inability to liquidate the collateral without great loss (Chapman et al. 2011).

MARGINAL PROPENSITY TO CONSUME, SAVE, AND THE MULTIPLIER EFFECT

Developed by John Maynard Keynes, marginal propensity to consume, marginal propensity to save, and the multiplier effect are key concepts to understanding the economic impact of fiscal policy decisions on an economy. When Congress deliberates on a tax cut or tax increase, a major concern is the total impact the action will have on the macroeconomy. To determine the economic impact prior to any tax action, policymakers need to know what percentage of each new dollar of disposable income (after taxes) will be consumed and what percentage will be saved. To measure this impact, they need to know the marginal propensity to consume (MPC) or the marginal propensity to save (MPS). For each marginal dollar, the consumer consumes a portion and saves a portion. Knowing the MPC and MPS, policymakers can make a reasonable prediction on how their actions will multiply in their impact on the economy. This prediction is known as the multiplier effect.

Marginal Propensity to Consume

The marginal propensity to consume is the percentage of each new dollar of disposable income (marginal dollar) consumed and not saved. MPC can be calculated by dividing the change in consumption by the change in income ($MPC = \Delta C / \Delta Y$). If the MPC = 0.9, policymakers can predict that for every $1 they give taxpayers in the form of a tax cut, the taxpayers will spend (consume) $0.90, or if they increase taxes, for every $1 of a tax increase, they will take $0.90 out of the economy.

Marginal Propensity to Save

The marginal propensity to save is the percentage of each new dollar of disposable income (marginal dollar) saved and not consumed. MPS can be calculated by dividing the change in saving by the change in income ($MPS = \Delta S / \Delta Y$). If the MPS = 0.1, policymakers can predict that for every $1 they give taxpayers in the form of a tax cut, taxpayers will save $0.10, or if they increase taxes, for every $1 of a tax increase, they will take $0.10 from consumers' savings.

As one can see from the example, MPC ($0.90) and MPS ($0.10) equal one marginal dollar received by the taxpayer or provided by the government. Knowing the marginal propensity to consume and marginal propensity to save, policymakers also know, in theory, that the impact of their actions will not be a straight dollar-for-dollar exchange. Rather, each marginal dollar added to or taken away from the economy will be multiplied as it makes its way through the economy from business to labor and back to business (i.e., through the circular flow of economic activity). To determine the multiplier impact of the marginal dollar, one also needs to know the multiplier effect.

Multiplier Effect

The multiplier effect is influenced by the MPC, MPS, and the injection of new dollars into the economy or removed as the result of increased taxes. Each time the level of money changes in an economy a multiplier effect occurs. To predict the multiplier effect of a potential policy action, divide 1 by 1 – MPC (1 / 1 – MPC). Or, since it is known that MPC and MPS must equal 1, another way of expressing the multiplier effect is 1 / MPS.

Returning to the above example, if MPC = $0.90, the multiplier effect is 10 (1 / 1 –0.90 = 1 / 0.1 = 10). So policymakers can now predict that for every $1 they give back to the taxpayer, $10 will be generated in the economy.

Tax cut recipients have been known to not follow the theory and consequently frustrate policymakers. Because of the recessionary economy of the early 2000s, the Bush and Obama tax cuts begun in 2001 did not fully meet expectations of increasing economic activity. Instead of following Keynesian theory and increasing consumer spending in the economy, many taxpayers used their new marginal dollars to pay off credit card debt (past spending) or increased saving because of the slow economy and an uncertain future, frustrating both fiscal and monetary policy leaders.

MARGINAL UTILITY

Marginal utility is the happiness or satisfaction achieved from purchasing or consuming additional goods and services. There are many types of utility used in economics, including diminishing marginal utility, maximizing utility, and even cardinal utility. Marginal utility is often used in game theory and various decision-making techniques.

Marginal utility decisions are made every day. Marginal utility can be equated to one's satisfaction or happiness with an action, such as the way we make decisions when dining out. Restaurant food ordering is not an in-total process but a series of marginal decisions based on the expected marginal utility, satisfaction, of each decision—hamburger or fish, French fries or potato chips, malt or soda, dessert or no dessert. Each is a marginal decision based on the expected marginal satisfaction of the good to the total dining experience. Starbucks changed the way people order coffee from a few marginal decisions (black, cream, sugar, etc.) to a series of marginal decisions (nonfat, cappuccino, latte, tall, grande, etc.).

Marginal utility can be applied to a person's financial life, overall health, work ethic, and rational decision-making process, in what economists call *marginal analysis*. Although utility is not directly measurable, economists use utility functions and observations to construct a method of predicting an individual's utility. This function is responsible for creating various utility or indifference curves that represent individuals' preferences. These functions could include variables such as hours worked and dollars or other items such as coffee and tea.

Economists are particularly interested in this theory because microeconomic theory assumes individuals make rational decisions on the margin. Economists often study how people spend their next dollar, decide their next meal or whether they will work an additional hour, and determine how they will buy their next home.

The utility of money is probably the most popular area of interest because it encompasses so many decisions individuals make. In fact, all of the examples already discussed ultimately come back to how people decide to spend their dollars. Businesses can benefit from insight into how consumers will spend their next dollar. Economists use this information to predict spending patterns and work habits. Economists study behavior and how scarce resources are allocated in order to know whether people will buy an additional item or if they are just as happy with one.

There are multiple types of marginal utility, including zero, positive, negative, increasing, and diminishing marginal utility. An example of zero marginal utility would be receiving two magazines that are exactly the same. While enjoyment from reading the first magazine is realized, simply having a second one exactly the same provides virtually no additional satisfaction. Positive marginal utility could be expressed from the happiness one receives when the vending machine accidentally dispenses two granola bars instead of just one. Negative marginal utility is quite the opposite and could be demonstrated by using more than necessary. For instance, this is true with medicine. Taking too much medicine doesn't necessarily warrant a quicker recovery but could have negative effects. Increasing marginal utility could be illustrated by the satisfaction attained when finding a piece of a missing puzzle since it completes the picture. Diminishing marginal utility, however, goes back to eating more than necessary to satisfy one's appetite.

Applications of marginal utility can be found in many disciplines. It can be beneficial to understand how marginal utility relates to topics such as personal finances and overall efficiency. Businesses will benefit from recognizing this concept to help predict purchasing patterns and employees' work ethic. Marginal utility should be viewed as the overall satisfaction or happiness a good or service provides and the information used to analyze behavior.

MARKET DISTORTIONS

When a free market is manipulated through government interventions such as price ceilings and/or price floors, the result will be disequilibrium. Even though interventions such as these are implemented in order to improve the common good, they cause a market distortion resulting in an economy's misallocation of resources and either a shortage or surplus of the good or service.

Price Ceilings

A price ceiling is a maximum price established by law that sellers can charge for their good or service. The government establishes price ceilings on items it considers to be essential but for which the perceived high market price may prevent a segment of the population from participating. The price ceiling will be set at a lower price than equilibrium. This lower than market price will generate a rise in quantity demanded and a reduction in supply, creating a shortage.

A common example of the government establishing a price ceiling is rent control. In order to provide housing, which is considered an essential good for consumers, the local government in New York City established price ceilings on apartment rent. The price ceiling was established to make housing affordable to citizens living in a specific area they could otherwise not afford to live in. However, when prices were lowered to below natural equilibrium a shortage occurred. With the rent price now below equilibrium price, the willingness of apartment owners to produce and maintain their apartments also fell, as predicted by the law of supply.

Price Floors

The opposite of a price ceiling is a price floor. A price floor provides a minimum price for a good or service. As with price ceilings, the government may impose a price floor in order to establish a minimum reward to sellers for their efforts. The two most commonly recognized price floors in the United States would be the federal minimum wage law and agricultural subsidies to farmers.

The minimum wage law establishes the lowest possible amount per hour paid to full-time workers for their efforts. The intent of the law is to provide a wage necessary to support a couple with one child. Some argue the minimum wage is set above the market equilibrium, resulting in a rise in unemployment. Two reasons suggested for the increase in unemployment are an increase in the supply of labor (labor force participation) caused by the incentive of a wage increase and/or a reduction of jobs due to layoffs since the employer may not be able to pay the increased minimum wage. Both of these issues will cause a surplus of labor as price floors, to be effective, are set above market equilibrium wage.

Federal farm subsidies as price floors create surpluses of agricultural products. With a guaranteed minimum price, farmers have the incentive to grow as much as possible. Producing beyond the domestic market quantity demand creates a surplus for exports to a global market. It also creates surplus food products the federal government may ultimately redistribute if possible. In many cases, this leads to a misallocation of resources as the products eventually spoil.

Price Discrimination

Another way to distort the market is through price discrimination. Price discrimination only works if the following three conditions exist: (1) Firms that use price discrimination must have some market power; (2) customers must be able to be divided into distinct groups based on the price of the good or service; and (3) buyers must not be in a position in which they can easily resell the good or service.

Business owners may use price discrimination if they have the ability to identify a specific segment of their consumer base. One common form of price discrimination is through targeted discounts. Many businesses offer these discounts for the sale of goods that may not be as desirable or are more difficult to sell otherwise. Other types of targeted discounts are offered to marginal consumers, such as the elderly and students. Senior citizen discounts are offered on many items in order to target and maintain a certain group of customers but at a reduced price.

The advantage of price discrimination is that the business owner is able to maximize profits by charging a different price in different regions or to different groups of customers in order to maintain as many customers as possible. This in turn maximizes the business owner's resources and anticipates increasing profits.

Predatory Pricing

A firm may attempt to dominate a market or eliminate the competition through predatory pricing tactics. In the short run, a firm may set the market price below its costs to drive competitors out of business. This practice can only be sustained in the short run since the predator loses money each time it attempts to eliminate a competitor. Once the competition has been eliminated, the predator will raise prices and gain more market power.

MARKET FAILURE

A market failure results from the inefficient allocation of goods and services that makes a specific economic interaction unfeasible, unproductive, or unresponsive to society. The term *market failure* encompasses a need for an outside agent, usually government, to become involved with a specific economic transaction. A market failure can be the result of the market price being too high for the transaction to be commercially feasible, a market not producing enough of a specific economic good, or the market interaction causing externalities (costs external to the transaction). Market failure can also be the result of too little information on the part of the buyer.

The three key sources of market failure are externalities, public goods, and imperfect information. Markets are most efficient when all the costs and benefits of a decision are internalized and borne solely by the buyer and seller. Externalities exist when the benefits or costs are not totally internalized and impact a third party not involved in the original decision. A market transaction fails to include external costs or external benefits. An outside agent such as a government is necessary to address the external costs or benefits of the transaction, or too much of some goods will be produced and not enough of others.

A negative externality results when the costs of a transaction spill over to someone other than those who were party to the original transaction. Pollution is a negative externality, as it is a transaction cost borne outside the original transaction that created the pollution. To correct for a negative externality such as pollution, the government institutes policies to alter the behavior of those involved and internalize as much as possible the transaction costs or reduce the size of the externality. Government may do this by imposing a tax or fine on the transaction, or it may provide an incentive to change behavior with a tax credit or subsidy.

If there is a positive externality, someone outside the original transaction benefits from the action. To expand a positive externality, the government can subsidize the good. A public good is also an example of a market failure. Public goods are nonexclusive, which means that everyone can use a good and no one can be excluded from its benefit. They are also nonrival, which means that consumption by one person does not reduce the usefulness of a good to others. The classic example of a public good is national defense.

Another example of market failure is imperfect information, which results in buyers and sellers having different amounts of information about a good. In this case, buyers depend on the firm's reputation and personal experience, and it is possible that they will pay more for a good or service than necessary.

A natural monopoly is the result of market failure. A natural monopoly can set prices higher than costs and does not allow for any competition. In some cases, though, it is more practical to have a government-operated or government-regulated natural monopoly in some industries, such as utilities. In these industries, there are relatively large fixed costs accompanied with low marginal costs. To have different companies competing for an undifferentiated commodity would be a gross misallocation of resources. The companies in these industries need to be very large to achieve the economies of scale necessary for the product to be priced so the consumer can afford it and the producer is willing to produce it and achieve a profit to stay in business. Market failure can also lead to government failure, which occurs when government intervention makes a situation worse. In some cases, this is because governments do not have information to correct the problem or the government intervention is more complicated than anticipated.

When examining market failure, one should apply the double market failure test. The problem should be identified and the possibilities for correcting the market failure should be considered. Potential solutions depend on the nature of the problem as well as the potential effect or anticipated results of the proposed resolution.

When looking at correcting a market failure, one must also consider the transaction cost. The transaction cost affects how an externality is dealt with, and if the costs become too high the desire to resolve the problem will disappear. The government may determine how to implement a resolution to a market failure based on this approach.

Market failure will continue to focus on goods and services that affect a large number of users and will only disappear when the costs of operating the price system are zero, which is impossible to achieve. Issues such as clean air and clean water will continue to be addressed by the government.

MARKET RISK

Market risk, also known as systematic risk, is the financial or fiscal danger that arises within changes in market prices and rates. These are possible risks investors experience because of events or factors that affect the overall matter of the financial markets. This can occur from natural disasters, a recession, political turmoil, changes in interest rates, or terrorist attacks. These changes in the market have several variables, such as exchange rates, interest rates, taxes, equity prices, foreign exchange rates, and commodity prices.

The connection between each of the variables corresponds to a financial risk that may result in loss of positioning or value. When entrepreneurs make new investments and financial choices there is always a potential for market risk. We experience risk every day; for example, when you decide to go snowboarding you risk the possibility of falling and breaking your leg. This is similar to market risk.

Most people try to avoid market risk because they are risk averse. That is, people dislike bad things happening to them more than they like good things happening to them. In a market, risk is inevitable, but one way to be ready in case of an emergency is to buy insurance. Buying insurance will not eliminate the risk of an accident or event happening; it will only help compensate for the incident.

Another way to deal with market risk is diversification; this refers to a way of reducing risk through replacing one large risk with many smaller unrelated risks. Sound advice is not to "put all your eggs in one basket." Diversification can eliminate the possibility of idiosyncratic risk, uncertainty associated with a specific business. Although it can help eliminate some factors, it cannot stop aggregate risk, the uncertainty associated with the economy as a whole. For example, market risk cannot be prevented when events like a recession occur and all companies face falling sales and reduced profit. Market risk is something one cannot prevent. When making financial decisions, there is always going to be some kind of risk.

MARKET STRUCTURES

Market structures can be defined by a series of market characteristics. These characteristics determine and define the competition within a market, how the competition differs between markets, and different pricing schemes between the different market structures. The market structure has a strong influence on how businesses answer basic questions regarding level of production, pricing, and how to successfully compete. Each feature of a market structure is determined by a series of questions:

- How many sellers participate in each market?
- What is the resource allocation to enter or exit the market? Can an individual easily gather the resources for a market, or is the market a complex structure?
- Do buyers and sellers have access to the same market information?
- Is the market homogeneous or heterogeneous? Can you tell the difference between the products?
- How much influence does a firm have in pricing within a market structure?

Table 1. Market Structures

	Perfect Competition	Monopolistic Competition	Oligopoly	Monopoly
Number of sellers	Many	Many	Few	One
Barriers to entry	None	Easy	Significant	Absolute
Product Differentiation	None; homogenous	Differentiated through advertising and marketing	Differentiated through frequent advertising and marketing	Unique; no close substitutes
Pricing Power	None; price taker	Some; firms are price-searchers	Some; price-searcher; game theory approach; closely watches and acts/reacts to competition	Considerable; but many monopolies are regulated and any pricing power is tempered through oversight commission, committee, etc.
Access to information	Full; symmetric information flow	Some with the seller; advertising and marketing	Mostly with the seller; advertising and marketing	Seller; asymmetric information flow
Long-term Profits	No	Short-run, Yes; long-run No	Yes	Yes; monopoly profits
Examples	Agriculture	Retail products	Manufacturing; automobiles, airplanes	Utilities

There are four key market structures: perfect competition, monopolistic competition, oligopoly, and monopoly. Each of the four structures has distinctive features.

Perfect competition and monopoly are the extremes. Most industries with these two market structures are distinct and do not change much. There are exceptions, as when government deregulates a previously regulated monopoly. The middle two structures, monopolistic competition and oligopoly, are more transitory and often industries may slide back and forth over time and conditions between the two.

Perfect competition is the most unique of the four structures. A perfectly competitive market structure has no barriers to entry and there are so many sellers they have no influence over price. Perfect competition sellers are price takers, and as such perfectly competitive firms have a perfectly elastic demand curve. These two characteristics are not common in the other three structures. Agriculture is the classic example of a perfectly competitive market.

At the other end of the market structure spectrum is monopoly. What perfect competition is, monopoly is not. Monopoly, as the prefix *mono* suggests, is when one firm controls the supply of or trade in a particular resource, and the barriers to entry are absolute. Yet, even with a monopoly, the firm does not have the ability to charge any price. The uniqueness of monopolistic firms is that they will always produce less and charge a higher price than the other market structures. Business monopolies are illegal in the United States. Yet industries with high economies of scale can often be most efficient in a monopoly structure. Utilities are a prime example of this type of monopoly. A local governmental unit gives monopoly rights to a company but at the same time maintains regulated authority over the company. Utilities such as home gas and electric companies, some local telephone companies, or cable companies are given exclusive monopoly power, under regulation, within a designated area.

Where perfect competition and monopoly have unique differences, monopolistic competition and oligopoly have some commonalities. Perfectly competitive markets rarely change and become another structure. Unless another firm enters a monopoly market and it is no longer a monopoly, monopoly markets do not change. Markets in these middle two structures, however, can change between the two. Monopolistic competitive markets can become oligopoly markets if the barrier to entry becomes more difficult, the number of sellers is reduced, or the pricing power changes. Oligopoly markets can become monopolistic competitive markets if barriers to entry become easier, pricing power becomes more dependent on advertising, or technology improvements add many more sellers. A general rule is that monopolistic competitive markets are retail markets and oligopoly markets are manufacturers of the goods to be sold retail. Automotive manufacturing firms can be described with the characteristics of an oligopoly. Yet, local Ford, Buick, or Chrysler dealerships follow the characteristics more common to the monopolistically competitive market.

MARKETS

Markets are where buyers and sellers meet to voluntarily exchange goods and services for money, other goods and services (barter), labor for wages, land for rent, or capital for profit.

Markets are everywhere. Whether the neighborhood garage sale, the local mom-and-pop corner store, the big box store, or the global production and sale of oil, each of us participates in functioning markets every day.

The term *market* is used in many different ways. There are financial markets, like the stock market, currency markets, and money markets. *Market* is a term used to describe segments of a larger market. The rental market is one market within the larger housing or real estate market. In today's world of the Internet, there are virtual markets where buyers and sellers "meet" and a voluntary exchange takes place online. The virtual market in some ways eclipsed the mail-order market, which exemplifies the notion that markets can change or even disappear over time. For example, there is not much of a market for buggy whips for the general population.

Markets are both microeconomic topics and macroeconomic topics, depending on the market. In the world of microeconomics, the inner workings of markets are viewed through the prisms of supply and demand, prices, or relative value. Institutions and firms are organized and measured to function efficiently and effectively. Markets are measured as to the allocation of resources in an economy. At the macroeconomic level, markets are viewed by how they relate to and are in balance with each other. Broader, more comprehensive markets, such as the product market or the resource market, are the topics of macroeconomists as opposed to singular markets like the market for automobiles or the labor market.

Markets are also defined by the involvement of outside influences. Free markets exist when outside influences are nonexistent. Closed markets are when governments intervene in a market to influence the market forces of a particular market or an entire economy. New markets (micro) or nations attempting to improve their markets (macro) are often called developing markets. On the other side, markets that have a certain level of sophistication (micro) or nations whose economies and markets are fully developed (macro) are developed markets.

When governments intervene in an attempt to influence a market, their actions are called *market distortions* and result in a distorted market. Price ceilings are distortions caused when a government believes the market price is too high. In these situations, governments restrict the price from exceeding the market price. A market shortage is always the result of a price ceiling. If the government believes the market price is too low, it will influence the market with a price floor. A market surplus is always the result of a price floor. Governments may also influence a market using subsidies or tariffs as forms of market protectionism.

Illegal and extralegal markets also exist. If a good or service is illegal to own or purchase, a black market, or illegal market, may arise. During the time of Prohibition, black markets existed for alcohol. Black markets today exist for drugs and other illegal goods and services. If a government restriction on a market is severe, even if the good or service is legal, an underground economy may exist. While underground economies deal with legal goods or services, they often exist to avoid something, such as taxes. An underground economy for tobacco products may develop if taxes rise beyond what tobacco users are willing to pay.

Markets free to function without undue influence or restrictions provide both buyers and sellers valuable information for their market decision-making. The most important information provided by unfettered markets is price information. Market prices provide sellers valuable information in allocating resources to their most optimum use. Efficient and free markets and market prices give buyers the relative information they need to make optimum consumer decisions.

MCI TELECOMMUNICATIONS CORP. V. AMERICAN TELEPHONE AND TELEGRAPH CO.

The case of *MCI Telecommunications Corp. v. American Telephone and Telegraph Co.,* 512 U.S. 218 (1994), showed that regulated monopolies in certain industries can be made obsolete through improved technology. In this case, the industry impacted was the long-distance communications industry and the regulated monopoly power that had been granted to American Telephone and Telegraph (AT&T).

In 1913, AT&T's company structure was that of a conglomerate of multiple Bell Companies. It had made an agreement with Congress, giving it a phone service monopoly. In 1934, Congress passed the Federal Communications Act with the goal of securing an economical and well-functioning system of national and global communications infrastructure. In the almost 80-year history of the act, the progression of technology and business acumen paralleled the growth of government regulation. The Federal Communications Commission (FCC) had extensive oversight in technologies such as wireless, satellite, and microwave communications and employed various techniques to maintain fair trade practices (i.e., competition, reasonable rates, and prevention of price discrimination).

The *MCI Telecommunications Corp. v. American Telephone and Telegraph Co.* case, however, limited the discretionary ability and power of the commission, referring the authority of intent back to Congress. The result of this decision was the Telecommunications Act of 1996, allowing economies of scale to work within the industry and decreasing regulation of the communications industry.

Case Summary

Historically, the communications industry in the United States has faced many legal challenges. After Alexander Graham Bell patented his new telephone device in 1876, the communications industry began a worldwide expansion. Early in the 20th century, the Bell companies evolved through reorganization and acquisition into the American Telephone and Telegraph Company, or AT&T.

In 1913, Congress gave AT&T a phone service monopoly. In 1935, the Federal Communications Act established the FCC. The courts gave the FCC significant leeway to regulate the communications industry. Congress has continually tried to update and amend commission policy and power to keep pace with technological changes and public interest.

In 1967, a fledgling business, Microwave Communications of America, Inc. (MCI), applied to the FCC for appropriate licenses as a common carrier (a company that transports goods for the general public, in this case communications). It was granted a license by the FCC to tap into the private line (a permanent communication channel between two or more places) to advance communications. Microwaves, fiber optics, satellites, and a myriad of other associated innovations culminated in the opening of the long-distance market in the 1990s. At the time of *MCI v. AT&T*, there were 481 nondominant carriers adding to the global communications infrastructure, all in direct competition with AT&T. The commission recognized the benefits of greater competition, and in staying with the intent and goals of the 1934 act, enacted regulations that would enhance competition.

In 1980, the commission studied the market and distinguished between dominant carriers (those with market power) and nondominant carriers, the former being AT&T and the latter being all others. In the original act, Section 203(a) stated that carriers were required to file with the FCC the amount of the tariffs they charged customers and to provide reasonable pricing for the public in a monopolistic market. The prices could not be changed without prior indication. Section 203(b) gave the commission the power to modify any of the requirements of the previous section.

Consequently, after a market review in the 1980s, the commission submitted new rules. Initially, filing tariffs seemed necessary to ensure that all customers had sufficient information about the price of services offered. Filing tariffs set prices at the rates posted. However, as technology allowed more competition to enter the market, this admirable intention did more harm than good. Posting prices facilitated parallel pricing and price stifling, leaning to the advantage of dominant carriers. If rates were not filed, prices could be negotiable, which was more to the advantage of newly emerging nondominant carriers. The FCC viewed "detariffing" (the release of carriers from this filing stipulation) as a significant step in encouraging price competition. Therefore, the FCC changed the rules, requiring only dominant carriers to file tariffs whereas it was optional for nondominant carriers. Later, the commission made nonfiling tariffs or "detariffing" mandatory for all nondominant carriers. Hence, only AT&T had to file its tariffs. In 1985, MCI transitioned into a greater share of the communications market and challenged this new interpretation of Section 203 in the United States Court of Appeals for the District of Columbia. The D.C. court struck down this new rule, disagreeing with the commission's interpretation of Section 203 of the Communications Act.

The commission considered the court's interpretation and reissued the policy, convinced they were right. MCI did not file tariffs and AT&T sued. The appeals court ruled that the FCC had violated Sections 203(a) and (b) of the Communications Act. MCI and the federal government, together with the FCC, petitioned for certiorari (a writ to the lower court to send the case to the Supreme Court for review). The Supreme Court granted their petitions and heard the case in March 1994. The question before the court was whether the FCC had overstepped the authority Congress had granted to it by eliminating rate-filing requirements for nondominant carriers of long-distance services.

The petitioners claimed that since 1980, the commission had held that it had authority to lift the rate-filing requirement. Furthermore, it stated that Section 203(a) and (b) had given the FCC the authority over formalities of rate filing, such as information regarding rate filing, printing, and posting place for public inspection, all of which were to be determined by regulations required by the commission. Hence, the modification to reduce the requirement to file rates by nondominant carriers of long-distance services was a formality legitimately within the authority of the commission. In addition, the rate filing had not been lifted for international calls or for a number of the local exchange carriers that did most of the interstate access services. Rather, it only eliminated the mandatory requirement for 40 percent of the long-distance market not served by AT&T. It was clear to the commission that Congress's intent was to enable it to change the rules when the circumstances required, in effect allowing the government regulation to adapt to a rapidly changing technological and economic marketplace. The plaintiff cited the fact that AT&T no longer held a monopoly over long-distance services as evidence of this special situation. This discretionary power is owed through substantial deference.

The respondent disagreed. AT&T claimed that the FCC had overstepped the authority granted by Congress in the Communications Act. In the respondent's view, Congress had intended rate filing as a means to secure equal rates for customers of like situations. This would eliminate price differences because all carriers' rates would be public so customers would know what they were and could request that rate. AT&T claimed that MCI and other nondominant carriers were charging lower rates than those set forth in the tariff and negotiating discounts of 5 and 10 percent below their valid rates. Thus, it argued that the FCC had the authority to modify but not obliterate that rule. The fact that there is competition in the long-distance market is significant but does not eliminate the need for the rate-filing requirements because price differences occur even in competitive markets. Furthermore, it cited the *Maislin Industries, U.S., Inc. v. Primary Steel, Inc.,* 497 U.S., 1990, case, which established that filing rates prevent price discrimination and that unequal rates were the opposite of what the Communications Act was designed to prohibit. The Rehnquist Court concurred. Justice Scalia penned the majority opinion and in summary said that rate filings were essential to the rate regulation of the communications industry as expressed in the Communications Act. It was not the intent of Congress to leave this core characteristic to the discretion of the commission. The term *modify* did not mean "to do away with." If the rate filings were to be eliminated, it must be by an act of Congress to change the authority of the commission to have that discretionary power. Justice Stevens, joined by Justice Blackmun and Justice Souter, dissented. They argued that the commission's authority was expansive for the specific job of dealing with special circumstances that would legitimately call for different regulatory treatment. Justice Stevens stated rather than guess what Congress meant when it attempted to regulate an almost completely monopolized industry, the court should acquiesce to the very solid, experience-tested, and well-explained judgment of the FCC. On June 17, 1994, the majority opinion of the court affirmed the decision of the federal appeals court.

MERGERS AND ACQUISITIONS

Mergers and acquisitions refer to the consolidation of companies. A merger is the joining of two companies to form one company. An acquisition is when one company purchases another company. Sometimes the two companies become the buying company and other acquisitions become a new company. Mergers can happen in two ways, and they often come in waves. When both companies pursue an acquisition it is known as a friendly acquisition. The other form of acquisition is when the company being bought did not want to be part of the acquisition. These are known as hostile takeovers.

There are two sorts of mergers between companies: horizontal integration and vertical integration. Horizontal integration involves acquisitions of companies to become larger, enter new markets, or increase product offerings. Horizontal integration often leads to industry consolidation, oligopoly, or even a monopoly. An example of a horizontal integration is when AT&T acquired T-Mobile. In vertical integrations, firms usually expand into another production stage. For example, in a vertical integration a company would expand from research and development to marketing, whereas a horizontal integration would mean buying other firms in the research and development industry. Vertical integration often increases the firm's control in the value chain, giving it more power in the marketplace.

Mergers are often cyclical in nature. There have been five major merger periods. The first era followed the 1883 recession. During the first wave of mergers there were mainly horizontal mergers, which formed a lot of monopolies. The second era of mergers occurred during World War I, continuing until the 1929 stock market crash. This era of mergers included more horizontal mergers versus vertical mergers. This was a period of increased government inspection. This created oligopolies instead of monopolies. The third merger era occurred between 1965 and 1969 because of a period of economic prosperity in the United States, making firms more able to acquire other companies. During this time, the government saw many mergers as highly suspect. Antitrust enforcement in these mergers was very keen. The fourth merger era occurred during Ronald Reagan's presidency (1981–1989). Mergers during this wave were larger and more hostile than before, and debt was more widely used to finance mergers. The fifth major era followed the economic recession of the late 1980s during Bill Clinton's presidency (1993–2001). During the fifth wave hostile takeovers diminished, debt-financed mergers were less common, and mergers of this period emphasized longer-term business strategies.

Acquisitions are slightly different from mergers. Acquisitions are when one company buys another company; mergers are when two companies come together to form another. Acquisitions are often a deliberate strategic move on the part of the acquiring business. An acquisition is often more efficient than the firm expanding on its own. Similar to mergers, acquisitions can be either friendly, with both participating companies cooperating, or hostile.

MERTON, ROBERT

Born: July 31, 1944, in New York City; Nationality: American; Professional Interests: finance economics, quantitative economics, Nobel Prize (1997); Major Works:

"The Pricing of Options and Corporate Liabilities" (with Myron Scholes, 1970), "The Theory of Rational Option Pricing" (1973), *Robert K. Merton: Sociology of Science and Sociology as Science* (2013).

Robert Merton is best known for his work in finance. After receiving his PhD in economics from the Massachusetts Institute of Technology (MIT) in 1970, his collaboration with Fischer Black and Myron Scholes produced the now-famous Black-Scholes option-pricing model. Myron Scholes and Robert Merton share the 1997 Nobel Prize in Economics for creating new methods in quantitative economics and their innovative work to determine the value of derivatives.

Robert C. Merton was born on July 31, 1944, in New York City. He began his studies in engineering at Columbia College, where he received a BS in 1966. He started a PhD in applied mathematics at the California Institute of Technology. His interests, however, had turned to economics. He left the California Institute of Technology with an MS in applied mathematics in 1967. He began additional graduate work at MIT in 1967 in economics, receiving his PhD in 1970.

During his first year at MIT, at his adviser's (Harold Freeman) suggestion, Merton took Paul Samuelson's mathematical economics course. Merton became Samuelson's research assistant for the next two and a half years. Merton also was greatly influenced by Franco Modigliani, who was part of MIT's Sloan School of Management faculty. When Merton completed his PhD, Modigliani helped him receive his first academic position, teaching finance at MIT. Merton taught at MIT from 1970 to 1988.

Moving to Harvard University in 1988, Merton was the George Fisher Baker Professor of Business Administration from 1988 to 1998. From 1998 through his retirement in 2010, Merton was the John and Natty McArthur University Professor at Harvard University. He is professor emeritus at Harvard Business School.

Merton's primary research interests are in financial engineering, financial innovation, and risk management. He is also interested in the following industries: banking, brokerage, financial services, insurance, investment banking, and retail financial services.

In the mid-1990s, Merton joined a hedge fund founded by John Meriwether, formerly of Salomon Brothers. As a board member of Long-Term Capital Management (LTCM), Merton (and Myron Scholes) worked with Meriwether. Their goal was to use academic quantitative models and traders' knowledge and expertise to secure extraordinary returns for investors. LTCM went active in February 1994, raising over $1 billion from investors. In 1998, substantial losses to the fund led the Federal Reserve Bank of New York to organize a bailout of $3.625 billion by commercial and investment banks. LTCM was liquidated and closed in 2000.

Merton has received numerous honorary degrees. These include an MA from Harvard University in 1989 and a doctor of laws degree from the University of Chicago in 1991. He is a past president of the American Finance Association, a member of the National Academy of Science, and a fellow of the American Academy of Art and Science. He currently holds positions in many businesses and other organizations, including Daedalus Software (chairman of the board); resident scientist at Dimensional Fund Advisors and Dimensional SmartNest LLC; member of the Quantitative Finance Advisory Board, Department of Applied Mathematics and Statistics, Stony Brook University; and member of the Board of Advisors, Santa Clara University Center for Innovation in Finance and Investment.

Awards received by Robert Merton in addition to the Nobel Prize include the Distinguished Finance Educator Award (2008) from the Financial Education Association; the First Annual Award for Foundational Contributions to Finance (2008) from the Owen School of Management at Vanderbilt University; the 2009 Robert A. Muh Award in the Humanities, Arts, and Social Sciences from MIT; the Tjalling C. Koopmans Asset Award from Tilburg University; the Award of Excellence for the Hall of Excellence from Hastings-on-Hudson High School; the Sigma Xi, Scientific Research Society, Life Member Award from Sigma Xi; the LECG Award for Outstanding Contributions to Financial Economics; and the 2010 Kolmogorov Medal from the University of London.

Robert Merton is the distinguished professor of finance in MIT's Sloan School of Management and is also a professor emeritus at Harvard Business School.

MICROECONOMICS

Microeconomics is the branch of economics that analyzes the interactions of individuals as consumers and their market interactions with businesses and producers. Microeconomics is also the study of how consumer behavior influences how producers use the factors of production (land, labor, capital). The market interactions of buyers and sellers influence the choices available to consumers. Microeconomics focuses on patterns of supply and demand and the determination of market prices and outputs in individual markets.

From Adam Smith and the *Wealth of Nations* in 1776 to John Maynard Keynes and his *General Theory of Employment, Interest, Money* in the late 1930s, the two main components of economic thought were monetary theory and price theory. After Keynes and his introduction of macroeconomic theory through the *General Theory*, the key divisions of economics became macroeconomics and microeconomics. Macroeconomics studies the economy as a whole entity. It provides basic knowledge of how economic factors work together in a dynamic economic world. Microeconomic studies focus on the dynamics of specific market interactions. As the *micro* prefix implies, microeconomics focuses on the smaller picture, including basic economic theories of supply and demand, price theory, price elasticity of demand and supply, externalities, producer and consumer surplus, and producer efficiency and the way they interact in various economics. Thus, for an overall perspective of how the economy works, an understanding of the economy at both the macro and micro levels is necessary.

Two of arguably the most popular economic laws intrinsically related to microeconomics are the law of supply and the law of demand. The law of demand focuses on consumer behavior and reveals the quantity desired of a given product or service at a given price. The law of demand states there is an inverse relationship between price and quantity demanded. As the price of a good goes in one direction, the quantity demanded goes in the opposite direction. If the price of a good or service goes down, the quantity demanded will increase, and vice versa.

A corollary to the law of demand for the resource market is derived demand. Derived demand states the producers' demand for land, labor, and capital is a function of the demand for the good or service the resources are being used to produce. If a product's demand reduces, the demand for the resources is also reduced, and vice versa. The resources demand is derived.

The law of supply concerns itself with the behavior of businesses and entrepreneurs, the producers of goods and services. It states that the quantity supplied of a good or service product is a direct function of price. All things being equal, producers will supply more of a good or service the higher the price. As the price of a good or service moves in one direction, the quantity supplied will move in the same direction.

When the actions of consumers are combined with the actions of the producer, a market is created. Microeconomics is the study of how consumers and producers interact within each market. Through the world of microeconomics, components of consumer and producer behavior are explored to better understand our economic world.

MODIGLIANI, FRANCO

Born: June 18, 1918, in Rome, Italy; Died: September 25, 2003, in Cambridge, Massachusetts; Nationality: Italian; Professional Interests: financial markets, Nobel Prize (1985); Major Work: *The Collected Papers of Franco Modigliani*, Volume 6 (2005).

Franco Modigliani is recognized as the most famous economist of Italian heritage. The son of a Jewish physician, his family fled fascist Italy in 1939. He became a naturalized American citizen in 1946. A professor at the Massachusetts Institute of Technology (MIT) at the time of his Nobel Prize in 1985, Modigliani was honored for his pioneering work on savings and financial markets. He developed several theories that have withstood the test of time, including the Duesenberry-Modigliani hypothesis, the life cycle hypothesis, and the Modigliani-Miller theorem. Modigliani died in 2003.

Franco Modigliani was born in Rome, Italy, on June 18, 1918. In 1932, his father unexpectedly died, altering young Modigliani's life. As the son of a physician (pediatrician), Modigliani was expected to follow his father's path into medicine. Young Modigliani had other ideas, instead enrolling in the University of Rome at the age of 17 to pursue a career in law. However, during his law studies, he also developed an interest in economics. Modigliani's interest in economics was firmly established when he won first prize in a national competition in economics. The fascist political environment in Italy at the time necessitated that Modigliani leave Rome. Following a stay in Paris to complete his studies at the University of Rome, he immigrated to the United States in 1939.

In the United States, he continued his studies in economics at the New School for Social Research in New York. At the New School, Modigliani developed his solid foundations in mathematics and econometrics as well as economics. Modigliani credited much of his success to his early days at the New School learning empirical analysis and theory from Jacob Marschak. He received his doctorate from the New School in 1944.

In 1944, Modigliani published his first article in English, "Liquidity Preference and the Theory of Interest and Money" (*Econometrica* 12, no. 1). Following two years at Columbia University, Modigliani returned to the New School to lecture and research at the Institute of World Affairs. It was here that he made his first contribution to the study of savings. This research spawned the Duesenberry-Modigliani hypothesis.

In 1948, Modigliani moved to Chicago when he was awarded the political economy fellowship at the University of Chicago, including the opportunity to join the Cowles Commission for Research in Economics as a research consultant. He then joined the University of Illinois to lead a research endeavor on expectations and business fluctuations. He remained on the University of Illinois faculty until 1952.

While his time at the University of Illinois was relatively brief, it was during this time in his career that he developed many of his economic theories. Modigliani and graduate student Richard Brumberg collaborated on two papers that were the early versions of what was to evolve into the life cycle hypothesis of saving. The life cycle hypothesis attempts to explain personal saving levels in an economy. The hypothesis explains that consumers' aim is to achieve a constant level of income during their lifetime. The life cycle can be briefly defined as describing one's saving behavior throughout life. People save during their working years so they can spend during their retirement years. While this notion by itself was not new, Modigliani created the quantitative model for use in economic research and ultimately as an economic theory.

This life cycle hypothesis has been the theoretical foundation for many economic empirical studies since its development, including many by Modigliani himself. He expanded its implications beyond the explanation of individual saving behavior to the savings behavior of an entire economy. Of major significance was his contribution that an economy's growth rate is a key variable in its total level of savings. An economy that is growing will have more savings, and vice versa. Modigliani also used the life cycle hypothesis studies to suggest that savings was also determined by the age distribution of a population and life expectancy, where higher rates of economic growth favored younger ages. Modigliani's model led to new studies in both savings and consumption, including studying the effect of pension systems on private savings.

In 1952, Modigliani joined the faculty at the Carnegie Institute of Technology (later named Carnegie-Mellon University). At Carnegie, Modigliani teamed with Merton Miller and they formulated the Modigliani-Miller theorem. The Modigliani-Miller theorem focused on determining the value of a firm. The core of the Modigliani-Miller theorem was that in determining the value of a firm, the type of financing to be instituted was not a significant factor. When certain conditions were met, whether the financing was with equity by buying shares or debt through borrowing, the type of financing was inconsequential in determining the final value. Later, Modigliani and Miller added a second theorem, asserting that a firm's dividend policy does not impact the value of the firm.

After a two-year stop at Northwestern University beginning in 1960, in 1962 Modigliani returned to MIT and the MIT Sloan School of Management and Department of Economics. Returning as a visiting professor, he later became an institute professor and received the James R. Killian Faculty Award in 1985. He was bestowed professor emeritus honors in 1988.

In 1985, Franco Modigliani was the recipient of the Nobel Prize in Economics, the only winner of Italian descent since 1969. He was honored for his life's work regarding savings and later financial markets.

Franco Modigliani died on September 25, 2003, in Cambridge, Massachusetts.

MOMENTUM INVESTING

Momentum is an investing strategy consisting of buying assets with rising prices and selling those with falling prices. It is based on an empirically proven tendency for rising asset prices to continue to rise and for falling prices to continue to fall. The profitability of the momentum strategy is proven for a holding period of 3 to 12 months based on the past 3 to 12 months' observation (Jegadeesh and Titman 1993; 2001).

Opposite to momentum is contrarian strategy. It consists of buying assets with falling prices and selling those with rising prices. It is based on an empirically proven tendency for rising asset prices to fall and for falling prices to rise. A proven profitability of the contrarian strategy is for a holding period of 3 to 5 years based on the past 3 to 5 years' observation (De Bondt and Thaler 1985; Lakonishok at al. 1994). The length of holding periods and periods of past observations play an important role in the performance of momentum and contrarian strategy. This way, neither momentum nor contrarian investors treat the market as a random walk. They make predictions. Momentum investors interpret price increases as signals to buy and price declines as signals to sell. Contrarians behave in the opposite way.

It is not clear what makes investors momentum or contrarian traders. De Bondt (1993) found that individual investors tend to predict trend continuation, whereas professional analysts are inclined to predict trend reversal. Thus, compared to contrarian investors, momentum investors seem to be less experienced.

Perhaps momentum investors follow an intuitive cognitive system, while contrarian ones use an analytical rather than intuitive approach. This speculation is in line with a finding by Morrin et al. (2002) that momentum investors spend much less time on decision-making regarding possible transactions than contrarian investors do.

Analogically to momentum and contrarian strategy, financial market psychologists list two kinds of basic tendencies in forecasting: positive and negative recency effects. The positive recency effect (momentum) is a belief that the event that occurred most recently is more likely to occur again, whereas the negative recency effect (contrarian) is a belief that an event that occurred most recently is less likely to occur again. For example, the positive recency effect (sometimes called hot hand) would predict that a basketball player will score yet again after a series of consecutive baskets. The negative recency effect (sometimes called the gambler's fallacy) would predict in roulette that the ball will stop on red after a series of consecutive stops on black.

Psychological research shows that people tend to believe that they can detect streaks in random sequences (Gilovich et al. 1985). There seem to be two sources for this tendency: (1) an innate neurophysiological inclination to look for patterns, and (2) misperception of randomness. Indeed, Huettel et al. (2002) presented a random sequence of binary events to a group of individuals using fMRI to visualize their brains' activity. They found totally different brain activity in the case of observing a streak and when the streak was broken. In turn, Bar-Hillel and Wagenaar (1991) show that people's notion of randomness is biased. In particular, individuals expect more alternations and fewer streaks than there are in actual random series. In line with this, further research examined when people tend to follow positive or negative recency effects (use momentum or contrarian strategy). A 2004 study showed that a crucial factor influencing forecasting strategy is the perceived nature of events: human skilled performance versus inanimate chance mechanisms. On the other hand, Burns and Corpus (2004) and Tyszka et al. (2008) claim that the perceived randomness of the sequence is crucial. When an individual perceives a sequence as random, the negative recency effect is expected; on the other hand, when an individual perceives a sequence as nonrandom, a positive recency effect is expected.

MONEY LAUNDERING

Money laundering refers to the process of “cleaning” money obtained through illegal activities by routing it through the financial system so it appears legal. Criminals, including terrorist organizations, attempt to disguise their proceeds, sources, and the nature of their illicit activities in this way.

Money laundering first became popular with organized crime as a way to legitimize the funds obtained through illegal activities. Today, illegal activities such as arms sales, smuggling, trafficking, embezzlement, insider trading, bribery, gambling, and computer fraud contribute to money laundering. These activities can generate substantial profits, but in order for the funds to be useful they need to be introduced to the financial system. While there is no concrete data on the true amounts of money laundered, it is estimated the funds generated from illegal activities and moved into the financial system account for billions, if not trillions, of dollars. This means the criminals working to launder money need to be sophisticated in order to avoid getting caught at various points in the financial system. They use a variety of highly sophisticated techniques to hide the true nature of these funds.

Money laundering involves three types of activity: placement, layering, and integration. Placement involves physically placing money that is illegally obtained into the financial system or the retail economy. This is usually done relatively close to where the illegal activity is taking place. Since this involves physically placing money into the system, it is easiest to detect money laundering at this phase. Criminals will try to avoid reporting and record-keeping requirements by structuring transactions to fall below particular thresholds, coercing or bribing employees not to file the proper paperwork, or by establishing businesses that appear to be legitimate to create preferred customer relationships. In placement, criminals make small deposits to avoid bank regulations and may purchase money orders, cashier's checks, traveler's checks, or other money instruments. Criminals will make small transactions under $2,000 to avoid the funds being reported on a suspicious activity report (SAR).

Layering is the process of creating a series of transactions to confuse the audit trail, creating distance from the illegal proceeds. Criminals use the complications involved in the banking system to their advantage. During layering, criminals wire transfer funds to multiple locations as a way to make the funds more difficult to track. Usually these wires end up in locations with lax record-keeping and reporting requirements or in "bank secrecy havens" that have little to no taxes and fewer reporting requirements. Criminals usually target countries that are highly secretive. They know that the countries' financial systems will protect their privacy by default and make it more difficult for authorities to trace the funds. The other method that criminals use in layering is to purchase funds in the form of money orders and traveler's checks for amounts under $3,000 in order to avoid reporting requirements. These are preferable to criminals because they are highly liquid and can easily be used in multiple locations.

Integration is the final stage of the money-laundering process. It involves the unnoticed addition of successfully laundered funds back into an economy. This is typically done using multiple transactions that appear to be legitimate. Typically, these transactions occur in wealthy economies with sophisticated financial systems. The criminals use the wealthier countries since that is where the majority of their customers are located. During this stage, many criminals will purchase luxury assets or real estate or invest in other business ventures. If criminals are allowed to purchase these assets unchecked, it can create an economy that thrives on illegal enterprises. Some criminals will even choose to invest funds in developing countries as a way to further their enterprise. Money laundering threatens the integrity of the financial system.

MONEY MARKET ACCOUNT

A money market account is a type of savings account that promises higher interest payments in exchange for a larger deposit. A bank money market account is also known as a money market demand or deposit account (MMDA). This type of bank account, in addition to requiring a larger minimum deposit base than a traditional savings account, may have additional restrictions, such as a limited number of monthly transactions. Banks vary in the amount of required minimum deposits from $500 on up. The interest rate usually increases for larger deposits.

In 2013, a time of historically low interest rates, the higher rates offered by money market accounts didn't seem too enticing. Today, an online bank money market account might pay 0.85 percent interest. During the past several decades, when market interest rates were higher, money market accounts paid rates from 5 to 10 percent.

As with all bank accounts, bank money market accounts are insured by the Federal Deposit Insurance Corporation (FDIC) up to the legal limit. In 2013, the FDIC insurance amount was $250,000 per depositor, per insured bank, for each account. In other words, as long as the consumer doesn't have more than $250,000 in the bank account, he or she is fully insured. For credit union members, the National Credit Union Association (NCUA) also insures money market accounts up to $250,000.

Money Market Extra-MMAX

Money market extra-MMAX accounts insure accounts with assets above $250,000. These accounts are usually created for corporations and commercial enterprises. The commercial customer deposits the large amount, such as $500,000 with the bank. The money is then divided into two $250,000 accounts and placed in distinct banks within the Institutional Deposit Corporation (IDC) network. Consequently, the $500,000 is eligible for FDIC insurance. There are other restrictions on this type of account, including a limited number of withdrawals.

Money Market Mutual Funds

Frequently confused with money market bank accounts, money market mutual funds are another type of higher-yielding cash investment. Money market mutual funds are not the same as bank money market accounts.

A mutual fund is an investment that combines money from multiple investors and places these funds in securities as determined by the fund charter. Quite simply, the money market mutual fund invests in money market instruments. Money market instruments are generally very short-term commercial paper or debt instruments of corporations and governments. Money market mutual funds are the safest of all debt securities (possibly with the exception of treasury bills). These short-term loans pay higher interest rates than a bank due to slightly higher additional risk.

Although not insured by the FDIC like money market bank accounts, money market mutual funds are very safe. They are regulated by the Securities and Exchange Commission (SEC) and normally invest in only very secure and short-term (maturities of less than 120 days) debt securities.

Historically, money market mutual funds' value remains consistent at one dollar per share. Due to the nature of the underlying commercial paper, the true value of each share occasionally drifts below or above one dollar. Most investment companies have agreed to keep the value at one dollar per share in spite of minor underlying deviations in value.

Advantages and Disadvantages of Money Market Bank and Mutual Funds

Both of these types of accounts offer higher returns than traditional savings accounts. They are quite liquid, and the money can be accessed quickly. These are great investments for the cash portion of an investor's portfolio. Many people use these types of accounts instead of a savings or even checking account.

Minimum account balance requirements may be a deterrent for some. The limited number of allowed transactions can hinder those with a need for extensive check writing and monthly transactions. Fees accrue if the minimum balance is not met or if the maximum number of transactions is surpassed.

Interest rates on these accounts are influenced by current market interest rates. In times when market interest rates are low, so are the rates on both types of money market accounts. Fortunately for savers, when market interest rates increase, so will the returns on money market accounts and funds.

Money market accounts are a viable option for savers looking to best interest rate returns from traditional bank savings accounts.

Historical Money Market Interest Rates—The Highs and Lows

Money market interest rates fluctuate along with market interest rates. For a bit of historical perspective, the following chart illustrates the returns of taxable money market funds in five-year intervals starting in 1975.

Notice how money market account rates peaked in 1980 at 12.68 percent and fell to less than 1 percent in 2010.

It's important to note that those returns are not inflation adjusted. That means the real return, or the return after inflation is subtracted, will be much lower than the nominal return (without an inflation adjustment) listed in the chart above.

For example, in 1975 inflation was 9.20 percent, in comparison with the inflation rate of 3.38 percent in 2000. One of the lowest inflation rates during the entire period was the 1.64 percent inflation rate recorded in 2010.

Table 1. Returns of Taxable Money Market Funds

1975	1980	1985	1990	1995	2000	2005	2010	2014
6.36%	12.68%	7.71%	7.82%	5.48%	5.89%	2.66%	0.04%	0.70%

In sum, interest rates bounce around quite a bit, and in order to understand the real purchasing power of the interest rate returns, they need to be considered in light of the inflation rate.

MONOPOLISTIC COMPETITION

One of the most common types of market structures is monopolistic competition. Much like the perfectly competitive market, there are many firms competing in the monopolistic competition marketplace. Because start-up costs are fairly low, new firms can join in the competition with relative ease. The barriers to entry in this type of structure are very low, and existing firms cannot work together to keep out new competitors.

Similar to monopolies, firms in the monopolistic competition market have some control over their prices because each firm produces slightly different products from its competitors and some people are willing to pay the extra price for the unique product. Yet unlike a monopoly with total price control, this type of market structure has only limited control over price. Customers are able to substitute the good for a similar good, so if a firm raises its price too high customers will choose a competitor's good.

Firms in this market do have some control over price because they focus on the differentiation of their good. Customers are willing to pay for the unique product, up to a certain price point. The main difference between perfect competition and monopolistic competition is that product differentiation enables the monopolistically competitive seller to profit from the differences between its product and the competition's.

Sellers use physical characteristics to distinguish their product, such as color, shape, taste, or texture. Location is another feature used in this type of market structure. Some sellers strategically place their store in the most convenient location or have the only location selling a particular product. Monopolistically competitive firms also use customer service in order to differentiate themselves and charge higher prices. Some customers are willing to pay more for a good or service simply because of the service they receive at a certain firm.

A unique element of this type of market is the use of nonprice competition to obtain customers through advertising and marketing. Even though the product may be exactly the same as other firms', the use of advertising creates a difference between products. An example of this is when firms use movie stars or athletes to promote their product to imply that the product is superior and used by a famous person even though the product is exactly the same as others in the market.

Price and Output

Even though firms have some power over price in this type of market structure, the number of firms and the ease of entry prevents firms from raising prices as high as they would in a monopoly.

Because monopolistically competitive firms sell their product at higher prices than do perfectly competitive firms but lower than monopolies, total output under this type of market structure falls somewhere between the two. If a firm in this type of market begins to earn profits largely above costs, one of two effects would happen. The large increase in profits would encourage competitors to differentiate their product in order to entice customers. For example, if one denim company hires a professional athlete to advertise its product, causing a rise in profits, the other denim companies may also hire famous people to advertise for them in hopes of gaining customers.

When profits rise for a firm in this market structure, it is a signal for new firms to enter the market since the barriers to entry are very low. As the existing firms raise prices for their product, some customers will switch to the new firm's product, which is typically available at a lower price. A common example of this is when a brand-name clothing line becomes popular and many other firms flood the market with similar clothing lines. Even though the brand-name firm can earn a large profit in the short run, it must work very hard to keep its product distinct and to remain ahead of the competition.

Customers reap the rewards in this type of market structure because there are many firms offering many products that are similar but unique. Even though prices of products may be slightly higher than in the perfectly competitive market, competition keeps prices from rising too high.

MONOPOLY

A monopoly occurs when one firm or sector has control over a product or market. Monopoly power exists when an enterprise controls 25 percent or more of the market. When an organization has this much control, it has the ability to set prices at whatever level it desires. In the absence of competition, the control lies with the organization. From the consumer's perspective, a monopoly happens when a consumer has no choice but to purchase a product from a particular seller. Monopolies can be dangerous to the economy because the abuse of controlling power over a product can lead to high prices, poor service, and the ability to oust competitors for internal gains.

As a result, governments regulate monopolies in various ways. They may highly regulate them as a regulated monopoly, such as a utility, or force the company to break up into smaller, more competitive companies. In early American history, the Interstate Commerce Act of 1887 aimed to regulate the railroad industry. At the time, the industry was controlled monopolistically. The Sherman Antitrust Act (1890) and the Clayton Antitrust Act (1914) followed the Interstate Commerce Act. Ensuring safe competition was one of the goals of the Federal Trade Commission Act of 1914 that created the Federal Trade Commission (FTC).

The FTC carefully regulates and monitors monopolies to maintain competition and consumer safety. In modern times, regulations may include price capping, prevention of mergers and acquisitions, unbundling of products, or forcing nationalization. Nationalization forces a privatized company to become publicly controlled; this is an extreme and unlikely action. The unbundling of products is the forced change of an item.

The power of monopoly also has a trickle-down effect to suppliers. If a firm has control over the market, it also has relative control over the suppliers to that market. This means it has the power to set prices and gain priority over potential competitors. The danger of this practice is that production suppliers that are not competitive in providing service to the firm can be rendered powerless and potentially bankrupted. By gaining advantage over competitors, the monopolistic firm can also squeeze out other organizations in the industry. These practices would be considered unethical and have greater ramifications for the consumer.

Governments regulate monopolies to prevent the abuse of power. For the consumer, unfair pricing and lack of competition can make products inaccessible and take away buying power. In some markets there exists a natural monopoly due to the limited access of a resource, such as natural resources. The need of very large economies of scale for a product or service to be commercially viable can lead to a government-regulated monopoly. Competition in these unique circumstances could lead to a significant misallocation of an economy's resources. Utilities are prime examples of regulated monopolies. These industries are highly regulated to maintain ethical standards and practices to protect consumers.

The criticism of government regulation is that in a free market, if an organization can gain monopolistic power, it should be allowed to function. It is possible that an organization has earned this power through efficient productivity, innovative products, and well-organized business practices. The consumer's ability to choose between organizations in competition allows consumer demand to set the market price fairly based on the financial capabilities and desires of the public. If an organization has earned market power through effective and fair businesses practices, consumers should naturally choose its product.

MOODS AND FINANCIAL MARKETS

The influence of moods on people's perceptions and judgments has been psychologically established, indicating the informative function of affective states (Schwarz and Clore 1983). Recently the role of mood in financial markets has gained attention, suggesting that financial activity, usually presumed rational, may be subject to such factors as weather-induced affective states (Saunders 1993).

Hirshleifer reviews psychological influences on security prices, with implications for economic modeling. Loewenstein et al. (2001) proposed the "risk-as-feelings" hypothesis that emotional states guide decision-making under risk differently than implied by normative models. Other phenomena include the impact of moods on financial aspects of information evaluation, prospective opinions, and risk attitudes.

The effect of psychological factors on individuals is insufficient to infer that moods are relevant to market activity. Simultaneous mood fluctuations of many investors (due to weather and seasons, for example), however, might not average out.

Seasonal affective disorder (SAD) is a type of circannual depression affecting a substantial segment of the population, especially in the northern regions. Its biological mechanism involves biochemical imbalances in the hypothalamus resulting from seasonal shortening of the photoperiod. Kamstra and others (2003, 2012) show the impact of SAD-induced moods on investors' risk aversion and stock returns. Kliger and Levy employ SAD and cloudiness to explain variations in subjective probability perceptions; Kliger, Gurevich, and Haim demonstrate SAD's influence on demand for initial public offerings; Kramer and Weber show that SAD is responsible for seasonally changing risk aversion; and Kliger and Kudryavtsev show SAD's impact on investors' reactions to news. Investors' moods due to additional factors are shown to influence financial markets. Kamstra, Kramer, and Levi demonstrate the impact of investors' sleep patterns (due to daylight savings time changes); Kliger and Levy show the relevance of weather-induced mood for investors' probability judgments and risk tolerance; Kuhnen and Knutson analyze the impact of affect on risk attitudes and belief formation; and Bassi, Colacito, and Fulghieri provide experimental evidence of the impact of weather-induced mood on individual risk attitudes.

MORTENSEN, DALE

Born: February 2, 1939, in Enterprise, Oregon; Died: January 9, 2014, in Wilmette, Illinois; Nationality: American; Professional Interests: labor economics, Nobel Prize (2010); Major Work: *Wage Dispersion: Why Are Similar Workers Paid Differently?* (2003).

Dale Mortensen was a contemporary theorist who specialized in labor economics with a focus on unemployment. His theories can be used to formulate and predict the impact of a variety of government influences on overall unemployment and wage distribution. Mortensen's professional pursuits led him to Northwestern University in 1965, where he remained until his death from cancer in 2014. His expertise regarding labor markets took him to many parts of the world, and his theories earned him a Nobel Prize in 2010.

Dale Thomas Mortensen was born on February 2, 1939, in Enterprise, Oregon, a small community in Willowa County. He graduated from Wy'east High School in 1957 before attending Willamette University in Salem, Oregon, where he was a trailblazer in the economics department, which focused on economics via a mathematical approach. While at Willamette, his pursuits included not only academic achievement but also leadership. Mortensen served as student body president during his senior year as he completed his bachelor of arts in economics in 1961. Following his time in Salem, Mortensen began working on his PhD at Carnegie Mellon University in Pittsburgh, Pennsylvania, which led him to his role in education and research. He earned his PhD in economics from Carnegie Mellon in 1967.

Mortensen began teaching at Northwestern University in Evanston, Illinois, in 1965, and he remained there until his death. Mortensen's upbringing and education led him into a career focused on labor markets and employment. He worked in a variety of educational settings and promoted his theories throughout his career at numerous institutions and for several organizations.

The years of research on labor markets led Mortensen to write his most famous work, *Wage Dispersion: Why Are Similar Workers Paid Differently?*, which was published by MIT Press in 2003. The book gained widespread praise from many of his contemporaries as it sought to use both theory and empirical data to explain labor markets theory. His research on wage dispersion and distribution of earnings opened the eyes of many as experts try to assess the relationship between potential employees and employers. Several reviews, both domestic and foreign, note that Mortensen's work was well written and inspired many to learn more about labor economics.

Mortensen's research culminated in perhaps his most significant achievement: a Nobel Prize in Economics. The Royal Swedish Academy of Sciences awarded Mortensen and two other colleagues the Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel in 2010. The committee selected Mortensen, Christopher

Pissarides of the London School of Economics and Political Science in the United Kingdom, and Peter A. Diamond of the Massachusetts Institute of Technology for their analysis of markets, such as employment, where people looking for work are not appropriately matched with those who are looking to hire these same workers. This is what is known as a search friction. Their extensive research on labor markets over the course of the past several decades helped explain how so many people can be unemployed while at the same time there are a tremendous number of job vacancies in the market. Much of their research focused on the impact of government regulation, monetary policy, and the overall involvement of government in the labor market, particularly the effect on employment data such as wages or job vacancies and the relationship between potential employees with their skill sets and employers' need for labor. The Nobel Prize was awarded not only for the principal research conducted by Mortensen, Pissarides, and Diamond but for the predictive power of their theories.

Many experts in economics refer to their theory as the Diamond-Mortensen-Pissarides model, which is used to predict how unemployment benefits, interest rates, the efficiency or lack thereof of employment agencies, and other inputs can affect the labor market and employment. During our current global economic situation, this research and model is of particular interest. Their model would seem to suggest a positive correlation between increased unemployment benefits and longer periods of unemployment and longer search times for those who are currently seeking employment.

Mortensen is well known for his work on labor economics, and though the crowning achievement in his remarkable career may be the Nobel Prize in Economics, he has been recognized by many other organizations and institutions as well. He served as a visiting professor or lecturer at several institutions, most notably at Aarhus University in Denmark. He worked as a research associate of the National Bureau of Economic Research (NBER), a research fellow of the Institute for the Study of Labor (IZA), and a fellow of the Econometric Society, the American Academy of Arts and Sciences, the Society of Labor Economics, and the European Economic Association. He also served in a plethora of other capacities for various committees, associations, and organizations. His remarkable efforts in labor economics received much acclaim. He received the IZA Prize in Labor Economics in 2005 and the Mincer Prize from the Society of Labor Economics in 2007 and was named the American Economic Association distinguished fellow in 2008. Mortensen's expertise and efforts in his field provided the economic and academic community with a wealth of knowledge that will further assist in understanding the complexities of employment and labor.

Dale Mortensen died on January 9, 2014, in Wilmette, Illinois.

MUTUAL FUNDS AND EXCHANGE TRADED FUNDS

Investors use mutual funds and exchange traded funds (ETFs), pooled investment vehicles, to invest in a variety of asset classes. Instead of an individual investing in a specific stock or a bond, mutual funds and ETFs collect a pool of capital from many investors and invest on behalf of these investors. Investors are charged a management fee for this service, referred to as the expense ratio.

Mutual Funds

With mutual funds, investors can participate in the stock, bond, or real estate investment market with a small amount of money. Investors pool their money and the fund company manages and invests those funds according to the specified investment policy of the mutual fund.

Over the last 20 years, mutual funds have become very popular, with more than 80 million people (half of all U.S. households) invested in them.

There are many varieties of mutual funds with a wide range of objectives. Index fund mutual funds have become quite popular recently, with the manager investing in approximately the same companies as those in the popular stock and bond indexes. For example, the Standard & Poor's 500 stock index measures the price movements of the 500 most important companies in the United States and is widely duplicated by stock index mutual fund companies. The S&P 500 is not an investable index (i.e., an investor cannot directly invest in S&P 500 index), so the mutual fund companies offer the opportunity to invest in that and many other popular stock market indexes.

Actively managed mutual funds attempt to beat the returns of index funds with additional security analysis and strategies. There are many actively managed funds with a variety of managers, strategies, fees, and approaches.

Exchange Traded Funds

Exchange traded funds (ETFs) are a relatively new form of investment vehicle. An ETF is very similar to a mutual fund, yet it trades during the day like a stock on organized exchanges. Unlike a mutual fund, the net asset value (NAV) of which is calculated at the end of every day, an ETF's price changes throughout the day based on supply and demand.

Originally ETFs were created to pool investors' dollars and earmark the monies into funds designed to track a stock or bond or proprietary index. For example, SPY (SPDR S&P 500 ETF Trust) is designed to track the performance of the Standard & Poor's 500 (S&P 500) index. Investors are able to gain exposure to S&P 500 index by investing in SPY ETF, which replicates the index such that the returns generated from the index and the ETF are similar.

As ETFs gained in popularity, they expanded in variety. Thus, by using ETFs, investors are able to access a wide range of strategies for their portfolios, including sector-specific exposure (XLF—SPDR Financial Select Sector ETF), country-specific exposure (MCHI—iShares MSCI China ETF), region-specific exposure (VGK—Vanguard FTSE Europe ETF), market capitalization–specific exposure with leverage (TZA—Direxion Daily Small Cap Bull 3X, i.e., leveraged three times), and commodity-specific exposure (GDX—Market Vectors Gold Miners ETF).

Tremendous benefits of these funds are their low expense ratios and the ability to buy or sell them on traditional stock exchanges throughout the day.

Fund Accessibility and Costs

Investors can access mutual funds and ETFs through a brokerage account, just like stocks. Many investment companies offer mutual and exchange traded funds.

In comparison to actively managed mutual funds, the cost of investing in index mutual funds and ETFs is lower for investors given their structure, which provides tax efficiency. Holdings in ETFs generally are not bought and sold as frequently as those in actively traded mutual funds, thereby keeping capital gains taxes lower.

The expense ratio varies across mutual funds. In general, index mutual and exchange traded funds have the lowest expense ratios. Some mutual funds also charge sales and distribution fees (load), charged either upfront at the time of purchase (front load) or when shares are sold (back load). A mutual fund could have different share classes for investment, each with a different minimum investment and expense ratio. Investors have to invest the minimum amount required by a particular mutual fund.

Types of Mutual and Exchange Traded Funds

Investors are able to access a wide variety of investments through mutual funds and ETFs. As a result, these vehicles have seen a large amount of investor fund inflows since they were launched. The most common classification in these vehicles is based on the asset class in which the vehicle invests. Simply put, *asset class* refers to the type of financial asset contained in the mutual fund; for example, stocks, bonds, real estate, commodities, or other.

Equity funds invest in stocks. Some stock funds are categorized according to the size of the company or market capitalization (current share price times the number of shares outstanding); large-cap (over $10 billion), mid-cap ($2 billion to $10 billion), small-cap ($250 million to $2 billion), and micro-cap (less than $250 million). Within each of these market capitalizations, the strategies vary by style: value, growth, and momentum. Each of these styles represents a distinct investment philosophy. Some of these strategies have an income (dividend) focus while some focus on capital appreciation. These funds can also be classified based on the geographic area that they invest in: domestic funds invest in the securities issued in the United States, international funds invest in securities issued throughout the world, emerging market funds invest in securities issued in emerging and frontier markets, and regional global funds invest in companies from across different regions.

Bond funds invest in bonds and may be categorized in many ways. Government bond funds include U.S. Treasury debt. Other types of bond funds carry municipal debt, corporate debt, convertibles, asset-backed securities, mortgages, and bond derivatives. Within each of these classifications the funds vary by the average maturity of the underlying instruments, by credit quality, and by the amount of income generated. Similar to equity funds, some bond funds have a mandate to invest outside of the United States. Bond funds are an important part of asset allocation strategy to reduce risk or volatility in the investor's portfolio.

Most bond funds pay a quarterly or monthly dividend, which endears them to retirement accounts due to their ability to generate income along with some capital appreciation.

Alternative funds have a mandate to invest in alternative asset classes of real estate, commodities, or other types of financial assets. A growing part of alternative funds are the complex strategies that differ from the traditional long-only strategies seen in equity and bond funds. These strategies include long/short equity, long/short credit, managed futures, event driven, and global macro strategies. These alternative strategies have traditionally existed in a hedge fund structure and have recently seen an explosion within the mutual fund space.

Regulations and Investor Protection

All funds are guided by a prospectus that defines the investment strategy and mandate for the fund. The prospectus also provides other useful shareholder information, such as fees charged, biography of management, and investment risks.

All mutual funds and ETFs in the United States are registered with SEC (Securities Exchange Commission) and are governed by the Investment Company Act of 1940. Being regulated entities, their funds have to comply with SEC regulations regarding liquidity, investor transparency, and fees, all of which have been implemented by SEC for investor protection.

NASH, JOHN

Born: June 13, 1928, in Bluefield, West Virginia; Died: May 23, 2015, in Monroe Township, New Jersey; Nationality: American; Professional Interests: game theory, Nash equilibrium, mathematics; Major Works: "Equilibrium Points in N-Person Games" (1950), "The Bargaining Problem" (1950), "Non-cooperative Games" (1951), "Two-Person Cooperative Games" (1953).

John Nash is a mathematician who developed advanced studies of game theory that expanded their application to broad categories of political science, economics, business strategy, biology, and personal interactions. In 1994, he was awarded the Nobel Prize in Economics for his work in game theory with John Harsanyi and Reinhard Selten. Nash equilibrium is the most widely used and applied solution concept of game theory. Nash was the subject of the 2002 film *A Beautiful Mind*, which portrayed his struggle with paranoid schizophrenia.

John Forbes Nash was born on June 13, 1928, in Bluefield, West Virginia. He was raised in a highly intellectual environment and developed advanced mathematical skills as a child. Awarded the coveted George Westinghouse Scholarship, he began his undergraduate studies at Carnegie Institute of Technology (now Carnegie Mellon University) in chemical engineering. He did not care for the regimentation of the engineering classes or the quantitative analysis of the chemistry classes and changed to mathematics.

From an international economics course at Carnegie, he derived the idea for his paper "The Bargaining Problem" and ultimately his interest in game theory. By graduation he had progressed in his studies of mathematics and was awarded an MA degree in addition to the BS degree.

He was offered fellowships to both Harvard University and Princeton University for further studies in mathematics. He chose Princeton because it was closer to home. During his graduate studies one of his discoveries led to "Noncooperative Games." He concurrently developed two theses, one in game theory and one based on his discovery relating to manifolds and real algebraic varieties.

His academic career began in 1950 at Princeton, where he taught for one year. In 1951, he accepted a higher-paying position as a C. L. E. Moore instructor at the Massachusetts Institute of Technology (MIT) where he remained until 1959. During this time, he solved a problem relating to differential geometry and developed the theorem known as the Nash embedding theorem.

He accepted the Alfred P. Sloan grant and returned to Princeton as a member of the Institute for Advanced Studies (IAS). While at IAS, he solved a problem involving partial differential equations. Unbeknownst to him, Ennio de Giorgi of Pisa, Italy, was also working on the problem and solved it prior to Nash. Had only one of the men solved this equation, it is speculated that he would have received the famous mathematics Field Medal.

John Nash made important contributions to game theory research. Game theory allows social scientists to evaluate interactive decision-making when the outcome for one participant is dependent on the actions or strategies of all other participants. Nash introduced the distinction of identifying cooperative and noncooperative games. Cooperative games allow players to form binding enforceable agreements and make irrevocable threats to other players. Noncooperative games do not allow for such possibilities. The science of game theory can be applied broadly in the areas of experimental economics, behavioral economics, industrial organization, and political economy. Noncooperative games are accurate at understanding and predicting social interactions, voting behaviors, fair division, auction, mergers and acquisitions, corporate compensation plans, bargaining systems, oligopolies, and duopolies. Nash identified the equilibrium point in such games. It is a set of strategies and the corresponding pay-offs when no player may benefit by changing his strategy while other players leave their strategies unchanged.

A player would not choose to change his or her strategy for optimal outcome even after learning the strategies of other players. This is known as Nash equilibrium. Nash equilibrium is the most widely used and applied solution concept of game theory because it yields the most accurate insights into the workings of the social situation to which it is applied. In 1994, John Nash, with John Harsanyi and Reinhard Selten, received the Nobel Memorial Prize in Economic Sciences as a result of his game theory work as a graduate student at Princeton.

John Nash struggled with paranoid schizophrenia beginning in early 1959, which resulted in an involuntary hospital stay, his resignation from MIT, and an attempt to renounce his U.S. citizenship, seeking political asylum in France and East Germany. His experience was portrayed in Ron Howard's 1998 movie, *A Beautiful Mind*, based on the book by Sylvia Nasar. Nash later spoke out against Nasar's false depiction that he recovered as a result of atypical antipsychotics when in fact he refused any medication after 1970. He credits his recovery to his decision to renounce his delusional hypotheses and to return to rational thought.

In addition to the Nobel Prize in 1994, Nash has been awarded the John von Neumann Theory Prize for his discovery of Nash equilibria (1978) and several honorary degrees and doctorates.

John Nash and his wife, Alicia, died in an automobile crash in New Jersey on May 23, 2015. Dr. Nash was 86.

NASH EQUILIBRIUM

John Nash's 1950 paper on game theory had a huge impact on economics. The central concept of his paper, coined the "Nash equilibrium," changed the way many people think about strategic environments, not only in economics but throughout the social sciences.

The Nash equilibrium is a conceptualization of stability as a necessary condition on the behavior of agents in strategic situations. When agents interact strategically, the payment each one receives depends not only on each individual's behavior but also on all the other agents' choices. In such situations, the Nash equilibrium defines a certain pattern of behavior and facilitates the evaluation of equilibrium payments.

The description of a Nash equilibrium is quite straightforward. Consider that there are n agents. Each agent can choose an option from a finite set. The vector of actions selected by all agents is called a profile. A profile of actions is a Nash equilibrium if no agent has an incentive to change her or his selected action, assuming that all other agents choose the actions specified by this profile. Formally, the Nash equilibrium can be formulated as follows: consider n agents with a finite set of actions denoted by A_i. A Nash equilibrium is a profile of actions $(a_1, \ldots, a_n)$ where

a_i belongs to A_i for i from 1 to n, and

$$u_i(a_1, \ldots, a_i, \ldots a_n) >= u_i(a_1, \ldots, b_i, \ldots, a_n) \text{ for all } b_i \text{ in } A_i$$

This formulation is called a Nash equilibrium in pure strategies. Nash's outstanding result is the existence of Nash equilibrium in any finite game where mixed strategies (strategies where agents can choose probability distributions over actions) are considered.

The question that arises from a behavioral viewpoint is whether agents really act as prescribed by a Nash equilibrium. In general, behavioral economics suggests that the answer to this question is negative. To illustrate this point, let us consider a well-known social dilemma: the prisoner's dilemma. Assume that there are two agents, each with two potential actions, namely "telling the truth" and "lying." If both agents choose "telling the truth," their payments are three units each. If both choose "lying," each agent gets only one unit. However, if one of them chooses "lying" and the other "telling the truth," the liar gets a payment of four units and the other receives nothing. Surprisingly, the only Nash equilibrium of the prisoner's dilemma is for both agents to choose "lying," thereby receiving one unit, instead of the efficient payment (three units each) if they both chose "telling the truth."

To check this result, note that in any other profile, there is at least one agent "telling the truth." Such a profile cannot be an equilibrium, because the agent "telling the truth" has an incentive to change his or her action to "lying" to increase the payment. Indeed, if both agents choose "telling the truth" and one of them changes to "lying," his or her payment will increase from three to four units. Similarly, in the profile where only one lies, the agent "telling the truth" increases his payment from zero to one if he or she chooses "lying." In other words, the profile in which both players choose "false" is the only stable situation (Nash equilibrium) of the prisoner's dilemma.

Despite this analysis, behavioral studies on the prisoner's dilemma do not generally support this result because agents may consider other issues beyond their payments. For example, they may consider making three units to be sufficient. Similarly, one agent may feel sympathy toward the other player and decide that it is not fair to make four units if he or she lies and the other tells the truth. Additionally, an agent may not be completely sure about the action the other player will choose, so he or she may view telling the truth as a reasonable alternative. All these ways of thinking are not considered in the definition of the Nash equilibrium, yet they are very reasonable patterns of behavior. Hence, new definitions of an equilibrium arise to give us a better insight into the actual behavior of agents. But the Nash equilibrium remains a powerful reference point for analyses on strategic interactions, which stimulated and paved the way for related research.

NATIONAL STEEL STRIKE, 1919

America's steel industry had been plagued for decades by labor problems over such issues as the 12-hour workday, the seven-day workweek, and low pay. Bloody strikes, such as the Homestead Strike of 1892, were common. Labor had failed to make any progress on union representation and collective bargaining, but labor unions were growing, and public support for unions was increasing. During World War I, however, President Wilson moved to prevent any major strikes that would disrupt war production.

In 1918, a special agency was created to handle labor disputes in the war industries. The agency, known as the National War Labor Board (NWLB), had limited authority, which required the president to force compliance with the government's labor policies. Priority one was to prevent production disruption caused by strikes and lockouts, but Wilson favored unionization and a progressive government effort to achieve this goal. However, the NWLB's principles were the right of labor to organize with no company action against organizing efforts and the right of union shops to exist. The Wilson administration often used these broad principles to award contracts to companies. The end of World War I provided an opportunity for the unionization of America's largest industry.

In contrast to the generally high wages paid during the war and shortly after because of a labor shortage, unskilled immigrant steel workers were underpaid and overworked. They worked 12-hour days, seven days a week. In 1919, wages for unskilled immigrant steelworkers were $1,466 a year, but subsistence level for a family of five was $1,575. These workers were ready to fight for better conditions. They had also developed solidarity with the skilled steelworkers, which had been lacking in earlier strikes. This unity had been forged by the growing American Federation of Labor.

The American Federation of Labor saw the opportunity to expand its organizing efforts in the steel industry as the end of the war was in sight. The issue would accelerate at Midvale Steel in April 1918 with a challenge from the International Association of Machinists, which had started an organizing drive at Midvale Steel. Midvale produced naval guns and shells and was critical to war production, so the government thought the NWLB would certainly force collective bargaining. Bethlehem Steel was also having problems with the International Association of Machinists, and the two companies were coordinating their approaches. *Iron Age*, the steel industry magazine, warned of NWLB's stated intent to "encourage union leaders to seize upon the national war emergency to organize every plant heretofore maintained as a non-union or open-shop."

In August 1918, the Midvale case came before the NWLB for review. The demands were collective bargaining, an eight-hour day, elimination of the present piece-rate system, and restoration of a beneficial insurance program. These, of course, were industry-wide issues. The NWLB recommended an employee representation plan, but Midvale Steel delayed any immediate action. These employee representation plans were company unions meant to slow the organizing efforts of the labor unions. United States Steel saw the threat of government intervention and in August 1918 called an industry meeting of steel executives at New York's Waldorf-Astoria Hotel. An industry plan was designed to make the eight-hour day the base but to allow workers to work 12 hours at a time-and-a-half rate after eight hours. The arrangement was popular with most workers, who realized a pay increase under the new plan. Companies like Midvale did not like the solution from a productivity standpoint. Union leaders like Samuel Gompers, social reformers, religious leaders, and community leaders did not like the solution either because they thought it reinforced the 12-hour day. The compromise had the effect of slowing real reform from union or management reformers. Still, collective bargaining remained the real issue from the government's standpoint.

In June 1919, between 200 and 300 of Midvale's 2,000-plus workforce walked out. The Labor Department, the navy, and the NWLB descended on the plant. The navy got things going again, but collective bargaining now had to be settled by the NWLB. Midvale Steel was asked to speed up work on an alternative plan. However, the company was more interested in an industry-wide solution. The old tricks of using company spies, local political pressure, and harnessing union leaders resumed. Judge Elbert Gary, chairman of United States Steel, would have nothing to do with collective bargaining, wage increases, or the elimination of the 12-hour day. In May 1919, the American Federation of Labor conference in Pittsburgh had discussed and approved a fall strike. The conference resolution called for collective bargaining, an eight-hour day, double-time pay for overtime, one day's rest in seven, abolition of the 20-hour shift used to rotate the men, seniority-based wages, and the abolition of company unions. By July 1919, war powers were approaching an end. Gompers and the union, realizing the NWLB power and support would be gone, thought the time was right to push for companies to accept collective bargaining.

After Labor Day in 1919, labor trouble started in Pittsburgh. Union organizers could not rent meeting rooms, and local police and private guards seized literature from some organizers and ran others out of town. The economic downturn gave companies the upper hand, but the disturbances soon spread to the Chicago district. The union appealed to President Wilson to accept the union and collective bargaining, and they were counting on his support. Judge Gary of United States Steel refused to deal with the union. Charles Schwab at Bethlehem Steel and William Corey at Midvale Steel were counting on their employee representation plans to protect them. On September 22, when Gary refused to negotiate further, a national walkout started. Wilson had a stroke on September 26, 1919, and many believe his medical condition prevented government intervention. With Wilson incapacitated, his advisers held back. Wilson had been rejected in the midterm elections, however, and public support was not with him. Furthermore, Wilson had been looking for money and support from steel companies for his League of Nations.

The strike first hit United States Steel hard, and most of its workers in Pittsburgh, Chicago, Cleveland, Lackawanna, and Youngstown went on strike. Bethlehem Steel continued to work with its employee representation plans in place. The steelworkers' resolve was strong, but public opinion remained mixed. On September 30, as many as 360,000 steelworkers were on strike. The owners and local politicians formed large armies of deputy sheriffs to prevent violence. The owners used the postwar Red Scare of the Russian Revolution of 1917 in arguments against the unions. Newspapers openly worried about the influence of communists in the union. Still, the steelworkers held together. The union gained public sympathy with the push for an eight-hour day. The strike was fought in the trenches. Local violence, beatings, and raids were commonplace. Hundreds of strikers were jailed. Pennsylvania State Police proved particularly brutal on picketers.

The companies moved to strikebreaking, using between 30,000 and 40,000 black and Mexican American laborers. Strikebreaking at United States Steel's Gary, Indiana, plant turned violent on October 6. The governor declared martial law and brought in the National Guard. The violence then spread to nearby Indiana Harbor. The guard completely suppressed the strikers, ending the strike in Indiana, but violence dragged on around the nation. In Pennsylvania and Ohio, the violence had a racial element against black strikebreakers and their families. By 1920, the strike was over. Most considered it a complete victory of the owners. Not a single concession was given; 20 died, and more than $112 million was lost in wages. However, within two years, with pressure from President Warren Harding, Gary and United States Steel were finally forced to accept the eight-hour day and six-day workweek.

NATIONAL STEEL STRIKE, 1959

At 116 days, the steel strike of 1959 was the nation's longest. It was also the nation's most widespread strike, bringing American manufacturing to a grinding halt. At the time, the steel industry was the nation's largest industry; there were 540,000 members in the United Steelworkers of America (USWA). The root of the strike was a dispute over management control and contract clauses in the workplace. In particular, management had the right to assign the number of workers to a task, reduce the workforce by replacing workers with machinery, and introduce new work rules.

The strike became a bitter battle in a nation totally dependent on domestic sources for steel. The strike ended when President Dwight D. Eisenhower invoked the 1947 Taft-Hartley Act. The union challenged the Taft-Hartley action, but the Supreme Court upheld it. The union eventually retained contract clauses on work rules and won a small wage increase. In retrospect, the strike was a disaster for the union, the management, and the nation, and it led to significant amounts of steel being imported into the nation, which devastated domestic production in the long run.

The steel industry had been unionized in the 1930s and continued to make major gains through the 1940s. The passage of the Taft-Hartley Act in 1947, which amended the Wagner Act, slowed the progressive government support of unions. The Taft-Hartley Act allowed the president to intervene in strikes that posed a national emergency, and the 1959 strike was the first application of this clause. The 1959 crisis was the result of overexpansion of the industry to meet war needs. The steel industry never got a rest as the Korean War created even more demand in the 1950s.

American steel manufacturing was at the peak of its power, but its very strength became a weakness. American steel companies made more than 60 percent of the world's steel. The industry overexpanded in the 1950s. Imports into the United States were less than 3 percent of the domestic market. After the 1959 strike, U.S. steel production dropped to 26 percent of the total world market (the lowest since the 1870s). Steel prosperity in the early 1950s resulted in labor contracts favorable to the steel workers' unions. In 1956, the United Steelworkers had won large wage increases of 4 to 6 percent per year. In 1957, American steelworkers were earning \$2.92 an hour compared with \$0.75 an hour for workers in Germany and \$0.45 an hour for workers in Japan. The industry approached 1959 with overcapacity and high costs—and imports were starting to come into the market.

Still, the first-quarter profits for the industry in 1959 were at a near record \$375 million, with an 11.7 percent return on stockholders' investment. This was due in part to a huge inventory buildup in steel-dependent industries. The underlying problems in the industry were masked by profits that reflected the end of a boom. The government was anxious about the 1959 steel negotiations because inflation was rising, and an expensive steel settlement would lead other big industries to grant large wage increases. The 6 percent wage increase for steelworkers in 1956 had significantly increased the costs of manufacturing overall. In 1956, 40,000 white-collar workers in the steel industry also unionized. Finally, in 1959, steel management thought the time was right to take a stand over years of wage increases. As the deadline approached, the Eisenhower administration became active in the negotiations; cabinet members were able to broker an extension with union chief David McDonald. However, the strike started on July 15, 1959, as negotiations broke down. The strike was national against all American steel producers.

As a result of the strike, more than 150,000 autoworkers and another 150,000 in the railroad industry were laid off. The United States lost its export market in the first few weeks of the strike. Even worse for the American steel industry was that foreign steel was pouring in at greatly reduced prices during the strike, so if the union got a wage increase and prices for American steel went up as a result, a large segment of the market for American steel would be lost. American auto manufacturers had to decrease production because of a lack of steel, as did thousands of other steel users. Steelworkers suffered as the union strike funds ran out. Workers and/or their wives found part-time work. To heat their homes, steelworkers took to the nearby hills to dig their own coal and glean fallen coal from around railroad tracks.

The strike soon threatened the whole of American industry. As the strike reached the critical stage, President Eisenhower invoked the Taft-Hartley Act to bring the workers back for 80 days of negotiations so the government could broker a deal. Eisenhower sent Vice President Richard Nixon to get directly involved. The government was successful at ending the strike, but it came at a high cost. The total package was worth about $0.40 an hour and boosted steel prices by $16 a ton. Two years later, imports were double the 1959 rate. The three-month strike forced the auto manufacturers and others to buy imported steel. These companies soon realized the benefits of cheaper, high-quality steel from the rebuilt mills of Europe and Japan, and American steel started a long slide, losing market share to lower-priced imported steel. Behind the strike headlines, America's first Japanese car imports were delivered at the port of San Francisco in 1959. The timing was perfect for Japanese importers as U.S. car prices rose because of the costs of settling the steel strike.

In 1962, inflation and the effects of the 1959 strikes caused more price increases, which the government used public pressure to prevent. Now inflation and wages combined with lost market share to reduce steel industry profitability. By the 1980s, the seeds of the 1959 strike had brought the end of the American steel industry. This was a far cry from the situation in 1944, when American steel mills outproduced the steel mills of Germany, Japan, Russia, Great Britain, and Italy combined.

NATURAL MONOPOLY

Use of the term *natural monopoly* likely began in 1848 when John Stuart Mill used it to describe a characteristic of a resource that resulted in economic rent. That is, a superior quality inherent in the resource would lead to a monopoly that was naturally determined as opposed to being legally granted. More generally, *natural monopoly* is used to describe industries in which competition does not lead to lower-cost production. Instead, the cost of serving the market is lowest with a single firm, and productive efficiency requires single-firm production. If that firm sets prices above its marginal cost of production (because it naturally faces no competition), allocative efficiency is sacrificed and social welfare declines. This intrinsic trade-off means market forces will fail to produce efficient outcomes, and natural monopoly is an example of market failure.

To illustrate the economic problem of natural monopoly, consider an electric utility supplying service to a small town. The company shares with telecom, cable, and railroad industries the need to invest in a fixed network. The high fixed cost of the network discourages multiple companies from providing electricity to the town once an incumbent is in place. Over some (possibly large) range of output, it would be economically inefficient to have competing firms. How large this range of output is depends on the magnitude and type of fixed costs and the scope for technological advancements.

Total costs of production combine the firm's fixed and variable costs. Variable costs are those that increase with output (e.g., wages paid to labor increase as hours worked increase). Fixed costs do not vary with output. As a result, average fixed costs will decline as more output is produced. As long as the firm's long-run average total cost is declining, a second producer would only increase the cost of producing the good. Declining average total cost over some range of output is referred to as *economies of scale*.

More formally, a firm is a natural monopoly if its cost function is subadditive. A firm with a subadditive cost function can serve a single product market at less cost than two or more firms could. Declining long-run average total cost is one reason for a firm to have a subadditive cost function for a single product, but it is also possible for a single-product firm to have a subadditive cost function over a range of output where its long-run average cost is increasing as long as it is still less costly to have one firm in operation than two.

If a firm produces more than one product (e.g., cable TV and Internet service) subadditivity implies the firm can produce any combination of the multiple products together at less cost than the individual products could be produced separately (by different firms). Therefore, economies of scope are necessary for subadditivity when firms produce multiple products. Baumol discusses the complexities of defining a natural monopoly in this context and provides the necessary and sufficient conditions for subadditivity.

If a natural monopoly is operating in a range of output where there are economies of scale, average total costs will exceed marginal cost and pricing at marginal cost will result in the firm suffering losses. Yet, when price is above marginal cost, there are social welfare losses resulting from units that are socially valuable not being produced.

Natural monopolies are often subject to price and or entry regulation in an attempt to minimize welfare losses. Entry regulation occurs when there are few barriers to entry but production costs are minimized when there is a single producer. Price regulation is used to ensure firms cover their fixed cost of production and earn a rate of return to encourage investment. If firms charge a single price and have to break even to avoid subsidies, some social welfare will necessarily be sacrificed. Welfare losses result when firms set price equal to average total (to cover their fixed costs) instead of marginal costs. When a natural monopolist produces multiple products, social welfare losses can be minimized by raising prices differentially depending on the elasticity of demand for each product. Because consumers reduce their quantity demanded less the more inelastic their demand for a product, the firm adds more to its revenue with larger price increases for more inelastic demand. This markup method is attributed to Frank Ramsey and is known as the Ramsey pricing rule.

Some formerly regulated network industries have been fully deregulated (e.g., railroads and airlines) while many others have undergone partial deregulation for portions of the business (e.g., electric utilities, cable television, and telecommunications). Regulation comes with its own bureaucratic and political costs that can outweigh the social gains. Time and resources are consumed while regulators decide the merits of rate increases, and regulators must rely on imperfect assessments of firms' cost of service. In addition, a judgment must be made about when to reduce or stop regulating an industry. If demand growth or technological change makes competition feasible, movement away from regulation should be considered.

Demsetz proposed an alternative to regulation of natural monopoly. He recommended having competition *for* the market as opposed to *in* the market. If firms can bid for the right to service the market, the price of service should be bid down to marginal cost if there are a sufficient number of bidders with marginal cost close to the lowest cost. The winner of the bidding process would then have an exclusive franchise for some period of time. On the surface, this appears to take care of both productive and allocative inefficiencies, but the franchisor is left with a role not unlike a regulator. Decisions must be made about rate increases, quality of service, franchise extension, and so on. If the franchise is of short duration and bidding is periodic, efforts must be made to ensure bidding parity between the incumbent firm and potential entrants, and arrangements must be made to transfer the franchise if an entrant is the winner in subsequent bidding rounds. Williamson discusses why these are nontrivial complications. Likewise, if the service being provided is very specialized, it is possible there will be few low-cost bidders, resulting in a winning bid well above the winner's marginal cost.

In the long run, technological advancements often remove the natural monopoly characteristics of an industry and competition becomes feasible. For example, a local telecommunications carrier may cease to be the lowest-cost provider of residential and business telephone services if cable companies can provide those services in addition to television. Other technological advances obviate the need for fixed-line networks and reduce barriers to entry. Wireless service is one example.

Also, an innovation that lowers the fixed cost of service will shift down the average cost curve and, as long as there are diseconomies of scale over some range of output, the firm's minimum efficient scale will fall. As the minimum efficient scale is lowered, the range of output that can support multiple firms expands.

Identifying natural monopolies, calculating optimal prices, deciding whether to regulate and deciding when to deregulate is challenging, especially when firms produce multiple goods. Network industries with natural monopoly characteristics are becoming increasingly competitive following technological advances that have lowered entry barriers and firms' minimum efficient scale of production. In some cases, only parts of the industry have become competitive.

NET WORTH

The net worth concept applies to both business and personal finance. Net worth describes how much the entity is worth. Determine the net worth of a business by adding the total of the things the business owns (assets) and subtract from this amount the total of what the business owes (liabilities). When it comes to determining an individual's net worth, we do the same thing. We add up all of the things the individual owns and subtract the amount of debt owed to determine his or her net worth. The amount that remains after subtracting the liabilities from the assets is called the net worth.

The Net Worth of a Business

As described above, the net worth of a business—net worth can also be referred to as net assets—is determined by subtracting the total liabilities of the company from its total assets. A company needs to determine its net worth in the event that it is sold off or forced to close.

For example, assume a company has total assets of $10 million. These assets might include land owned by the company and inventory. Assume the company owes its creditors $5 million—these are its liabilities. These liabilities include an expansion loan and a mortgage on a factory. To determine this company's net worth, subtract its liabilities, in this case $5 million, from its assets of $10 million. The company's net worth is $5 million.

A company's balance sheet shows its net worth. A balance sheet is an accounting document that lists a company's total assets and liabilities along with the net worth. Of course, the balance sheet may not reflect the company's current net worth depending on when it was completed; it shows the value of the company at a particular point in time.

There are advantages and disadvantages when calculating a company's net worth. The biggest advantage is that it is a relatively easy way to determine a company's value if it were to stop operating. In addition, looking at a company's balance sheet provides this information in an easy-to-read and understand format.

A disadvantage is that since a balance sheet is similar to a snapshot, it reflects the company's net worth at a specific point in time. It does not always reflect the current value. In addition, net worth does not always take into account items such as patents and intellectual property. For example, if you had examined Apple's net worth before the iPod came out, you would not count that invention as part of Apple's assets since it was not released yet but was only a part of Apple's intellectual property at that time. We now know how valuable this idea was—along with the advent of the iPhone and iPad, which sprang from the popularity of the iPod. If you had determined the net worth of Apple in the summer of 2001 (before the iPod was released) you would not have been able to determine the true value of Apple since there was no way to foresee the impact of its intellectual properties.

The Net Worth of an Individual

The purpose of calculating a net worth statement for an individual is similar to that of a business. It is a way to figure out how much money one has if all of one's assets were sold. In general, personal property, with the exception of vehicles, is not included in the individual's net worth statement because one will not normally sell everything in order to raise money. When completing an individual's net worth, one usually estimates the value of one's home and vehicle using comparable sales of similar assets.

Many of us think that someone is wealthy if he or she has a lot of stuff. However, the accumulation of stuff can actually lower one's net worth.

Table 1. Calculating Net Worth

Assets (What Richard Owns)	
House (current value	$100,000
Car (current value)	$10,000
Retirement Account	$30,000
Savings Account	$5,000
Checking Account	$2,000
Savings Bonds	$1,000
Total Assets	$148,000
Liabilities or Debts (What Richard Owes)	
House/Mortgage	$100,000
Car Loan	$20,000
Student Loan	$15,000
Credit Card Balances	$10,000
Total Debt	$145,000

To illustrate, take a look at a hypothetical example for Richard Stevens.

All of Richard's assets total $148,000. That includes the current value of his home, car, retirement savings, and checking accounts along with savings bonds he received as a graduation present.

Richard's debts include his home mortgage, which is the exact worth of the home. His car loan is actually greater than the current value of his car. This is because after a car is purchased its value tends to decline or depreciate significantly in its first several years. So the car actually has a negative worth ($10,000 – $20,000) of –$10,000. His additional debt includes student loans and credit card charges, which he does not pay off in full during the month the items are charged. Thus, Richard's total debts are $145,000.

Richard's net worth is $3,000, which is calculated by subtracting his liabilities of $145,000 from his assets of $148,000.

If a person purchases many things with a credit card and doesn't pay the credit card bill in full at the end of the month, he or she can amass a lot of debt. If the debts are greater than assets, this is called a negative net worth. That is how someone who might appear wealthy because they have a lot of stuff might actually have a lot of debt and thus a negative net worth.

Net worth is an important concept for businesses and individuals. It is a way to measure whether the entity is making financial progress.

OLIGOPOLY MARKETS

In microeconomics there are four different market structures of firms: perfect competition, monopolistic competition, oligopoly, and monopoly. At one end of the spectrum is perfect competition, where firms have no market control over price, and at the other end is monopoly, where firms have a high degree or even total control over market price. The four-firm concentration ratio of firms (output of the four top firms divided by the industry output of all firms) determines in which category businesses are classified by exhibiting the amount of market power firms possess. There is no specific number of firms that result in an oligopoly, but as a rule of thumb, oligopoly markets have 10 or fewer firms with a large amount of market power—80 percent or more control of market share by a few firms. The concentration of market power may not be equally shared between firms.

Characteristics of Oligopolies

Oligopoly markets have high barriers restricting the ease of market entry. Examples of barriers are high fixed costs (capital expenditures), access to resources, and legal barriers (patents and trademarks), to name a few.

Products may be similar or dissimilar in nature. Companies may produce goods that are similar, but they will work to differentiate the product in consumers' minds. Examples are automobiles, soap, toothpaste, and cereals. Examples of non-differentiated products are timber, oil, steel, and aluminum.

Because there are relatively few firms in the market, there is interdependence between businesses. Firms watch the actions of other firms carefully and consider their response in making their own decisions. In more competitive markets, the actions of one firm have little or no effect on the decisions of other firms, but in oligopoly markets this is not the case. Firms possess enough power to affect the market based on their decisions.

Because firms are interdependent, there are strategic consequences in the decision-making process. Firms must make a decision to either compete or collude based on their perceptions on how the other firm(s) will respond. Game theory is used to help explain this process and to illustrate how firms may behave based on their competitors' decisions.

Game theory uses applied mathematics to help explain how individuals will interact in strategic decision-making when outcomes are determined by competitors' choices. A commonly used method to illustrate strategic thinking is the prisoner's dilemma. Two robbery suspects have been arrested and have agreed beforehand to keep quiet. The suspects are interrogated separately, and investigators use two different incentives to encourage the suspects to confess. If they both refuse to confess, they face a shorter prison sentence of two years. However, if one confesses and the other one does not, the confessor gets one year and the loyal partner who does not confess gets seven years, but if they both confess they will receive five years each. There is a strong incentive to confess by both criminals because the penalty is greater if one criminal cheats on the agreement while the other does not. In the end, both confess and receive five years because the incentive structure of one year in prison is far more favorable than seven years. In the end, it is highly likely both will confess and receive five-year sentences. This dilemma can be applied to a market in which there are two firms deciding whether or not to advertise or decrease prices. The actions of one company will affect the actions and the profitability of the other company.

In the marketplace, firms actively attempt to cooperate or collude on price and restrict output in an effort to gain greater profits. These are collusive oligopolies. There are several ways in which firms attempt to fix price and quantity. The first is formal collusion, where firms take specific action and form a cartel, a formal business arrangement. Firms actively work together to set a specific price or a specific output. Additionally, firms may agree to restrict innovation and the use of new technology or agree not to advertise their product in a way that competes with the other firm. In this way, the firms work together to essentially create a monopoly and enjoy economic profits. The most well-known cartel is the Organization of Petroleum Exporting Countries (OPEC), which regularly meets and sets production quotas in hopes of creating higher oil prices.

The second way in which firms attempt to fix price and quantity is tacit or informal collusion, where a single dominant firm establishes price leadership and other firms follow the lead and align their prices to the dominant firm. There is no formal agreement, and firms are reluctant to cut prices, which would result in a price war and make it much more difficult to maintain profitability or even survive in an extended price war with the dominant firm. This does not mean firms do not compete, as they may compete on nonprice items such as quality, service, or brand power.

A third type of oligopoly is a noncollusive arrangement, where firms compete against one another, resulting in price competition. In this environment, firms consider the action of competing firms when making pricing and output decisions and how the other firms will respond. The price-leading firm must make a decision regarding whether or not to increase prices. If it raises its price, and other firms do not follow with a price increase, the leading firm will face reduced market share and total revenue. If the price-leading firm tries to gain market share by lowering its price, other firms follow suit, resulting in a price war that lowers total revenue for all firms.

Disadvantages

Because oligopolists are price makers, or have significant control over market price, they are able to raise prices above the point where marginal cost (MC) is equal to marginal revenue (MR). Because there are significant barriers to entry, they can set prices above the efficient level of pricing where MC = MR, thus they create productive and allocative inefficiencies. There are significant incentives to collude on price and/or output restrictions to achieve large economic profits, thus reducing competition, which allows for increased innovation and efficiency.

Advantages

Oligopolist firms are able to maintain economic profits, and as a result could make sizable investments into research and development that leads to improved technology and productivity. Increased research may have spillover effects and in the long run lead to lower consumer prices in this industry or others.

OLSON, MANCUR

Born: January 22, 1932, in Grand Forks, North Dakota; Died: February 19, 1998, in College Park, Maryland; Nationality: American; Professional Interests: group dynamics, public goods, labor; Major Works: *The Logic of Collective Action: Public Goods and the Theory of Groups* (1965), *The Rise and Decline of Nations: Economic Growth, Stagflation, and Social Rigidities* (1984), *Power and Prosperity: Outgrowing Communist and Capitalist Dictatorships* (2000).

Mancur Olson is best known for his work introducing the concept of the free-rider problem with public goods. Olson is remembered as an outstanding economic thinker with a keen ability to integrate ideas from sociology and political science into economic theory. He made lasting contributions to how we study and understand our world. Olson died in 1998.

Mancur Lloyd Olson Jr. was born on January 22, 1932, in Grand Forks, North Dakota. He studied as an undergraduate at North Dakota Agricultural College. From there he was awarded a Rhodes Scholarship and attended University College, Oxford. Upon returning to the United States, he performed his doctoral work at Harvard University, where he completed his widely recognized thesis, "The Logic of Collective Action" (1965). After finishing his doctoral work, Olson was hired at Princeton University in their economics department and later worked in the government under the Johnson administration in the Department of Health, Education, and Welfare for two years. After his stint in the government, Olson returned to academia at the University of Maryland, where he spent the rest of his career.

Olson was a leader and pioneer in the study of group dynamics within a nation. He developed the concept known as the free-rider problem. Free riders are people who join a group and expect to gain the benefits that the collective action of the group yields but are not willing to incur the costs associated with the work of the group. In his book *The Logic of Collective Action*, Olson shows that individuals can and will act in a self-interested manner that works contrary to the goals of collective action. For example, in a perfectly competitive market where there are many producers of a single identical good, it is in the collective interest of the producers to organize and raise the price of the product as high as possible in order to ensure higher profits for all. This is unlikely to happen because a single firm may well consider that it is in its self-interest not to join the price-setting collective action. If one producer refuses to join the group and sells at below market price, it will gain the majority of market share. This explains how sometimes the individual self-interest of a firm can be opposed to the interest of collective action.

Another example of problems that can result from the dissymmetry between individuals and groups is that of people who seek benefits from collective actions, such as in the case of unions. All workers benefit from the higher wages and better working conditions that result from the collective bargaining actions of the union, including workers who are not members. Since there is a cost associated with joining the union, the nonjoiners gain the benefits of membership without paying their dues. Nevertheless, people still do join unions, likely because they recognize that if too many people attempted to free ride, there would not be enough members to achieve their goals. One solution addressing the free-rider problem in the case of unions has been to pass legislation requiring membership, or to use selective incentives individuals will want, such as insurance, but can obtain only through membership.

Olson addresses the issue of mandatory union membership not from the perspective of rights as some of its critics do. He likens it to paying taxes or a military draft, not something we have constitutional protections from. Olson thinks the more relevant consideration is how a society values the benefits of strong unions in a country.

In Olson's second book, *The Rise and Decline of Nations* (1984), he makes the counterintuitive claim that long-term political stability can have a negative impact on economic growth. He supports his claim by showing how small interest groups become entrenched within a political system, achieving successful lobbying efforts that result in inefficiencies for the rest of the economy. As opposed to larger interest groups where the free-rider principle is at work, smaller groups have the incentive to work and successfully lobby for their interest. Their success secures certain political benefits for their groups, which stifles innovation, limiting long-term growth. Olson called this idea *institutional sclerosis*. Japan and Great Britain after World War II are examples of surprisingly fast economic growth that could be attributed, in part, to the clearing away of the old institutions that resulted from the war.

Olson was also concerned with the role of the government in fostering or blocking economic growth. While many had argued that the government merely extracts benefits from citizens, Olson showed that even governments have an interest in ensuring at least minimal prosperity for their citizens. Olson's view was that government is not perfect, but it can do some things right if given proper incentives.

Mancur Olson died on February 19, 1998, in College Park, Maryland.

OPTIONS

Exchange traded options were first traded in the 1970s. An option contract is a type of derivative security in that the value of the contract is derived from the value of the underlying asset. An options contract is an agreement that gives the owner the right, but not the obligation, to (1) buy or sell a specific asset (2) at a specific price (3) during a specific period of time.

When you buy an option, it is called a *call option*. A call option gives the owner the right but not the obligation to buy an asset at a fixed price during a specific period. The fixed price of an options contract is called the *strike price* or *exercise price*. The rights of a call option do not come without a price; the owner of a call option pays a fee for these rights, called an *option premium*.

The other side of this trade is called *selling a call option*. The owner who is selling a call has an obligation to sell an asset at a fixed price (strike price) during a specified period. As compensation for accepting this obligation, the owner who is selling a call option receives the options premium.

The other type of option contract is called a *put option*, where the owner buying a put option has the right but not the obligation to sell an asset at a fixed price during a specific period. The cost of this right is the option premium. The other side of buying a put option is selling a put option, where the owner has the obligation to buy an underlying asset (if other side of the trade exercises his or her right to sell an asset) at a strike price during the life of the contract.

Options occur in everyday life. If you are interested in buying a car, you might go to a dealer, find a car you like, and negotiate a price. You give the dealer a down payment to hold the car at the negotiated price for a period of time so you can come up with the entirety of the negotiated money. The down payment (option) gives you as the buyer the right but not the obligation to purchase the car at the negotiated price (strike price). The cost of the call option (option premium) is the down payment you gave the car dealer. You may then go back to the dealer with the remainder of the negotiated price to buy the car (exercise the option), completing the transaction (call option).

In the 1970s, options pricing theory made a great leap forward with the development of the Black-Scholes options pricing model. In 1997, Myron Scholes and Robert Merton were awarded the Nobel Prize in Economics for their work in options pricing theory. Their model explained the current value of an option contract using five input factors: (1) current price of asset; (2) strike price of the option contract; (3) risk-free interest rate over life of the option contract; (4) time remaining until option expires; and (5) price volatility of the underlying asset.

Option trading provides many advantages over other investment vehicles, including leverage, limited risk, and insurance. Options may provide investors with the benefit of increased cost efficiency, they may be less risky than investing in equities, they have the potential to deliver higher returns, and they offer a number of strategic alternatives not available with other derivatives. However, the improper use of options, like that of any derivative, can lead to major losses. One of the most severe losses with options was when Scholes and Merton's hedge fund Long-Term Capital Management (LTCM) went bankrupt in 1998.

ORGAN DONATION AND FRAMING

The need for organ transplants continues to outstrip the supply through donation. Economically, this shortage would normally be alleviated through the price mechanism. However, relying on the price mechanism for this type of allocation is associated with an important sociocultural constraint: repugnance. In the economic sense, this is a situation where there are willing participants (some out of economic desperation) to an exchange, but this exchange is prevented by a third party that disapproves.

In light of this constraint, there are two broad approaches to alleviating the shortage. The first is an attempt to increase the number of *living* donations (for example, kidney, bone marrow, and blood). Herein, message framing may have effects on donor attitudes, cognitions, and behaviors. One example of this line of research examines the impact different messages have on organ donor registration (Siegel et al. 2008). As it turns out, not all messages are created equal. In fact, a *counterargument appeal*, one that was designed to debunk some of the common myths associated with organ donation and registration, was found to be nearly twice as effective as the least effective appeals toward eliciting donations. Other forms of appeal included *emotional* (designed to elicit an emotional response), *motivating action* (designed to overcome the procrastination barrier), and *dissonance* (intended to create a sense of cognitive dissonance). Some work in the field of implicit cognition suggests that counterargument appeals may require more critical thinking, and this may result in more favorable donor-relevant attitudes.

A second approach to alleviating the shortage of donations is to create increases in *deceased* donations, where individuals agree to donate organs that are usable in the event of death. It is in this approach that a second behavioral aspect of framing is also important: framing through the default option. More specifically, under what is referred to as *presumed consent legislation*, a deceased individual is classified as a potential organ donor unless explicit steps are taken to indicate the individual's opposition prior to death. Under traditional assumptions of economics, so long as the costs of indicating one's preference are low, the resulting number of donations under either system should be similar. Behavioral economics often emphasizes the significant influence default options have on choices. There are a number of reasons why framing through default options may play an important role in an individual's decision to donate. First, defaults suggest a socially recommended action (English and Sommerville 2003). In addition, making this decision involves a cost, which includes effort, whereas there is no cost to selecting the default option (Johnson and Goldstein 2003). Finally, many individuals would prefer to avoid making an active decision about the unpleasant and stressful issue of donation.

Research by Johnson and Goldstein has provided evidence that the specification of the default is a significant factor with respect to organ donation. They conducted an online experiment in which respondents were asked whether they would agree to be organ donors. Each was faced with one of three possible situations. In the first, they were asked to assume that they had just moved to a new state where the default was not to be an organ donor; the second was identical, but where the default was to be a donor; in the third, they were asked to choose with no prior default. Donation rates were about twice as high for the opting-out option (82 percent) than for opting-in option (42 percent). There was no significant difference between the opt-out condition and the neutral one. Importantly, higher donation agreement rates may not translate into higher rates of donation if potential factors preventing donations from actually occurring are significant.

However, in one study, even when comparing *actual* deceased donations after controlling for factors known to influence propensities to donate across countries over 10 years, where donation is the default, there remains a significantly higher number of actual donations per million (a 16 percent increase). In another similar study, also controlled for other factors affecting donations, donation rates were 30 to 35 percent higher in the default countries. But evidence suggests (Bilgel 2012) that the magnitude of this impact is highly dependent on the involvement of family and the establishment of donor administration systems.

P

PARETO, VILFREDO

Born: July 15, 1848, in Paris, France; Died: August 19, 1923, in Lausanne, Switzerland; Nationality: Italian; Professional Interests: income distribution, equilibrium analysis, quantitative economics; Major Works: *Cours d'économie politique* (1896, 1897), *Trattato di sociologia genérale* (1916), and the English edition *The Mind and Society* (1935).

Vilfredo Pareto was an Italian economist who developed many mathematical formulas used in economics today. Educated as a civil engineer, Pareto was an advocate of free trade. His economic ideas reflected those of Leon Walras and the Lausanne School of economics, which held the view that economics was a mathematical science. His theories addressed a wide range of topics in both economics and sociology. Two of his most lasting ideas were the Pareto principle and Pareto optimality. The Pareto principle held that 80 percent of a country's wealth was held by 20 percent of the country's population. Pareto optimality asserted that the resources of a society are not optimally allocated if at least one person can still be made better off without diminishing the wealth of others. Pareto died in 1923.

Vilfredo Pareto was born on July 15, 1848, in Paris, France, of an Italian father and a French mother. He graduated from the Polytechnic University of Turin with an engineering degree in 1870. His early fascination with equilibrium analysis seemed to have begun while he was a student, evidenced by his thesis on the equilibrium analysis of solid bodies. Following graduation, he worked as a civil engineer for the Italian Railway Company. He began his teaching career in 1886 at the University of Florence in economics and management. In 1893, he joined the economics faculty at the University of Lausanne, where he taught until his retirement.

Pareto, along with Leon Walras, is considered one of the key figures of the Lausanne School of economic analysis. The Lausanne School of economic thought is based on general economic equilibrium theory and the advanced application of mathematical formulas to economics.

Vilfredo Pareto was noted for many theories in economics. Using complex mathematical formulas to identify historical patterns of wealth distribution, he created the law of income distribution. He is also credited with beginning welfare economics through his Pareto optimality theory, which he developed in 1906. Pareto optimality postulated that the resources of a society are not optimally allocated if at least one person can still be made better off without diminishing the wealth of others. The optimality Pareto was striving for in his theory was efficiency. According to Pareto, optimality was reached when all outcomes have been achieved except the one that makes someone else worse off. This definition of optimality, and associated mathematical formula, is the basis for much of the social policy and welfare economics of today.

Pareto has been considered by some to have initiated microeconomics. In 1906, Pareto wrote *Manual of Political Economy.* This work uses the study of equilibrium to solve individual economic problems and relies on the previous work of Francis Edgeworth on indifference curves. In it Pareto created the theory of the consumer and the theory of the producer and replaced utility theory with his Pareto optimality. Pareto optimality has been used to identify perfectly competitive markets as the optimum market structure to distribute wealth.

Pareto's second major contribution is now known as the Pareto principle. Pareto researched the distribution of income in different countries and concluded that a small percentage of a population own a large percentage of the wealth. In his *Cours d'économie politique* (1896, 1897), Pareto expanded on his law of income distribution. He argued that the distribution of income, regardless of country or era, followed a similar pattern that could be interpreted in a mathematical formula. Pareto suggested that 80 percent of a country's wealth is owned by only 20 percent of the country's people. This 80/20 ratio of income distribution became known as Pareto's law. The ratio was later expanded to include other input/output ratios (such as in management) and was expanded to the 80/20 Pareto principle or 80/20 Pareto rule.

Pareto is credited for several other ideas basic to economics. He was critical of the economic concepts of marginal analysis and utility. The sociological element of his studies was evident in his explanations of human behavior and consumer preferences. He contended that humans make economic decisions based more on what they want than what will make them better off. Pareto's ideas about human behavior were the foundation for the later work of Daniel Kahneman and others, known as behavioral economics.

Crossing over both disciplines, Pareto was also a vigorous critic of Karl Marx, particularly Marx's theory of class struggle between laborers and capitalists. Pareto asserted that the struggle between these two classes was only one of many different struggles between different groups.

Pareto later directed his studies more to sociology as his interest in human behavior expanded. He also argued that the field of economics devoted too little time to the subject and was too narrow in its scope when it did consider human behavior as an economic action.

In 1916, he published *Trattato di sociologia generale*. In it Pareto expanded on his study of human behavior, explaining that people act on sentiment and justify their sentimental decisions later. He labeled the decisions of sentiment *residues* and the explanations *derivations*. His idea that human decisions are based on emotion conflicted with the notion of the rational decision-making process asserted by economics. *Trattato di sociologia generade* was first published in English using the title *Mind and Society*. Italian fascist Benito Mussolini claimed that the lectures and theories of Pareto while he was a student at the Lausanne University were a significant influence on his ideas (Mussolini 1928, 14).

Another theory of Pareto's was that a society had two elites: a governing elite and a nongoverning elite. What made this theory so fascinating in later years was his contention that one of the elite factions is progressive, the other one is conservative, and in strong societies they alternate in holding power. Pareto contended that as the power-holding elite used up its goodwill with the people, the other elite would rise. Pareto asserted that the power holding between the two elites was both cyclical and predictable. This theory led Pareto to the conclusion that all political classifications were labels for different elite positions to obtain power.

After his death, Pareto's legacy was solidified in the 1930s and 1940s. John Hicks, Maurice Allais, and Paul Samuelson all popularized Pareto's work on consumer preferences and welfare economics. His welfare economics theories became the foundation for the welfare economics movement of the mid-20th century with such economists as Harold Hotelling and Oskar Lange.

Vilfredo Pareto died in Lausanne, Switzerland, on August 19, 1923.

PARETO OPTIMALITY

Pareto optimality describes a state of affairs in which resources are distributed such that it is not possible to improve a single individual without also causing at least one other individual to become worse off than before the change. If economic allocation in any system is not Pareto efficient, there is potential for a Pareto improvement, or an increase in Pareto efficiency: through reallocation, improvements can be made to at least one participant's well-being without reducing any other participant's well-being. A perfectly competitive market can be shown to deliver a Pareto optimal allocation of resources. Whether this is the most desirable allocation of resources is a value judgment.

Pareto optimality originated from Vilfredo Federico Damaso Pareto (1848–1923), an Italian economist who contributed seminal work to microeconomics, income distribution, and land distribution in Italy. Best known for his contributions

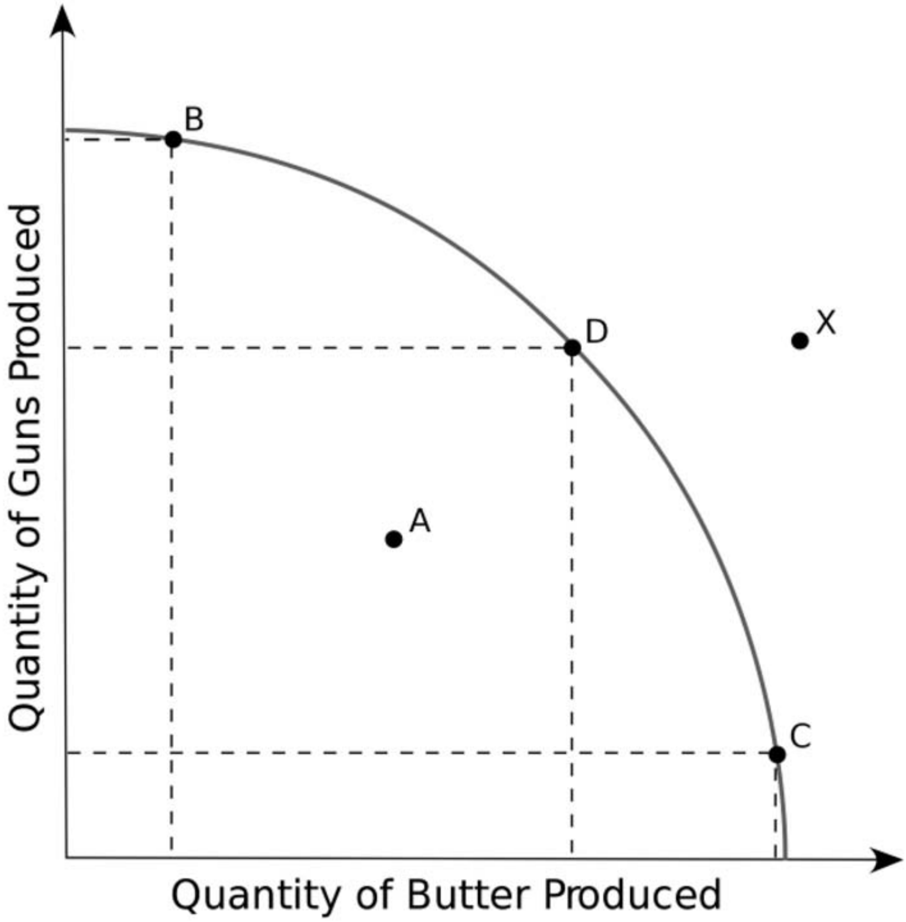

Figure 1. Pareto optimality

in economics, Pareto was a true Renaissance man, delving into diverse disciplines that included sociology, political science, philosophy, engineering, and mathematics. Pareto's engineering background shaped the way he expressed economic theory, relying on graphs, maps, and statistical analysis to prove scientific points. He was able to transform the field of economics from philosophical conjecture to a quantifiable science discipline. Pareto optimality provides economists with a certain perspective and criteria for judging the efficiency of a distribution system. Additionally, this way of looking at economic efficiency and income distribution helped Pareto himself and other economists develop microeconomics as a field of study.

A production-possibility frontier is an example of a Pareto-efficient frontier, as seen in the graph comparing the production of guns produced to the production of butter. Assuming that the economy's available quantity of factors of production does not change over time and that technological progress does not occur (this would alter the location of the curve itself), the economy is operating on this production possibilities frontier. If production is efficient, the economy can choose between points on the production possibilities frontier curve: *B* if guns are of interest, *C* if more butter is needed, *D* if an equal mix of butter and guns is required. In the production possibilities frontier, all points on the curve are points of maximum productive efficiency; all points inside the frontier (point A) can be produced but are productively inefficient.

PEAK OIL

The term *peak oil* refers to the point in time when oil production reaches its maximum (the peak), after which consumption will steadily decline and lead, ultimately, to depletion. The study of peak oil attempts to estimate the peak date, the total amount of available oil, and the date of ultimate depletion. Peak-oil research is based on the surprisingly accurate prediction by M. K. Hubbert in 1956 of the peak of U.S. crude oil production in 1970. Hubbert's parsimonious analysis estimated this peak by fitting a simple logistic distribution (a bell-shaped curve similar to a normal distribution) to observed oil production. Importantly, Hubbert did not include economic variables such as prices in his analysis, and peak-oil proponents have generally followed his lead. Despite the limited economic analysis, peak-oil proponents have drawn economic conclusions (many of them dire) from their work. These predictions of catastrophe have fueled the efforts to estimate the peak in world oil production. However, peak-oil analysis has not gained widespread acceptance, and many of its conclusions remain controversial.

The standard model underlying most peak-oil analysis assumes that oil production follows an essentially random process. To illustrate, think of the world as a giant checkerboard with oil randomly deposited under some squares but not others. Suppose that each year, we explore a number of squares, some of which yield oil and some of which do not. Oil production then begins from the oil-producing sites: first ramping up over time, then holding steady at a maximum level determined by internal wellhead pressure, and finally declining to zero. Under this model, oil production should follow a bell-shaped curve: growing over time as more and more sites are developed, but then declining over time as fewer and fewer sites remain to be developed. Importantly, under this model, the peak date can be estimated from observed production. Moreover, under Hubbert's symmetric logistic version of the model, the total amount of available oil and the date of ultimate depletion can also be estimated.

Despite Hubbert's early predictive success, applying the peak-oil model to other regions has been less successful. In particular, while oil production in many regions does exhibit evidence of peaking, in many regions it does not. For example, Ohio production seems to have multiple peaks, and Iraqi production seems to be at best chaotic.

Moreover, Hubbert's logistic model does not clearly dominate other models (e.g., exponential or linear), and allowing for asymmetric increases and decreases in production fit the data better. Unfortunately, the more flexible, asymmetric models cannot be used to reliably estimate the peak date, the total amount of available oil, or the date of ultimate depletion.

Despite these technical difficulties, predicting the peak might be important as an indicator of scarcity. Unfortunately, the peak in oil production has little systematic relationship with the underlying scarcity of oil. In fact, it is easy to construct simple examples where an improvement in technology could either hasten or delay the peak. Thus peaking is not necessarily a good indicator of scarcity.

Economics offers an alternative model of depletable resources. This model, originally developed by Hotelling, describes both how oil should be used to maximize the benefits to society and how oil would be used under competitive markets. As with the peak-oil model, Hotelling's model gets some things right and some things wrong. Importantly, simple versions of the model unrealistically predict steadily increasing prices and decreasing consumption. These unrealistic features of the basic model have reduced its applicability; however, relatively straightforward extensions of the model make it more realistic. In fact, recent work shows that by adding realistic features, the Hotelling model can be extended to predict peaking in oil production.

The dire economic predictions of the peak-oil analysts follow from assumptions of irreversibility and nonsubstitutability. Once decline starts, there is essentially nothing that can be done to reverse it, and because oil is essential to society, declining oil production will lead to a declining standard of living, wars, and famine. However, these predictions following the peak in world oil production may or may not turn out to be true. If the prediction is simply based on a correlation, there is no scope for policies to affect the outcome. However, if the prediction is based on a causal relationship, there is scope for policy. For example, if the relationship between peaking and catastrophe is causal, by delaying oil peaking we may be able to delay or prevent the catastrophe. The case for causality would be strengthened by carefully explaining a mechanism by which peaking leads to catastrophe. The crucial assumption of any such mechanism is substitutability: How quickly can society substitute away from oil to other energy sources or to reduced energy consumption? If we can readily substitute away from oil, there will be no catastrophe. But if we cannot, catastrophe may be imminent.

Whether society can substitute away from conventional crude oil is clear: we can. First, much peak-oil analysis focuses solely on conventional crude and ignores heavy crude such as the Canadian oil sands. Second, with the introduction of electric cars, we can substitute even further away from oil to run our cars on natural gas, coal, or even nuclear power. Thus, it is hard to argue that a peak in conventional crude oil production leads to catastrophe and that governments should actively work to delay the peak.

Although oil peaking may not lead directly to catastrophe, there are other issues to consider. First, although substitution is certainly possible, it is costly. Substituting from cheaper oil to more expensive electric cars will decrease our standard of living as oil production declines. Second, each of the substitutions given earlier has environmental costs. Coal and heavy crudes have much higher greenhouse gas emissions; natural gas supply is even more limited than oil; and nuclear power has catastrophic risks that rival anything that could be imagined from peak oil. Thus substitution to other resources is fraught with other difficulties.

The catastrophes predicted by peak-oil analysis are unlikely to follow as a direct consequence of a peak in global conventional crude oil production. Nonetheless, there is substantial scope for policies to improve oil markets. Hotelling's analysis points to a number of market failures, for example, unpriced externalities from pollution, common pool extraction, excessive private discount rates, market power, and insecure property rights. Each of these market failures leads to oil markets that are not best for society. Similarly, concerns about sustainability remain: How can we meet the needs of current generations without compromising the ability of future generations to meet their needs? Peak-oil analysis can be helpful by heightening attention to these areas with legitimate scope for policy.

PENSION PLANS

A pension plan is a type of retirement plan under which an employer makes contributions toward a pool of funds set aside for an employee's future benefit. The pool of funds is then invested on behalf of the employee. That allows the employee to receive benefits upon retirement. A pension plan is usually tax exempt. The two main types of pension plans are (1) defined benefit plans and (2) defined contribution plans.

Defined Benefit Plan

A defined benefit plan promises a specified monthly benefit at retirement. This promised benefit may be an exact dollar amount, such as $100 per month at retirement, but usually the benefit is calculated through a plan formula that considers such factors as salary and length of service. For example, it may be equal to 1 percent of average salary for the last five years of employment for every year of service with an employer. The benefits in most traditional defined benefit plans are usually protected by federal insurance provided through the Pension Benefit Guaranty Corporation (PBGC).

Defined pension plans contrast with other types of retirement plans whose payouts are dependent on returns of the underlying investments within the plan. Employees were required to work for a certain period of time (called a vesting period) before they were eligible to receive benefits in a defined benefit plan. In addition to a monthly payment, these pensioners frequently received a health care insurance plan. In many cases, these benefits were on top of the Social Security benefits the retiree received.

These plans were established in the late 1800s, according to Patrick V. Seburn in "Evolution of Employer-Provided Defined Benefit Pensions" (1991). The early pension plans covered workers in the railroad, banking, and public utilities industries. In 1974, the Employee Retirement Income Security Act (ERISA) was enacted to protect employees' benefit rights in private pensions.

By the 1980s, the private pension system assets had expanded exponentially. In spite of the growth of the assets within the defined benefit pensions, during the mid-1980s, the medium- and large-sized companies who offered these plans began to shift toward private plans financed completely by the employees. These defined benefit pensions became very expensive to administer, and new retirement savings options became available.

Furthermore, with the increase in smaller, service-oriented firms, employer-funded retirement pensions increased. Today, the individual who works for the same company throughout his or her career and receives an employer-sponsored pension is rare.

Defined Contribution Plans—401(k) and 403(b)

A defined contribution plan does not promise a specific amount of benefits at retirement. Under this type of plan, the employee or the employer or both contribute to the employee's individual account, sometimes at a set rate (e.g., 5 percent of earnings annually). These contributions are generally invested on behalf of the employee. The employee will ultimately receive the balance in his or her account, which is based on contributions plus or minus investment gains or losses. The value of the account will fluctuate due to the fluctuations in the value of the investments. Examples of defined contribution plans are 401(k) plans, 403(b) plans, employee stock ownership plans, and profit-sharing plans.

A 401(k) plan is a defined contribution plan that is a cash or deferred arrangement. This type of plan is available to all employers except governmental employers. With a 401(k), employees can elect to defer a portion of their salary, which is instead contributed on their behalf, before taxes, to the 401(k) plan. Sometimes the employer matches these contributions. There are special rules governing the operation of a 401(k) plan. For example, there is a dollar limit on the amount an employee may elect to defer each year. Employees who participate in 401(k) plans assume responsibility for their retirement income by contributing part of their salary and, in many instances, by directing their own investments.

The tax benefits to employees who contribute to a defined contribution plan such as a 401(k) are important. For example, if an employee earns $4,000 per month, that employee ordinarily pays tax on the entire amount earned. Yet, if the employee elects to contribute $500 per month to the 401(k) plan, he or she will only be taxed on $3,500 ($4,000 – $500) per month. When the employee retires and withdraws the retirement savings, income taxes will be due on the amount withdrawn at that time.

Although the employee owns his or her plan contributions, some employers require the employee to work for the organization for a predetermined length of time before becoming vested or "owning" the employer's contributions. Thus, if the employer requires five years to become vested and receive the employer's contributions, and if the worker leaves the firm after three years, he or she would be ineligible to receive the employer's portion of the contribution to the pension plan.

A 403(b) plan is similar to a 401(k). The basic difference between the two is eligibility. The 403(b) plan is limited to 501(c)(3)s or tax-exempt nonprofit organizations. This type of plan is frequently administered by government or nonprofit employers, such as k–12 schools and nonprofit colleges and universities. Another substantive difference between the 401(k) and 403(b) is that the latter is normally required to fund the investments with annuity contracts and mutual funds.

A profit-sharing plan or stock bonus plan is a defined contribution plan under which the plan or the employer may determine, annually, how much will be contributed to the plan (out of profits or otherwise). The plan contains a formula for allocating to each participant a portion of each annual contribution. This plan is quite flexible in that the contributions can be adjusted annually. This plan offers a secondary benefit; it allows employees to feel as though they have a stake in the future of the company, and when the company profits, so do the employees.

An employee stock ownership plan (ESOP) is a form of defined contribution plan in which the investments are primarily in employer stock. Similar to a profit-sharing plan, employees also benefit in the company's growth. When the firm's stock increases, so does the value of employees' stock options. There are additional tax benefits to both the employer and employee.

There are many other types of pension plans, including individual retirement accounts, Roth individual retirement accounts, and other varieties of the aforementioned accounts. The government and financial industry frequently devise new retirement savings alternatives so that workers are not completely dependent on the Social Security system for their future financial well-being.

PERFECT COMPETITION

The simplest yet rarest market structure is perfect competition. This type of market structure is an example of a true free market with the market finding a natural equilibrium without any interference. There are very few industries that meet all of the characteristics of this type of market structure, but farm products may be the closest.

Characteristics

In a perfectly competitive market there are many buyers and sellers. With so many people in the market, the prices of goods are set without any influence from suppliers or consumers. With so many individuals on both sides of the market, neither buyers nor sellers have enough influence in the market to shift prices.

Another reason that equilibrium is found without any influence in a perfectly competitive market is that the products being sold are identical. Therefore, a buyer will not pay extra for one particular company's good, since there are many identical products being offered. Buyers will always choose the *commodity* that is offered at the lowest price.

In addition to buyers having many choices of identical products, they are also well informed about the goods or services that they are purchasing. Consumers have a lot of information about the features of the product and its price. Sellers also have an advantage in this market structure in that it is very easy to enter and exit. Individuals who wish to become sellers of goods in this market can do so with ease.

With so many competitors entering and exiting the market, the price of goods in a perfectly competitive market fluctuate often. When prices are higher, there is an incentive for more sellers to enter the market and compete. However, as more sellers enter the market, competition increases, which causes prices to fall to their lowest possible point. When prices fall, some sellers will easily exit the market, causing prices to rise once again. The equilibrium point in the perfectly competitive market is constantly fluctuating with the entry and exit of firms.

Price and Output

Since sellers in this market are price takers, they are extremely efficient. Production costs must remain low, and firms must use all of their factors of production as efficiently as possible. The price consumers pay and the revenue firms make is a reflection of how much the market values the resources that have gone into making the product.

In a perfectly competitive market, firms charge the lowest price sustainable for the firm to remain in business. The firms that use their resources most efficiently will remain in business while those that do not or cannot will lose revenue. Because no supplier influences prices, producers will make their output decisions based on the most efficient use of their land, labor, and capital. In the long run, firms will be able to just cover their costs, which includes paying the firm's owners enough to make the business worth keeping.

Because producers have no control over prices, their only real decision is how much to produce, which is based on their resources available, the cost of production, and the current market price.

PREFERENCE POLLUTION

Markets are often praised for giving people what they most want. This is a very limited view of people, since everyone can recall situations in which they were unhappy with their choices. Smokers often don't like their choices, nor do individuals who are overweight. While this phenomenon—displeasure at one's personal choice—has a long history, a consideration of second-order preferences can lead to the conclusion that markets fail when it comes to creating the desires that we wish to have.

Recognition that markets fail when there are spillover benefits or spillover costs can be traced back to the work of the economist Arthur Pigou. If people besides the buyer and seller benefit from the production or consumption of a good, it can be shown that market forces result in too little of the good being produced. If they are harmed, it is the opposite; too much of the good is produced.

Preference pollution occurs when the tastes that sellers cause us to have are, by our own judgment, worse than the tastes that they replace. The preferences that receive attention from economists (*regular preferences*) are rankings of "things." The things being ranked lie outside of the person, and when a choice is made, the enforcement of property rights assures that the item selected belongs to the purchaser and cannot be taken away. Thus, if someone goes to a restaurant where both salads and cheeseburgers are sold, her choice of the salad is said to "reveal" her preference as "salad preferred to cheeseburger." If following the purchase of the salad the restaurant's owner were to suddenly take away the salad and replace it with a cheeseburger, it is obvious that harm has been done. A thing that this person prefers and selects cannot be taken from her.

Applying the same reasoning to *second-order preferences* (also known as *metapreferences*), one can show how market failure can occur in the shaping of tastes. Second-order preferences are rankings of regular preferences. Imagine that this person is happy with the regular preference that she has. She not only prefers the salad but also prefers having this preference (salad preferred over cheeseburger) to having the other possible preference (cheeseburger preferred over salad). Now imagine a different scenario. She has just entered the restaurant, with a second-order preference for the salad and a regular preference for the salad as well. If she were to decide at that moment, she would choose the salad. But what if the owner of the restaurant has the pleasant aroma of cheeseburgers wafting through the restaurant or has a tempting picture of the cheeseburger on the menu? Notice that there is nothing preventing the owner from "taking away" the customer's regular preference and replacing it with the other one. For although the customer "has" regular preferences just as she "has" all her material possessions, she does not have ownership rights. Because of this, it is legal to "take away" a preference and replace it with another one. As standard economic theory would predict, the creation of worse preferences would occur too often. The owner is not forced to compensate the customer to make up for the harm she has suffered and would thus be expected to engage in these activities too often.

If this line of argument is accepted, certain types of policy and behaviors can be identified as part and parcel of market failure. Evidence suggests that the problem has been getting worse. Talk of addiction is at an all-time high. A search of the *New York Times* reveals that before 1930 the expression *good habit* appeared twice as often as *bad habit*. It is now the reverse. Prohibitions intended to shape tastes as people want them to be shaped were more common then than they are today. Reports of food addictions, credit addictions, and porn addictions have become more frequent. Sellers who used to face social sanctions for creating "bad tastes" are more likely today to see it as their responsibility to give consumers what they prefer. Many people today do not understand that the creation of the preference that results in the most profits might not be aligned with consumers' preferences.

Moral philosopher Harry Frankfurt argued that the ability to have such second-order preferences was what distinguished humans from other living creatures. Markets might be good at meeting our regular preferences, the sort of preference that we share with animals, but fail in the formation of second-order preferences, the very preferences that, according to Frankfurt, make us human.

PRIMING AND FINANCIAL DECISIONS

Priming is an implicit memory process, where exposure to stimuli or events affects the availability of specific information categories and response to subsequent events. As a result, it also influences decision-making (Baron and Byrne 1997, Chapter 3). Priming may also be viewed as changes in preliminary conditions that make it more likely that subjects will have a particular response following the stimulus (Cramer 1968). Tulving refers to priming as facilitation of performance of one task on that of following identical or similar tasks. Noteworthy is that the availability of a specific knowledge category stored in memory is positively related to the probability of using it to interpret perceived information (Bruner 1957).

Priming processes are routinely activated in a variety of situations. For example, watching a horror movie may intensify attention and modify interpretations and reactions to subsequent stimuli, such as a squeaking gate, thereby causing the exposed person to act as in alarming situations. The same stimulus when not followed up may be left consciously unnoticed, or interpreted in a different, unexciting manner.

Priming procedures in the lab are usually comprised of two consecutive stages, *exposure* and *testing*. In the first stage, subjects are exposed to a stimulus, and in the second, they are requested to execute a particular action, make a decision, or interpret a situation or the meaning of some substance. The exposure stage may be subconscious, also known as automatic priming (flashing words or pictures for brief time spans such that the participants are not aware of seeing them), or conscious, gaining subjects' full awareness.

Several papers have dealt with priming and financial decisions. Erb, Bioy, and Hilton, employing a procedure for subconscious priming of risk attitudes, induced risk-seeking or risk-averse preferences across a range of decision scenarios. Subsequently, they showed that drawing participants' attention to the priming event may reverse the induced priming effects. Their results support the view that the formation of risk preferences may be based on preconscious processing, as for example postulated by the affective primacy hypothesis, rather than hinging on deliberative mental operations, as posited by several models of judgment and decision-making.

Meier-Pesti and Penz, building on the observations that, in investment decisions, women are more risk-averse than men and, in Western cultures, risk taking is perceived as a masculine characteristic, hypothesized that the more people associate themselves with masculine attributes, the more financial risks they would tend to take. Their first study showed that differences between men and women in financial risk taking decreased when identification with masculine attributes remained constant, while femininity was not related to financial risk taking. In their second study, gender priming on masculinity and femininity affected risk taking of the male sample.

Gilad and Kliger explore the influence of priming on financial decisions by reinforcing subjects' risk-seeking behavior under uncertainty and comparing it to behavior in control groups. They focused on professionals: commercial banks' investment advisers and accountants in CPA firms. The results indicate that priming affects subjects' risk attitudes and investment decisions. Professionals' decisions were affected more than undergraduates', suggesting they employ a more intuitive and less analytic approach in making their decisions.

Kliger and Gilad explore the role of colors as priming substance. Colors are widely present in the financial decision-making arena, with red and green prominently employed. Their between-subject experimental analysis exposed subjects to financial information on colored backgrounds and explored the effect on their investment decisions. The results indicate that red color priming emphasize value losses of the underlying asset. To wit, subjects who were exposed to red assigned higher valuations and probabilities to events involving the loss domain than to events involving the gain domain relative to the valuations assigned by subjects who were exposed to green.

PRODUCTIVITY

The goal of every business is to be productive. The goal of every economy is to be more productive and as a result increase society's standard of living. For most economies, productivity can be translated into economic growth. Productivity relates to both microeconomics and macroeconomics.

Productivity in the academic sense is the measure of the relationship between the use of inputs and resulting outputs. To be productive is to be efficient with the use of available inputs in the production of goods and services (outputs): the ratio of output per unit of input.

Productivity can be defined in two simplified relationships. One measure is to use fewer inputs to generate the current level of outputs. In this measure output has not increased but fewer inputs are being allocated to the production of the output. Inventions that increase production and changes in input relationships (for example, moving from labor to capital) would be an example of this productivity. The other relationship allocates the same level of inputs, but used differently or uniquely, to generate more output. This measure is reflected in new and innovative processes. Henry Ford increased productivity in this fashion when he brought the assembly line to the automobile industry.

Measuring productivity can look different depending on the production being measured. In microeconomics productivity measures focus on the efficient and effective use of inputs. Labor productivity is an important productivity measure for companies. Measured as output per hour, companies even search for additional productive measures, such as number of hours of a worker per unit of output. Measuring other inputs is also important. Efficient use of materials, land, and energy per unit are also important productivity measures.

In macroeconomics the idea of productivity takes on a different perspective. Since macroeconomics is the big-picture economic view, macroeconomic productivity is also a big-picture view. Identifying the productivity of an entire economy has its own set of issues. With many interrelated parts, one of the most important issues to address is to avoid double-counting capital inputs (intermediate goods) used in producing goods. To avoid this dilemma, a nation's productivity is measured by the value added of each production. This is accomplished by measuring the final value of an economy's goods and services, an economy's gross national product (GNP) or gross domestic product (GDP). Both GNP and GDP are also used to measure the income (wages, rents, profits) generated by an economy's inputs. Comparing these two measures (final value of goods and services and income) provides insights regarding an economy's productivity, growth, and standard of living.

Measuring productivity can also involve both microeconomics and macroeconomics simultaneously. To achieve economic growth, it's also important to understand the productivity of the different markets within an economy. The Bureau of Economic Analysis (BEA) collects data on households, businesses, governments and public services produced, and overall activity in both the product and resource markets.

Being able to calculate productivity is central to a business, industry, or entire economy. It supports the ability to improve production through new machines and processes and increases profitability and the standard of living for a nation.

PROFIT MAXIMIZATION AND BEHAVIORAL ECONOMICS

Traditional economics makes the behavioral assumption of maximization—that consumers, investors, and businesses maximize, and that in real life, individuals and businesses endeavor to maximize, with the most successful of them succeeding in doing so. Behavioral economics is in part descriptive economics and does not begin with any particular assumption about the behavior of individuals, such as that they seek to maximize profits. Indeed, to the extent that many individuals are not owners, and, moreover that some very successful enterprises consider the welfare of others, even an objective of maximization does not entail profit maximization, certainly not in anything but the very longest run. And that is true even before taking into consideration elements such as trust and emotional factors that would interfere with maximization (although, admittedly, some would encourage careful calculation and thus contribute to maximization).

Factors identified by behavioral economics, such as loss aversion, mental accounting and myopia, and unstable and changing preferences—considerations that affect much human activity—interfere with the maximization of profits in any absolute sense, though not necessarily maximization given those constraints. The lack of complete information or the cost of obtaining such information, along with difficulties in perceiving certain information accurately, prevent any type of maximization or constrained maximization, however, and descriptive economics reveals the impact of at least some of that incomplete, costly, and imperfectly perceived information on decision-making.

While much of behavioral economics does not assume profit maximization, there are exceptions, however, with contributors such as Truman Bewley assuming that businesspersons attempt to maximize in fact, but in doing so, take factors such as the morale of their employees and its effect on productivity into account. What we seem to be left with, then, is that behavioral economics is inconsistent with traditional economic formulations of profit maximization, but, emotional considerations aside, may allow for an effort to maximize that takes account of introspective considerations that would be completely outside the realm of traditional microeconomic analysis, and/or that may lead to efforts to satisfice—to do what seems to be the best that is possible under the circumstances.

PROSPECT THEORY

Prospect theory is the most prominent of a family of nonconventional models of economic decision-making that have emerged at the interface between economics and psychology during the final quarter of the 20th century and have led to the recent behavioralist turn in modern economics. In prospect theory, decision-making is construed as a two-stage process. During an initial "editing" stage, the decision problem is reduced in complexity by applying certain heuristics. This is followed by the evaluation stage, where potential outcomes or "prospects" are assigned a value in relation to a reference point and then differentially weighted on the basis of a subjective and context-dependent assessment of relative likelihood. The resulting theory is able to account for a number of anomalies that arise in traditional approaches to rational choice under risk and uncertainty.

A prospect p = (x, v; y, w) describes an uncertain outcome that results in value x with probability v, and value y with probability w. Consider a coin toss with a winning value of 200 for heads and zero for tails. The prospect of tossing a fair coin that yields heads with a 50 percent probability can be written as p = (200, 0.5; 0, 0.5). Choice under uncertainty raises the question of how to decide between the prospects of different courses of action. Consider alternative prospect q = (100, 1; 0, 0). Here heads is the certain outcome in all cases. The expected value of the two prospects is the same, but behavioral evidence suggests that we evaluate these prospects differently depending on our appetite for risk.

Conventional approaches in economics recognize this by proceeding from expected utilities rather than expected values, but this still leaves much of observed behavior unaccounted for. Prospect theory aims to offer a theory of choice under uncertainty that is descriptively more accurate. During the editing stage, prospects are given a simplified representation through various operations, including rounding of numerical values and aggregation or discarding of common elements. In a two-stage game, for example, that has a 25 percent chance of proceeding to the second stage or winning nothing, and where at the second stage there is a choice between prospects p' = (199, 0.8; 0, 0.2) and q as above, with initial editing p' is equivalent to p after rounding and acknowledging the zero value alternative common to both prospects. With behavioral cancelation of the first stage as a common element to these resulting prospects, a loss-adverse individual will find q more attractive while p dominates q on the basis of expected values that result from consideration of both stages of the game.

At the second stage after editing, prospects are evaluated according to two dimensions by assigning outcomes a subjective value u (.) and by giving probabilities a weight t (.) according to their impact on the overall assessment of the prospect. The result is a procedural model in which outcomes are evaluated asymmetrically in respect to a contextual or psychological reference point, allowing for loss aversion, endowment effects, and various kinds of framing effects, on the basis of an overall value V (x, v; y, w) = u (x) t (v) + u (y) t (w). Prospect theory therefore allows for the expected utility approach as a special case.

Also of critical importance is that in prospect theory, unlike in traditional economics, gains are weighted differently than losses. And there is some evidence that individuals assign twice the weight to losses than they do to gains. Even if there were a prospect where gains slightly outweigh losses, individuals would reject this wealth-maximizing option given their high aversion to losses.

Critics of prospect theory have identified a number of inconsistencies that arise depending on which heuristics are employed during the editing stage, and this has led to second-generation "cumulative" prospect theory. It should also be pointed out that descriptive accuracy requires the theory to allow for rationally inconsistent behavior given that this is an observed characteristic of choice under uncertainty. A more general methodological concern relates to the lack of normative status of prospect theory. In principle, a rational decision-maker could exploit an agent described by the behavioral model. Behavioralists respond to this by pointing out that conventional approaches conflate normative recommendation with empirical accuracy and thus fail to properly address the implications of actual behavior.

PURE FOOD AND DRUG ACT OF 1906

After many years of debate, including proposals and a defeated bill, the Pure Food and Drug Act passed through Congress and became law the same year when signed by President Theodore Roosevelt on June 30, 1906. Prior to this, the United States did not have a statute for the provision requiring compositional food standards. Food standards had been in existence since ancient times for limited commodities such as bread. In addition, there were standards for butter and milk. However, these standards were in place to protect honest farmers from dishonest competition rather than to protect honest consumers from dishonest manufacturers.

The father of the Food and Drug Act is considered to be Dr. Harvey Wiley. Born in 1844, Wiley grew up in Indiana. His 50-year campaign for pure food began in the 1880s. At that time, marketplaces in America were filled with poorly made and harmful products. There was no government regulation, and manufacturers were free to alter food in the name of cutting costs. Manufacturers would print one ingredient on the label while using a substituted cheaper ingredient in the contents of the food. For example, the FDA notes that honey was sometimes diluted with glucose syrup. Olive oil was made with cottonseed, and "soothing syrups" were often laced with morphine. The country was ready for reform, and Dr. Wiley was ready to head the cause.

Upton Sinclair joined the Socialist Party in 1903 and later that year began to write for a socialist magazine. In 1904, the Chicago meat-packers union went on strike, demanding better wages and improved working conditions. The editor of the magazine who employed Sinclair suggested he write about the strike. Sinclair took the advice and traveled to Chicago to learn about the working conditions of immigrants and the meat-packing problem. In 1906, Sinclair published *The Jungle* on the atrocious and horrendous working conditions of immigrants specifically in the meat-packing industry.

The Pure Food and Drug Act of 1906 outlawed any food that was an imitation of another food or advertised under the name of another food. The food was considered legal if packaging mentioned the imitations or blends of the contents inside.

The Library of Congress notes a few very important dates with relation to the law passed in 1906. In 1889, soldiers fighting in the Spanish-American War were dying from causes not associated with the war. They were dying because they consumed very badly preserved meat. In 1902, Dr. Wiley assembled a group of individuals to experiment on to determine the side effects of the food additives most commonly used at the time. During the experiments the members of the group were given additives in additional doses until they became sick. Dr. Wiley recorded the impacts on the body of the additives as the amounts and the individuals' responses increased. The experimental group became known as the Poison Squad.

RANDOM WALK

The concept of random walk can be applied to professional fields and academia alike. At its base, it is a mathematic theory that centers on the randomness and unpredictability of events. A random walk is frequently associated with phenomena such as stock prices and other probabilistic models typified by Markov chains or stochastic processes. Stochastic processes are fundamentally a probabilistic set of events used to describe the randomness and unpredictability of a certain outcome based on the core principle of choice. Random walk implies that there is not a set outcome of an event but rather an infinite number of outcomes.

This theory is specifically applied where multiple complex predictors exist. The random walk as a core principle suggests that picking a specific outcome is not possible and therefore that predictors are not necessarily effective. Similarly, the scientific application, typified by a Markov chain, explains that the changing state of a particle (from solid to liquid, etc.) is not dependent on prior states but rather solely on the current state and the randomness of events to influence change into a future state. With regards to the random walk, this suggests that historical events do not necessarily have an effect on the future of that item.

Most famously, random walk principles have historically been the center of debate within the field of economics and investing in the stock market. Investment experts are challenged by the random walk principle as it undermines their profession. Investment professionals rely on predictors and gathered historical results and analysis to predict short- and long-term changes in specific stocks. Their expertise and experience should allow for greater returns on investments. However, many academics argue that the stock market follows random walk principles. These principles indicate that the prices of stocks are in reality random and unpredictable. Furthermore, historical indicators are not relevant to changes in stock prices.

The most largely accepted as well as debated academic work on this topic was presented in *A Random Walk Down Wall Street* by Burton Malkiel (2007). He submits investing professionals claim fundamental and technical analysis are in fact evidence that random walks in stocks are ineffective. His base argument is that it is impossible to outperform the market without assuming additional risks.

A more successful option often proposed for investment is to buy and hold stocks. This relies on the base principle that generally the market as a whole shows steady and incremental gains. This concept gave rise to the popular theory of passive investing, whereby ordinary people could invest in entire indexes (now called index funds) rather than specific stock.

Investment professionals may argue conversely that past performance and indicators are effective predictors and therefore that selecting the best times to sell, hold, or buy stock is the key to success in investing. This topic is still highly debated today with studies showing that in the long run, even high-end hedge fund managers have been unable to outperform the market.

The random walk concept maintains its usefulness with a myriad of applications from the outcomes of sports plays to the route a bus takes. In certain fields, random walk provides insight into the multitude of possibilities, thereby becoming useful in choosing the optimization of a specific route, particularly with respect to logistics in deliveries and more recently supply chain management.

REAL ESTATE INVESTMENT TRUST

Real estate investment trusts (REITs) are a type of mutual fund. A pool of capital is collected from investors and invested directly in real estate or mortgages. REITs acquire, develop, lease, and manage real estate properties with the purpose of generating revenues from rents. They are traded on an exchange, like stocks, or grouped together in mutual funds or exchange traded funds. For example, Simon Property Group Inc (NYSE: SPG), the largest U.S. shopping mall owner, owing Simon Malls across the country, is a REIT that buys or builds shopping malls and generates revenues from the rents collected from leasing out the property to various stores. In order for a fund (pool of capital) to be qualified as a REIT, it must distribute 90 percent of its income back to the investors in the form of a dividend (also referred to as *distributions*). Given the periodic distributions, REITs are sought after by investors looking for securities with the ability to generate income along with capital appreciation.

Types of REITs

REITs are commonly classified based on the type of property in which they invest.

REITs that invest exclusively in real estate properties are referred to as equity REITs. Within equity REITs there are various subclassifications.

Retail REITs invest in properties that derive rents from retail stores (i.e., regional malls, shopping centers, free-standing stores, etc.), which usually have a large anchor store like a grocery, pharmacy, or department store, and several small stores. As investors in these malls, the REITs generate revenues from the rents collected from tenants. REITs are responsible for the daily maintenance and upkeep of the property. Simon Properties (described above) is a good example of a retail REIT.

Office REITs invest in office buildings and corporate centers and generate revenues from the rents paid by the office tenants. REITs are responsible for daily maintenance and upkeep of the office buildings. In times of recession, more office buildings become vacant, and this impacts the revenues of office REITs. Boston Properties Inc (NYSE: BXP) is an office REIT that owns several office buildings in major cities including New York City; Washington, D.C.; Boston; and San Francisco.

Residential REITs invest in apartment communities and generate revenues from the rents paid by the tenants. Based on their expertise or location, some of the residential REITs focus on one particular geographic area or sector. For example, American Campus Communities Inc. (NYSE: ACC) owns and operates private student housing units across college campuses. Home Properties Inc. owns and operates apartment communities in select cities in the United States.

Health care REITs invest in real estate serving the health care industry, such as senior housing communities, assisted living communities, medical offices, hospital buildings, research facilities, and skilled nursing facilities. Health care REIT Welltower Inc. (NYSE: HCN) is a good example of a health care REIT that invests across all of the above-mentioned facilities.

Other types of REITs target specific market niches. Included in these niche REIT investments are lodging and resorts (Hersha Hospitality Trust, NYSE: HT), self-storage properties (Public Storage, NYSE: PSA), farmlands (Gladstone Land Corporation, NASDAQ: LAND), timberlands (Weyerhaeuser Company, NYSE: WY), and data storage centers (Digital Realty Trust, NYSE: DLR).

Mortgage REITs differ from equity REITS and invest in real estate mortgages and real estate debt, which can be both residential (housing related) and commercial (nonresidential property types).

American Capital Agency Corp. (NASDAQ: AGNC) is a specific type of mortgage REIT that invests in residential mortgages (loans given out to homeowners) for which the principal and interest payments are guaranteed by the U.S. government or related agencies like Government National Mortgage Association (GNMA) or Federal National Mortgage Association (FNMA). Specifically, the lender of a government-guaranteed mortgage sells individual mortgages to the REIT company, which then combines many mortgages together into the REIT security (mutual fund). Investors purchase the REIT, which invests in the government-guaranteed mortgages. GNMA and FNMA give investors in this type of REIT a layer of protection against defaults by mortgage holders.

REITs that invest in both real estate properties and mortgages are referred to as hybrid REITs. For example, Ellington Financial LLC (NYSE: EFC) is a hybrid REIT that invests in residential mortgages, commercial mortgages (property loans issued to commercial property like office or warehouse owners), and other real estate–related securities (derivative instruments related to real estate companies).

Some REITs invest in a combination of the above property types and are referred to as diversified REITs. Vornado Realty Trust (NYSE: VNO) is a diversified REIT that invests in office buildings, shopping malls, strip malls, and lodging properties.

Leasing and Vacancies

For any property, the percentage of property that has been rented or leased is referred to as *leased* and the percentage of property that has remained vacant is referred to as *vacancy rate*. REITs aim to keep the vacancy rate as low as possible since higher vacancies lead to reduced revenues. A highly vacant shopping center will not drive the same amount of business toward the leased stores as will a fully leased center. This could lead to unhappy tenants. Hence, vacancy rate is an important measure of quality of property within the real estate space.

REITs add diversification to an investment portfolio along with cash flow through dividend distributions. REITs give investors an opportunity for exposure to real estate in their portfolio without the need to own individual properties.

RENEWABLE ENERGY

Renewable energy comes from the use of nondepletable sources, such as sunlight, wind, or moving or falling water. In the United States, most renewable energy is used to produce electricity. There is considerable public excitement over renewable energy options. They produce electricity with little or no emissions of greenhouse gases and other pollutants, and many of them, such as solar, contain the allure of new technology. What is the current status of these technologies? How competitive are they with other technologies? What policies are used to promote them, and what policies should be used to promote them?

According to the U.S. Energy Information Administration, in 2012, roughly 12 percent of the electricity produced in the United States was generated using renewable sources. About 56 percent of that renewable electricity was produced by hydroelectric dams, and just below 30 percent came from wind turbines. The remainder came from biomass, geothermal, and solar technologies. Hydropower dams have been around for many decades, but wind energy and solar power have grown rapidly just over the past decade. Wind generation in the United States grew from 6 billion kWh in 2000 to 140 billion kWh in 2012. Electricity generation from solar power in the United States has increased more than fivefold since 2002 and reached about 4 billion kWh in 2012.

The economics of renewable electricity depend on the costs of exploiting the renewable resource, and these costs vary by technology and quality of the resource (wind speed and persistence or solar intensity, for example). The economics also depend on the opportunity costs of the other technologies (coal, gas, or nuclear) against which renewables compete. Renewables tend to be very capital-intensive, and, with the exception of biomass, fuel costs are very low. In contrast, fuel prices, which can be variable and hard to predict, account for a large share of the cost of fossil fuel generators. Also, unlike fossil fuels, which can be transported from mines or wells to generators at low cost, renewable resources must be tapped where they are found. Many places with abundant renewable resources are distant from populated areas where electricity demand is concentrated, and therefore the cost of transmitting renewable electricity to markets can be substantial. Although renewable costs have come down over time, recent low natural gas prices and technological improvements have also reduced the costs of new natural gas generators. Overall, the average cost of a kWh produced by both wind and solar is typically greater than that of electricity generated using coal or natural gas.

The economics of renewables also depends on the value of the electricity they produce. Unlike most fossil fuel generators, which can vary their rate of electricity output to match demand, some renewables such as wind and solar are available intermittently, as they can only operate when the wind blows or when the sun is shining.

This intermittency affects the market value of wind and solar. Electricity that is supplied during periods of high demand has greater value than electricity produced when demand is low, so the value of renewable power depends on how well resource availability aligns with demand. This alignment varies by resource and region of the country. For example, wind power in the interior plains tends to be more abundant at night when electricity demand is low, whereas in coastal regions, windy periods may overlap more with peak electricity demand in late summer afternoons. Sometimes the amount of wind power generation leads to excess supply and spot wholesale electricity prices can be negative. Some renewables, such as rooftop photovoltaic installations, can be installed on a customer's premises and may generate more power than the customer needs at certain times. The excess generation can affect voltage stability and create other problems for managing the local distribution network.

Given these considerations, intermittency reduces the market value of wind and solar compared to other technologies. Greater access to energy storage, perhaps in the form of plug-in electric or hybrid electric vehicles or compressed air, might help to solve the mismatch between supply and demand. However, adding storage to a power system would affect the value of other technologies as well, and storage may or may not increase the overall value of nondispatchable renewables compared to other technologies.

Renewable technologies currently have higher costs and lower market values than conventional technologies, particularly natural gas. To overcome these economic hurdles, numerous federal, state, and local policies in the United States promote the use of renewables. Since the mid-1990s, with a few brief interruptions, the United States has had a federal policy of providing production tax credits for every MWh of electricity generated by wind and other selected renewable sources. Alternatively, investors can claim a federal tax credit for up to 30 percent of upfront investment costs for solar and other technologies. In addition, 30 states plus the District of Columbia have adopted renewable portfolio standards that typically require that renewables account for a minimum (and often growing) percentage of electricity sold in the state. These policies have helped to fuel the recent growth in renewable generation. But they also raise the question, when does it makes sense to use policy measures to promote the use of renewables?

Three rationales present themselves. The first is to counteract the failure of private markets to fully capture the environmental externalities associated with burning fossil fuels to produce electricity. Environmental emissions impose a cost to society in the form of environmental degradation and poor human health. When that cost is not included in electricity prices, electricity producers rely too much on the use of fossil fuels to produce electricity. The optimal policy raises the cost of burning fossil fuels to include those social costs. Policies such as tax credits can partially remedy that shortcoming by reducing the cost of using renewables. However, these policies are inefficient because they do not correct the market failure directly by increasing the private cost of emitting pollution.

The second policy rationale is to correct market failures associated with spillovers in research and development. Private markets produce suboptimal spending on research and development because the benefits of such activity can spill over to others without compensation to the innovator. This market failure is particularly relevant for new technologies, such as tidal or wave power, advanced wind generator technologies, or photovoltaics. These cases represent a clear rationale for government subsidies for research and development, such as the Department of Energy's Advanced Research Projects Agency Energy (ARPA-E) program.

The third rationale is to correct for underinvestment in learning. There is often considerable learning associated with developing and using new technologies. For example, rooftop photovoltaic system installers may learn how to install systems to operate more efficiently, and wind manufacturers may find ways to improve manufacturing efficiency. Learning can be thought of as an investment; the firm should price to the learning curve by initially offering the product at a low price to increase sales and to learn more. However, if firms are not able to capture the benefits of this learning, they would not reduce prices to learn and therefore will underinvest in learning. For example, other installers may observe what the first installer does and capture the benefits of learning. Subsidies for the development or use of the technology are justified if the firms are not able to capture the benefits of their own learning.

RETIREMENT ACCOUNTS

A retirement account is a type of investment account that allows workers to invest today's dollars for use in retirement. There are many types of retirement plans, and one can invest in one or several simultaneously depending on one's income level and personal situation. The underlying benefit of a retirement account is to provide tax benefits for individuals to increase their net worth for retirement. In general, retirement accounts are structured to give a financial incentive (usually in the form of lower taxes) and encourage workers to save and invest for retirement.

Individual Retirement Arrangement (IRA), Roth IRA, SEP (IRA), 401(k), and 403(b) are the names of the most common retirement accounts, although there are additional retirement account options for small-business owners and others.

Retirement accounts are designed to be funded during individuals' working life with the proceeds withdrawn during retirement. There are penalties and tax liabilities for withdrawing funds before retirement or age 59.5 (whichever is earlier).

This entry will discuss the most common types of retirement accounts 401(k), 403(b), traditional IRA, and Roth IRA.

401(k) or 403(b)

Named after the tax law, 401(k) retirement accounts are offered by for-profit companies, whereas 403(b) plans are offered to employees of nonprofit companies, such as schools, hospitals, and religious groups. These retirement accounts are similar; their main difference lies with the type of organization offering the plan. The law stipulates the maximum amount one can contribute to these and all retirement accounts annually.

There are several major benefits to 401(k) and 403(b) accounts. First, employees contribute a set amount every pay period into the account with pretax dollars. In other words, the contribution is taken from one's paycheck before taxes are deducted. The result is a lower taxable income. The employee chooses from a menu of various investment options for these funds.

The second benefit is that the money in the account grows tax free. No tax is due during the time the contributions are in the account. This benefit allows the money in the 401(k) or 403(b) account to compound more quickly.

Additionally, some plans allow account holders to borrow funds from their own account. There are regulations governing these withdrawals, and it is generally a poor idea to borrow from a retirement account.

In some organizations, an employer also contributes to the employee's retirement account. In most cases, the employer matches the employee's contribution up to a certain percentage. Employers most frequently use a 3 to 6 percent "matching" benchmark.

Compound Returns Increase Retirement Account Balances

Consider this common workplace retirement scenario. Colleen earns $1,000 per week, contributes 5 percent to her retirement account, and receives a matching contribution from her employer of an additional 5 percent. So Colleen contributes $50 per week and her employer contributes another $50 for a total of $100 per week. In one year, Colleen's retirement account contributions equal $5,200.

The financial benefit of investing this money for retirement is massive. Assume Colleen invests in a combination of stock and bond mutual funds, whose average annual return is 7 percent. If Colleen's account contributions continue from age 30 until age 65, she (and her employer) will have contributed a total of $182,000 ($5,200 x 35) over 35 years.

Yet, Colleen's account, invested in stock and bond mutual funds, and compounding at 7 percent per year, is worth $769,150 at age 65. These savings, along with government Social Security income, will provide Colleen with funds to live on during retirement.

There are certain restrictions for these retirement accounts. If you make a withdrawal before age 59.5, you may incur a 10 percent early withdrawal penalty as well as any taxes that are due on the withdrawal.

Traditional IRA

The traditional IRA is another type of tax-advantaged retirement account. Individuals and their spouses (if filing joint tax returns) can contribute if they have taxable compensation and are younger than age 70.5. There are contribution limits for a traditional IRA. In 2014, each individual could contribute up to $5,500, or $6,500 for those older than age 50. One cannot contribute more than one earns.

High-income workers covered by a retirement plan at work may not be able to contribute the full amount, or at all, depending on their income level.

Unless the worker is not covered by a retirement plan at work, the contributions are made with after-tax dollars. However, workers not covered by another workplace retirement account may contribute pretax to the traditional IRA and receive the same reduction in taxable income as 401(k) or 403(b) plan participants.

As with all retirement plans (except Roth IRAs), once the contributions are made, they are invested and can grow tax deferred until withdrawn at retirement.

Roth IRA

This retirement account is distinct from the other types in that the contributions are always made with after-tax income. In other words, contributions aren't tax deductible. Unlike other retirement accounts, in most cases, no tax is due when Roth IRA contributions are withdrawn.

If one has taxable income, there is no age restriction for contributing to a Roth IRA, although one's modified adjusted growth income must be below certain levels in order to make a contribution.

The contribution levels for Roth and traditional IRAs are the same, and you cannot surpass those amounts in totality. In 2013, the total amount individuals over age 50 could contribute to traditional and Roth IRAs was $6,500 each.

If monies contributed to a Roth IRA are rolled over from another type of retirement plan, to avoid penalties, they must remain in the account for at least five years. Additionally, if the Roth IRA funds are withdrawn before age 59.5, there may be a 10 percent penalty levied.

The Roth IRA is unique in another way. Funds may be withdrawn without penalty before age 59.5 if the participant is totally and permanently disabled, uses the distribution to buy a first home or to pay qualified higher education expenses, and a few other circumstances.

Required Minimum Distributions from Retirement Plans

The law requires most retirement account holders (with the exception of Roth IRA account owners) to take required minimum distributions (RMD) when they reach 70.5 and yearly thereafter. If the account holder does not comply, the amount not withdrawn is taxed at 50 percent.

Because the contributions to these retirement accounts (except Roth IRAs) were made before tax, they are taxable upon withdrawal. Employees assume that during retirement their income will be less than while working and thus they will pay lower taxes than they would have on that income without the retirement account.

There are no required minimum distributions for Roth IRAs. If the account owner is over 59.5, there is no penalty to withdraw funds from a Roth IRA, otherwise, as with a traditional IRA, there is an additional 10 percent tax penalty for ineligible early withdrawals.

The limits, types, and constraints of modern retirement accounts are constantly changing and evolving. In general, these tax-advantaged accounts are a cornerstone of modern personal finance.

REVENUE: TOTAL, AVERAGE, AND MARGINAL

Revenue is the goal of every business. Revenue is the money businesses obtain through their market interactions with consumers. To the business owner, the difference between gross revenue (all the revenue received) and net revenue (revenue retained after paying all costs) is significant to whether a business continues to operate. Economists take a different approach to revenue. For the economist, the difference between gross and net revenues is important for a business's operation, but identifying a firm's average and marginal revenues can help it achieve maximum revenue as it works to allocate limited resources more efficiently and effectively.

Total Revenue

Total revenue (TR) is all revenue received by the business before paying any costs or taxes. Total revenue equals the price per unit (P) multiplied by the total number of units sold (Q) (P x Q = TR). With the total revenue businesses receive, they pay their costs of production and operation, including labor, rents, and variable production costs. What remains is the accounting profit for the business to share with stockholders as dividends or remain with the firm as retained earnings.

Average Revenue

Average revenue (AR) is revenue per unit produced. Average revenue is calculated by dividing total revenue (TR) by the quantity sold (Q) (TR / Q = AR). By extension, TR is equal to P x Q (TR = P x Q). Implementing some elementary algebra, P x Q is substituted for TR so the equation is now P x Q / Q = AR. Again, simple algebra, the *Q*'s cancel so price is equal to average revenue, P = AR. Average revenue provides a picture of the firm's per-unit pricing strategy. This can be used as a measure against per-unit costs to determine the firm's per-unit profitability.

Marginal Revenue

A firm's revenue is maximized when it can efficiently allocate its limited resources to achieve maximum revenue as it adds additional resources to produce or provide additional products or services. The additional revenue earned through selling additional units of its good or service is known as marginal revenue (MR). Marginal revenue is calculated by dividing the change in total revenue by the increase in change in output (Δ TR / ΔQ). Marginal revenue can be either positive or negative, determined by the law of diminishing marginal returns. Marginal revenue can also be affected by changes in production capacity and by the firm's industry. In a perfectly competitive industry, AR and MR are always the same. However, a monopolistic or oligopolistic firm may see its marginal revenue reduced as it achieves significant size so its marginal costs per unit produced actually decrease, known as achieving economies of scale.

RIGHT-TO-WORK LAW

Right-to-work laws are states' initiatives that guarantee that workers do not have to belong to or join a labor union to secure or keep a job. Under a right-to-work law, any form of agreement that stipulates union membership or the paying of union dues as a job requirement is illegal. Unions are not illegal under right-to-work laws, nor is it illegal for a union to collect union dues.

Right-to-work laws go back to 1935, when President Franklin Roosevelt signed the Wagner Act, which initiated a new set of rules and definitions to collective bargaining and labor union membership, including union shop, agency shop, closed shop, and open shop. A union shop is an employer whose employees do not have to be union members to get the job but must join the union within a specified period. Agency shop employees do not need to belong to the collective bargaining union but must pay dues. In a closed shop, employees must belong to the collective bargaining labor union to be employed, and in an open shop employees are neither required to join the union nor pay union dues. With these new classifications in place, labor unions were in a much stronger bargaining position to dictate the terms of employment and union membership.

In 1947, Congress amended parts of the Wagner Act with the passing of the Taft-Hartley Act. Specifically, Taft-Hartley repealed the idea of closed shop employment. It also gave the states permission to make illegal the employment conditions of union or agency shops, setting up the possibility for states to pass their own employment statutes or what have become known as right-to-work laws.

Right-to-work laws have both strong support and strong opposition. Those who supported such state legislation laid claim to several addressed the rights of minorities to choose how or to whom they support with their time and money. Several court cases during the 1930s supported their contention for minority right of expression. A second major argument in support of right-to-work laws centered on one's right to associate, or not, as one chooses. Finally, proponents argue that individuals should not be required to pay for or support political contributions made by a labor union if they do not agree with the union's political and campaign activities.

Opponents of right-to-work laws are just as strong in their opposition. A main opposition is the free-rider problem: Employees who do not belong to or pay for the collective bargaining activity still receive the resulting benefits. An interesting side argument of opponents is similar to that of proponents. Opponents make a strong argument that right-to-work laws actually violate freedom of association and place an undue burden on unions. As a result, opponents claim that right-to-work laws are not as freedom oriented as supporters like to propose. Finally, right-to-work law opponents argue these laws are used by states for partisan political and economic means to better compete against other states and not for the benefit of the unions.

Right-to-work laws are not a promise of employment or keeping a job. Twenty-five states and the U.S. territory of Guam have right-to-work laws as of 2015.

RISK

Risks are situations where individuals, families, or organizations are exposed to the possibility of a harmful aftermath through injury, death, or financial loss.

Risks can be either pure risks or speculative (investment) risks (Day et al. 2013; MacMinn 2000; Schuchardt et al. 2007; Teale 2008).

Pure Risks

Pure risk is defined as a risk with a certain negative outcome; there is no possible positive outcome. Pure risk can be handled by avoiding it altogether, controlling it, or financing it. Examples of pure risk include premature death due to illness or a natural disaster, or identity theft.

Risk avoidance is the ideal solution. The person facing the peril either removes the offending asset or stops the risky situation from taking place. Sadly, not all risks can be avoided completely, making room for risk control.

Risk or loss control is a method used to either reduce the size (magnitude) or the number of times (frequency) of the financial consequences of a loss.

The risk-financing approach is to transfer the risk to another party, such as an insurance company, by way of contract. A second risk-financing method is where someone decides to personally carry the risk (risk retention/self-insurance). This occurs especially where risk cannot be transferred and the cost of handling it oneself is less than transferring it.

Pure risks are the possibility of a peril occurring that always results in a financial loss. The main income earner of a family could die prematurely, leaving his or her financial dependents without sufficient income to pay their daily living expenses. This type of pure risk can be transferred to an insurance company or other third party.

Pure risks comprise personal risk, property risk, liability risk, and nonperformance risk.

Personal Risk

Individuals are vulnerable to personal risks when they face the possibility of death, illness, or injury causing a financial loss. If someone with financial dependents suffers a major trauma so that he or she is unable to work and earn an income, it can ruin him or her financially.

Property Risk

Property risk typically occurs when physical assets are stolen, damaged, or destroyed. Two types of property risks are direct property losses and indirect property losses. Direct property losses occur when the property itself is lost, damaged, or destroyed. On the other hand, indirect loss refers to the consequential losses or additional financial cost that occurs after suffering initial direct losses.

For example, a direct loss occurs when a driver's car is damaged in an accident and can't be driven anymore. The driver not only faces a direct loss, the damaged car, but also the indirect losses of the additional cost of using public transport, notwithstanding the inconvenience and extra travel time.

Liability Risk

When someone's actions result in the loss to another's property, the upshot is the liability risk of an expensive lawsuit. The liability can arise under statute law, common law, or the law of contract.

The government of a country creates statute law. Common law, which has developed over many years, states that everyone owes a duty of care toward others in certain circumstances. They should be held responsible for harm or loss caused by failing to observe appropriate standards, including negligence. A liability under contract explicitly or implicitly affirms that the parties entering into this agreement accept this liability, such as an employer being liable for an employee if he or she is injured at work. Public liability occurs when a member of the public sues for damages occurring on someone's business premises. An example of personal liability is a tradesperson suing for damages occurring at a residence where he or she is working.

Nonperformance Risk

Nonperformance risk is the risk of financial loss should one party agree to perform a certain service for another and then fail to perform this service completely.

Speculative Risk

Speculative risk, also known as investment risk, involves both the chance of a financial loss and, unlike pure risk, the possibility of a financial gain on an investment.

Someone who invests money in shares on the stock exchange is exposed to the possibility that the share price of the investment may decrease below the price he or she paid for the investment, leading to a financial loss. Investors are averse to realizing losses on their investments. Yet the same investor could experience a gain if the share price rose more than the purchase price. The investor has no control over this.

Investors can limit the effects of these risks by avoiding or controlling them. Not investing in the share market is a method of risk avoidance.

The risk control method used by investors is called *diversification*. Diversification means ensuring that funds are spread over a range of countries, markets, market sectors, companies, and different types of investment products rather than putting all one's eggs in one basket. If one investment performs poorly, this will be supported by the other better-performing investments.

Using hedging and derivative products is a form of risk financing when facing speculative risks. In order to protect the investment against potential losses or adverse market movements, a hedging strategy uses the performance of one investment to counter losses in another investment.

Derivative financial products comprising options, forward rate agreements (FRAs), futures, and swaps are forms of insurance against speculative risk that lock in existing gains. Assume an investor already holds shares in Coca-Cola and has significant unrealized profit. He wants to continue holding the shares but is concerned that a market correction will cause the value of shares to drop. So the investor purchases an option to gain the right to sell the shares at the current high price sometime in the future. If the share values do drop in the future, the investor can exercise his right and sell the shares at the higher price that was locked in when the Coca-Cola shares were high.

Some risky events may be relatively unimportant and have no significant effect on someone financially. Bearable losses have a severe impact on a person's financial situation but do not result in bankruptcy. Unbearable losses may result in bankruptcy. The severity and probable frequency of the peril will determine how risks should be managed to eliminate or minimize financial loss.

RISK PREMIUM

Risk premium is the excess return an investor receives to compensate for the excess risk borne by investing in any particular security other than the risk-free treasury bill. *Premium* refers to the excess return that an investor receives over a certain benchmark of return. The benchmark is usually the rate of return on an investment in a treasury bill (T-bill). T-bills are short-term borrowing instruments that are used by governments to borrow money from the public. And since the government is deemed the least risky issuer in most countries, T-bills are referred to as the risk-free asset.

Risk premium is calculated by deducting the rate of return on the risk-free asset (T-bill) from the expected rate of return on the security under consideration. For example, if a company decides to borrow long term from investors in the capital market, it will sell investors a long-term bond, and if the rate of return on that bond—referred to as the coupon rate—is equal to 10 percent and it has a maturity of five years (i.e., investors can get back their invested capital after a period of five years) and if the rate of the T-bill is 3 percent, the risk premium for the company bond will be 7 percent.

Risk premium = company bond expected return − T-bill rate (risk-free rate)

Risk premium = 10% − 3% = 7%

The 7 percent in the previous example should compensate investors for risks associated with investing in that company. Risks include default risk, since the company is riskier than the government and the odds of it defaulting are higher than the government's. Another source of risk is liquidity risk; the company's bond is a longer-term instrument (five years versus one year for the T-bill) and thus reselling it in the secondary market might not be as easy as selling a short-term instrument like the T-bill. The secondary market for securities refers to the market where securities are exchanged between investors without the involvement of the original issuers of the securities. The original issuer of a security is only present in the primary market when the security is first offered.

Risk premium was defined by the capital asset pricing model (CAPM) developed by William Sharpe in 1964. Risk premium was categorized into market risk premium (by investing in an asset with a greater than the market level of risk) and security risk premium (the riskiness of an individual security when compared with the overall market). The CAPM determines the level of return required on any investment by adding a risk premium to the risk-free rate of return.

Required Return on Asset=Risk-Free Rate+Risk Premium

The risk premium has to compensate the investor for investing in financial markets in general instead of investing in the risk-free asset. This is referred to as the market risk premium and is calculated as the difference between the return on the market portfolio (indexed by the return on a broad market index like the S&P 500) and the risk-free rate.

The security risk premium shows how much additional return an investor demands by investing in a specific asset and compensates the investor for purchasing this asset in particular. The security risk premium is determined by multiplying the market risk premium by the security's systematic risk given by beta (a measure of how much a specific security varies in return when compared to the overall market's volatility).

Taking both types of risk premium into consideration, the CAPM equation can be rewritten as: required return on an asset = risk-free rate + beta (market risk premium).

In general, the higher the risk of a security, the greater the risk premium required by the investor. Investors in the equity market purchase stocks, which entitle them to an ownership claim in a company. Equity (stock) holders endure more risk than holders of government bonds and thus should be compensated with higher returns. That explains why government bonds have lower rates of return than stocks. The excess return required by equity holders over holders of government debt is referred to as the equity risk premium.

Equity risk premiums are significant because they are the basis for many of our personal financial decisions, such as saving, investing, and choice of retirement accounts. The degree of risk an individual is willing to take, referred to as degree of risk aversion, determines the risk premium required and thus the type of investment that would achieve this. In general, riskier investments carry higher returns and greater risk premiums.

RUST BELT, 1980s

The ultimate result of two decades of free-trade policies, rapid technological change, high demands of union workers, and deindustrialization in the United States was a devastating collapse of the industrial infrastructure in a belt of states that included New York, New Jersey, Pennsylvania, West Virginia, Ohio, Michigan, Indiana, Illinois, and Wisconsin. The economic leveling of this geographic belt, once known as the "Arsenal of Democracy," created economic changes that led to a population shift to the west and the south. The population decline in such cities as Detroit, Cleveland, Pittsburgh, Cincinnati, Milwaukee, Buffalo, Toledo, St. Louis, Trenton, and others rearranged the list of America's top 20 cities. Medium-size cities of the Rust Belt, such as Dayton, Ohio, and Jackson, Michigan, suffered as well. These major Rust Belt cities lost an average of 40 percent of their populations, and the median incomes of those who remained fell 20 to 40 percent.

The term *Rust Belt* was popularized in the 1984 presidential race. The fall of heavy industry in the Rust Belt changed the electoral weight of the states as the country's population shifted. The Rust Belt became a scar on the American landscape by the late 1980s and remains so today. America had never seen such a devastating loss of jobs, taxes, industry, and economic hope in such a large geographic region. In 1950, the Rust Belt had more than 50 percent of the nation's aggregate employment; by 1980, it had declined to 30 percent and is under 20 percent today. The job losses in the region had been decried for decades, but the end of the 1980s saw a great migration south. This reversed a century-long trend of southern workers moving north for jobs. Chicago and Pittsburgh experienced significant loss of their African American populations as workers returned to the South.

After two decades of efforts to counteract industrial job losses by retraining workers for high-tech jobs failed to improve their employment prospects, population migration began. Efforts to revitalize the Rust Belt with new industry were not successful for the most part. The unionized workers of the Rust Belt brought too much baggage to their new jobs for these new operations to be successful. State laws in the Rust Belt required or favored unionization, preventing labor costs from declining so companies could become competitive again. In addition, the number of local government jobs started to collapse after years of lower tax receipts. Crime increased dramatically with the decline of manufacturing and rising unemployment. These factors even destroyed small businesses, services, and entertainment. The spiraling decline turned Rust Belt neighborhoods into ghettos. Empty shopping malls stripped away even the hope of retail jobs in the Rust Belt. In addition, the massive early retirements in the steel, rubber, and auto industries made the move to Florida and southern states realistic for former workers. The same south offered employment for the younger Rust Belt workers.

Initially, Rust Belt companies tried to maintain some industry in the region by implementing employee buyouts, which slowed migration in the early 1980s. The employee-owned companies lasted only temporarily as they did not address the issue of noncompetitive wages. Other strategies involved building casinos and shopping malls, but a dwindling population meant these brought only minor economic improvement. Other parts of the Rust Belt attempted to develop intellectual and high-tech centers, with varying degrees of success. The migration south would end the Rust Belt's hopes of transformation and greatly reduce its political capital.

One of the major factors that encouraged the movement of industry and workers south was the right-to-work laws in the southern states. The source of these laws was the Taft-Hartley Act of 1947, which amended the Wagner Act and slowed the progressive government support of unions. The Taft-Hartley Act outlawed closed shops but permitted union shops that required union membership after a period of time. The act allowed states to pass right-to-work laws and allowed the president to intervene in strikes that posed a national emergency. The passage of the Taft-Hartley Act had been hard fought, with President Harry Truman vetoing it and Congress overriding the veto.

The key issue the act dealt with was the so-called *closed shop*. Under the Wagner Act, once a union was certified by a National Labor Relations Board election, the union could not be removed. Furthermore, workers would be required to join the union to work at the shop. In the heavily unionized North, the closed shop was the standard. In 1947, the Taft-Hartley Act limited the application of a true closed shop, though it allowed a union shop, which is a form of closed shop. However, under the Taft-Hartley Act, states could pass right-to-work laws to make even union shops illegal.

The spread of right-to-work laws in southern and western states grew in the 1970s as a means to attract jobs. These right-to-work laws caused a movement of northern factories south because they offered companies the ability to pay wages and benefits that could compete globally. In addition, these states attracted new car-building plants from Japan and Germany. The shift of companies from the Rust Belt helped the rapid decline of the industrial unions such as the United Auto Workers. The influx of Japanese and German plants into right-to-work states divided and muted the efforts for "Buy American" campaigns by the northern unions. It is only recently that some Rust Belt states have turned to right-to-work laws to attract new industry.

SAVING VERSUS INVESTING

For centuries saving and investing money have offered different approaches to achieving financial security, but it was not until the late 19th and early 20th century that saving money in banks became widespread in many developed societies.

Saving in the financial sense means depositing funds in an institution under terms that leave funds available upon request without fear of financial fluctuations impacting the amount at hand. In exchange for allowing the institutions, usually banks, to be custodian of the funds, the institutions promise and pay a regular interest rate of return on the funds deposited, allowing the depositor's assets to grow over time.

Traditional savings vehicles include savings accounts, checking accounts, and certificates of deposit (CDs). CDs involve investing for specified periods, after which the funds can be accessed. They traditionally pay a higher rate of interest than savings and checking accounts. The combination of a guaranteed interest rate and ready access to one's money affords a sense of security and peace of mind. Technically, depositing funds in an institution for savings purposes is investing in that institution, yet one does so with some expectation of moderate growth via interest rate earnings.

Savings funds afford security and ready access to funds. If one's goal is to use the funds for a major purchase in the near future, it's prudent to deposit the money at hand in a savings account. In the event of unexpected events that require funds, such as repairs to property not covered by insurance, medical expenses, and other such emergencies, funds saved in commercial institutions with retail offices can be readily accessed for use.

In practice, investing involves a more speculative approach and more risk than a guaranteed interest rate. Investing means committing funds to a pursuit with the expectation that a profit will be earned by the project's efforts, increasing the wealth of the investor. Individuals and institutions can and do invest widely, from commercial companies to real estate undertakings to intellectual proposals that evolve into inventions. Investing in a company is commonly done by receiving shares of stock in the firm in return for one's money.

As companies can grow and produce profits as well as lose money and fail, investing in commercial interests traditionally affords no guarantees of increasing one's funds. A greater risk is involved with investing than saving money in the traditional sense. There is also the possibility of a greater return than a guaranteed interest rate might offer.

The first historical case of major financial investing with a profit in mind was in the 17th century when British investors committed money to the East India Company with the anticipation the firm's voyages would yield positive financial returns. Both the London and New York stock exchanges date from the late 18th century, and prior to the 20th century it was rare for individuals without considerable wealth to deal with the banks or invest. Industrialization and innovation in the late 1800s made a variety of American business ventures attractive to investors and had many entrepreneurs seeking investors as well. The post-World War I boom of the 1920s saw Americans depositing funds for saving in banks in record numbers. In the interest of receiving a return on this money beyond what they would have to pay to their depositors, banks invested their account holders' funds in the roaring stock market of that decade. When the stock market crashed in 1929, the banks' investments were lost as were depositors' money.

To prevent savings institutions from engaging in investment banking practices in the future, Congress passed the Glass-Steagall Act in 1933. That same year the government created the Federal Depositors Insurance Corporation (FDIC) to insure deposits with government guarantee against losses and to build confidence in the banking system. In 1999, Congress repealed the Glass-Steagall Act. The FDIC currently insures individual deposits up to $250,000 in member banks. Savings banks now engage in a variety of investment practices and offer such services to their customers.

A growing awareness of the need to plan for retirement years in the late 20th century prompted many individuals to pursue investing on an individual basis through their banks and other retail operations. Many employers offer investment plans to their workers that also help them to save money for their retirement years.

Since the 1929 crash, the New York Stock Exchange has outperformed the returns offered in traditional savings accounts. Investing prudently can provide a return that will better help one to fund longer-term personal or institutional priorities, such as a college education a decade or more away, retirement, or other personal or business ventures well in the future. Investment opportunities usually involve risk, such as a piece of real property or company stock losing value.

Bank accounts designed for savings will occasionally require depositors to keep a minimum balance in the institution and may charge fees in the event that the funds drop below that amount. Retail investment operations such as stock brokerages charge fees for managing accounts and also for executing trades—that is, when the investor decides to sell one stock or purchase shares of a new one. A collection of stocks from one sector of the economy, such as utilities or energy companies, are also assembled in mutual funds. These funds allow investors to commit money to an entire range of companies. For a fee, fund managers endeavor to buy the best stocks in that sector and sell the worst performing ones to enhance the fund's overall performance. Investment professionals must be certified with licenses issued by the federal and state governments in which they operate, and they are trained to provide advice to individuals for fees. Technology has allowed individuals to buy and sell investments such as stocks independent of professionals, however, and day traders who devote time and research to doing so have become more common in recent years.

SAVINGS ACCOUNT

A savings account is a type of financial account held at a bank or other financial institution. These accounts protect the consumer's bank deposits and also offer a low interest rate. There are many types of savings accounts, and most financial institutions offer a menu of account options. All bank and credit union accounts are insured and protected against loss up to $250,000 for each social security number, making these accounts very safe. Bank accounts are insured by the Federal Deposit Insurance Corporation (FDIC), and credit union accounts are insured by the National Credit Union Share Insurance Fund (NCUSIF).

Savings accounts are considered one of the most liquid investments and allow consumers easy access to their funds. These accounts are frequently linked to a checking account for easy funds transfer. Depending on the type of account, there may be monthly charges or limits on the number of transactions allowed. Online banks and financial institutions with savings and checking accounts are becoming more popular and frequently offer higher interest rates due to their lower overhead costs.

Use of a Savings Account

A savings account is where people keep money they need to access easily for emergencies and unexpected expenses. Unlike a checking account, which is used to pay monthly expenses, a savings account is used to pay for short- and medium-term financial goals as well as unexpected expenses.

Consumers use savings accounts for vacations, upcoming larger purchases such as appliances, a down payment on a car, or intermittent bills such as semiannual car insurance payments.

Types of Savings Accounts

Regular Savings Account—This account is easy to set up and use. Linking this account to a checking account at the same bank allows the consumer to quickly transfer funds between checking and savings accounts for sound money management. Many banks allow linked accounts to protect one from accidentally overdrawing the checking account (paying a bill valued at more than the checking account balance).

In spite of the convenience and accessibility of this type of regular savings account, the disadvantage of a basic savings account is low interest payments. It's a wise financial decision to keep some money in a savings account, for easy access, but maintain other types of investment and savings accounts for longer-term savings needs.

Online Savings Account—Serving the same purpose as a regular savings account, this type of savings accounts has no physical building or branch. All business is transacted online, by telephone, and/or mail. Because banks save money by not having a physical location, which is more expensive than an Internet location, they may pass those savings on to the customer. Online savings accounts frequently pay higher interest rates. Fees and expenses may also be lower than for regular savings accounts.

Money Market Deposit Account—Both regular and online banks may offer this type of savings account. In general, these accounts pay the highest interest rates of any type of savings account. The consumer's deposits are lent to corporations with very short-term financing needs in exchange for a higher interest payment. These accounts are quite safe and are insured by the same FDIC or NCUSIF insurance as other types of savings accounts.

This type of savings account is not the same as a money market mutual fund, which is uninsured and available through investment brokerage accounts.

In most varieties of savings accounts, consumers receive higher interest rate payments with higher account balances (the balance is the amount in the account).

Disadvantages of Savings Accounts

Due to their low interest rate payments, savings accounts aren't suitable for retirement or long-term goals that require a large amount of funding. One of the benefits of other types of financial vehicles, such as stock and bond mutual funds, is their higher investment returns.

How to Start Saving

Workers benefit by instructing the human resources office to automatically transfer part of their paycheck into a savings account. This automatic saving is a smart way to build an account for emergencies and short- and medium-term financial goals.

Another version of automatic saving is to have the financial institution regularly transfer a set amount from the checking to savings account.

Psychologically, the consumer is less likely to spend money that is not readily accessible. If the funds are transferred into a savings account, it is easier to consider that money "off limits" for discretionary spending.

In summary, a savings account is an account in which money is placed to save for the near future. The focus of this account should not be on earning interest; it is there to pay for unexpected life events and near- to medium-term financial expenses.

SAVINGS AND LOAN CRISIS, 1986

The savings and loan crisis of the 1980s represents the greatest collapse of American financial institutions since the Great Depression. Although it had roots in the 1970s, the crisis was marked by the insolvency of the Federal Savings and Loan Insurance Corporation (FSLIC) in 1986. It was a classic bubble with overspeculation and excessive growth in the savings and loan industry. The FSLIC was the federal insurer of savings accounts at these thrift institutions, the thrift industry's equivalent to the Federal Deposit Insurance Corporation. By the end of 1986, 441 thrifts with $113 billion in assets were insolvent, and 533 thrifts with $453 billion in assets were on a watch list for institutions with less than 2 percent of their total assets in tangible capital. The period 1986 to 1995 would see the failure of 1,043 thrifts with combined assets of more than $500 billion. The cost to the taxpayers of bailing out these institutions was in excess of $200 billion. The savings and loan crisis would result in a number of new regulations and a 50 percent reduction in the size of the industry. Even more interestingly, the savings and loan crisis would foreshadow the 2008 banking and mortgage crisis.

American thrifts, which became known as savings and loans, were focused on housing loans and experienced rapid growth after World War II. In the 1960s and 1970s, the savings and loans competed for savers by offering high interest rates in a time of spiraling inflation. The stagflation of the 1970s, with its slow growth in housing and high interest rates, weakened the financial assets of the savings and loans. In the early 1980s, lower interest rates caused savers to move to other saving options, which further weakened the savings and loans. Congress looked at ways to help the savings and loans grow out of their problems by expanding savings and loans products and decreasing regulation.

The Depository Institutions Deregulation and Monetary Control Act of 1980 allowed savings and loans to issue credit cards, make consumer loans, invest in real estate, and offer interest-earning checking accounts. These products put savings and loans in competition with commercial banks, but without many of the regulations that governed banking activity. The Economic Recovery Tax Act of 1981 allowed savings and loans to sell their mortgage loans to Wall Street firms and allowed losses to be offset against taxes.

Savings and loans began the process of making loans, bundling them, and selling them at steep discounts to obtain new money to make more loans. The trouble began when small savings and loans became overextended, while others suffered because their loans were insufficiently backed by solid assets. The public became aware of the mess in March 1985 with the failure of Home State Savings Bank of Cincinnati. Depositors began a run on the bank's branches, causing the governor of Ohio to call for a bank holiday and the closure of the state's savings and loans. Only federally backed (FSLIC) savings and loans reopened as other depositors' withdrawals drained the state's insurance funds. The problem soon spread to other states. As federal regulators were forced to take over these savings and loans, the federal FSLIC fund was depleted by late 1986. The federal government continued to back all insured savings and loans.

From 1986 to 1989, the government bailed out an additional 296 institutions. Things got worse as the Senate and House ethics committees uncovered political scandals affecting both parties in Congress. Three U.S. senators—Alan Cranston (D-CA), Don Riegle (D-MI), and Dennis DeConcini (D-AZ)—were forced out of office; and John Glenn (D-OH) and John McCain (R-AZ) were rebuked for poor judgment and influence peddling with the Lincoln Savings and Loan, which had also failed. The scandals kept the savings and loan crisis in the news, requiring more reform by Congress. In January 1987, the Government Accounting Office declared the FSLIC officially insolvent by more than $3.8 billion. Meanwhile, the whole savings and loan industry in Texas was near collapse. Texas was home to savings and loans that had more than 50 percent of the industry's liabilities, and the situation there was worsened by a deep recession in the oil industry. In the end, 14 of the 20 biggest losses would be Texas savings and loans. The Texas savings and loan problem threatened the whole U.S. system.

By 1989, the savings and loan crisis was dragging the economy into recession. In February 1989, President George H. W. Bush announced a $50 billion bailout of the savings and loan industry. In August, Congress passed the Financial Institutions Reform, Recovery, and Enforcement Act of 1989. The Savings Association Insurance Fund (SAIF) replaced the FSLIC. The Resolution Trust Corporation was created to resolve insolvent savings and loans. A new regulatory agency, the Office of Thrift Supervision, was created. Freddie Mac and Fannie Mae were given additional responsibility to support the mortgages of low-income families. By the official end of the savings and loan crisis in 1995, more than 1,600 savings and loans were closed or had received substantial federal aid, representing 50 percent of the industry. Regulation helped restrict liberal banking practices, but many observers believe the root causes of the crisis were never fully addressed.

SCHELLING, THOMAS

Born: April 14, 1921, in Oakland, California; Died: December 13, 2016, in Bethesda, Maryland; Nationality: American; Professional Interests: game theory, conflict strategy, Nobel Prize (2005); Major Works: *Strategy of Conflict* (1960), *Arms and Influence* (1966), *Arms and Influence* (2008).

Thomas Schelling was awarded the Nobel Prize in 2005 with Robert Aumann for his work in the field of game theory. Schelling served the U.S. government during World War II as an analyst and foreign policy adviser. During his academic career, he was a pioneer in game theory. Schelling committed the bulk of his studies to conflict situations and how best to manage military conflicts and weapons deterrence. Consistent with the times, much of his work focused on the Cold War conflict between the United States and the Soviet Union. He wrote of the importance of both sides having a credible nuclear threat, which neither was likely to use, to serve as a deterrent.

Thomas C. Schelling was born in Oakland, California, on April 14, 1921. He earned his bachelor's degree in economics from the University of California, Berkeley, in 1944 and his PhD in economics from Harvard University in 1951. Prior to beginning his PhD work at Harvard University, he worked as an analyst with the U.S. Bureau of the Budget and then with the Marshall Plan. He continued working in the government, serving as a White House foreign policy adviser. Schelling later moved into academia, working as a faculty member at Yale University, and then spent the majority of his career, more than 30 years, at Harvard. At Harvard he worked in both the Department of Economics and International Affairs and the Kennedy School of Government. Over time, he consulted with presidential administrations from Kennedy to Nixon. After the invasion of Cambodia during the Vietnam War, Schelling led a group of Harvard faculty to meet with Nixon's national security adviser; they expressed their opposition to the invasion and severed ties with the administration.

Schelling's book *The Strategy of Conflict* is one of the more influential books on weapons policy and military deterrence. In it, Schelling proposed the rather unique idea that effective conflict strategies could be applied to any conflict situation. There are similarities in dealing with common everyday conflicts and large-scale, international military conflicts.

Schelling coined a now common game-theory term, *focal point*, also known as the Schelling point. The term refers to the solution to a problem where the players are not able to communicate with each other but must cooperate to reach the same point. The focal point is the point at which both players believe they are most likely to reach a common agreement or understanding.

Later in his career, Schelling devoted his time to studying addictive behaviors. He was motivated to explore this area by his involvement with the National Academy of Sciences on Substance Abuse and Addictive Behavior. Schelling looked at the conflict between our rational and impulsive natures and the steps we take to try to manage the two and overcome addictions. He wrote numerous essays on the subject, many of which are included in his books *Choice and Consequence* (1984) and *Strategies of Commitment and Other Essays* (2005).

Schelling embarked on a new area of economic exploration when he was invited by President Carter to chair a committee on carbon dioxide pollution. Schelling himself admitted that he knew very little on the subject at the time. However, he would go on to study the issue over a two-year period with the Carbon Dioxide Assessment Committee of the National Academy of Sciences. Schelling stated that he believed that climate change will be to the 21st century what nuclear arms control was to the 20th century.

Schelling was awarded the Nobel Prize in Economics in 2005. He was a corecipient of the award along with Robert Aumann, though the two never worked together. Schelling was awarded the Nobel Prize for his specific work on the strategic decision-making (game theory) processes through which individuals, organizations, and countries are sometimes able to cooperate and sometimes not.

Thomas Schelling was a distinguished professor of economics at the University of Maryland. He died December 13, 2016, in Bethesda, Maryland.

SCHOLES, MYRON

Born: July 1, 1941, in Timmins, Ontario, Canada; Nationality: Canadian; Professional Interests: financial markets, asset pricing, Nobel Prize (1997); Major Works: "The Market for Securities: Substitution versus Price Pressure and the Effects of Information on Share Prices" (1972), "Rates of Return in Relation to Risk: A Reexamination of Some Recent Findings" (with Merton Miller, 1972), "The Valuation of Options Contracts and a Test of Market Efficiency" (with Fischer Black, 1972).

Myron Scholes is a Canadian economist who was awarded the Nobel Prize in 1997. At the Massachusetts Institute of Technology (MIT), he worked closely with Robert Merton and Fischer Black, developing a new method in asset pricing, known as the Black-Scholes model. In 1995, Scholes was a founding member of Long-Term Capital Management (LTCM), a hedge fund that used the mathematical models of Scholes and others for selecting investments. LTCM went bankrupt when Russia defaulted, and the Federal Reserve was needed to save the financial markets. However, his influence in financial markets continued when he founded the investment firm Platinum Grove Asset Management in 2006 and was placed on the boards of the Chicago Mercantile Exchange and Dimensional Fund Advisors.

Myron S. Scholes was born in Timmins, Ontario, Canada, on July 1, 1941. In 1951, his family moved to Hamilton, Ontario. His formative years in Canada were characterized by hardships and a keen interest in economics. He was exposed to the stock market through watching investments his family made. When Scholes's uncle died, the family disputes that followed over the family business were his first exposure to the disagreements that contracts can evoke. As a teenager, he faced the death of his mother and the loss of his eyesight in a short period of time. At the age of 26, his eyesight was restored after a successful cornea transplant.

In the wake of his mother's death, Scholes wanted to stay near his family for his undergraduate work and became a student at McMaster University, graduating in 1962 with a bachelor's degree in economics. While at McMaster, Scholes read the works of future Nobel laureates George Stigler and Milton Friedman with great interest. Scholes would subsequently enroll at the University of Chicago, where he earned his MBA in 1964 and his PhD in 1969.

After finishing his dissertation, Scholes accepted an academic position at the MIT Sloan School of Management, where he met two people he would work closely with to develop the formula that would earn him a Nobel Prize in Economics. Robert Merton and Fischer Black together with Scholes developed groundbreaking work in asset pricing, including their famous option-pricing model known as the Black-Scholes model.

The Black-Scholes model was a pioneering effort because never before had traders been able to value options precisely. The impact was that investors could significantly reduce their risk by hedging their bets in the options market. Options are investment vehicles that allow one the right, but not the obligation, to buy or sell a given security at a set price in the future. With this formula, firms and households could select an appropriate amount of risk by effectively redistributing it throughout the financial markets to those who are willing and able to assume it.

The first historical attempt to use advanced mathematics to model financial markets was in 1900 and is credited to French academician Louis Bachelier. The options contract had long been an object of study by academic financial mathematicians because of the fact that it can potentially eliminate all the downside risk of trading when used as a hedge against an adverse move in the market. Before the discovery of this mathematical model by Scholes and Black, options and derivatives contracts were much more obscure, mostly because traders were not able to accurately price them. Today, options contracts and derivatives are widely traded in financial markets.

In 1995, Scholes went on to become a founding member of hedge fund called Long-Term Capital Management (LTCM), which used proprietary mathematical models to guide investments. His reputation and notoriety as a Nobel Prize winner helped him attract vast amounts of capital from high-profile investors worldwide, as people were eager to have him invest their funds. In the first three years of LTCM, the company was widely successful and outperformed all other funds. It soon became clear, however, that certain underlying market conditions were developing for which the models at LTCM were insufficient. In 1997, the Asian financial crisis caused panic in the markets, and LTCM borrowed large sums of money to hold positions because their models predicted that markets would return to normal. They were able to stay in business until August of 1998, when the highly improbable event of Russia defaulting on its foreign debt occurred. This caused a major swing in the market, which LTCM was not able to bear, and subsequently brought their operations to an end. The result was a massive bailout by the Federal Reserve for fear that LTCM was so immersed in financial markets on such a large scale that its default could lead to a freeze-up of the entire system. Scholes and his investors lost millions.

Scholes's contributions to financial economics opened markets to vast new opportunities and revolutionized how risk is managed by investors. His formula is used millions of times every day by traders as it continues to shape the development of financial markets in the world today.

SELTEN, REINHARD

Born: October 5, 1930, in Breslau, Germany (now Wroclaw, Poland); Died: August 23, 2016, in Poznan, Poland; Nationality: German; Professional Interests: game theory, Nash equilibrium, multistage games, experimental economics, bounded rationality, Nobel Prize (1994); Major Works: *The Chain Store Paradox* (1974), *Game Theory and Economic Behaviour: Selected Essays*, Volume 1 (1999), *Game Equilibrium Models I: Evolution and Game Dynamics* (2010), *Models of Strategic Rationality* (2013).

Reinhard Selten was a mathematician and economist who won the Nobel Prize in 1994 for his work in game theory, specifically by furthering and deepening the equilibrium equations of fellow Nobel laureate John Nash. Selten is the only German to have won the Nobel Prize in Economics. Selten was also a leader in the field of experimental economics. He believed all economic theories should be supported by empirical evidence, so he set up economics testing laboratories where he could see his ideas in action.

Reinhard Selten was born in Breslau, Germany (now Wroclaw, Poland), on October 5, 1930. His father, Adolf Selten, was an ethnic Jew, and as a result of his mixed heritage he faced discrimination from the Nazi regime. His father was forced to sell his small business, and Reinhard was not permitted to pursue an education past the age of 14. Many of the Seltens' Jewish relatives were killed during the Holocaust. The family feared Soviet occupation even more than the Nazi threat, however, and when Red Army troops closed in on Breslau at the end of World War II, the Selten family escaped on one of the last trains out of the city.

The family fled to Austria, and Selten worked briefly as a farm laborer before he was able to return to school. He studied math in college and graduate school.

Rather than take astronomy, the standard minor for math students, he requested economics and began to apply sophisticated mathematics to social questions. When he eventually visited a game theory conference at Princeton University in the United States, his career path was sealed.

Selten's work expanded on the idea of the Nash equilibrium, which posits that given rules and a perfect knowledge of opponents' choices in a given competitive situation, one can calculate the strategy that the game players will choose. The Nash equilibrium works as a sort of snapshot of the strategic options that competitors face. Selten took it further. He explained that sometimes games unfold in stages, and while each stage has its own equilibrium (i.e., a best possible strategy), the game as a whole, what Selten called a *supergame*, has its own equilibrium, which may in turn affect the equilibria of each stage and even go back and change them.

The example he used was called the "chain store paradox." In this example, a chain store is the only store of its kind in a particular town, but there is another chain that is thinking about moving in. The original chain has a choice: Should it lower its prices to such a point that the newcomers will be unable to make a profit and therefore decide not to come? This would make sense because it would deter future competition, which could devastate the chain, but it would hurt the chain's profits in this current stage. If a second competitor appears and the choice must be made a second time, cutting prices would still be a good strategy since the point is still to discourage *future* attempts at competition. But whenever the final stage of the "game" arrives—that is, when there is only one possible competitor remaining—then it would not be worth it to lower prices. The chain would accept the new competition. But this is where the paradox begins.

Reasoning backward, we see that if the store does not lower prices in the final stage, the time before that final stage becomes the new final stage. Therefore, the store would opt a second time not to slash prices. This logic continues all the way back to the first stage. This led Selten to believe that the company would never cut prices in the first place. It would allow the competition to exist.

Selten was also a leader in experimental economics. He thought that all economic theories should be supported by empirical evidence, and to this end he set up economics testing laboratories where he could see his ideas in action. In the case of the chain store paradox, he found that companies in fact choose a middle road. They often allow some competition for a while, but at some point decide to retaliate and begin a price war. The explanation for this seemed to be simply that humans do not operate strictly according to the pure logic of game theory. There are instincts, emotions, and relationships to consider, even among competitors. These factors and the fact that people have imperfect information when making decisions led Selten to work in still another important area: the theory of bounded rationality. This theory holds that, while people are generally rational in their decision-making, their rationality has limits. Even so, such tendencies can be modeled and predicted.

In 1994, Selten was awarded the Nobel Prize along with John Nash and John Harsanyi for their work in game theory. Selten joined the University of Bonn in 1984 and later became a professor emeritus there. He died August 23, 2016, in Poznan, Poland, at the age of 85.

SHAPLEY, LLOYD

Born: June 2, 1923, in Cambridge, Massachusetts; Died: March 12, 2016, in Tucson, Arizona; Nationality: American; Professional Interests: mathematics, game theory, Nobel Prize (2012); Major Works: "A Value for *N*-Person Games" (1953), "College Admissions and the Stability of Marriage" (1962), *Values of Non-atomic Games, Part II* (with Robert Aumann, 1969), "On Market Games" (with Martin Shubik, 1969).

Lloyd Shapley received the 2012 Nobel Prize in Economics for his work in the fields of mathematical economics and game theory. A Bronze Star World War II veteran, Shapley is known for many mathematical economics and game-theory theorems that bear his name: Bondareva-Shapley theorem, Shapley value, Shapley-Folkman theorem, Gale-Shapley algorithm, and the Shapley-Shubik power index, to name only a few. Shapley was also influential in the development of game theory. Shapley was a professor and professor emeritus at University of California, Los Angeles (UCLA), from 1981 until his death.

Lloyd Stowell Shapley was born on June 2, 1923, in Cambridge, Massachusetts, the son of the distinguished astronomer Harlow Shapley. Shapley began his college studies at Harvard University but his studies were interrupted when he was drafted during World War II. During World War II, he was awarded the Bronze Star for breaking a Soviet weather code. Following the war, he returned to Harvard, graduating with his bachelor's degree in mathematics in 1948. Shapley next went to Princeton University, earning his PhD in mathematics in 1953, where he studied with fellow future Nobel laureate John Nash.

Shapley began his academic career by staying on at Princeton as an instructor. In 1954, Shapley left academia and rejoined the RAND Corporation where he had been a research mathematician in 1948 and 1949. At the RAND Corporation, Shapley worked on problems associated with matrix games, the Von Neumann-Morgenstern stable sets, and nonatomic games with Nobel laureate Robert Aumann. His early work on matrix games is considered so comprehensive that he left little room for future improvement. Shapley's work has significantly influenced economic theory on competition and utility theory.

Shapley has been called one of the most prolific economic mathematicians. The theorems, algorithms, and game-theory solutions that bear his name are numerous. Besides his significant work with Robert Aumann on nonatomic games, his work included block voting with the Shapley-Shubik power index and the Bondareva-Shapley theorem addressing convex games. The Shapley value was introduced in 1953 as a solution concept in cooperative game theory. In cooperative game theory, the value assigns distributions of a surplus created by a coalition of players.

In 1962, Shapley and David Gale developed an algorithm on marriage matching. The Gale-Shapley algorithm was designed as a way to create a marriage market that could pair individuals for marriage even if the individuals did not agree on what would make a good marriage.

In 2012, Lloyd Shapley and Alvin Roth were awarded the Nobel Prize in Economics for their work in market design and game theory. They were noted for the applications of their research, especially in creating markets for the purpose of matching different individuals, such as his work on matching marriage couples with the Gale-Shapley algorithm.

The 2012 Nobel Prize in Economics was one more honor for Shapley. In addition to the Bronze Star and Nobel Prize, Lloyd Shapley was a fellow of the Econometric Society, American Academy of Arts and Sciences, and INFORMS (Institute for Operations and Management Sciences). In 1981, the year he left RAND Corporation for UCLA, he received the John von Neumann Theory Prize. In 1986, Shapley received an honorary PhD from Hebrew University of Jerusalem. He died on March 12, 2016, in Tucson, Arizona.

SHERMAN ANTITRUST ACT OF 1890

Named for Senator John Sherman, Ohio Republican, the Sherman Antitrust Act forbids certain business practices that would diminish the competitiveness of a market. The act gave the federal government the right to investigate and bring federal suits against businesses if it deemed a business practice to be in violation of the act. The act focused primarily on monopoly behavior by businesses and the collusion of companies through cartels. It was the first federal act to interfere in a private market, sharply limiting or making illegal monopolies and cartels. Even though the act was signed on July 2, 1890, by President Benjamin Harrison, it was not until 1901, under President Theodore Roosevelt, that the act was first enforced to limit the monopoly and cartel behavior of businesses.

There were three key sections to the Sherman Antitrust Act. The first was directed at defining noncompetitive behavior by businesses. This section deemed illegal any organizational structure or contract that led to restraint of trade among either the states or with another country. The second section defined which market results would constitute noncompetitive behavior. Violation of the act was a felony. The third section extended the reach of the act to include U.S. territories and the District of Columbia.

The spirit of the act was to protect consumers from the uncompetitive behavior of businesses that have either monopoly power in their market or companies that have banded together to exert cartel market behavior. Monopoly and cartel power allows the monopoly company, or companies that make up the cartel, to impose two disadvantages on consumers. First, they have the ability to withhold market information from the consumer. This allows them greater market power than would otherwise be the case under purely market conditions. This leads to the second disadvantage to consumers. Companies are allowed to charge a price higher than would be the case under pure market conditions and to control the quantity produced for the market. The Sherman Antitrust Act was legislated to diffuse and balance the market between the business and the consumer.

The act was an effort by the federal government to keep businesses from restricting market competition and trade so they could raise prices. To that end, however, the federal government clearly distinguished between purposeful monopolies and businesses that found themselves in a monopoly position purely as the result of business success. The focus of the act was on deterring and punishing those who deliberately created either monopoly power in a market or the collusion of several companies to create the market result of monopoly power.

One of the major issues at the time of the Sherman Antitrust Act was whether Congress had the authority to pass a law with such broad market limitations. Congress asserted its power to do so by way of the Constitution and its role in regulating interstate commerce. Several Supreme Court case decisions solidified the Sherman Antitrust Act as law. The act was meant to protect the competitive nature of a market, not interfere with it. Prominent Supreme Court cases confirming the Sherman Antitrust Act as law included *Addyston Pipe and Steel Company v. United States* (1899) and *Standard Oil Co. of New Jersey v. United States* (1911).

The term *trust* in the name of the act references a type of business structure that was popular at the time of the legislation. Although not a popular form of business today, at the end of the 19th century and early 20th century, C. T. Dodd of Standard Oil Company of Ohio invented the trust agreement, allowing Standard Oil to circumvent an Ohio law regarding companies owning stock (ownership) in other companies. This new business structure allowed Standard Oil to construct a vertically integrated company that eventually had such large market share that it enjoyed monopoly power. It was this intentional type of business activity that led to the 1890 Sherman Antitrust Act.

SHILLER, ROBERT

Born: March 29, 1946, in Detroit, Michigan; Nationality: American; Professional Interests: behavioral economics, housing and real estate economics; Nobel Prize in Economics (2013); Major Works: *Market Volatility* (1989), *Macro Markets: Creating Institutions for Managing Society's Largest Economic Risks* (1993), *Subprime Solution: How the Global Financial Crisis Happened and What to Do about It* (2008), *Animal Spirits: How Human Psychology Drives the Economy and Why It Matters for Global Capitalism* (with George Akerlof, 2009), *Finance and the Good Society* (2013), *Irrational Exuberance* (2013).

Robert Shiller is an American economist who teaches at Yale University and the Cowles Foundation. His contributions to the economic community are varied and far reaching. While he has provided valuable insight into a variety of economic fields, such as financial markets, economic behavior, and others, his most recent contributions focus primarily on the stock market collapse of the early 21st century. His contributions include a direct analysis of the 2008–2009 subprime lending crisis and economic systems, both of which played a pivotal role in the current economic environment. Robert Shiller was awarded the 2013 Nobel Prize in Economics.

Robert James Shiller was born in Detroit, Michigan, on March 29, 1946. He earned his bachelor of arts from the University of Michigan in 1967 and continued his studies at the Massachusetts Institute of Technology, where he earned his PhD in 1972. His academic career includes time spent at the University of Pennsylvania and the University of Minnesota before he accepted a position in the economics department at Yale University and the Cowles Foundation for Research in Economics in 1982. He now serves as the Arthur M. Okun Professor in Economics, professor of finance, and fellow at the International Center for Finance at the School of Management at Yale University.

His extensive study of the housing market has proved to be a valuable addition to the real estate industry. The Standard & Poor's Case-Shiller Home Price Indices track changes in the housing market by evaluating those changes based on a three-month average with a two-month lag time. The data are based on the sales figures of specific single-family residences and condominiums at a variety of price points across 20 cities throughout the nation. These indices are produced and released each month by Fiserv Lending Services.

Much of Shiller's work has extended beyond the classroom and into the bookstores. *Market Volatility*, published in 1989, provided readers with an in-depth statistical analysis of markets and how they operate. *Irrational Exuberance* explored the stock market bubble of the late 1990s and its rapid decline near the turn of the century. In the book, Shiller claims that the rapid, extreme, and largely volatile stock market growth in the latter part of the 1990s led to the overvaluation of technology-based stocks. He argues that the tremendous growth could lead to an exponential catastrophic decline. His work proved to be largely correct as the economic environment rapidly changed as market instabilities prevailed and an economic decline plagued the global economy. The book was a great success, even becoming a *New York Times* best seller. This widespread popularity prompted Shiller and his publishers to develop and expand with a second edition in 2005. The second edition included his work on the housing and real estate markets, explaining how the extension of credit to borrowers would have a negative effect on the economy.

Shiller continued his exploration of the dire subprime lending situation through his work in the *Subprime Solution: How Today's Global Financial Crisis Happened, and What to Do about It. The Princeton Review* published this work in 2008. In it, Shiller provided a brief history of how the subprime lending crisis emerged and offered an aggressive, multifaceted remedy to resolve the crisis in the mortgage industry, including a substantial restructuring of the complex system. While some of Shiller's solutions are focused on the immediate and imminent crisis faced by many borrowers and homeowners, he also emphasizes the long-term need to develop a complex system of safeguards and protective measures to prevent similar situations from arising again. He claims that his solutions would promote further economic recovery and growth in the future as people strive to reclaim the American dream.

Shiller's contributions to economics are not limited to his writings; any estimation of his work must also take into account his career in the classroom and other economic associations, boards, and advisory councils. He has been a research associate for the National Bureau of Economic Research since 1980, he served as vice president of the American Economic Association in 2005, and he was president of the Eastern Economic Association from 2006 to 2007. He writes "Economic View" for the *New York Times* and "Finance in the 21st Century" for Project Syndicate. His career has provided much to the economic community in a variety of fields and specialties, and his contributions to his area of expertise are immense and far reaching.

Robert Shiller was awarded the 2013 Nobel Prize in Economics for his work on financial economics in the 1980s. He concluded that stock markets are inefficient and that one can predict stock market pricing only over a long period.

Shiller is a professor at Yale University and the Cowles Foundation as the Arthur M. Okun Professor in Economics and professor of finance and fellow at the International Center for Finance at the School of Management.

SIMON, HERBERT

Born: June 15, 1916, in Milwaukee, Wisconsin; Died: February 9, 2001, in Pittsburgh, Pennsylvania; Nationality: American; Professional Interests: economist, political scientist, sociologist, Nobel Prize (1978); Major Work: *Models of Man* (1957).

Herbert Simon was a 20th-century economist, political scientist, psychologist, and sociologist who spent 52 years pioneering new departments as a faculty member of Carnegie Mellon University. He is known for his research in the fields of economics, mathematics, computer science, and psychology, receiving numerous awards and recognitions over his lifetime, including the Nobel Prize in Economics and the National Medal of Science. Simon died in 2001.

Herbert Alexander Simon was born on June 15, 1916, in Milwaukee, Wisconsin, to Jewish parents. His father was a successful inventor and electrical engineer. As a young student, Simon developed an interest in economics and human behavior as he attended public school. He entered the University of Chicago in 1933 to study economics and received his BA in 1936. That same year, he became a research assistant with Clarence Ridley in the field of municipal administration, which then led him to directorship of a study at the University of California, Berkeley, from 1939 to 1942.

In 1943, Simon earned his PhD in political science from the University of Chicago. He gained a teaching position in political science at the Illinois Institute of Technology in 1942, where he remained until 1949. Being in Chicago, Simon was a contributor to the Cowles Commission for Research in Economics. His doctoral work became the focus of his publication *Administrative Behavior* in 1947. In it, Simon applied the theory of behavior and cognitive process to organizational problem solving.

Simon left Chicago and joined the faculty of Carnegie Mellon University in 1949, then known as Carnegie Institute of Technology. He, along with G. L. Bach and William W. Cooper, worked to establish a graduate school for industrial administration. He teamed with David Hawkins from 1950 to 1955 to formulate and prove the Hawkins-Simon theorem, a quantitative approach to the input-output analysis of an economy. Simon's 1957 publication, *Models of Man*, presented mathematical models of human behavior in social settings.

Over the course of his career, Simon received many awards and recognitions. For his research in the decision-making of organizations, Simon was awarded the Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel in 1978. He was awarded the National Medal of Science in 1986. In 1994, he was inducted into the Chinese Academy of Sciences, an honor that had been given to only 14 scientists. He was given the Award for Outstanding Lifetime Contributions to Psychology from the American Psychological Association in 1993. Simon also received awards from the International Joint Conferences on Artificial Intelligence and the American Society of Public Administration in 1995.

In 1991, Simon published an autobiography of his life, *Models of My Life*, in which he describes his cross-disciplinary work in various fields of science.

Herbert Simon died on February 9, 2001, in Pittsburgh, Pennsylvania.

SMITH, VERNON

Born: January 1, 1927, in Wichita, Kansas; Nationality: American; Professional Interests: microeconomics, experimental economics, Nobel Prize (2002); Major Works: *Experimental Economics: Induced Value Theory* (1976), *Papers in Experimental*

Economics (1991), *Rationality in Economics: Constructivist and Ecological Forms* (2008).

Vernon Smith was the 2002 winner of the Nobel Prize for establishing laboratory experiments as a methodology for empirical economic analysis and study of alternative market mechanisms. Smith revolutionized the traditional view that controlled experiments of economic theory were not possible due to the difficulty of controlling other important factors. Smith was instrumental in the use of experimental economics to study air traffic and airport management and electricity and energy trading in the utility industry and as an effective method in regulating property rights without government intervention.

Vernon L. Smith was born on January 1, 1927, in Wichita, Kansas. He was raised on a Kansas farm by his father, Vernon Chessman Smith, and his mother, Lulu Belle Lomax, under the difficult circumstances of the Great Depression. Years of struggle, unemployment, and finally foreclosure confirmed his mother's political commitment to socialism. Smith's undergraduate studies included physics and electrical engineering, and in 1949 he received his BS in electrical engineering from the California Institute of Technology. He was motivated to pursue advanced studies of economics after recognizing the correlation between the principles of physics and economics in Samuelson's *Foundations* and the reasoning found in von Mises's *Human Action*. He went on to earn his MA in economics from the University of Kansas in 1952 and his PhD in economics from Harvard University in 1955.

Vernon Smith's diverse teaching career began in 1955 at Purdue University, where he served until 1967. He went on to work as a visiting assistant professor at Stanford University in 1961–1962 and as a tenured professor at Brown University in 1967–1968 and University of Massachusetts from 1968 to 1975. In 1975, Smith moved to the University of Arizona, where he remained until 2001, followed by George Mason University, where he served as a professor of economics and law until 2008. In 2008, Vernon Smith joined the faculty as professor of economics and law at Chapman University upon founding the Economic Science Institute.

Smith began using experiments in his first year of teaching at Purdue as a tool to make microeconomic theory more comprehensible to his undergraduate students. Through Smith's induced-value experiments, students experienced actual market conditions in which price equilibrium was achieved without the participants having any knowledge of the value conditions of the other participants. Smith also observed that the efficiency of achieving equilibrium increased over several trading periods, with subsequent periods experiencing a reduced standard deviation from the theoretical equilibrium price.

Smith's continued development of experimental methodology was articulated in *Experimental Economics: Induced Value Theory* (1976) and was further expanded six years later in the article "Microeconomic Systems as an Experimental Science" (1982). Smith identifies two distinct components of a microeconomic system: the environment and the institution. The environment consists of all the participants, commodities, and characteristics within the institution and cannot be altered by the agents. The institution is the system that specifies and administers the rules and laws created within the system. The goal of the experiment is to evaluate whether the incentives created by the institution result in outcomes that are conducive to the established goals of the institution. He has authored more than 250 articles and publications.

Experimental economics has been used to solve economic problems such as determining slot allocations used by national airport management for efficient scheduling and to create new systems of electricity and energy trading that transformed the utility industry throughout the nation. Experimental economics has also been demonstrated to be effective at regulating private property rights without government intervention.

In 2002, Vernon Smith was awarded the Nobel Prize in Economics for establishing laboratory experiments as a methodology for empirical economic analysis and study of alternative market mechanisms. Smith revolutionized the traditional view that controlled experiments of economic theory were not possible due to the difficulty of controlling other important factors. The inability to empirically test traditional theory could potentially inhibit the development of economics due to the difficulty of determining the exact components or causes of success or failure of the theory. Observation of these components allows for new theories to emerge and undergo testing.

Smith received the Friedrich-August-von-Hayek-Gesellschaft Award (2008) and the 1995 Adam Smith Award. The Vernon Smith Prize for the Advancement of Austrian Economics, sponsored by the European Center of Austrian Economics, is named after him.

SNOB EFFECT

Harvey Leibenstein showed three cases in which a market demand curve is not the horizontal summation of the individual consumer demand curves. The three cases are the bandwagon, snob, and Veblen effects. A horizontal summation means that the market demand for a product at any price can be calculated by adding the amount each buyer will purchase at that price. This assumes that all buyers are making decisions independent of other buyers—they are each Robinson Crusoe. The existence of a snob effect means that consumers are not independent of each other. The snobs buy an amount that is dependent on their expectation of how much others are buying.

There are three consumers in the market for fish tacos: Moe, Larry, and Curly. Without a snob effect, the market demand curve shows that at any price, the amount purchased is calculated by adding up what Moe + Larry + Curly buy, at any price. At $5 a fish taco, Moe buys 5, Larry buys 6, and Curly buys 16 each week. The market demand at $5 is 5 + 6 + 16 = 27. We expect that at a price of $4, the quantity purchased will be more than 27; let's say that 7 + 8 + 18 = 33. At $3 the total is 39. Lower the price and one moves down the market demand curve. However, if Moe, Larry, and Curly are dependent on the others, the quantity purchased will not be the horizontal sum of the individual demand curves. Rather, how much Moe buys depends on how much Larry and Curly purchase.

Let's assume that Moe is a snob. In the bottom table, at $5 a fish taco Moe buys 5 each week if he expects Larry and Curly to buy a total of 22 (6 + 16) each week. However, if at $4, Larry and Curly buy a total of 26 (8 + 18), Moe will buy *less* than 5; let's say he buys 4. The total at $4 is now 28, not 33. And, at $3, the total is 33 (3 + 10 + 20), not 39, because Moe buys less when Larry and Curly buy more.

What do snobs do to the market demand curve? In the upper table, without the snobs, as price falls from $5 to $3, the quantity purchased rises from 27 to 39. With the snobs, quantity rises only from 27 to 33. In other words, the elasticity of

Table 1. Snob Effect

Price	Moe	Larry	Curly	Total
$5	5	6	16	27
$4	7	8	18	33
$3	9	10	20	39
$5	5	6	16	27
$4	4	8	18	30
$3	3	10	20	33

demand of the market demand curve is less price elastic, or more price inelastic. Without the snobs, the arc price elasticity of demand is –0.72. With the snobs it is –0.40.

Sometimes the snob effect is defined as the inverse relation between the quantities purchased by lower-income people with the resulting quantity purchased by higher-income people. The examples given are luxury cars or rare works of art. The problem with these examples is that lower-income people do not purchase such luxury goods. These luxury goods are valuable, at least in part, because of their high price. These goods are, therefore, purchased in order to show off one's wealth. This may lead to an upward-sloping (to the right) demand curve: as price rises so does the quantity purchased. These are known as Veblen goods, named after Thorstein Veblen, who wrote the famous tract on conspicuous consumption, *The Theory of the Leisure Class*. The snob effect can be illustrated by the behavior of Democrats and Republicans, or USC and UCLA fans. As the price of hamburgers at Joe's Burger Shack in Malibu falls, more UCLA fans (or Republicans) purchase more burgers. USC fans (or Democrats) will be seen there in fewer and fewer numbers.

SOWELL, THOMAS

Born: June 30, 1930, in Gastonia, North Carolina; Nationality: American; Professional Interests: political economy, economics, author; Major Works: *Race and Economics* (1975), *Inside American Education* (1993), *Basic Economics* (2007), *The Housing Boom and Bust* (2009), *The Thomas Sowell Reader* (2011), *Intellectuals and Race* (2013).

Thomas Sowell is an economist, author, professor, and syndicated columnist. He currently serves as the Rose and Milton Friedman Senior Fellow on Public Policy at the Hoover Institution of Stanford University. He has served as faculty at various institutions, including Cornell University and University of California, Los Angeles. He is the author of 40 books and numerous articles about politics, education, ethnic relations, and child development. He has a syndicated column that appears in numerous newspapers around the United States.

Thomas Sowell was born on June 30, 1930, in Gastonia, North Carolina. At the age of nine, he moved to Harlem, New York, with his family. He dropped out of high school as a teenager and began working various jobs. Sowell was drafted into the U.S. Marine Corps during the Korean War and served as a photographer. After his service, he attended classes at Howard University in Washington, D.C., receiving high marks and earning acceptance into Harvard University on recommendations from professors. At Harvard, much of Sowell's study was on German philosopher Karl Marx, on whom he wrote his senior thesis. He received his bachelor's degree in economics in 1958 and his master's degree from Columbia University in 1959. In 1968, Sowell obtained his doctorate degree from the University of Chicago, studying under George Stigler and Milton Friedman.

Sowell's economic career began when he became a labor economist for the U.S. Department of Labor from 1960 to 1961. He taught at Howard University and Rutgers before accepting a position as an economic analyst at AT&T from 1964 to 1965.

From 1965 to 1970, Sowell was on the faculty at Cornell and Brandeis University. From 1972 until 1974, he was affiliated with the Urban Institute. He served on the faculty at the University of California, Los Angeles, and he has served as a senior fellow at the Hoover Institution since 1980. When Ronald Reagan was elected president in 1980, he offered Sowell a cabinet position to bring a conservative voice to African Americans, but Sowell declined. He served on the White House Economic Advisory Board for a one-meeting stint for Reagan but quit because of the difficulty in traveling to Washington, D.C., from California.

Sowell's writings span a range of topics, including economics, political ideology, race relations, affirmative action, education, and child development. Known for his conservative and libertarian viewpoint, Sowell's writings have drawn criticism from liberal counterparts. Sowell's position on race and income is the theme of his 1975 publication, *Race and Economics*. In this book, he analyzed the relationship between blacks and wealth, drawing on factors from slavery, contrasting to other ethnicities, and criticizing government policies directed at blacks.

Also a strong critic of affirmative action, in his 1990 book *Preferential Policies: An International Perspective*, Sowell criticized the use of quotas in college admissions and employment. He asserted that such policies led to degraded standards and did not allow individuals to reach their full potential. His 2004 publication, *Affirmative Action around the World: An Empirical Study*, compares policies in recent U.S. history to those of other nations. His concluding arguments are that affirmative action policies have negligible effects on their intended groups and lower incentives for achievement. His work received critical reception, with some arguing that affirmative action had gone too far beyond its purpose.

Aside from his writing on economics and policy, Sowell has taken to writing on child development and education. His book *The Einstein Syndrome: Bright Children Who Talk Late* investigates the phenomenon of late-talking children, a follow-up to his earlier book *Late-Talking Children*. The research in his book argues that these children are misdiagnosed as autistic or as having a disorder, but he theorizes instead that they are simply developing other areas of the brain. In Sowell's book *Inside America's Education*, he is highly critical of the American educational system. He argues that the standards, practices, and programs used in educational institutions lack credibility, and he calls for reform.

Sowell detailed his life story in his book *A Personal Odyssey*, published in 2001. He writes about his childhood and stages of life and his education from growing up in the poor South, moving to Harlem, and eventually entering the Ivy League at Harvard. He also accounts for the vast differences of wealth that he has experienced in his life in this personal story.

In addition to Sowell's books, he is a syndicated columnist, writing for mass media. His column focuses on issues in the economy, affirmative action, government policy, and social issues from a free-market viewpoint. It appears in over 150 newspapers in the United States and has been featured in *Newsweek*, *Forbes*, and the *Wall Street Journal*. His conservative opinions often draw criticism from liberals. Some of his essays were published in his work *Ever Wonder Why?: And Other Controversial Essays* in 2006.

Sowell was a recipient of the Francis Boyer Award, given by the American Enterprise Institute in 1990. He was awarded the National Humanities Medal in 2002 and the Bradley Prize in 2003.

Sowell serves as Rose and Milton Friedman Senior Fellow on Public Policy at the Hoover Institution of Stanford University.

SPORTS ECONOMICS AND ECONOMIC PSYCHOLOGY

Behavioral economics has contributed to sports economics by placing the analytical spotlight on the importance of information complexity (information is costly and asymmetric), heterogeneity or differences across individuals in preferences and capabilities, and noneconomic variables for understanding decision-making and outcomes. This is in contrast to the traditional economic toolbox, which focuses on prices and incomes. The latter two variables remain important, but enhancing the traditional economic toolbox enriches our understanding of sports.

Some evidence exists that athletes tend to choke (are less productive) under pressure and that higher levels of remuneration contribute to choking, thereby reducing productivity. On the other hand, there is evidence that, *controlling for levels of remuneration*, many athletes don't choke but rather perform well. Much depends on the athlete's level and quality of training, experience, and confidence. Higher pay does not appear to cause choking and, therefore, lower sports productivity. But increasing pay will not reduce choking. Largely noneconomic variables determine whether or not athletes choke, having a large productivity effect, especially on critical marginal outcomes.

Contrary to what conventional wisdom predicts, fans adopt what appear to be objectively ineffective rituals to help their teams improve their performance, and athletes often do the same to improve their own performance and even to win major events. This appears to be highly irrational behavior, but these rituals seem to have a positive effect on the confidence of athletes. As a counterfactual, banning such rituals should reduce productivity, especially with regards to the athletes' rituals. Belief affects performance, even if "objectively" it should not. Even to the extent that fan rituals do not affect team or athlete productivity, they positively affect the level of happiness of the fans. From this perspective, they are rational since they enhance the utility of fans.

Athletes' behavior is often most consistent with loss aversion, meaning they are more concerned with avoiding a loss than achieving an identical-sized gain. A dollar lost has more impact on a person's level of satisfaction or well-being than a dollar gained (perhaps as much as twice the impact). Many athletes therefore expend more effort to avoid a loss compared to realizing an equivalent gain. The framing of an event as a potential loss can have greater motivational impact than when it's framed as a win.

There is evidence that, on average, athletes discount future income much more than nonathletes. Many athletes and their families heavily discount the future because they believe that the athlete will be a world champion and that his or her career will be short-lived. This often results in significant investments in the present, whilst sacrificing potential future income by reducing savings and reducing time and financial investments in education. This is especially the case for athletes (and their families) who adopt the "win-at-all-cost" approach to sports. Athletes tend to adopt this approach in the face of false and misleading information, when they are uncertain about future outcomes, and when they misunderstand the viability of alternative strategies to achieve excellence in sports.

There is substantial evidence that in the short and medium term, stock market prices do not reflect the fundamental values of the assets they represent. This deviation of asset prices from fundamental values is motivated by a variety of noneconomic variables, including the outcomes of major sports events. The home team winning causes the local stock market prices to increase; losing has the opposite effect. When people feel better about themselves and their community they gain confidence, and this impacts overall investment behavior. To the extent that investment in real assets is affected by outcomes of major sports events, one can hypothesize that these can impact on the real economy.

The stereotype of the wealthy athlete ending up as a pauper is not that far off the mark. Many athletes, earning substantial sums of money, spend it all (do not save), invest in very high-risk prospects (losing most of their investments), or have their funds stolen by unscrupulous investment advisers. Although being characterized by a high rate of time discount is a problem for some athletes, a larger problem appears to be a dire lack of financial literacy and trusting individuals who, objectively, should not be trusted. But given information complexity and lack of financial literacy, and in the absence of outside intervention (such as their team or players association), athletes all too often make disastrous financial choices.

SPORTS ECONOMICS AND PERFORMANCE INEFFICIENCIES

Behavioral economics contributes to an understanding of why and how performance outcomes of sports teams and athletes can be suboptimal and how market forces can't easily correct this inefficiency. The conventional model presumes that efficient outcomes will prevail, at least in a reasonable period of time.

There is significant evidence that organizational inefficiencies exist and often persist in sports organizations and in the piecing together of competitively successful sports teams. One good example of this was portrayed in the book *Moneyball*, where a relatively uncompetitive baseball team, the Oakland A's, adopted a different recruitment approach, paying attention to players who did not fit the accepted standard of prospective excellence. The traditional model assumed that there are only a few particular characteristics that contribute to player excellence—a one-size-fits-all approach. This is consistent with the representative agent assumption in economic theory. Such players were way too expensive for smaller franchises, so they seemed doomed to be losers given their low-revenue budget constraint. These smaller teams are assumed to be x-efficient, doing the best they can given their inputs, which are constrained by their budget.

The alternative approach, backed by statistical analysis, presumes that players regarded as subpar given their characteristics might actually be high-performance players given the right organizational mix. But given the prevailing recruitment model (what determined optimal team and player performance) these players were highly undervalued. Tapping into this player pool allowed Oakland (and other teams following this alternative model) to dramatically improve its performance. In effect, significant organizational x-inefficiency was dramatically reduced by introducing a different model of what makes for excellence in individual and team performance.

In sports, there can be significant x-inefficiencies in performance, largely assumed away by the conventional wisdom. Efficiency is linked to certain physiological and behavioral traits of players. Often, the traits of current winners are assumed to be ideal. There is a presumption of a unique equilibrium—one size fits all. There is also a small sample size bias—winning characteristics are derived from a small and unrepresentative sample. Plus, there is a clear availability bias—the data that's considered is only what's easily and cheaply available. These biases can be rational given complex and costly information. Apart from this, advocates of the status quo (experts, trainers, coaches, managers, scouts, and even athletes) have a vested interested in not changing their approach—decision-makers ignore or dismiss pertinent information. This is a form of loss aversion. There can be (or might be) a loss of power, prestige, and pride in changing one's approach to athlete selection and training. This can lock a team into an x-inefficient equilibrium unless it's shocked into another more efficient set of organizational approaches and outcomes. This approach can remain successful for wealthy teams that can purchase prized traditional talent or inputs. Other teams, with tighter budget constraints, remain financially viable in spite of being losing ventures. Such x-inefficient teams can be sustained even in the long run, through subsidies, fan support, or ownership subsidies (where owners' utility is enhanced through team ownership even while they are accruing economic loses—these are not wealth maximizers).

The performance (productivity) of athletes, whether athletes are performing at their full potential, is critically affected by human capital variables in conjunction with informational imperfection, conflicting information, uncertainty, and the capacity to understand relevant information (what we refer to as *athletic literacy*). This is similar to the variables that impact the efficiency of health care outcomes, a point elaborated upon in 1963 by Nobel laureate Kenneth Arrow. Given these realities, there can be market failures in performance outcomes.

There are different models of what determines athletes' potential performance and the pathways to achieve this potential. One perspective maintains that the potential output and even pathways are genetically determined. This incorporates the view that certain people are born to be great athletes. Body type, given one's chosen sport, yields potential performance. If trainers, coaches, and parents accept this model, they will make particular decisions on athlete selection and even training. Some young athletes even self-select out of particular sports because they don't fit genetically based models.

More recent research on genetics, brain development, the level of performance of individuals, inclusive of athletes, suggests that genes play only a partial role in determining performance. Moreover, no one individual knows what her or his potential performance is given genetic endowments—there is considerable immeasurable uncertainty here. Of equal or even greater importance to genetic endowment is the quantity and quality of training. Some argue that athletes (and others) require an average of 10,000 hours, usually over 10 years, of purposeful training (goal oriented, quality controlled with feedback, and setting higher achievement benchmarks or pushing beyond the comfort zone) to achieve high levels of performance outcomes. In other words, performance outcomes are largely a product of rigorous and persistent training; athletes are not born to be great. In addition, the parts of the brain that help determine performance outcomes evolve as a function of one's training (neoplasticity). One's capabilities are not fixed or given a priori; they are dynamically determined. Also of importance is the athlete's confidence level. Confidence, controlling for other variables, improves performance.

Whether athletes do their best and whether the best individuals are chosen to be competitive athletes often depends on the decision-makers, the model adopted in the decision-making process, and the variables that influence the decision-makers' choices. Whether the best model is chosen depends, for example, on the decision-makers' *athletic literacy*, the extent of loss aversion, and status quo bias (sticking with the status quo in the face of new information). Also, these decision-makers are typically "experts" who are trusted to make the correct choices on behalf of the athletes, in the face of information asymmetry and the uncertainty of outcomes. Moreover, parents, trainers, coaches, and others can game the selection process so that their preferred athletes are selected. This can result in underperforming athletes and the exclusion of athletes who might otherwise achieve excellence (high levels of performance outcomes), resulting in performance x-inefficiency.

STANDARD OIL CO. OF NEW JERSEY V. UNITED STATES

The Standard Oil Company was the largest and richest trust in the United States at the beginning of the 20th century. By 1904, it owned a Leviathan's share of all the oil production in the United States and had interests in other markets as well. Through a process of acquisition, Standard Oil ingested all market competition. Through vertical integration, Standard Oil controlled aspects of oil production from drilling to refining and eventually retail sales to customers. John D. Rockefeller, along with the other trustees, implemented product standardization that greatly enhanced sales by streamlining production, reducing costs, and undercutting competition. However, when power is unchecked or not limited by competition, that power has the potential to become corrupt.

A monopoly exists when one company has all the power to control the market. Standard Oil monopolized the petroleum industry. This market dominance was contrary to the principles of free enterprise, in which competition is fundamental. In this case, there were no viable substitutes, and prices could be set and supply could be minimized. Congress passed the Sherman Antitrust Act in 1890 to deal with monopolies that threatened consumers. The Supreme Court used the Sherman Antitrust Act to check the power of monopolies and restore the principles of the market. This case ordered the dissolution of the Standard Oil Company monopoly into separate firms due to unreasonable restraint of trade.

Case Summary

John D. Rockefeller came from modest beginnings, but his aptitude for mathematics and business helped him become one of the richest men in the world. His relationship with Standard Oil began as a partnership between himself, as an expert on running a corporation, and Samuel Andrews, who knew the petroleum industry. Competition in the fledgling oil industry was fierce. However, Rockefeller had a plan. He gathered a few partners: S. V. Harkness provided financial assets, H. M. Flagler had the power to get the railroads to cut their rates so the company could ship oil at a cheaper cost than competitors, and his older brother William Rockefeller provided a refinery. These partners formed a group of trustees that ran the company for shareholders. Through a series of acquisition strategies, the company carved out a solid foothold in the oil industry. This foothold led to a stronghold and finally a stranglehold.

During an early skirmish in the battle for total control of the oil industry, Standard Oil fought the Pennsylvania Railroad. Standard Oil had had the foresight to invest in various means of transport for its oil. It turned to new methods, such as the pipeline and the railroad tank car. In addition, anticipating the competition, Standard Oil developed its own ships, docking facilities, barrel-making plants, warehouses, and everything else connected to the manufacture, distribution, and sale of its product. Because the company did not need to rely on other businesses, the railroad eventually capitulated to Standard Oil and the monopoly was near perfect.

However, the government was slowly catching up with legislation that prohibited companies from owning the stock of another company. This made the reorganization of Standard Oil necessary. A new business arrangement emerged in the early 1880s whereby shareholders assigned their shares to trustees who held the decision-making power of the company. These new organizations became known as trusts, but soon the technical term was less important than its reputation. Many Americans believed trusts suppressed competition and led to collusion and price setting.

Meanwhile, journalist Ida Tarbell published a series of articles systematically chronicling the misdeeds of John Rockefeller and Standard Oil. *McClure's Magazine* ran the 19 articles from 1902 until 1904. Later they were compiled in a book, *The History of the Standard Oil Company* (1904). Tarbell's own father owned one of the small refineries forced out of business by Standard Oil. This condemnation added to the political pressure for government to do something about these trusts.

President Theodore Roosevelt, known as the "trust buster," encouraged the commissioner of corporations to study Standard Oil's undertakings. By 1900, Standard Oil had morphed into a holding company based in New Jersey in an effort to keep a step ahead of antitrust laws. Rockefeller had retired from active control of the company to focus on his philanthropic endeavors. At the conclusion of the government's investigation of Standard Oil, it confirmed that the trust participated in unfair competition practices and had violated the Sherman Antitrust Act. In 1909, the U.S. Department of Justice sued Standard Oil in the Circuit Court of the United States for the Eastern District of Missouri. The circuit court ruled against Standard Oil. Standard Oil of New Jersey plus 33 other holding companies, along with Rockefeller and the other trustees, appealed the case to the Supreme Court. The Court agreed to hear the case in 1910, and arguments were heard the next year.

A corporation is a legal entity that protects individual owners from the consequences of company actions. In the case of *Standard Oil Co. of New Jersey v. United States,* 221 U.S. 1 (1911), the responsibility of the Supreme Court was to determine if the Sherman Antitrust Act had been violated. The government claimed Standard Oil was an unreasonable monopoly. Standard Oil would get cheaper shipping rates and other companies would be charged higher rates regardless of distance traveled or weight, resulting in an unreasonable advantage over competitors. In addition, Standard raised prices where there was no competition and its customers had no other choices. Furthermore, it used fake companies that did not appear to be owned by Standard Oil to drop the prices of its product when competition was plentiful, starting a price war that the competition would not win.

In response to these allegations, Standard Oil disagreed upon the construction and application of almost all sections of the Sherman Act but particularly the first and second sections referencing "contract in restraint of trade." The words were vague and unclear. The company argued that the framers did not have the dismemberment of companies in mind when they included the commerce clause in Article I of the Constitution. Standard Oil produced a laundry list of underappreciated contributions. Through its better quality of goods and uniform standards, Standard Oil improved the daily lives of citizens by providing kerosene to heat and light their homes. Furthermore, in an effort to be more efficient, the company used the refinery by-products and created new uses such as paraffin wax, lubricating oils, and heating oil. In addition, it improved the environment by recycling the sludge into fertilizer for farmers instead of dumping it into the ocean. The bottom line was simply that if left alone, the market regulates itself. Standard Oil reinvested its profits into expansion, innovation, and efficiency, resulting in a benefit for the general welfare.

Chief Justice White wrote the opinion of the Court. He expressed the necessity to clarify words and terms that had meaning from English common law. Terms such as *freedom to contract* had changed over time in response to the injurious consequences of monopolies. He concluded that Congress has the right to set definitions of what a trust is as well as to prohibit restraint of trade in accordance with Article I of the Constitution. However, White briefly stated concerns about the lower courts' decree in that modifications should be made in accordance to the amount of harm or danger it may have on the public. Oil was a vital resource to people all over America, and any disruption in that market could have negative effects on the general welfare. The Court affirmed the lower court's decree with the modification that the dissolution should not affect the safety of the public. Consequently, the breakup of Standard Oil mirrored somewhat the breakup of AT&T, where the former spawned baby Standards and the latter baby Bells.

The penalty for being found guilty of conspiring to set prices and engage in unfair labor practices actually increased John Rockefeller's fortune. The price of his stock went up, and his spinoff companies became more valuable than the original.

In the case of Standard Oil, the dissenting opinion of Justice Harlan clearly expressed the idea that the Court had no business interpreting what Congress meant when it passed regulatory legislation. Nor did it have any business discussing the merits of policy passed by Congress. Harlan asserted for the minority that only Congress can make laws, and only it should make clear what it intended that law to mean.

The lack of specificity in wording of the Sherman Act made it difficult for the courts to enforce while giving Congress the benefit of appearing to be tough on monopolies. This case made Standard Oil synonymous with "trust busting." It propelled Congress to clarify the antitrust legislation and three years later pass the Clayton Antitrust Act of 1914.

STATUS QUO BIAS

Status quo bias is one of the most powerful behavioral economic phenomena. It is defined as a preference for choice options that are the most obvious or usual, for example, the first item appearing in an Internet search, even if other options are better. Preference for the status quo is frequently nonrational (from a conventional economics perspective) because it depends on which option constitutes the status quo. Hence, changing the status quo may cause preference reversal.

Several economic and psychological factors may drive the status quo bias: (1) preference stability often results in a "naturally" preferred alternative that becomes the status quo, for example, one's regular gas station; (2) transaction costs of changing the status quo may result in relatively few deviations, for example, sticking to one's current stock portfolio; (3) uncertainty about the consequences of the non-status quo option may lead to choice of the status quo option; (4) one may believe that a status quo option is presented because it constitutes the best available option from a supplier, for example, the default type of car insurance; (5) deviations from the status quo may lead to anticipated regret that should be avoided, for example, switching between service providers; (6) status quo options may act as reference points, deviation from which is considered as a loss—the loss being considered as more painful than the forgone gain experienced by choosing the status quo, according to prospect theory; (7) anticipated blame of others for not choosing the status quo option may influence choice; (8) status quo options may be chosen in order to reduce anxiety caused by uncertainty about the value of choice options. Anxiety may be due to difficult-to-make value trade-offs between positive and negative aspects of the choice options as, for example, staying married or getting divorced. The first three factors may be considered rational, but the other factors are not, according to standard economic theory.

Status quo bias is related to two other instances of decision avoidance: omission bias and choice deferral. Omission bias is a preference for no action, resulting in choosing the default option, for example, the clause "Yes, I would like to be informed about product information" marked as the default option in an online transaction. In cases where the default option equals the status quo, status quo bias and omission bias are the same. In fact, both are influenced by the same factors mentioned above. Choice deferral is a preference for delaying the choice, for example, in order to find better alternatives, avoiding responsibility for the choice or refusing to make a choice. Choice deferral is caused to a large extent by the difficulty of making a choice.

Examples of status quo bias abound, both in experimental and field research. Frequently cited examples from the laboratory or from surveys are choice of investment portfolios (status quo being an inherited portfolio), topping up a pizza (status quo being the empty pizza) or scaling it down (status quo being the full pizza), and status quo government policies (such as voting by mail or in person). Examples from the field are insurance choices biased toward options presented as the default (from which one can deviate easily and without cost), default pension schemes for employees and default contribution rates, and opt-in versus opt-out organ donation systems in various countries.

Default options can be changed effectively by legal and commercial institutions and are considered "lightly paternalistic" because they still allow people to make free choices. However, this kind of "nudging" may in some cases be considered unethical. For example, an opt-out system for organ donation may be considered as violating the individual's or the relatives' right to make decisions about the body. Also, an opt-out system would be incompatible with the fact that organs are situated in the body of the donor at the time of death. The switching test and the reversal test are two commonly used methods to eliminate the status quo bias when deciding whether opting in or opting out is the preferred system. The switching test requires one to imagine the alternative option (opting out) as the status quo and then consider the arguments for changing back to the actual status quo. The reversal test is based on imagining a change in the opposite direction as the deviation from the status quo, for example, by increasing the transaction costs of a donation. If the reversal is rejected, the optimality of the current status quo may be questioned, which may eventually lead to the acceptance of the alternative opt-out system. Given the known power of the status quo bias, these methods might eventually lead to a reconsideration of current status quo options in legal and commercial systems.

STIGLER, GEORGE

Born: January 17, 1911, in Renton, Washington; Died: December 1, 1991, in Chicago, Illinois; Nationality: American; Professional Interests: microeconomics, price theory, economics of information, government regulation, Nobel Prize (1982); Major Works: *The Theory of Competitive Price* (1946), *The Organization of Industry* (1968).

George Stigler was a scholar, teacher, and author, and his contributions to the field were immense. Stigler's primary contributions to economics were in the fields of price theory, economics of information, government regulation, and organization of industry. Stigler wrote many articles and books during his tenure in academia. His emphasis on microeconomics and empirical data changed the direction of economic study during the second half of the 20th century and even drove the development of new areas of exploration, such as organization of industry, economics of information, and capture theory. Stigler died in 1991.

George Joseph Stigler was born in Renton, Washington, on January 17, 1911, the son of two European immigrant parents. He attended public schools throughout grade school and upon graduation attended the University of Washington. Stigler earned his bachelor of arts in 1931 during the early part of the Great Depression. The challenging economic times led Stigler to apply for and receive a fellowship for graduate studies at Northwestern University in Illinois. He earned his master of business administration in 1932 before continuing his education at the University of Chicago during the mid-1930s. He earned his PhD in 1938.

While obtaining his education in Chicago, Stigler worked with and was greatly influenced by W. Allen Wallis and Milton Friedman. He was part of an economic movement during the 1930s and 1940s that altered the way people viewed economic policy and decision-making. Stigler taught at a variety of colleges and universities for over five decades, including Iowa State College, University of Minnesota, Brown University, Columbia University, and the University of Chicago. Stigler held positions with several organizations, including the Mont Pelerin Society, the American Economic Association, and the National Bureau of Economic Research.

The Theory of Competitive Price was one of Stigler's earliest works, published in 1942. He wanted to know how the real world operated and used this book as an inquiry into this realm as he tried to mesh price theory with authentic observation. His goal was to test theories with real-world data and research.

In 1947, Stigler was one of 36 economists, including some of the most influential economic minds of the time, selected by F. A. Hayek to attend a meeting in Switzerland to discuss the dangers facing the free-market system. The Mont Pelerin Society formed at this monumental meeting of academic elites to research, renew, and promote the key principles of a free society. Stigler served as president of the group from 1976 to 1978.

Stigler's most prized contribution to the field of economics is arguably his article "The Economics of Information." He believed that information itself was largely overlooked and undervalued. His study of price dispersion and advertising changed that. According to Milton Friedman, Stigler had a way of explaining familiar things in a unique and insightful manner. Stigler's study of information prompted many other scholars to follow and began a new discipline within economic circles.

Stigler's curiosity about how the real world worked guided much of his research. Government regulation and its effects were one of Stigler's curiosities. He understood that government regulation was intended to help people, but there was a substantial lack of data and research on the topic. Stigler wanted to go beyond just the effects of regulation and understand its causes. He studied a variety of topics, from the markets for electricity to securities. As a result of his data-driven studies, he developed a greater skepticism about the role of government in the economy. He claimed that government influence had little effect on prices and in fact harmed consumers and created monopolies in some instances. This general idea is known as the *capture theory*. The businesses that benefit from regulation will capture more of the market than their competition will. Through regulation, he claimed, the government interfered with competition, therefore generating monopolies in the market. His work led to the emergence of public choice economics. His influential study gained considerable support in the economic community and led to the deregulation movement of the Carter administration in the late 1970s.

The Organization of Industry, a collection of 17 of Stigler's articles, was published in 1968. Stigler used empirical data to test theories related to various aspects of the organization of industry and other topics, most notably evaluating past economic policy and offering recommendations for future policy.

The Nobel Prize in Economics was awarded to George J. Stigler in 1982 for his comprehensive and exhaustive study of the causes and effects of government regulation.

George Stigler died on December 1, 1991, in Chicago, Illinois.

STOCK MARKET

A stock is a share of ownership in a company. Companies offer shares of their ownership in order to raise additional sources of capital. In the U.S. market, individuals invest in the stock market to save for retirement and other long-term financial goals.

The stock market, also called the equity market, is the aggregation of buyers and sellers exchanging stocks. The stock market has grown to become a multitrillion-dollar market. The full spectrum of asset classes available to investors offers a variety of risk and return profiles, and the stock market remains relatively attractive. In 2013, the S&P 500, the stock market index composed of 500 large U.S. companies, soared by nearly 30 percent.

The Stock Market as a Source of Funds for Companies

Before tackling the stock market from an investor's perspective, it is critical to understand the essence of the market and its function as an important economic agent.

The stock market is an important place for companies to raise funds. The first time that a company decides to raise money through the stock market is called an initial public offering or IPO. This offering happens in a primary market and is orchestrated by investment bankers. Once the IPO is completed, the stocks continue to trade in the stock market (secondary market).

By listing their stock in the stock market, firms become public corporations. A public corporation's goal is to maximize shareholders' wealth. As a result, the value of the stock becomes the essential metric to assess the corporation's success.

Companies can raise funds by issuing equity or by borrowing money in the debt markets. While debt is usually considered cheaper than equity, because interest expenses are tax deductible (unlike dividends, for instance), increasing debt is not always optimal when it comes to managing the firm's capital mix. Managers will seek the right balance between debt and equity, and this balance can be found by issuing more money in the stock market.

The Stock Market as a Mirror of the Economy

The stock market is often considered a good proxy for the U.S. economy. A positive trend in the stock market often translates into a positive trend in GDP growth, a positive consumer sentiment, a strengthening housing market, and positive trends in most of the macroeconomic drivers. Investors reward stocks of companies with good growth prospects. As a result, the aggregation of all the stock should approximate an aggregation of growth prospects for all the companies. Also, stocks' performance, when divided into sectors, industries, or other categorizations, can offer insights on how a particular group is anticipated to behave.

How to Invest in the Stock Market

The U.S. stock market offers a diversified range of investment options. Investors can choose to buy stock of companies with different categories of market capitalization or size, different sectors appurtenance, different positions in the business cycle (growth companies; mature companies), different exposure to the global marketplace, different risk profiles, and so on.

Before investing in or purchasing a stock, the investor needs to analyze the company. The investment analysis to conduct when investing in the stock market will depend on whether you are investing in many stocks or one security alone. When looking at one particular stock, it is very important to understand what causes stocks to appreciate or depreciate. When valuing stocks, investors always consider the ability of the firm to create future value. The ability of the firm to generate future cash flows will be rewarded by an appreciation of the value of the stock. The methods used to value a stock will differ depending on the company. The reader interested in stock valuation methodologies should consult literature about valuations. Professor Aswath Damodaran at NYU Stern has a website with all the stock valuation models.

When valuing a firm, it is important to keep in mind the key drivers of growth associated with the business model. For example, if the investor is looking at a pharmaceutical company, the competition around the drugs and the patents associated with the drugs are key drivers of the top line. When looking at a biotechnology firm, the value of its research pipeline and its ability to innovate as well as the regulation of the drug industry will be critical to make financial forecasts.

The equity analyst should be familiar with business analysis, accounting, and financial statements analysis and be able to intelligently analyze special trends in the industry in which the company is involved. Different investors of the stock market have different investment philosophies and value different signals and drivers. New trends in equity investments also involve high-frequency traders who use advanced technologies to make money by reacting very rapidly on small changes that happen at the stock level.

Equity Portfolios

When you invest in many stocks at the same time, you are building an equity portfolio, and the relationship between the different stocks requires an additional overlay of analysis. For example, investors who are trying to build a portfolio with an exposure to all the sectors will have to think about the allocation of their money in every sector. Also, investors usually invest in a portfolio of stocks versus one stock alone as a way to diversify their investments and reduce the risk of holding one very volatile security.

The principle of diversification is based on the fact that if an investor is able to find companies that are uncorrelated, when one of them is being hurt financially, the others will be able to offset the investment loss. When managing a portfolio of equities, portfolio construction becomes as important as the selection of stocks. Also, building a portfolio can be a way for investors to incorporate their macroeconomic outlook to the investment process. For instance, if an investor thinks that oil prices are going to increase because of a shortage in the supply due to increasing turmoil in the Middle East, he or she might buy stock in oil companies that generate their revenues by selling oil and sell stock in companies that use oil as a raw material. Institutional investors who manage portfolios of equities will usually use an existing index as a benchmark for their stock-picking skills. For example, investors who focus on large U.S. companies will assess their stock-picking skills by comparing their returns to the returns of the S&P 500 index.

Most consumers invest in the stock market by purchasing mutual funds instead of individual stocks. As discussed in the mutual fund entry, these investment vehicles allow investors to pool their money with others and buy a basket of stocks managed by a professional. This gives consumers exposure to investing in the stock market without the responsibility or effort of researching and buying and selling individual stocks.

STOCKS

A stock, also called an equity, is a financial security that represents an ownership stake in a publicly listed corporation's equity. A corporation can finance its operations by using debt or equity. Debt means borrowing money. Equity refers to the nondebt cash injected into the company by the owners and investors.

The terms *stocks*, *shares*, and *equity* are often used interchangeably. There are two types of stock: common stock and preferred stock. Common stock confers voting rights on the stockholder on top of receiving cash payments called dividends. Preferred stockholders do not have voting rights but have seniority over common stockholders. Seniority means that preferred stockholders receive dividend payments before common stockholders. It also means that in case of bankruptcy or liquidation, preferred stockholders are paid prior to common stockholders.

A public corporation's goal is to maximize shareholder wealth, and the value of the company's stock is a good proxy for shareholder value. Thus, every corporation will make financial decisions that will increase its stock price. When a consumer purchases stock in a corporation, he or she becomes a partial owner. When the corporation prospers, share price goes up, and the stockholder makes money.

Equity Financing

Corporations can use equity, debt, or both to finance their operations. The proportions of debt and equity define the capital structure of the corporation. Debt financing is generally cheaper than equity financing because debt expenses are tax deductible. However, debt is not always available to corporations, and using too much debt can alter a corporation's financial strength. If a corporation has too much debt and experiences a drop in sales, the interest payments may be too great to handle. That is why it's important for corporations to maintain reasonable debt levels.

Public corporations are able to raise money by issuing new shares of equity. In order to issue new stock, corporations need to use investment bankers who orchestrate the new issue by underwriting the stocks and organizing the primary sale in the stock market. For example, Twitter and Facebook recently issued stock and began trading in the public stock markets. Investors can buy shares in these newly issued stocks and become part owners.

Investing in Equity

Most retail investors invest in the secondary market by buying or selling shares of stocks from equity retail brokers. Investors will buy a company's stock if they think that the value of the company will appreciate over time. The gains made by holding a stock and selling it at a higher price are called capital gains. Investors will also buy a stock if they think that they will receive dividend payments. The total gains or losses incurred by a stockholder are calculated as the sum of capital gains and dividend payments. For example, if an investor buys company ABC stock at $100 and then receives $10 in dividends and sells it for $200, the total gains are $110 comprised of $100 capital gains and $10 from dividend gains. If we divide the total gains by the initial investment, we calculate a total return of 110 percent.

Equity Valuation

In order to make profitable investments, investors need to educate themselves on the stock they are choosing and to value the company in order to derive the value of one share of the equity. Fundamental equity valuation has evolved to become a whole industry comprised of analysts who thoroughly follow a universe of stocks or a particular industry.

In order to value a stock, an analyst prepares financial projections for the company drawing on his or her forecasts of the economy, the industry, and the revenue drivers. Once future cash flows are projected, they are discounted to the present to derive the equity value. This equity value divided by the number of shares outstanding is equal to the intrinsic value of a stock. If this intrinsic value is higher than the market price, investors should consider investing in the stock, and if it's lower than the market price, they should not consider investing in it.

Although equity or stock valuation sounds straightforward, it is based on assumptions and future projections. The intrinsic value is very sensitive to the assumptions made about the future; this is why the stock market is considered a barometer of investors' sentiment about the economy.

Another way to value a stock is to compare it to the stock of a similar company. If a comparable stock trades at a certain multiple of its earnings, we can assume that our stock would trade at the same multiple of its earnings. For example, if company A trades at five times its earnings per share, and we know that comparable company B's earnings per share are $2, then we can price company B at $10 per share. We can also use multiples of revenues or any other fundamental measure. Most analysts will apply different valuation frameworks and take some weighted average of the results as the intrinsic value. As mentioned earlier, it's essential to have knowledge of a stock and its industry to conduct equity valuation. In addition to fundamental equity valuation, there are many other methods to value stocks, such as quantitative analysis and technical analysis.

Risk

When investing in a stock, investors expose themselves to two kinds of risks: systematic and nonsystematic. Systematic risk refers to how the stock moves when the market fluctuates. Systematic or market risk is common to all stocks. For example, a major disaster such as a tsunami in Japan will likely impact all stocks in Japan. This risk is captured by a measure called beta. Beta measures the comovement of a stock with the market. Market risk is inherent in all stock investing and cannot be diversified away. In other words, no matter how many stocks are in an investment portfolio, systematic or market risk remains.

The second type of risk is related to the company's specific risk and is called nonsystematic or firm-specific risk. It is measured by the company's volatility, which is commonly calculated as the standard deviation of historical returns. Unlike systematic risk, stand-alone risk is diversifiable. This means that by investing in negatively correlated stocks, an investor can hold a portfolio that is overall less risky than investing in one stock alone because the different holdings' stand-alone risks will cancel out.

For example, if we know that when company A is profitable, company B does not perform well, we can say that these two companies are negatively correlated.

Thus, company A and B stock prices will tend to move in opposite directions. If we hold a portfolio composed of company A and company B, we are offsetting movements in company A by movements in company B, which makes our position less volatile than holding a single stock. When investing in stocks, assessing risk is as important as the valuation.

Investing in the stock market offers individuals an opportunity to participate in the growth of corporations and offers companies a ready source of funding.

STUDENT LOAN MARKETING ASSOCIATION (SALLIE MAE)

The Student Loan Marketing Association (also known as Sallie Mae) is a financial services organization whose primary function is to provide student loans. Sallie Mae is publicly traded on the New York Stock Exchange. Sallie Mae was incorporated as the Student Loan Marketing Association in 1972, originally as a government-sponsored enterprise. In 2004, Congress ended Sallie Mae's federal charter, allowing it to become fully independent. Sallie Mae owns the debts of millions of students, approximately 25 percent of all U.S. student loans, totaling over $150 billion of debt. In 2013, Sallie Mae had a profit of $1.4 billion.

The federal government's purpose in supporting Sallie Mae was to direct credit toward those seeking student loans. Sallie Mae has been credited with allowing millions of students to borrow as they pursued their education. Sallie Mae has also been cited in numerous controversies, especially in the wake of the U.S. financial crisis that began in 2007.
