Preface

When I was in graduate school a professor described the subject of economics as the "clothesline of life." There were several meanings to his phrase. One, there are many ways to approach the world of economics. Two, economics is a living, breathing discipline we use to play out our lives every day. Economics is part art, part science, part history, and all human behavior. If one digs down into the subjects of life, one will find a component of economics in virtually every subject. Economics surrounds us daily. *Economics: The Definitive Encyclopedia from Theory to Practice* has been created in a way to make economics come alive. Within our four volumes, including the comprehensive glossary, document excerpts, and other appendices, *Economics: The Definitive Encyclopedia from Theory to Practice* explores all corners of economic history, the individuals who gave economics life, the economic events that have shaped our world, and the foundational concepts and ideas that make, define, and sculpt our economic world.

We began this project with several goals. Our first, and most important, was to assemble a comprehensive and varied collection of entries on economic history, personal finance, money and banking, environmental, and behavioral economics, to name a few of the subdisciplines that hang from the "economics clothesline." An extension of that first goal was to provide a comprehensive, readable, one-stop resource for the general reader as well as for students, teachers, and researchers of economics, personal finance, and entrepreneurship.

To do so required assembling a diverse collection of economics material. Contained within the four volumes of the *Definitive Encyclopedia* are the people who laid the groundwork for economics as a science, the historical events upon which economics grew, and the concepts and ideas on which they built their legacy. I strongly believe we have accomplished these goals.

Volume 1, Foundations of Economics, is the "economics clothesline." In Volume 1 we present the people, concepts, history, the events, and places and institutions on which economics is built. It includes basic economic concepts such as opportunity cost and marginal analysis. Also included are the business tycoons who shaped the early U.S. economy, such as Henry Ford and John D. Rockefeller. No book on foundations of economics would be complete without the economists who laid the groundwork for economics such as Adam Smith, John Maynard Keynes, and Friedrich Hayek. Not to be forgotten are the political leaders whose contributions to their respective economies during their lives is still with us today, including U.S. president Ronald Reagan, Great Britain's Margaret Thatcher, and the Soviet Union's Joseph Stalin.

Volume 2, Macroeconomics, is our big picture volume. As the title suggests, Volume 2 focuses on the institutions, people, events, and places that have shaped the roles and responsibilities of the economy as a whole—the macroeconomy. Volume 2 presents the different methods and ways in which economies are measured and also explores government's role in the economy. Macroeconomics is about the institutions that measure our economies, such as the Bureau of Economic Analysis (BEA) or the Bureau of Labor Statistics (BLS). Key political figures such as Winston Churchill and President Franklin D. Roosevelt are featured for their economic contributions to world history.

Volume 3, Microeconomics, takes on markets, prices, and looking at the economy under the proverbial microscope. Volume 3 presents how markets function and the institutions that allow markets to work more efficiently and equitably for both the producer and the consumer. In Volume 3 you will find the concepts, economists, institutions, and historical events along with major market events such as the transitioning of the automobile industry and the economic bubbles, such as the "dot-com" bubble, that have determined the behavior and interaction of producers and consumers in today's modern economy. In Volume 3 we explore subfields such as environmental economics with entries such as "Tragedy of the Commons," "Clean Water Act," and "Clean Air Act," along with other environmental issues. Personal finance is a highlighted subfield in the "Annuity," "Debt Credit Counseling," and "Health Insurance" entries.

Volume 4, Global Economics, is the volume of the future. Volume 4 encapsulates the first three volumes in the context of an ever-growing global economy. Barring a cataclysmic event, today's world will continue to get smaller and smaller, translating into a more global economic community. Volume 4 includes concepts such as "Comparative Advantage" and "Balance of Payments." Volume 4 introduces the reader to the individuals changing the world, such as Muhammad Yunus and his Grameen Bank. As the new rules of a global community take shape to include all of the world's 7 billion inhabitants, at the forefront of those conversations and debates are the global institutions: the International Monetary Fund (IMF) and the World Bank, along with the United Nations.

Of equal value to the teacher, student, and researcher are primary documents in economic history; a list of Nobel laureates in economics; a timeline of economic events; and a glossary. The Primary Documents section includes 27 documents, such as the Tariff Act of 1930 and the Financial Reform Act of 2010, better known as the Dodd-Frank Act. The *Definitive Encyclopedia* would not be complete without highlighting some of the most important documents that have shaped the economic landscape of the United States. The Appendix of Nobel laureates highlights those individuals who have changed the course of economics. The Timeline presents key events in the global economy from 1776 to 2016. The Glossary presents a second layer to the all-inclusive nature of the *Definitive Encyclopedia*. Approximately 1,000 additional concepts, people, and events in the Glossary go beyond the four volumes' 850-plus entries.

Throughout my career in economics and economic education one of my main concerns has been that economics often has been presented as a subject beyond the scope of the average reader. In compiling *Economics: The Definitive Encyclopedia from Theory to Practice* we took aim at that notion head-on. Our goal was to bring to both the general and experienced student of economics a readable source to better understand the economic world around them. I strongly believe we have succeeded in this goal.

Of course, a project of this magnitude would not be possible without a team of highly dedicated contributors. I owe a huge debt of gratitude and big thank-you to the contributors without whose efforts this project would not have succeeded. My team of contributors possessed the quality and expertise needed for this project. As some of the best college professors and high school AP economics teachers anywhere, they represent all that is good about economic education. I am humbled they would give of their precious time to be part of the team. I owe them a major debt of gratitude. I owe a debt of gratitude as well to Jillian Davidson for her research and editing assistance.

I would like to thank Brian Romer for bringing me onto this project and then passing the baton into the capable hands of Hilary Claggett, Patrick Hall, and the rest of the ABC-CLIO team who had a hand in this project's development. Thanks for making us look good. I also need to thank my many colleagues, students, and friends who also provided support, feedback, and a kick in the pants when necessary. Most of all I need to thank my family and friends for putting up with me during this time. There were times I was a bit like the candy bar commercial. I owe a big thanks to each and every one of them for their patience and understanding. Finally, I dedicate this project to my mom and my four daughters—Branda, Laura, Jillian, and Mary. They say behind every successful man is a woman. Well, I don't know about being successful but I do have five very precious women behind me. This is for you.

Introduction to Volume 1: Foundations of Economics

Economics is a word that conjures up different meanings for different people. If one were to stand on a street corner with clipboard in hand (or in today's world, an iPad) and ask 100 individuals the first thought they have when they hear the word *economics*, the array of different responses would be vast. Some would state "money," while others might mention "inflation" or "markets." Of the 100 individuals, most certainly some would respond, "I don't know." Other than the "I don't know" group, all the other responses would probably be partially correct in that the response would have something to do with the economy. But an absolutely correct response would probably not be in the group of responses—or it would be in only be a few of the responses. If it is not money, or inflation, or markets, then what is economics? Glad you asked.

How many of the 100 individuals would have responded with "decision-making"? Possibly a handful who have had a good economics course. In its purest form, economics is the science of decision-making. The world of economics is the constant battle between (1) the human condition of always desiring goods and services and (2) the ever-present condition that the resources available to produce them are limited. Pitting the human desire for unlimited wants against the limited resources available to produce them presents a conundrum. People have to make decisions about where to allocate those precious limited resources to the goods and services they desire most. Notice that in economics, *want* is a noun, even though we still use the word as a verb. Because we live in a world of scarcity, people have to choose.

Having to choose is one of the core principles of economics. Economics, therefore, is the science of decision-making. How we make decisions is vitally important to us, because it will determine how we use our valuable, limited resources. However, there is a second part of the decision-making story that is just as important as choosing: the question "What are we willing to give up?" When we make a decision, two events occur simultaneously. First, we make a decision to do something. This may be as minor as going to the movies or buying a hamburger. It may be a major decision like going to college, asking that special someone to marry, or choosing a career to pursue. In all cases, a second principle of economics is at work: Every decision we make has a cost.

Economics is not only the science of decision-making, where we decide what we are going to do or buy, where we are going to live or work, and so on. It is just as important to understand that with each decision, we are going to give up the opportunity for another action with those same resources. In economics, the alternative we give up is called the *opportunity cost*. We forego the opportunity to have another item in favor of the one we choose. An opportunity cost is the next best alternative *only*; it is not *all* the alternatives.

Remember the collision between unlimited wants and limited resources? The bottom line is that we can't have it all. Because our resources are limited, every time we choose to do one thing, we are giving up the opportunity to do something else. When people go into the local fast-food hamburger restaurant with one dollar, they can have a hamburger, French fries, a milk shake, or a soda. They just can't have them all. One of these items will be chosen, a second one will be the opportunity cost, and yet another one was not an option. For people who are more hungry than thirsty, the shake and the soda are not really options, even though they are on the menu.

Economics, as the science of decision-making, leads us to the study of how to make decisions in the most efficient and effective way, so that we use the smallest amount of our limited resources at the same time that we receive the greatest amount of goods and services. This dilemma applies not just to individuals, but to organizations and social structures as well—to families, to businesses, and to governmental units, whether local, state, or federal. It applies to everyone and everything, even though people sometimes act like they are immune to these two basic economic principles. We all have to make the same choices. With every choice we make, we are giving up the opportunity to choose something else.

Decisions are often made based on emotion or desire, and not economics. All decisions have a third principle, in that all decisions have consequences that lie in the future. The future may range from shortly after the decision is made to as far off as a generation, or longer. Consequences can be positive or negative. Throughout economic history, decisions were made long before the consequence was realized. For example, in *The Wealth of Nations*, Adam Smith's view was that private property and the invisible hand were the positive consequences of generations putting nationalism ahead of individualism. Another example: Adolf Hitler was elected in 1933, partially as a consequence of the result of World War I and the winning nations' desire to impose heavy war reparations upon a losing Germany. And another: The near collapse of the U.S. domestic automobile industry can be traced back generations to the decisions made during bargaining between the unions and the automakers. Time is not a factor.

Knowing that a decision comes with an opportunity cost and a consequence is a good start. Opportunity costs and consequences, however, are not the entire story. If we want to avoid regretting a decision because we didn't consider the opportunity costs or future consequences in advance, then how decisions are made becomes critically important. Decision-making can be as straightforward as weighing the expected costs of a potential decision against its expected benefits. Decisions can be approached in a more complex, quantitative formula. A decision tree identifying possible outcomes with their costs and consequences is a form of decision-making.

A population that is economically literate is a population that explores the expected costs and consequences before making a decision, not experiencing the consequences or realizing that the decision costs were too high after the decision was made. All of us have made decisions based on emotions or on a desire to have a good or service. But the realization that we can control, in some manner, how we are affected by decisions can go a long way toward creating an economically literate society. Of course, there can be consequences or costs that we did not consider. We often hear of these unintended consequences in the political world. As individuals we can certainly experience them. But having the foresight to consider the costs and consequences, as well as the benefits, can go a long way toward producing a society that allocates our precious limited resources efficiently.

Ask any builder what is the first thing needed for any structure to last; the response will be "a solid foundation." Every subject taught in school has a foundation on which it is based. To learn advanced math, we must first learn how to add, subtract, multiply, and divide. Any of the sciences have principles and foundations upon which the advanced subject matter is based. Economics, too, has its foundation.

A

ACCOUNTANT

An accountant is an individual who is integral to the functioning of U.S. (and international) businesses. This individual measures, discloses, and/or provides financial information professionally. The accountant's findings are provided to managers, investors, tax authorities, and others. This information is used to assist decision-makers with financial resource allocation.

The accounting duties for companies include performing audits and creating financial statements and analyses. This information is crucial to the proper functioning of modern business. A business needs to understand how much money is coming in and going out. Financial records must be maintained and properly updated for tax reporting as well. Firms either employ their own internal accountants or contract their accounting work to specialized organizations.

Individuals frequently hire an accountant to assist with complicated personal financial decisions as well as tax preparation.

Accountants Skills and Job Tasks

All financial transactions, record-keeping, and analyses fall under the accountant's responsibilities. An accountant's duties in a company span payroll, cash collections, payments or disbursements, procurement, inventory, and property accounting. Preparing the company's budget and financial statements is another common accounting responsibility.

Payroll is the task of managing the salary and wages of every employee. This massive responsibility includes maintaining accurate work records, calculating gross and net pay. As a quick explanation, *gross pay* is the total amount earned before any deductions such as taxes, Medicare, or Social Security payments. The *net pay* is the amount of pay left after normal deductions. This is the money that remains for the employee to spend and save.

It's not unusual for new workers to suffer a shock when they find out their promised $13 per hour pay is really closer to $10 per hour after all of the deductions are factored in. The $520 per week income they earned is reduced to $400 for them to spend and save. Fortunately for the accountant, there are many computer programs that assist with the payroll process.

The cash collections responsibilities require the accountant to identify, record, and monitor all cash transactions. In addition to the cash being tracked, it must be included in the financial reports. Deciding how much cash to keep on hand and how much to bank—and which account(s) to put the cash into—is another administrative accounting task.

As one would expect, after monitoring the incoming cash, the accountant needs to oversee payments or disbursements. The accounting department of a firm may prepare checks or it may pay bills and expenses electronically. These bill payment duties are similar to the ones required by individuals in everyday life.

Large and small companies need to make purchases in order to run smoothly. Accountants use purchase orders to track all procurement. The accountant implements and maintains the systems that track purchases and methods of payment, and reconciles them with inventory. Cash management is important for ensuring that credit purchases are paid for on time without accruing interest or late fee penalties.

Accounting departments integrate with sales departments to track which products are selling and which are languishing on the shelves. This information is used to drive business strategy decisions.

The corporate financial records and required government filings are under the accountant's umbrella as well. The accountant prepares the financial statements, which include budget, cash flow statement, income (or profit and loss) statement, and balance sheet.

Generally Accepted Accounting Principles

All of these statements and tasks are driven by generally accepted accounting practices. *GAAP* (pronounced "gap"), the common term for "Generally Accepted Accounting Principles," is a set of accounting principles, standards, and procedures that include "common practice" and regulated procedures.

GAAP are crucial for standardizing the accounting field. For companies to maintain their own systems of recording and tracking financial records would be quite confusing when the time came to do business with other companies. This would be a problem not only for employees and managers within a company, but also for the tax authority and shareholders of public companies.

GAAP cover revenue recognition (or when income is recorded), balance sheet items, and financial statements. Although there are standards and procedures for creating accounting documents, leeway remains within the documents. Thus, investors and other stakeholders need to scrutinize, interpret, and analyze accounting statements.

An article exploring some famous examples of unscrupulous accountants who have massaged financial data to their own benefit is listed under "Further Reading" at the end of this entry.

Professional Certifications and Types of Accountants

Accountants are a loosely regulated profession. Accounting professional certifications give companies and consumers a designation by which to assess a minimum level of competency. In general, the Certified Public Accountant (CPA) designation offers a consumer confidence and indicates a level of competency. Other designations also indicate expertise in specific accounting-related areas.

There are ethical standards and professional certifications for accountants. The CPA designation is a prestigious qualification that the individual earns by completing an examination and fulfilling specific work requirements. The American Institute of Certified Public Accountants (AICPA) oversees this qualification. The Chartered Accountant (CA) is the Canadian equivalent of the U.S. CPA.

Additional accounting certifications include the Certified Management Accountant (CMA), Certified Financial Manager (CFM), Certified Fraud Examiner (CFE), Certified Internal Auditor (CIA), Enrolled Agent (EA), and Certified Government Financial Manager (CGFM).

The various certifications equip the accountant for specialized accounting work. For example, enrolled agents are tax experts and are the only federally licensed tax practitioners who can also represent the taxpayer before the Internal Revenue Service (IRS). These tax professionals pass an examination of the tax code or have worked at the IRS and interpreted the tax code for at least five years.

The CMA combines skill in accounting and strategic management. In order to obtain this designation, the college graduate must attend a CMA program and pass a series of tests. Upon completion, the CMA is well versed in both accounting and management skills and would be an asset to a company looking for a manager with accounting expertise to make important business decisions.

In addition to an accountant, a bookkeeper may complete the company's more basic financial duties. Ultimately, the accountant oversees the bookkeeper's work and uses the inputs for more advanced financial processes.

Accounting responsibilities are performed in every business, and the accounting field continues to evolve. Although the proliferation of computer programs makes routine accounting tasks more efficient, the accountant is responsible for financial analysis and interpretation.

AGRICULTURE AND THE ENVIRONMENT

Agriculture affects the environment, and at the same time is affected by the environment. Agriculture affects the environment mainly because agricultural lands comprise over a third of the world's land area. At the same time, agricultural productivity is directly tied to the environment through the quality of topsoil, climate, and weather. Air pollution and water pollution can also affect agricultural productivity. Given the direct importance of climate's effect on agriculture, climate has been a key focus of studies on the potential impacts of climate change.

Land dedicated to agricultural production is composed mainly of pasture, range, and croplands. Except for Africa and parts of Latin America, the vast majority of arable land on the planet is now used as cultivated pasture or in crop production. In more developed nations, a relatively small portion of arable land has been converted to urban and suburban uses. The physical scale of agriculture shows farmers are indeed key stewards of our environment.

Agricultural production affects environmental quality in many ways, both direct and indirect. Many native landscapes, such as the tall grass prairies of the midwestern United States, nearly vanished generations ago as they were displaced with some of the most productive cropland in the world. Regular tilling of former grasslands has contributed to widespread erosion of topsoil.

Aside from loss of soil and some key wildlife habitats, agricultural production is a source of many nonpoint source water pollutants—especially nitrogen and phosphorus fertilizers, but many other chemicals as well. New crop varieties were bred to take advantage of these chemical fertilizers, which allowed plants to better harness the sun's energy and soil moisture in photosynthesis. These advances created a green revolution that grew crop yields three- to fourfold over the last 75 years. This growth in productivity has helped to feed a rapidly growing human population that possesses an ever-growing appetite for resource-expensive foods like meat and dairy products.

An externality from fertilizer applications is that crops or other plants in photosynthesis never absorb a portion of of that fertilizer. In time, the fertilizers leach out of the soil into streams and rivers, upsetting natural aquatic ecosystems. Livestock animal waste can also leach into waterways. Altogether, agriculture is perhaps a principal source of water pollution, especially in developed nations. These excess nutrients feed algae blooms that rapidly absorb oxygen in the water, giving rise to vast aquatic dead zones that are nearly devoid of sea life. The broader ecological consequence of such dead zones remains unclear and is an active research area.

In her famous book *Silent Spring*, Rachel Carson made the general public aware of the loss of habitats that was resulting from vast chemical use. The book helped to inspire early environmental movements that were probably instrumental in bringing about the ban on dichlorodiphenyltrichloroethane (DDT), the establishment of the Environmental Protection Agency (EPA), and the enactment of the Clean Water Act.

Over the last decade or so, a fair amount of controversy has erupted over the emergence and rapid adoption of genetically modified crops, or genetically modified organisms (GMOs). The most prevalent kinds of GMOs include a gene that makes crop plants resistant to glyphosate (brand name Roundup), a popular herbicide developed by Monsanto. These so-called Roundup-ready crops make it much easier and less costly for farmers to control weeds. Although there has been no evidence or scientific rationale for how these crops could cause direct harm to humans, widespread use of the seed and glyphosate has bred weeds that are resistant to the herbicide. Farmers and seed companies are now looking for new herbicides to control weeds that have become resistant to the herbicide.

While it is easy to see some of the environmental harm caused by modern chemical-intensive agricultural production, there are also great, if indirect, environmental benefits. Were it not for the great advances in productivity that has been brought about principally by chemical use, much more land would need to be cultivated to feed burgeoning human populations. Agricultural commodity prices would be much higher than they are today. Millions and perhaps billions more people would be hungry and malnourished, and remaining forest and grasslands areas would be even less prevalent.

Of course, environmental attributes also affect agriculture. Soil depth, soil acidity, nutrient content in soils, precipitation, temperature, carbon dioxide concentrations, and solar radiation are all fundamental to plant development and photosynthesis, from which nearly all food and life are ultimately derived. To some extent, human activities can augment these characteristics of the environment, but doing so can be costly.

Land is allocated to various crops, livestock, and other land uses depending on the geophysical attributes that determine its greatest comparative advantage. Wheat is most often grown in relatively cool climates; corn and soybeans are grown in warmer climates, and rice is cultivated in warmer regions that have access to plentiful and inexpensive irrigation water.

Pollution also affects crop outcomes. High ozone concentrations are known to reduce grain yields, and reduced ozone concentrations in the United States may have contributed significantly to productivity growth over the past few decades.

Deforestation and burning of fossil fuels have caused atmospheric carbon dioxide concentrations to rise rapidly, with the result that the earth's climate has warmed and rainfall patterns are probably changing. All of these changes affect agricultural production. Higher carbon dioxide concentrations can increase the efficiency of water and radiation use in some plants, possibly boosting crop yields and drought resistance. At the same time, warmer temperatures may lengthen growing seasons and open up new areas in northern latitudes to crop production.

But warmer temperatures may also increase water loss through evaporation and evapotranspiration, and they may cause other heat-related stresses. Total rainfall is expected to increase, but its spatial and temporal patterns could change markedly. Episodes of flooding are expected to increase.

While considerable uncertainty remains about the net global influence of climate change on agricultural production, early optimism about global gains now seems more dubious, as mounting evidence and recent experience suggest that extreme heat can be very damaging and that the benefits from carbon dioxide may be less than previously believed.

AMERICAN ECONOMIC ASSOCIATION

The American Economic Association (AEA) was founded on September 8, 1885, in Saratoga, New York, to encourage the study of economics. Prior to the creation of the AEA, Dr. Edmund J. James and Simon N. Patten discussed creating the Society for the Study of the National Economy. But the society never caught on; instead, the idea of forming an "American Economic Association" came into being. The AEA was established by a group of economists who sought to focus on economic research, on publications on economic topics, and on economic discussion that was not limited by partisan views.

When a draft of this potential economic organization's constitution was released, a meeting was set for September 8–11, 1885, in connection with the American Historical Association (AHA). At the annual AHA meeting, members began looking into the formation of an American Economic Association. By September 9, the objectives and statement of principles were revised and agreed upon, and the American Economic Association was born. Francis A. Walker served as president; Henry C. Adams served as first vice president, Richard T. Ely served as secretary, and Edwin R. A. Seligman served as treasurer (the organization also had a second and third vice president). Some of these men, as well as other members, had studied in Germany under what was referred to as the German school of thought and had also studied political economy (the name for economics at the time).

As an early organization, the AEA had as its goal to bring economists together, and everyone who expressed an interest in membership was accepted as a member. Geographical regional branches were created across the United States to encourage further discussion of economic ideas and thought. As the field of economics gained more attention and became its own discipline, it began making its way into the college and university curricula, and later into the secondary schools.

The organization started its first academic journal, *American Economic Review*, in 1911. This journal depended on scholars to write articles on meaningful economic topics. The journal also published book reviews to attract attention to the field of economics. Two other journals would later follow: the *Journal of Economic Literature,* in 1963, and the *Journal of Economic Perspectives*, in 1987.

After the start of World War I, the AEA gained some notoriety. The federal government paid attention to this organization as it criticized the statistics being used by the U.S. Department of Agriculture. The organization gained more attention, and in 1939 it pushed for the formation of the American Finance Association.

During and after World War II, the AEA sought to define its role in society. Due to changes in economic thought, there was an increase in the demand for economists. Furthermore, economics became a part of the curriculum at various military academies and also had a role in national security and affairs.

The organization is still well known, and it holds an annual meeting in which papers on economic subjects are presented. The AEA also regularly publishes seven journals that cover various aspects of economic thought. It has various committees that enable it to address many different economic issues. The AEA has approximately 18,000 members, including many college professors and business professionals.

AMERICAN FEDERATION OF LABOR AND CONGRESS OF INDUSTRIAL ORGANIZATIONS

The American Federation of Labor and Congress of Industrial Organizations (AFL-CIO) is an umbrella federation. It consists of 56 national and international unions that represent 12.5 million people. The American Federation of Labor (AFL) and the Committee for Industrial Organization (CIO) merged in 1955 to create the AFL-CIO, a voluntary federation providing representation to multiple unions. In addition, through its community affiliate Working America, the AFL-CIO provides representation to 3.2 million people who do not have a union at their work. Further, the AFL-CIO has partnerships with working centers and other groups of people—such as day laborers, nannies, housekeepers, and in-home caretakers—who do not have the protection of many labor laws. The goals of the AFL-CIO are (1) to provide one voice that can help improve workers' wages, hours, and working conditions and (2) to protect the rights of the workers who are members of the AFL-CIO. The AFL-CIO provides an all-inclusive national federation for all labor unions.

Since membership in the AFL-CIO is generally unrestricted, the federation is made up of a variety of different unions representing multiple different careers. The AFL-CIO includes the unions that people typically think of, such as miners, teachers, firefighters, pilots, and public employees. It also represents unions such as farm workers, bakers, engineers, doctors, and nurses, as well as various other trade groups. The largest union in the AFL-CIO is the American Federation of State, County and Municipal Employees (AFSCME), which has more than 1.6 million members, both working and retired. Some of the best-known unions that are part of the AFL-CIO are the American Postal Workers Union (APWU); the Screen Actors Guild-American Federation of Television and Radio Artists (SAG-AFTRA); and the United Automobile, Aerospace & Agricultural Implement Workers of America, International Union (UAW). The AFL-CIO also has six trade and industrial departments that are mandated by the UAW Constitution. These are the Building and Construction Trades Department, the Maritime Trades Department, the Metal Trades Department, the Department for Professional Employees, the Transportation Trades Department, and the Union Label and Service Trades Department.

The AFL-CIO holds a convention every four years during the last six months of the year; delegates from each member union attend, and all AFL-CIO members are represented. The national or international union and organizing committees is entitled to a certain number of delegates based on their proportional representation. The delegates should represent the racial and gender diversity of their membership in order to better serve their constituents. Each state, area, or local central body is entitled to one delegate. Every directly affiliated local union, and each trade and industrial department, is also entitled to one delegate. At the convention, the delegates help to set policies and goals for the union movement, set dues, and vote on changes to the AFL-CIO's Constitution. The delegates at the convention also elect the president, secretary-treasurer, and executive vice president of the AFL-CIO. These three officers, along with vice presidents from each union, make of the AFL-CIO Executive Council. The Executive Council is the governing body of the federation during the four-year gap between the conventions. The Executive Council is authorized to carry out the decisions that were made at the conventions. The Executive Council is required to meet at least twice a year, but it may meet more often than that if necessary. The Executive Council is also responsible for monitoring legislative activities that would impact the goals and beliefs of the AFL-CIO. If the AFL-CIO Executive Council believes that legislative activities may negatively impact the unions they represent, the Council is empowered to take action to help change the legislation.

In recent years, the AFL-CIO has seen multiple changes in its affiliated unions. The union UNITE HERE was formed in 2004 when the Union of Needletrades, Industrial, and Textile Employees (UNITE) and the Hotel Employees and Restaurant Employees Union (HERE) merged. In 2005, the International Brotherhood of Teamsters (IBT); the Service Employees International Union (SEIU); the United

Farm Workers (UFW); the United Brotherhood of Carpenters (UBC); the Laborers' International Union of North America (LIUNA); the Union of Needletrades, Industrial, and Textile Employees and Hotel Employees and Restaurant Employees Union (UNITE HERE); and the United Food and Commercial Workers (UFCW) all disaffiliated from the AFL-CIO to form the Change to Win Federation (CtW). The Laborers' International Union of North America (LIUNA); the Union of Needletrades, Industrial, and Textile Employees and Hotel Employees and Restaurant Employees Union (UNITE HERE); and the United Food and Commercial Workers (UFCW) all decided to rejoin the AFL-CIO due to dissatisfaction with the CtW. In 2006, the AFL-CIO's Executive Council authorized worker centers to formally affiliate with state labor federations, local labor councils, and Working America. The AFL-CIO also entered into a partnership with the National Day Laborer Organizing Network (NDLON), under which the two organizations pledged to work together on immigration reform and on state and local enforcement of workers' rights. In September 2011, the National Taxi Workers' Alliance (NTWA) became the first nontraditional workers' organization in over six decades to become formally chartered by the national AFL-CIO. The International Longshore and Warehouse Union (ILWU) disaffiliated from the AFL-CIO in August 2013; the ILWU objected strongly to affiliated unions within the AFL-CIO crossing ILWU picket lines without repercussions and also disagreed with the AFL-CIO's positions on immigration, labor law reform, health care reform, and international labor, which they perceived as moderate and overly compromising.

ANCIENT THOUGHT, OR *OECONOMICUS*

Oeconomicus is a Socratic dialogue written by the Greek philosopher Xenophon. One of the earliest works on economics, it focuses on household management, providing details on the daily life of the ancient Greeks during the fourth century BCE. It presents the *oikos*, or "household/family," as the center of society and consumption in Greece, where it was imperative for the household to keep order both in organization and also financially. In *Oeconomicus*, the woman's role is to manage her husband's wealth by budgeting carefully and keeping track of household expenses.

Oeconomicus is written as an account of a conversation that Xenophon's mentor Socrates had with a Greek gentleman named Ischomachus. According to Xenophon, wealth is more than just money and property, because income and expenses must be taken into account. Xenophon felt that large amounts of property were unnecessary; he believed that property could be viewed as a form of wealth only if the owner used it properly. He also considered knowledge and information to be important and necessary for achieving wealth. He makes this clear in *Oeconomicus* in an exchange that Socrates has with Critobulus (the son of an Athenian businessman) about property; Socrates advises Critobulus that first he needs to acquire wisdom.

In *Oeconomicus*, Socrates seeks to teach Critobulus to think beyond the concept of money and more about doing things that are worth the time and effort. In the end, the goal is to turn Critobulus into a Greek gentleman, but he is far from having the gentlemanly virtue that Socrates saw exhibited by Ischomachus.

In *Oeconomicus*, Socrates is seen as wealthier than Critobulus because of his lower ratio of income to expense. Socrates also gained skills regarding household management from Ischomachus. Socrates uses Ischomachus as his role model, and discusses his conversations with Critobulus in an effort to see if Ischomachus's way of life was one worth emulating. The meaning of *Oeconomicus* focuses on people being able to manage all aspects of their lives, not just their household affairs.

Some scholars believe that *Oeconomicus* was written carefully as an apology, by both Xenophon and Socrates. Xenophon may have been apologizing for not choosing to adopt Socrates's lifestyle, and Socrates may have been apologizing for not making it clear that he approved of Xenophon's way of life.

Oeconomicus gives advice regarding the organization of the household as well as farming. For Greek gentlemen, the goal was to increase their wealth and then to make proper use of their resources, including their money. Xenophon also stressed the desire to have good labor and productivity within the community, and he favored the specialization of labor. Another important part of *Oeconomicus* is education; Xenophon pushed for women to be educated in order to carry out the managerial roles of the household.

Oeconomicus offers much insight into the field of economics. Wealth, labor, specialization, and education were all topics that were considered important in ancient Greece and still influence economic thought today.

ANIMAL SPIRITS

Animal spirits is a term that broadly describes individual economic behavior when that behavior is influenced by psychology forces such as feelings and dispositions. Animal spirits are seen as producing outcomes that are different from the outcomes assumed to result from rational expectations as defined by traditional economics, where emotions play no substantive role in decision-making. The idea of animal spirits constitutes an important foundation of behavioral macroeconomics. There has been a growing integration of animal spirits in contemporary research, especially after the Global Financial Crisis and the Great Recession of the early 21st century. Animal spirits are used mainly to explain phenomena such as economic fluctuations, financial and housing crises, and persistent unemployment. In some cases, animal spirits function as a separate fundamental feature in economic modeling and have the same methodological status as preferences, endowments, and technology.

As introduced by John Maynard Keynes (1936, 161), animal spirits are a "spontaneous urge to action" and "spontaneous optimism." They represent the innate disposition of entrepreneurs characterized by "temperament and constructive impulses" (Keynes 1936, 150). Keynes used the notion of animal spirits to describe the driving force of entrepreneurship—in particular, real-world decision-making about the prospective yield of an investment when knowledge about the future is thin and, therefore, mathematical expectations cannot justify action under fundamental uncertainty.

Animal spirits have been situated within Keynes's broader theory of fundamental uncertainty, which was developed in the post-Keynesian tradition. In this account, animal spirits are interpreted as influencing both expectations and confidence and interacting with cognition. Beyond production, this process also takes place in financial markets. Through variations of optimism and pessimism in an uncertain financial environment, animal spirits lead to changes in confidence and in liquidity preference—and they can cause financial crises. The incorporation of animal spirits in financial markets stands as an important challenge for modern macroeconomic modeling.

After a long period during which it was rarely utilized, the idea of animal spirits has been given renewed and considerable attention in mainstream economics. The best-known contemporary approach, by Akerlof and Shiller (2009), links animal spirits to human psychology and describes them as individual feelings, impressions, and passions and as a basic mental energy. This account transforms animal spirits into a general psychology force that influences the entire economy. In addition, animal spirits are represented by five aspects: confidence, fairness, corruption and antisocial behavior, money illusion, and media stories.

Contemporary mainstream macroeconomic modeling utilizes a variety of economic expectations related to animal spirits, including self-fulfilling, extrapolative, regressive, and adaptive expectations. Initially, animal spirits were understood in modern macroeconomic models as self-fulfilling expectations. Their impact was generalized as a random exogenous shock to beliefs, which could explain economic fluctuations. However, recent research in behavioral macroeconomics endogenizes animal spirits in adaptive models of heterogeneous expectations to produce multiple unemployment equilibria.

There has been extensive debate on whether Keynes used the notion of animal spirits to imply irrationality. Some economists support the implication of irrationality because it relates to irrational exuberance, unconscious mental action, and visceral reactions. However, other authors claim that explanations based on animal spirits do not imply irrationality. Contradictory views have ranged from the idea that impulses and sentiment are perfectly rational to the proposition that animal spirits operate fully in the human subconscious. A middle ground has also been sought, attempting to situate animal spirits between perfect rationality and irrationality (Dow and Dow 2011).

A promising approach that effectively resolves this conflict is to consider animal spirits as part of a strong form of bounded rationality. Kahneman (2003) has introduced a dual-system framework of bounded rationality, in which perception and intuition belong in a primitive automatic system while reasoning takes place within another more advanced system. Animal spirits in the form of emotions (described by an affective heuristic) and automatic reactions function within the primitive system of bounded rationality, but they interact with cognitive processes of reasoning. Considerable research, which is already under way, will be required to successfully explain animal spirits in terms of modern human psychology and to operationalize animal spirits in a coherent manner for behavioral macroeconomic modeling.

ASSET ALLOCATION

Asset allocation is widely considered the first step in investment portfolio management. Investing is a money management strategy to increase the investor's long-term financial wealth. Investors are assumed to desire the largest financial return on their funds for the least amount of risk. Asset allocation is designed to smooth out the volatility or risk of a portfolio while maximizing investors' returns. Diversification among asset classes reduces an investment portfolio's risk. Asset allocation is a way to create a diversified investment portfolio.

An asset allocation represents an investor's choice of broad asset classes and the percentages distributed across the categories. This decision divides total investable funds by percent into specific investment categories.

An *asset class* refers to the categorization of financial investable assets. The asset classes used most often include stocks, bonds, and cash equivalents. A *stock asset class* contains individual stocks and groups of stocks combined and sold as mutual funds, as well as many additional categorizations within the broad stock category. The *cash asset class* refers to bank savings accounts, money market mutual funds, and short-term U.S. Treasury bills. There are many varieties of bonds for the cash asset class; governments, municipalities, and corporations issue bonds for this class, and it also includes bond mutual funds. The bond category is also considered the fixed income asset class.

Fixed income refers to a financial asset such as a bond or a certificate of deposit that pays the holder regular interest or a regular dividend.

The asset allocation concept is derived from the seminal work of Harry Markowitz, founder of modern portfolio theory (Markowitz 1952). The asset allocation decision is grounded in a study of observed historical asset class returns and volatility. From January 1926 through June 2012, the rolling 10-year annualized geometric returns of the broad U.S. stock market averaged 10 percent (Davis et al. 2012). That stellar return hides shorter periods of low and even negative stock market returns. The benefit of asset allocation is that when several less-correlated asset classes are combined in an investment portfolio, if one component underperforms, the other asset classes serve to reduce the losses and may increase or at least maintain the portfolio's total value.

How to Create an Asset Allocation

The asset allocation decision has two parts. Part one is an assessment of investors' individual risk tolerance. Generally, retirees are more conservative or risk-averse than younger investors. This is because if the value of a retiree's portfolio goes down, the retiree does not have a long work-life remaining during which to earn back the loss in value. Younger individuals may be more aggressive or risk-tolerant, for the opposite reason. If 30-year-old investors have losses in the value of their investment portfolio, they have many years to recoup that loss. Of course, older individuals are not always more conservative investors than younger ones. Some 30-year-olds cannot tolerate the volatility of an aggressive portfolio, and they do not want to see even a moderate decline in the value of their investments; conversely, there are aggressive investors who are older and can tolerate the ups and downs in value of their investments.

There are many publicly available measures to help investors ascertain their personal risk tolerance. A popular risk quiz, first published in the *Wall Street Journal* in 1998 (Bodie et al. 2011), showed that people who have a higher risk tolerance and are more willing to experience ups and downs in the value of their investments will allocate a greater percent of their total investable assets to riskier investments. Stocks and stock mutual funds are widely considered riskier, because although historically they have offered higher returns, there is an accompanying chance of greater losses in the stock investments. Investors with less tolerance for risk will stick to less volatile asset classes, such as cash equivalents and bonds. For example, older investors and less-risk-tolerant investors might allocate a greater percent of assets to bonds and cash investments and a smaller percentage to stock investments.

The second part of the asset allocation decision deals with choosing which financial assets to include in each broad category. For example, in the stock asset class, investors can choose from individual stocks, actively managed stock mutual funds, or passively managed stock index funds. Simply put, a *stock* is a part ownership in a company. For example, if Matthew buys 10 shares of Apple stock, he owns a tiny portion of the company. A *mutual fund* is a combination of many individual stocks, bonds, or both, managed by a company. The mutual fund gives the small investor access to many stocks and/or bonds for a relatively low fee.

The bond category might include investments in individual bonds, bond mutual funds, or bond exchange traded funds. A *bond* is a loan to a company or government. In exchange for the loan, the bond holder receives periodic interest payments. A bond mutual fund contains only bonds. An exchange-traded fund is similar to a mutual fund. The distinctions between mutual funds and exchange-traded funds are discussed fully in their individual entries.

Asset allocation may be as simple as holding two mutual funds in an investment portfolio. For example, a two-fund asset allocation might include one all-world international stock index mutual fund for the equity (or stock) portion of the portfolio. This is simply a fund that buys a small amount of the stock of many different companies from the United States and across the globe. This gives the investor an opportunity to own lots of stock investments for a small amount of money.

The second mutual fund in this simple asset allocation might be a diversified bond fund. Similar to the stock mutual fund, this bond fund would buy bonds from many individual companies and may include some government bonds as well.

The percentages in each portion are determined by the investor's age and risk tolerance. Other investors divide the asset allocation decision into more complicated asset classes, and they may include percentages in small, medium, and large company stock mutual funds or other types of categories. More sophisticated asset allocation decisions may include international securities and alternative investments such as real estate and commodities.

Rebalancing

In deciding on their personal asset allocation percentages, investors review the historical asset class performance of their investments and adjust for the expected future returns and volatility, based upon economic projections and personal judgments. In general, after making asset allocation decisions, investors check the percentages in each category annually—to ensure that any changes in the value of the financial assets have not deviated significantly from their original asset allocation decision.

The rebalancing decision returns asset class percentages to their original proportions. For example, conservative investors might choose an asset allocation of 50 percent in an international stock mutual fund and 50 percent in a diversified bond mutual fund. At the end of one year, if the international stock markets outperformed the bond markets and the investor's stock holdings were 60 percent and the bond investments were only 40 percent of the overall total, then the investors would need to sell enough of the stock investments and buy enough of the bond investments to return to the previously determined 50 percent amount in each of the asset classes.

Tactical Asset Allocation

Advocates of traditional asset allocation maintain a consistent asset allocation for years, and they adjust when the investor ages and approaches retirement or if the investor's risk profile changes. Historically, the asset allocation decision took a "Set it and forget it" approach. Recently, changes in the research introduced the concept of "tactical asset allocation." This approach is an answer to the problem of long periods of subpar performance of certain asset classes and an attempt to boost investment returns. Tactical asset allocation adjusts the percentages allocated to specific asset classes based on market valuation or other economic factors.

In the Financial Planning Association's "Trends in Investing" special report, 81 percent of respondents indicated that they regularly reevaluate their asset allocation decisions (Kitces 2012). In an article about the report, Michael Kitces reported that planners made tactical asset allocation decisions twice year, on average. This is decidedly more frequent than the traditional age- and risk-based adjustments.

A new class of mutual funds called *target date mutual funds* uses an asset allocation age-based approach to adjust the asset allocation of the mutual funds based on investor age, with more equities for younger investors, transitioning to more fixed investment percentages as investors reach retirement age. The target date funds use asset allocation research, along with investor age, to provide a comprehensive financial planning product.

In summary, the asset allocation decision is an investment method to reduce the volatility in an investor's portfolio by investing in diverse classes of investment assets. Lower correlation between asset classes enables an opportunity for higher investment returns with less risk.

ASSOCIATION OF ENVIRONMENTAL AND RESOURCE ECONOMISTS

The Association of Environmental and Resource Economists (AERE) is an international association for economists working on environmental and natural resources issues. The AERE was founded in 1979 and has about 1,000 members. Most of the members hold a doctoral degree and work in academic institutions. The AERE's goal is to promote communication among economists who are interested in environmental and natural resource economics. The major activities of the association are joint sponsorship of the World Congress of Environmental and Resource Economists, hosting of the AERE Summer Meeting, sponsorship of sessions at other conferences, the publication of two journals and the *AERE Newsletter*, and various honors and awards. The AERE is governed by a president, president-elect, past president, vice president, secretary, treasurer, and six elected board members.

The World Congress of Environmental and Resource Economists is jointly sponsored by The AERE and the European Association of Environmental and Resource Economists. Locations alternate between North America and the rest of the world. It has been held in Venice (1998), Monterey (2002), Kyoto (2006), Montreal (2010), and Istanbul (2014). It is a large conference with over 500 paper presentations and participants from more than 50 countries. The annual AERE Summer Conference is an extension of the original AERE Workshops. Between 1985 and 2009, 22 Workshops were held—small conferences with presentations of 10 or more papers that focused on a specific topic such as energy, fisheries, or health. The first AERE Workshop was held in Boulder, Colorado; the last one was held in Washington, D.C., in 2009, hosted by Resources for the Future. The inaugural AERE Summer Conference was held in Seattle, Washington, in 2011 with 340 attendees. The AERE Workshop lives on through thematic sponsored sessions within the summer conference. The

AERE also sponsors sessions at the Allied Social Science Associations annual meeting, Agricultural and Applied Economics Association annual meeting, and regional economics conferences such as the Southern Economic Association and Western Economic Association International.

The *Journal of Environmental Economics and Management* (JEEM) began publication in 1974 and became the official journal of the AERE in 1983. JEEM publishes theoretical and empirical papers devoted to environmental and resource issues, and it is widely considered the top journal in the field. The November 2013 issue of JEEM was the last published as the official journal of the AERE; the association is planning to launch a new official journal, the *Journal of the Association of Environmental and Resource Economists*. The journal *Review of Environmental Economics and Policy* (REEP) publishes nontechnical articles that "fill the gap between traditional academic journals and the general interest press." The journal's content includes symposia on a focused topic, articles that survey the current literature, and regular features such as policy monitor and individual reflections. The *AERE Newsletter* is published twice each year and contains a president's column, announcements, and essays.

The AERE honors and awards are the Distinguished Service Award, Fellows, Outstanding Publication in JEEM, and the Publication of Enduring Quality. There have been eight recipients of the AERE Distinguished Service Award, including founding members, JEEM editors, and the executive secretary. In 2005, the AERE began its Fellows Award to recognize members who have made significant contributions to the field. Six members were awarded fellowships in 2005, 2006, and 2007, and three members have been awarded fellowships annually since. The Publication of Enduring Quality award is given to a publication that has had a lasting and significant contribution to the field. Since 1989, 30 articles and books have received the Publication of Enduring Quality Award. In 2009, the AERE began to recognize the Outstanding Article in JEEM. A list of all past recipients of AERE awards can be found on the AERE website (www.aere.org).

AUSTRIAN ECONOMIC THOUGHT

The economic philosophy known as Austrian Economic Thought was founded in 1871. Its first formal introduction came in *Principles of Economics* (1871) by Carl Menger. In this classic text, Menger focused on the economic decisions of individuals and how individuals make decisions at the margin. Menger's propositions on individual decision-making and marginalism received further support from the works of both Stanley Jevons and Leon Walras. Through his work, Menger has been credited with focusing on individual choice as the central tenet of economics and not consumption.

The Austrian School of economics is based on a series of market-oriented, individual-choice foundations. The first foundation focuses on the most basic economic principle: individuals make choices, and all choices involve a cost and a consequence that lies in the future. Important to this principle is the identification of as many consequences as possible and the avoidance of any unintended consequences of a choice. A second foundation of the Austrian School includes the study of markets, of consumer and producer behavior, and of the role that prices play in creating orderly markets and their institutions.

A key foundation is the belief that people behave based on what they know. In this case adherents to the Austrian School differentiate their philosophy from other economic philosophies with their focus on human action, not economic prediction or quantitative analysis. Human action is so important to the Austrian School's philosophy that the book which some consider the "bible" of modern Austrian economics bears its name: Ludwig von Mises's *Human Action* (1949).

This basic foundation of human action experienced a major philosophical confrontation with objective and quantitative 19th-century economic philosophy. While the British economist Alfred Marshall argued for applying objective values to costs, the Austrians held that values to costs were subjective and were based on one's decisions and the alternative choices that were not chosen—that is, opportunity costs.

A follow-up foundation is the important role that prices play in creating such a market. According to Austrian economists, prices when allowed to function properly determine the rules by which markets function most efficiently.

Of all the foundations on which Austrian economic thought is based, the private ownership of productive resources and private property is the most important. Private ownership of the productive resources provides the incentives necessary for any economy to grow. Ludwig von Mises, considered by some to be the father of Austrian economics, strongly emphasized how socialism (government ownership of the productive resources) eliminated the proper incentives for efficient resource allocation. According to von Mises, the inefficient allocation and lack of proper incentives limits the ability of prices to function properly as an allocation mechanism. This scenario ultimately dooms any economy.

A final foundation of Austrian economic thought focuses on an economy's ability to promote both competition and, by extension, the entrepreneurial spirit. Competition leads to a role for the entrepreneur in an economy. Without competition, the desire and incentives for entrepreneurial and technological advancements are not present. An economy becomes stagnant. Through the right incentives (private property, free markets), an economy finds the most efficient allocation of productive resources and achieves economic growth and a higher standard of living.

In the 20th century, the most notable Austrian economists were Ludwig von Mises and Friedrich von Hayek. Their writings and teachings still serve as the basis and foundations for most modern Austrian economic thought. Other notables include Eugen von Böhm-Bawerk, Israel Kirzner, Ludwig Lachmann, Fritz Machlup, and Murray Rothbard, along with Menger, Jevons, and Walras.

BANKING

Banking is the financial activity of protecting and storing capital for individuals and institutions. The bank lends that capital to others for a profit. Depositors earn interest on their deposits, the banks use the depositors' funds to make loans to borrowers, and the borrowers use the funds to buy homes, expand businesses, or for a variety of personal uses.

Banks profit from the difference between the interest paid on deposits and the interest payments received from borrowers, called the "interest rate spread." For example, if the bank pays the depositor 1 percent interest on deposits and charges borrowers 5 percent interest, the bank's profit or spread is 4 percent. Banks also make money selling investment products and services.

Banking participants began as banks, savings and loan mutual companies, and credit unions and grew to include credit card companies, large financial conglomerates, investment brokerage companies, and some large retail institutions. Initially, banking occurred at a brick-and-mortar location that handled all transactions. Today, Internet, mobile, electronic, home, and automatic teller machine (ATM) financial management are surpassing traditional banking methods. Banking methods, locations, services, and products are evolving at a rapid rate.

History

Banking in the United States began with no regulation or oversight. Anyone could open a bank, take in deposits, and make loans. By 1920, the United States was home to almost 30,000 banks. At that time, there were more banks in the United States than in all countries in the rest of the world combined. After the Great Depression and a tidal wave of bank failures, the federal government created the Federal Deposit Insurance Corporation (FDIC) in an attempt to reduce bank failures and protect consumer's deposits. The FDIC insures every depositor funds up to $250,000 per insured bank.

Historically, banks operated exclusively within a particular state and could not expand across state lines. In 1994, interstate banking was passed into law. The Riegle–Neal Interstate Banking and Branching Efficiency Act of 1994 improved convenience and product availability for consumers and completely reshaped the banking industry in the United States.

Payment Services

Traditional banking services include checking or demand deposits. Designed as a method to pay bills, a checking account is usually a no-interest deposit account; funds are transferred into and out of it to meet financial obligations. Electronic bill payment and check deposits are replacing paper check payments in popularity. Automatic teller machines (ATMs) have added to the convenience of depositing funds and withdrawing cash. A debit card, issued by the bank, gives consumers ready access to their bank funds and can be used at ATMs as well as to make purchases from merchants.

Fees are occasionally charged on checking accounts. Some checking accounts pay interest if depositors agree to maintain a specific minimum level of cash in the account.

Savings

Savings accounts or time deposits pay interest on customers' deposits and are useful for protecting and growing cash for the future. Consumers deposit funds for easy access at a later date. Banks usually pay interest on savings accounts. Banks may charge fees for these accounts if deposits fall below a specified amount. Banks offer certificates of deposit (CDs) to consumers who are willing to tie up their funds for longer periods of time in exchange for higher interest payments.

Borrowing

At some time in their lives, most consumers need to borrow funds for a major purchase. Vehicle loans and home mortgage loans are among the most common types of loans. Consumers may also take out personal loans to fund expenses such as home improvements. Businesses borrow to fund start-up and expansion costs.

In the past, banks were a major source of funding for mortgage, business, and personal loans. Consumers would apply for a loan and provide information about their work and credit history; if applicants were deemed reliable, the bank would loan them the funds. After lending the money, the banks serviced the loan (collected the payments due on it) until the loan amount was paid off. Today, it is common for banks to immediately sell their loans to other financial market participants.

Supplementary Financial Services

The differences between banks, credit unions, savings and loan mutual companies, credit card companies, investment brokerage companies, insurance companies, and other financial management organizations are blurred as additional financial services are offered.

Over time, banks have sought new ways to serve customers and increase bank profits by offering investment and insurance products. Credit card, investment brokerage, insurance, and other financial companies now offer banking services as well. Banks and financial companies offer investment products, insurance services, and a variety of accounts through which consumers can access these additional offerings.

Specialized retirement accounts that were once the purview of investment brokers are now available at banking institutions as well. The best-known types of these are Individual Retirement Accounts (IRAs), Roth IRAs (which allow the account holder to withdraw funds from the account during retirement without paying any tax), and educational savings accounts commonly known as 529 Savings Plans.

Quasi-Banking Entities

PayPal and peer-to-peer (PTP) or social lending are two banking-related services through which nontraditional quasi-banking entities fill a banking need. PayPal provides payment transfer services for electronic money transfers. Used to pay merchants and individuals online, this nonbank entity also links individual's credit card and bank accounts to offer a myriad of payment transfer options.

Customers have alternative borrowing and lending options through PTP or social-lending networks. These networks connect individuals who have funds to lend with borrowers who are in need of small to medium-sized loans. Lenders receive interest payments, and borrowers get funded by their peers.

Banking Trends

Banking began as a location-specific service industry confined to operations during weekday business hours. As society came to be based more and more on the Internet, mobile devices, and a global and electronic society, time-pressed consumers demanded around-the-clock access to their financial transactions. As the number of brick-and-mortar bank, savings and loan, and credit union branches decreased, their business hours expanded to include weekends in addition to the traditional Monday-through-Friday hours.

Banking access continues to expand with the advent of Internet-only banks and banking services offered by credit card companies, investment brokers, and large retail conglomerates. Banking today is location-independent, with options spanning a multitude of providers.

Fee structures range from free to fee-for-service. Returns and interest rates vary by institution and type of service. Banking from home has overtaken branch banking, with consumers paying bills and transferring funds electronically. Check writing is rapidly being replaced by online bill payment. Mobile devices allow customers to make bank deposits remotely by simply scanning a check and sending it straight to the financial institution.

Quasi-banking has expanded further along with the growth of electronic commerce (e-commerce) and nontraditional banking and borrowing options, including PayPal payment systems, peer-to-peer lending, and prepaid debit cards. The banking industry is rapidly growing and changing to meet the needs of a demanding and evolving public.

BANKING, HISTORY OF

Banking began around 2000 BCE in Babylon and Assyria, with the use of grain loans to farmers and traders who carried goods between cities. Later, in ancient Greece and the Roman Empire, lenders based in temples made loans and added two important features to banking: deposits and money-changing. There is evidence that banking and money-lending took place in ancient China and India as well.

The first recorded use of paper money was in China in the seventh century. However, the practice of "banking" did not become widespread until nearly a thousand years later. In the 17th century, bankers began to specialize—with the rich and more influential ones associated increasingly with foreign trade and exchange transactions. Since these wealthy businessmen (bankers) were richer and more sophisticated than the general population, they became increasingly concerned with questions of political significance. Stability of a country's currency, war and peace, dynastic marriages, and worldwide trading monopolies became the focus of the financiers.

The bankers' relationships with governments were always in monetary terms and not real terms, since the bankers' focus was with the stability of monetary exchanges between countries. The bankers used their power and influence to get all money and debts expressed in terms of a strictly limited commodity; ultimately, this commodity was gold. Bankers believed that with a stable commodity such as gold, private banking could handle these exchanges better than governments could.

Currency, particularly coins, needed to be kept in a safe place. Since ancient homes did not have the benefit of steel safes, wealthy people held accounts at their temples. Priests or temple workers, who were believed to be both devout and honest, occupied the temples, providing a sense of security. Records from ancient Greece, Rome, Egypt, and Babylon suggest that temples loaned money in addition to keeping it safe. The fact that most temples were also the financial centers in their cities is the major reason why they were ransacked during wars and invasions.

The Roman era parallels the biblical accounts of various banking events and guidelines for lending with interest. In the Roman Catholic Church, charging interest was considered a sin if a Christian charged another Christian. The same teaching applies in the Old Testament. However, the Old Testament book of Deuteronomy (23:20) allows Hebrew lenders to charge interest if the borrowers are non-Hebrew ("foreigners"). Charging interest—sometimes at very high rates, or *usury*—is now a staple of successful banking. This now-common practice has fueled anti-Jewish sentiment throughout history.

Banking in Europe

Banking, in the modern sense of the word, can be traced to the Middle Ages and to the Renaissance era in Italy, specifically in the wealthy cities of Florence, Venice, and Genoa. The Bardi and Peruzzi families dominated banking in 14th-century Florence, and they established branches of banks in many other parts of Europe as well. Probably the most famous Italian bank was the Medici Bank, established by Giovanni Medici in 1397.

The oldest bank still in existence is Banca Monte dei Paschi di Siena. Located in Siena, Italy, it has been in operation continuously since 1472. In the 16th century, the position of the Medicis was eventually taken over by the Fuggers and the Welsers. Many important banking innovations took place in Amsterdam during the Dutch Republic in the 17th century and in London in the 18th century.

The development of banking spread from northern Italy throughout the Holy Roman Empire. The Romans moved banking out of the temples and formalized it with distinct buildings. Even though the Roman Empire eventually crumbled, some of its banking institutions remained in the form of papal bankers who emerged in the Holy Roman Empire and the Knights Templar during the Crusades.

Commercial capitalism in the period from 1440 to 1815 was marked by the supremacy of chartered companies such as the Hudson's Bay Company, Dutch East India Company, and East India Company British Company, the Virginia Company, and the Company of Merchant Adventurers. England's greatest rivals in all of these activities were defeated by England's greater power and isolationist security.

Great Britain's victories over Louis XIV in the period of 1667–1715 and over the French Revolutionary governments and Napoleon in 1792–1815 had many causes, but one in particular was England's discovery of credit. Economically, England had embarked on the Industrial Revolution.

The Founding of the Bank of England

The use of credit was known to Italians and Netherlanders long before it became one of the instruments of Great Britain's world supremacy. The founding of the Bank of England by William Paterson and his friends in 1664 is one of the most noted dates in world banking history. For years, men had sought to avoid the one drawback of gold, its weight, by using pieces of paper that represented specific pieces of gold. Today such pieces of paper are called gold certificates.

Gold certificates entitled bearers to exchange said certificate for its piece of gold on demand, but in view of the convenience of paper, only a small fraction of certificate-holders ever made such demands. It became clear early on that gold needed be kept on hand only in the amount needed to cover the fraction of certificates likely to be presented for payment. The rest of the gold could be used for business purposes. In addition, the number of certificates issued could be greater than the volume of gold reserves available for payment of demand against them. These excess paper claims against reserves are now called banknotes.

Modern Banking in the New World

Banking was already well established in the British Empire when Adam Smith wrote *An Inquiry into the Wealth of Nations* in 1776. Empowered by Smith's views of a self-regulated economy, moneylenders and bankers managed to limit the state's involvement in the banking sector and the economy as a whole. This free market, capitalism, became the way of doing business in the New World, where the United States of America was about to emerge.

In the beginning, Smith's idea of a free market economy did not benefit the American banking industry. The average life for an American bank was five years, after which most banknotes from the default banks became worthless. These state-chartered banks could only issue notes against the gold and silver coins they had in reserve.

In 1791, Secretary of the Treasury Alexander Hamilton established a national bank in the United States with a 20-year charter. The roles of the bank included the following: The bank would (1) accept and hold the money that the government collected in taxes; (2) help the government carry out its powers to tax; (3) borrow money in the public interest; (4) regulate interstate and foreign commerce; (5) issue representative money in the form of banknotes (which were backed by gold and silver); and (6) ensure that state-chartered banks held sufficient gold and silver to exchange for banknotes should the demand rise. The First Bank of the United States succeeded in bringing order and stability to American banking.

In 1811, when the First Bank's charter ran out, state banks began issuing banknotes that they could not back with gold or silver. Without no supervision or regulation, financial confusion reigned. Neither merchants nor customers had confidence in the value of the paper money in circulation. Different banks issued different currencies, and the temptation for banks to print more money than they had in gold or silver was real.

To eliminate this financial chaos, in 1816 Congress chartered the Second Bank of the United States. Like the First Bank, the Second Bank was limited to a 20-year charter. Despite the creation of another central bank, the people of the United States distrusted the federal government's banking power.

The fall of the Second Bank of the United States once again triggered a period dominated by state-chartered banks. The period between 1837 and 1863 is known as the Free Banking Era (aka the Wildcat Era). The number of state-chartered banks tripled, leading to a series of problems in banking. State-chartered banks did not keep enough gold and silver on hand to back the paper currency that they issued. Some banks were located in extremely remote areas. A few banks engaged in fraud by issuing banknotes for deposited gold or silver and then disappearing. Anyone who had bought the notes lost that money. During this era, state-chartered banks were allowed to issue currency—and so were private banks, railroads, stores, churches, and individuals. By 1860, an estimated 8,000 different banks were circulating currencies.

With the Civil War raging, the federal government enacted reforms aimed at restoring confidence in paper currency. These reforms resulted in the National Banking Acts of 1863 and 1864. Together, these acts gave the federal government three important powers: (1) the power to charter banks, (2) the power to require banks to hold adequate gold and silver reserves to cover their banknotes, and (3) the power to issue a single national currency. The new national currency led to the elimination of the many different currencies in use and helped stabilize the country's money supply.

Despite the reforms made during the Civil War, the country was still plagued by money and banking problems. In the 1870s the nation adopted the gold standard. This monetary system required that any paper or coin money issued would be equal to the value of a certain amount of gold. It set a definite value for the dollar, so that one ounce of gold equaled about $20. It also forced the government to issue currency only if it had gold in the Treasury to back the notes. The gold standard fulfilled an essential requirement of a banking system: a stable currency that inspires the confidence of the public.

Merchant Banks

Because the national banking system was so inconsistent, most of the economic duties that would have been handled by the national banking system fell to the large merchant banks to handle. During this period of unrest, which lasted until the 1920s, these merchant banks used their international connections to increase their political and financial power. These banks included Goldman and Sachs, Kuhn, Loeb, and J. P. Morgan and Company. While upstart banks came and went, these family-held merchant banks had long histories of successful transactions.

J. P. Morgan and Company emerged at the head of the merchant banks during the late 1800s. It was connected directly to London, which at that time was the financial center of the world and had considerable political clout in the United States. Although there were well-established merchant banks at the dawn of the 1900s, it was difficult for the average American to get loans from them. The merchant banks did not advertise, and they rarely extended credit to the "common" people.

In 1907, when the collapse of shares of copper trust set off a panic that had people rushing to pull their money out of banks, the need for a central bank became obvious. It took J. P. Morgan to stop the panic; he used his considerable clout to induce all of the major economic players to maneuver their credit and any capital they controlled—similar to what a government-run bank would do to slow a panic. The fact that it took a single man with immense banking power to resolve the Panic of 1907 prompted the federal government to act.

U.S. Banking in the Modern Era

Banking today still revolves around an act of Congress from 1913. In 1913 the Federal Reserve Act was passed, creating the United States' central bank: the Federal Reserve System. This act of Congress, signed into law by President Woodrow Wilson, restructured the banking industry in the United States.

The Federal Reserve's Board of Governors are appointed by the president and confirmed by the Senate. The Federal Reserve System is made up of 12 regional Federal Reserve Banks, each with its own president and board. The major responsibilities of the nation's central bank are to regulate member banks, act as lender of last resort for banking stability, serve as the federal government's fiscal agent, and monitor the nation's money supply. The main tools Federal Reserve uses to monitor the money supply are the reserve requirement, the discount rate, or the buying and selling of government securities through the Federal Open Market Committee (FOMC).

BANKRUPTCY

Bankruptcy is a legal process that allows individuals and businesses that can no longer pay their bills to seek protection from their creditors. There are several types of bankruptcy, and various methods of debt settlement and repayment. Often referred to as an "economic fresh start," bankruptcy is addressed in the U.S. Constitution, Article I, Section 8, which authorizes Congress to enact "uniform Laws on the subject of Bankruptcies."

All individual consumers who file for bankruptcy must first undergo credit counseling with an approved nonprofit budget and credit counseling agency within six months before filing their bankruptcy petition. Also, before the court will grant a discharge of debt, consumer debtors must complete a financial management instructional course with an approved provider.

History of Bankruptcy

In medieval Europe, when merchants or tradesmen failed to pay their bills, they were deemed *banca rotta*, or "broken bench," and the lender to whom they owed money would literally destroy their means of livelihood. Treatment of debtors could be harsh; for example, in England this included imprisonment and in extreme cases even death (Tabb 1995).

As the founding fathers were drafting the U.S. Constitution, they made a provision for bankruptcy. Yet it wasn't until 1898 that a long-term and comprehensive bankruptcy code was passed. It was also the first time that bankruptcy law became more favorable to the debtor, as previous laws were more creditor-focused.

The most recent update to the bankruptcy law was the passage of the Bankruptcy Abuse Prevention and Consumer Protection Act of 2005, also known as BAPCPA.

Bankruptcy Process

Because bankruptcy is governed by federal law, the process is administered in federal courts and cannot be filed in a state court. The individual or business filing a case in bankruptcy court is referred to as a debtor. The creditors are those to whom the debtor owes money. The bankruptcy court assigns a trustee to administer the bankruptcy estate that is created by the filing of the petition. The trustee's responsibilities include reviewing the paperwork that the debtor has submitted to the court and bringing actions against creditors or the debtor to recover property of the bankruptcy estate.

In a Chapter 7 bankruptcy, the trustee liquidates property of the estate and uses the resulting money to repay creditors. In a Chapter 12 or Chapter 13 bankruptcy, the trustee oversees the debtor's repayment plan by actually receiving monthly payments from the debtor and then forwarding those payments to creditors. The judge in a bankruptcy court may hear and decide any matter related to a bankruptcy case; however, much of the bankruptcy process is administrative; and a debtor's involvement with the judge is usually very limited.

Bankruptcy Chapters

The different types of bankruptcy that individuals and businesses can file take their names from the actual bankruptcy code itself, which appears in Title 11 of the United States Code.

Chapter 7 bankruptcy is also known as liquidation bankruptcy. The reason for this is that the debtor's non-exempt (debtors are allowed to keep some items) assets are collected and sold by the trustee. The cash proceeds are then used to repay the creditors. Upon completion of the case, the debtor receives discharge and forgiveness of the debts under Chapter 7, with certain exceptions that are prohibited from discharge, such as taxes, child support, and student loans. Forgiveness means that certain debts do not need to be repaid. Consumer debtors are required to complete a financial analysis, referred to as a means test, to determine whether, based on their income it is more appropriate for them to file a Chapter 13 bankruptcy. Most bankruptcies filed in the United States are Chapter 7 cases.

Chapter 11 bankruptcy is also known as the rehabilitation bankruptcy. Debtors can use Chapter 11 to reorganize their debts while continuing to operate their business. The vast majority of Chapter 11 cases are filed by businesses, although higher-income individuals may also use this chapter. These debtors often work with their creditors (who will form a creditor committee) to create a reorganization plan, in which they repay all or part of their debts. Upon completion of the case, the debtor receives discharge and forgiveness of any remaining debts, with certain exceptions that are prohibited from discharge.

Chapter 12 is the bankruptcy chapter specifically designed for family farmers and fisherman. This chapter is similar to Chapter 13, except that it allows for higher debt levels and more flexibility regarding when payments can be made to the courts, thereby making allowances for harvest schedules. In Chapter 12, debtors may keep their property and not be forced to liquidate it. They will repay all or part of their debts by making payments through the court-appointed trustee over a period of three to five years. Upon completion of the case, the debtor receives discharge and forgiveness of the remaining debts, with certain exceptions that are prohibited from discharge.

Chapter 13 is also known as the wage-earner's bankruptcy. Debtors can use this chapter to reorganize their debts, as long as they can demonstrate to the court that they have a regular income. Also, to be eligible for Chapter 13, a debtor may not have more than a certain amount of debt, as set forth in the Bankruptcy Code. In a Chapter 13 bankruptcy, debtors may keep their property and not be forced to liquidate it. They will repay all or part of their debts by making payments through the court-appointed trustee over a period of three to five years. Upon completion of the case, the debtor receives discharge and forgiveness of the remaining debts, with certain exceptions that are prohibited from discharge.

Bankruptcy Considerations

The U.S. population continues to see growth in outstanding consumer credit levels, while the national savings rate has declined to less than 3 percent per year. Each year, over one million Americans file for bankruptcy. Before filing for bankruptcy, each of these consumers must weigh both the pros and the cons of this important decision.

There are advantages to filing for bankruptcy protection; the most notable of these is debtors' economic fresh start after they receive their discharge. The idea is that when debtors are no longer burdened by unmanageable debt, they can become productive and contributing members of the economy. Also, with the filing of the bankruptcy petition all collection efforts must stop. Further, individuals cannot be fired from their jobs because they have filed for bankruptcy.

There are disadvantages as well. Because bankruptcy filings are a matter of public record, debtors may find that for several years after they have filed, they have to disclose this information whenever they apply for professional licenses or credit. Also, for up to 10 years the information will show on their credit reports, which can impact consumers' future finances and the cost of credit. A study by Purdue University found that about one-third of consumers who filed for bankruptcy had obtained new credit within three years of filing, and by the fifth year one-half had obtained credit, even with the negative information on the credit report.

BASIC ECONOMIC QUESTIONS

The *basic economic questions* are the universal questions that all economies, past and present, seek to answer:

- What goods and services shall we produce?
- How shall we produce them?
- For whom shall we produce them?

How an economy answers these basic questions helps to distinguish one economic system from another. There are many ways to classify economies. Economists often consider how the basic economic questions are answered by traditional economies, pure market economies, and pure command economies. In reality, there are no pure economies operating in the global economy. Instead, all economies are "mixed economies." Today, most economies lean toward the market economy model, while a few lean toward the command economy model.

The question "What goods and services shall we produce?" deals with decisions that individuals, firms, and countries make about which goods and services should be produced. A *good* is any object that satisfies a person's wants or needs. A *service* is any productive activity that satisfies a want or need. In a market-oriented economy, such as the United States or Japan, individuals are mainly responsible for answering the "What goods and services shall we produce?" question. This is because consumers cast their "dollar votes" for or against certain goods and services through their buying decisions. Today, consumers value automobiles and the skills of auto mechanics, so consumers' dollar votes are cast in favor of this good and this productive service. Dollar votes are no longer cast for horse-drawn carriages or blacksmiths, however, because newer technologies have rendered this good and this productive service obsolete. In command-oriented economies, such as Cuba or North Korea, government economic planners dictate the answer to the question "What goods and services shall we produce?" Government planners create central plans, often called *five-year plans*, to allocate scarce resources. In command economies, government-determined goals are more important than the individual's wants or needs.

The question "How shall we produce them?" concerns the employment of society's factors of production: natural resources, human resources, and capital goods. In market-oriented economies, business firms answer the "How shall we produce them?" question. In the highly industrialized market economies, such as the United States, business firms determine the most efficient mix of resources to use in production. Often, firms employ sophisticated capital goods—such as precision tools, robots, computers, and software—to increase productivity in their plants. Firms in market economies also employ other needed resources, including human and natural resources. Production in the United States and other highly industrialized market-oriented economies is *capital-intensive*, or heavily reliant on capital goods and technology, to produce products. In command-oriented economies, the question of "How shall we produce them?" is largely determined by the central planners. These planners control society's factors of production, and they allocate natural, human, and capital resources to meet government objectives.

In today's global economy, production in the few command-oriented economies tends to be *labor-intensive*, or heavily reliant on human labor. This is mainly due to the low development status of countries such as Cuba and North Korea, however, rather than their commitment to a centrally planned economy.

The question "For whom shall we produce them?" concerns the distribution of society's output. In effect, this question deals with who will receive the goods and services that are produced. In the market-oriented economies, "For whom shall we produce them?" is determined mainly by an individual's income and the prevailing prices of goods and services. People with higher incomes are better able to purchase goods and services than people with lower incomes. As a result, higher-income groups have a higher standard of living than people with lower incomes. During the 20th century, all industrialized market-oriented economies instituted programs to influence income distribution. The government adjusts the distribution of income through public transfer payments, which supplement the income of the needy. Transfer payments improve people's access to necessary goods and services, and thus they elevate people's standard of living.

Examples of public transfer payments in the U.S. economy include Temporary Assistance to Needy Families (TANF), food stamps, Medicare and Medicaid, and Social Security payments. In command-oriented economies, the “For whom shall we produce them?” question is determined by the government. Government planners set both the wage rates for workers and the prices of most goods. By controlling wages and prices, the government determines each person’s share of national output. In command economies, the government also provides some low-cost or no-cost services, such as health care and housing, to support a minimum standard of living.

BASTIAT, FRÉDÉRIC

Born: June 30, 1801, in Bayonne, Aquitaine, France; Died: December 24, 1850, in Rome; Nationality: French; Professional Interests: proponent of free trade; Major Work: *The Law* (1850).

Frédéric Bastiat was a French economist and journalist who championed free trade and laissez-faire government. His career as an economist began in 1844 during a time when France was undergoing a trend toward socialism. Most of his works were published around the time of the French Revolution of 1848. Bastiat’s arguments against socialism are characterized by their clear organization, use of parables, and understandable writing style. In his most famous work, *The Law*, Bastiat argues that government should exist only to protect humans’ God-given rights, which are life, liberty, and property. This work was published in June, just a few months prior to his death. Bastiat died in 1850.

Claude Frédéric Bastiat was born on June 30, 1801, in Bayonne, Aquitaine, France. Bayonne, Aquitaine, is located in the south of France on the Bay of Biscay. Bastiat was orphaned at the age of nine and was raised by his paternal grandparents. He spent his youth on his grandfather’s farm in Mugron in the south of France. Not fond of working on the farm, he passed most of his time reading. At age 17, he left school to work at his uncle’s trading company. While working at his uncle’s firm, he perceived that its inability to flourish was due in part to the government’s restrictive economic controls. It was at this time that young Bastiat declared that his ambition was “nothing less than to become acquainted with politics, history, geography, mathematics, mechanics, natural history, botany, and four or five languages.”

Bastiat was particularly inspired by the works of Jean-Baptiste Say and Adam Smith. Their ideas convinced Bastiat that social and economic progress could not exist outside of a free-market economy. When Bastiat was 24, his grandfather died, leaving him the countryside family estate in Mugron. Bastiat spent the next 20 years running the farm and quietly debating politics with his friends. During the French Revolution of 1830, Bastiat was inspired to join the cause in the name of driving out oppressive government rule in France. His analytical thinking and dedication did not go unnoticed. Soon after the Revolution of 1830, Bastiat was named justice of the peace in Mugron, and two years later he was elected to membership in the General Council of Landes.

Even under a new ruler, Louis Phillipe, France soon fell back into the same oppressive patterns. Poor citizens were not allowed to vote, the publication of negative articles about Louis Phillipe were prohibited, and the king used the power of the government to benefit some citizens at the expense of others. Witnessing the once-promising ruler fall into the socialist patterns of his predecessors, Bastiat became even more convinced that increasing government regulation was not beneficial to the citizens of a society.

Bastiat was particularly sensitive to the issue of tariffs. After traveling to Spain and Portugal, and seeing those countries mirror some of the same mistakes France had made, he became more passionate about free trade and fighting government protectionism. To defend himself against criticism from his fellow Frenchmen, he began reading English works. It was while reading *The Globe and Traveler* that he discovered the ideas of Richard Cobden and the Anti-Corn-Law League. Inspired by what he read, Bastiat submitted a treatise on tariffs to the *Journal des Economistes*. The article was printed in October 1844, and Bastiat's career as a journalist began.

Bastiat's articles were popular with French readers, and he became a regular contributor to the *Journal des Economistes.* His writing was characterized by satirical wit and the use of parables. His early articles were published collectively as *Economic Sophisms* in 1845. One of the articles in *Economics Sophisms* uses the analogy of a broken railroad to explain how tariffs are counterproductive. The illustration tells a fictitious story of a railroad built between Spain and France to facilitate trade. Soon, the producers in each country complain that the importing country is now able to provide certain goods at lower prices, threatening the profitability and security of the exporting countries' businesses. The producers demand that tariffs be enacted to artificially raise the price of the competing goods. Bastiat suggests that the tariffs negate the benefit of the cost of building the railroad in the first place, and that the consumer suffers by not enjoying the most competitive price. He sarcastically suggests that instead of imposing tariffs, the government should simply destroy the railroad anywhere that competition threatens to lower the price to consumers.

One of Bastiat's most famous parables attacking protectionism is "The Petition of the Candlemakers." In this satirical essay, he asks that a law be passed requiring that all doors, curtains, and other openings be closed in order to block out the sun, which is competing unfairly with the candle-makers' products. In the essay, on behalf of the candle makers, Bastiat declares that the candle-makers' occupation is under attack by the sun, which certainly has an unfair competitive advantage. The sun can provide an abundance of light at a very low price. Bastiat goes on to claim this law against the sun is absolutely necessary to prevent this French industry, candle-making, from totally disappearing.

In 1846, Bastiat established the Association of Free Trade and began his own newspaper, *Le libre-échange*, devoted to free trade. He began a journey through France to establish affiliate free-trade associations. The free-trade movement in France failed to gain popularity, however, and in 1848 Bastiat's association ceased to exist. Bastiat was elected to the French National Assembly in 1848. He continued to write, lecture, and serve in the Assembly until his death in 1850.

In June of 1850, Bastiat returned to Mugron for a few days and penned his most famous work, *The Law*. In this last work, Bastiat warned against socialism and again praised limited government and individual freedom. In *The Law*, he asserts his belief that the responsibility of the law is to preserve life, liberty, and property. He argues that the law was instead being used to benefit one group of citizens to the detriment of another group.

Frédéric Bastiat died on December 24, 1850, in Rome at the age of 49 after contracting tuberculosis. His works are still considered relevant arguments against the effects of socialism, and they are better known in the United States than in France. Since Bastiat offered no unique economic theories, some current economists do not consider him an economist in his own right but instead a talented journalist and communicator.

BEHAVIORAL ECONOMICS

In contrast to traditional economics, a key distinguishing feature of behavioral economics is its particular emphasis on the realism of the behavioral, sociological, and institutional assumptions that form the basis of economic models. Although all models require simplifying assumptions, behavioral economics places strong emphasis on avoiding simplistic assumptions that have little to do with how individuals behave in the real world. Traditional economics can produce misleading economic analyses and predictions, and it can confuse correlation with causation. Related to this, behavioral economics is strongly rooted in building economic theory through an understanding of how individuals actually behave—and then explaining this behavior.

Contemporary behavioral economics is often associated with the contributions of Hebert Simon and, more recently, Daniel Kahneman, Amos Tversky, George Akerlof, and Richard Thaler. Behavioral economists have developed new theories that either supplement or revise conventional microeconomic and macroeconomic theories when these can't explain economic behavior or economic events. A cornerstone of behavior economics has been the introduction of noneconomic variables or factors to the economic toolbox, especially psychological, sociological (including gender and economic class), institutional (political), and, more recently, neurological variables. But behavior economics does not reject the importance of relative prices and incomes determining decision-making and choices. It's just that traditional economic variables alone often are not good enough to produce rigorous economic analysis.

Simon introduced the concepts of *bounded rationality* and *satisficing*, integrating into economic theory the fact that the brain's cognitive—or processing and information-gathering—capacity is limited, making these tasks costly. The brain is, in fact, a scarce resource, like clean water, oil, and food. In addition, the individual's decision-making environment is often less than ideal. Information is not only costly to obtain but also asymmetric; that is, some individuals have better information than others. For example, the seller of a used car or a financial asset has better information than the buyer, and the worker has better information about the work process than the employer. In additional, individuals can't predict with any degree of certainty the implications of their choices for their future. This imposes additional constraints on how rational people can go about making decisions. For these reasons, bounded rational or smart individuals—as opposed to the unboundedly rational individuals of traditional economics—develop and adopt procedures and decision-making shortcuts or heuristics to limit such costs. These decision-making procedures typically differ quite significantly from what is suggested by traditional economics, which assumes that the brain is not a scarce resource and that the decision-making environment is ideal.

"Satisficing," as opposed to maximizing, is what rational individuals attempt do in a world of bounded rationality. They attempt to achieve the best possible outcomes given the constraints that they face. In a world of bounded rationality, a firm's output and profit and the individual's level of satisfaction or utility can be less than these might in in world where there brain is not a scarce resource and where the decision-making environment is ideal. However, some behavioral economists argue that given bounded rationality, individuals often end up making *superior* decisions when applying satisficing decision-rules as opposed to those recommended in traditional economics. In fact, economist Friedrich Hayek, analyzing the dynamics of complex information, made this point in the 1940s. In additional, economic models based on bounded rationality and satisficing can be more descriptively and causally accurate than traditional economic models.

Apart from bounded rationality and satisficing, Simon and more contemporary behavioral economists also emphasize the significance of differential power relationships among decision-makers, conflicts, fairness, altruism, trust, emotions, identity, intuitions, norms, social capital, and institutions for modeling human decision-making in the realm of economics. These variables were not given much attention in traditional economic theory, as they were assumed not to be of much consequence to understanding economic outcomes. The evidence now shows that these factors often play an important role in decision-making. For example, contrary to conventional economics, individuals often don't simply focus on increasing their own income; often they willingly sacrifice some income in the name of fairness or justice. Also, emotion and intuition often play a role, often a positive one, in decision-making.

More recently, Kahneman and Tversky (two psychologists) developed *prospect theory*, which is a hallmark of contemporary behavioral economics, based on their empirical findings on human decision-making. Prospect theory is offered as a new and improved alternative to traditional economics subjective expected utility (SEU) theory. In contrast to SEU theory, in prospect theory individuals, on average, aren't income or wealth maximizers after their preferences regarding different levels of risk are accounted for. Rather, individuals are willing to sacrifice income for the certainty of outcomes. Individuals, on average, aren't willing risk significant losses today for uncertain gains and possible losses in the future. Also, a dollar gained is given a lower weight than a dollar lost. So, unlike in the conventional wisdom, on average, if you win a dollar and you lose a dollar, your net gain is not zero; rather it is negative. So, it is argued, individuals tend to be adverse to losses (loss aversion). In addition, individuals tend to evaluate losses and gains from a subjective benchmark, as opposed to their absolute net gains in income and wealth. Also, individuals often evaluate their well-being relative to others. Therefore, absolute increases or levels of income and wealth are less important than improvements to a person's relative positioning are. Much of this is driven by the role of emotions in decision-making, as compared to "rational" calculation. For this reason, wealth maximization is not the end game in prospect theory's descriptive modelling framework. In addition, Kahneman and Tversky, as well as other behavioral economists and economic psychologists, have argued that individuals' decisions are affected by, among other things, lack of self-control: individuals often do things that they prefer not to do, and they soon regret so doing. Individuals also tend to be overconfident, shortsighted, or myopic, and they are heavily influenced by the behavior of others, driving them to "copycat" or "herding" behavior that, according to many behavioral economists, results in errors in decision-making.

Harvey Leibenstein developed the concepts of efficiency wages and X-efficiency theory. Based on the evidence, he assumes that effort inputs into the process of production are variable—not fixed, usually at some maximum, as is assumed in conventional theory. Therefore, costs need not be minimized nor output maximized. In this model, effort maximizing remains the ideal for wealth maximization or X-efficiency to be achieved. However, for this to transpire, appropriate market conditions and in-firm incentive environments (often far removed from neoclassical norms) must be developed. For example, fairness, trust, happiness, and voluntary cooperation, as well as competitive pressures, become important to motivating increasing effort levels. The efficiency wage modeling has being extended to provide rational explanations for nominal wage rigidity.

Two major perspectives have developed in behavioral economics. One follows and extends the work of Kahneman and Tversky. This perspective is especially focused on demonstrating through experiments the extent to which human decision-making deviates from conventional economics best-practice behavioral norms. The latter are typically used as the benchmark for economic rationality. By such standards individuals are often found to be irrational, generating inefficiencies in consumption and production. But such behavior can often be corrected through education or government intervention.

The other approach to behavioral economics builds on the contributions of James March and Herbert Simon. Individuals are assumed to be largely rational and intelligent, even when they deviate significantly from traditional economic behavioral norms. Rather, individuals develop procedures and institutions that best suit their individual needs given the constraints they face. More often than not, such deviant behavior yields superior and more efficient outcomes in consumption and production than would conventional behavioral norms. Errors in decision-making are often corrected through learning, experience, and improvements to the decision-making environment. This approach to human behavior is sometimes referred to as "ecological rationality," and it is championed by experimentalist Vernon Smith and psychologist Gerd Gigerenzer.

Behavioral economics enriches conventional economic theory by introducing important variables and parameters that are often neglected. This helps generate more rigorous models in terms of prediction, description, causality, and policy. It allows us to better understand how and why individuals make the choices they make given the constraints they face and their psychological and neurological endowments.

BEHAVIORAL FINANCE

Behavioral finance is the field of research that studies how investors make judgments and choices in financial markets. Its models incorporate findings from different social sciences (economics, psychology, and sociology) and, more recently, brain sciences to explain investor preferences and behaviors. In contrast to traditional finance, which is based on normative rationality (based on traditional economics) assumptions, behavioral finance proposes more descriptive market theories. One of the most important aims of this research area is to show how cognitive errors or biases and affective reactions of individual investors influence and modify price changes on the market.

Behavioral finance theories are typically classified into two groups: belief-based and preference-based. The former refers to judgments concerning risks and expected returns, whereas the latter is related to decisions on what and when to trade.

When making intuitive judgments in a complex environment (a financial market), people typically use different mental shortcuts that psychology defines as *heuristics*. Empirical research has demonstrated that heuristic information-processing may lead to systematic biases and deviations from traditional economic rationality. Examples of cognitive biases that can be observed in financial judgment are *anchoring* or *representativeness*. Anchoring can be interpreted in terms of investors relying too much on a past reference (initial share price) or a certain piece of information (earnings announcement) when making financial forecasts for the future. When people make judgments according to the representativeness heuristic, they base those judgments on different stereotypes. For example, investors tend to be optimistic about prospects of stocks that were recent winners and pessimistic about the future of stocks that were recent losers. In other words, they fail to think in terms of the regression to the mean phenomenon (DeBondt and Thaler 1985).

Biases in financial judgment result not only from cognition but also from motivation. It has been shown that investors are overly confident in their knowledge and tend to be prone to wishful thinking. One of the consequences of the overconfidence illusion is exuberant trading frequency resulting in a worse performance (Barber and Odean 2000).

The second category of behavioral finance models concerns preferences and choices. The main basis for these models is *prospect theory*, which shows that people's preferences are context-dependent and strongly loss-averse. Researchers have used both effects to explain investors' tendency to hold on to losing stocks for too long and sell winning stocks too soon—the tendency referred to as the *disposition effect* (Shefrin and Statman 1985). Prospect theory suggests that people are risk-averse in the domain of gains but risk-seeking in the domain of losses. If stock appreciates, investors sell it early because they do not want to accept the risk of trend reversal. On the other hand, if stock declines and its price falls below the purchase level, investors accept the risk of further price decreases to avoid losses resulting from selling.

Behavioral finance research on preferences examines not only the when-to-trade issue but also the what-to-trade issue. It has been documented, for example, that investors are not rational (or highly calculating and search-intensive) in how they diversify their portfolios, and that they rarely use the sophisticated methods offered by traditional financial models. For example, they use the 1/N heuristic (Benartzi and Thaler 2001) to invest, meaning that they divide their assets evenly across different funds (50 percent of assets are invested in safe bonds and another 50 percent in risky stocks). Another illustration is represented by the home-bias effect (French and Poterba 1991): Investors tend to choose equities that they are more familiar with (domestic stocks) and avoid those that are less-recognized (international stocks), which results in a poor portfolio diversification. But some scholars argue that such heuristic behavior can yield the best possible results in a world of complexity, and that they are therefore bounded rational (Gigerenzer).

For many years, behavioral finance was perceived as a controversial field of research, with its ideas used to explain the so-called anomalies of investors' beliefs and preferences. Today, behavioral finance is becoming increasingly the norm—and an important part of the theory of financial economics.

BERNOULLI, JACOB

Born: December 27, 1654, in Basel, Switzerland; Died: August 16, 1705, in Basel, Switzerland; Nationality: Swiss; Professional Interests: quantitative economics; Major Work: *Ars Conjectandi* (1713).

Jacob Bernoulli proved equations in calculus and created equations that helped businesses grow. Even though he made his mathematical discoveries in the 1600s, they are still used today to help describe and explain our economy.

Jacob Bernoulli was born on December 27, 1654, in Basel, Switzerland. The Bernoullis were an intellectual family with a background in philosophy and theology. Jacob's mother Margaretha came from an important family of bankers and councilors, while his father Nicolaus was a member of the council of Basel. Jacob also had a brother, Johann, who became a well-known mathematics professor at Basel University. Jacob graduated from Basel University in 1671 with a master's degree in Philosophy. He had a hidden interest in mathematics and astronomy, and studying mathematics was his true passion. He made two amazing findings in the mathematics field: the Constant *E* and the Law of Large Numbers.

Bernoulli's Constant *E* is a way to measure compound interest. Compound interest is one of the most efficient ways to measure finance, while *E* is one of the most important numbers and is irrational. The *E* is used in Bernoulli's equation to try to determine the interest of something. It gives value, which is added to interest over time.

The Law of Large Numbers is an economic equation for determining whether a company might grow so large that it will be larger than the economy. The law claims that a business or some type of entity cannot keep growing forever—that at some point, the growth will diminish or decline. This law can be used to show businesses whether their company is growing at a rate that cannot be sustained in the long run.

The Law of Large Numbers has various uses in describing a company or an economy. In the investing world, the equation can be applied to determine whether buying stocks in a given company is a good idea. The investor can predict if the business still has growth potential and is worth investing in the company. Note that Apple and Google are types of businesses that have continued to grow and the law has not applied.

In the 1600s, Jacob Bernoulli established new ways for economists and investors to view today's economy. Using his equations, economists and financial strategists can measure the growth rate of a business and find the compound interest. Both mathematical concepts are extremely useful in economics.

Jacob Bernoulli died August 16, 1705, in Basel, Switzerland.

BIODIVERSITY

Biodiversity does not have a single, clear definition. The United Nations Convention on Biological Diversity defines *biodiversity* as the variability among living organisms from all sources, including, among other things, terrestrial, marine, and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species, and of ecosystems. *Genetic diversity* is a range of genetic characteristics within a species, and *species diversity* is the measure of different types of organisms at the community level, ecosystem, or higher level of ecological organization. Commonly, species diversity serves as a proxy for biodiversity. Species diversity has two major components: species richness and species evenness. *Species richness* is the total number of species within a community. *Species evenness* is the relative abundance with which each species is represented in an area.

In addition to definitional difficulties, there exists great uncertainty with regard to the estimate of the number of species. This level of uncertainty is nontrivial. Approximately 8.7 million species exist globally, with only 14 percent, or 1.2 million species, described. Given this high level of uncertainty, taxonomic surveys are important instruments in the understanding of biodiversity. Unfortunately, taxonomic surveys are time-consuming and costly.

Economists are interested in biodiversity because variability among living things provides important benefits but is threatened by human activity. Cultural values (especially for indigenous peoples), recreational opportunities, regulation of nutrient cycles, carbon sequestration, natural pest control, pollination, genetic resources, food, and fuelwood are among the benefits derived from biodiversity. In addition to the use-value motives for biodiversity preservation, there are preservation motives that are based on passive-use value and future-unknown-use values. As regards passive-use value, individuals are better off simply knowing that certain species and ecosystems exist, unrelated to any current or expected future usage. Because future needs are unpredictable, there is also a significant option value associated with biodiversity. For example, the Pacific yew tree, once considered to be of little commercial value, was crucial in the development of the anticancer drug Taxol. The irreversible destruction of species such as the Pacific yew tree would have precluded the discovery of the previously unknown benefits.

Similar to the definitions and measures for biodiversity, the threats to biodiversity are also numerous and include habitat destruction, invasive species, overexploited resources, pollution, and climate change. Habitat destruction, or modification due to expansion of human populations and human activities, is the greatest threat to biodiversity. Habitat destruction may be carried out in a complete form, where an area of land is directly developed, or it may be done in a partial form (fragmentation). Habitat fragmentation occurs where relatively continuous geographic areas are split into smaller discontinuous areas, which may be too small to maintain viable native populations. Invasive and alien species can also be extremely detrimental to biodiversity. For example, the introduction of the Nile perch to Lake Victoria was the cause of possibly the largest single vertebrate extinction in the 20th century. Mainly due to Nile perch predation, it is estimated that 200 to 300 of the endemic *Haplochromine cichlids* species have gone extinct or are threatened with extinction. Climate change affects biodiversity adversely by altering the distribution or range of many terrestrial species and causing stress on other species. It also impacts marine systems by changing the timing and length of the spring bloom of phytoplankton and changing ocean chemistry. Finally, biodiversity is threatened by pollution. For example, pollution in the form of agricultural runoff, especially nitrates, is responsible for the decline and/or the extinction of certain amphibian species.

In an ideal world, decisions regarding biodiversity would be addressed through cost-benefit analysis with certainty and complete information. Unfortunately, this is not the case. There is evidence that biodiversity expenditures are based on intuition or on the ranking of the projects without consideration of the costs. Also, conservation efforts are greatly affected by the characteristics of the species and the public's knowledge of the species. People are more willing to donate to conservation efforts if they are familiar with the species or if they perceive the species to be attractive. As a result, certain threatened species, including many invertebrates that play critical roles in ecosystem function, are underrepresented in conservation efforts.

Although climate change and the preservation of biodiversity are considered to be the two most significant environmental issues today, both are plagued by underprovisioning and by the complexities associated with global public goods. Since biodiversity is a normal good, richer countries have a greater willingness and ability to preserve biodiversity, while poorer countries have the incentive to convert areas of biodiversity into pasture and arable land. However, areas of rich biodiversity (e.g., rainforests and coral reefs) tend to be located in poorer countries. This discrepancy in the distribution of monetary and species wealth has prompted various nations and nongovernmental organizations to engage in environmental assistance in the form of financial transfers and technical expertise. However, many biodiversity projects are beset with the weak enforcement of property rights, poor monitoring, and other factors that reduce the effectiveness of these efforts.

BÖHM-BAWERK, EUGEN VON

Born: February 12, 1851, in Vienna, Austria; Died: August 27, 1914, in Vienna, Austria; Nationality: Austrian; Professional Interests: Austrian School economist; Major Work: *Capital and Interest* (vols. 1, 2, and 3, 1884–1890).

Eugen von Böhm-Bawerk's early contributions led to the further advancement of the Austrian School of economics. His contribution to the Austrian School was his theory of capital and interest. He published three volumes of his magnum opus, *Capital and Interest.* A focus of his writing was the basis of the Austrian School's theory of the business cycle, later communicated by Ludwig von Mises and Frederick Hayek. Early in his career, he wrote a damaging critique of Karl Marx's exploitation theory. As Austrian finance minister, he advocated for tax reform, a fixed gold standard, and a balanced budget. Böhm-Bawerk died in 1914.

Böhm-Bawerk was born February 12, 1851, in Vienna, Austria. He was studying law at the University of Vienna when he read Carl Menger's *Principles of Economics.* He became a dedicated supporter of Menger's theories and those of the Austrian School of economics. Böhm-Bawerk's unique contribution to the Austrian School was his theory of capital and interest. After completing his university studies, Böhm-Bawerk taught at the University of Innsbruck. He was appointed minister of finance in 1895, serving till 1900. In 1904, he returned to teaching economics, at the University of Vienna.

Böhm-Bawerk's principal contributions to economics were his theories of interest and capital. During the 1880s, he published two of the three volumes of his magnum opus, *Capital and Interest*. The first volume, titled *History and Critique of Interest Theories* and published in 1884, is an exhaustive survey of the alternative treatments of interest—including the use theories on productivity and abstinence, which were only two of the many that Böhm-Bawerk put forward. Böhm-Bawerk stated that interest would be paid to the owners of capital, irrespective to who owned the capital. Economists today continue to accept this argument.

Böhm-Bawerk did not go beyond monetary theory in his thinking and writings. If he had, he would have conveyed the Austrian School's theory of the business cycle. His bull's-eye concentric circles could have reflected how lower interest rates create new money, eventually misallocating resources and creating unsustainable growth leading to economic crises. This was later communicated by von Mises and Hayek.

Böhm-Bawerk's economics analysis was one of the first serious examinations of the works of Karl Marx. Early in his career Böhm-Bawerk wrote a damaging critique of Marx's exploitation theory. Böhm-Bawerk submitted that capitalists do not exploit their workers, but in fact just the opposite: Capitalists provide workers with an income before receiving any revenue from production. Böhm-Bawerk maintained that the exploitation of workers did not create interest. He also maintained that production was cyclical and that therefore some financing that Marx attributed to workers must go toward capital. Böhm-Bawerk's alternative views of the exploitation theory gained him recognition in the discipline of economic thought. This rebuttal of Marx and socialist doctrine brought a new spectrum in economic thought to capitalism.

Böhm-Bawerk's work in the area of capital change formulated the early Austrian thought on the relationship between saving and consumption. He asserted a tradeoff between consumption and saving. Savings could increase only with a decrease of consumption, and vice versa. This zero-sum interpretation was broadened to include the relationship between saving and capital formation. Using his bull's-eye model, Böhm-Bawerk asserted that capital increases in the inner rings could be accomplished only with increased savings in the outer rings. In a market economy, the relative value of the capital among the different rings would determine the economic activity of businesses.

Böhm-Bawerk was a classical liberal, yet by today's standards he would not fit the label of Austrian economist. His writings exhibited a concern for completely unfettered free markets. Combining his theory of interest and theory of marginal value proposed by his early champion Menger, Böhm-Bawerk showed that given a market wage rate, capitalists engage in activities that employ a full labor force.

Böhm-Bawerk presented a bull's-eye type of figure to more fully illustrate his work on capital and interest. This bull's-eye pattern of concentric rings portrayed timing in the production of goods. The center circle (the bull's-eye) represented the factors of production (land and labor). Each succeeding concentric circle represented a new time frame in the production process, until the final outside circle represented the final good. Böhm-Bawerk also used the bull's-eye illustration to represent an orderly economy. Even though the bull's-eye model was static by design, it was intended to reflect a dynamic analysis of change.

On his economic theories, Böhm-Bawerk also had his detractors, both within the Austrian School and outside it. Within the Austrian School, it was considered that his theory relied too much on psychology and subjective. Outside the Austrian School, many thought that his work lacked mathematical strength and that his perspective was historical.

Later in his career, Böhm-Bawerk served as the Austrian minister of finance. He held this position at various times during the 1890s until 1904. As finance minister, he advocated for tax reform and a rigorous preservation of a fixed gold standard and a balanced budget. His tax reforms were considered very successful.

He also eliminated the long-standing sugar subsidy. He increased the financial demands to support the army, creating serious budget imbalances. This led to his resignation in 1904. He was honored later by being the image on Austria's 100-schilling note.

After his service in the Austrian government, he returned to teaching. In 1904, he became chair at the University of Vienna. He joined Friedrich von Wieser on the faculty, as well as succeeding the retired Menger. His legacy of work continued through the work of his students during his tenure, including Ludwig von Mises and Joseph Schumpeter.

Eugen von Böhm-Bawerk died in Vienna on August 27, 1914.

BOULDING, KENNETH

Born: January 18, 1910, in Liverpool, England; Died: March 18, 1993, in Boulder, Colorado; Nationality: naturalized U.S. citizen; Professional Interests: capital theory, evolutionary economics, pricing, income distribution; Major Work: *A Reconstruction of Economics* (1950).

Kenneth E. Boulding was an economist with a very broad disciplinary and topical sphere of influence. Born the son of a plumber in Liverpool, England, in 1910, Boulding was the first in his family to receive more than an elementary school education. He was classically trained in politics, philosophy, and economics at Oxford, after an initial brief foray into chemistry. Shortly after he received his undergraduate degree in 1931, his paper on displacement costs was published in *The Economic Journal*, which at that time was edited by John Maynard Keynes. Boulding held a postgraduate fellowship at Oxford and then received a Commonwealth Fellowship to study in the United States, primarily at Harvard and Chicago, where he was influenced by luminaries such as Joseph Schumpeter, Frank Knight, and Jacob Viner. And he influenced them as well. Knight's article "The Theory of Investment Once More: Mr. Boulding and the Austrians" was published in the *Quarterly Journal of Economics* in 1936, when Boulding was just 26 years old.

From the beginning, Boulding's work challenged conventional assumptions on a range of topics, such as capital theory, pricing, and income distribution. Although a strong theorist to the core, he was averse to economic canon that failed to capture the complexity of real-world problems. While mathematically competent himself, he decried what he viewed as economics' overemphasis on mathematization in the mid-20th century. As his career evolved, he dedicated more attention to a fully integrative model of social science that drew heavily from psychology, sociology, and philosophy, as well as economics. This interdisciplinary approach may reflect the influence of his wife, Elise, a distinguished scholar of sociology, but it also revealed a curious mind stimulated by the complexity of life. His topics of inquiry evolved as well from an early emphasis on conventional matters of capital, markets, and income to more unorthodox topics (for the time) of peace, conflict, population, and the environment. A Quaker, Boulding was deeply committed to the ideals of social justice.

Boulding's work on the environment became evident first in his book *A Reconstruction of Economics* (1950), which proposed an ecological framework for the workings of society and the economy, and somewhat later with his work on evolutionary economics and principles of entropy, which comingled with the work of Nicholas Georgescu-Roegen and K. W. Kapp. His attention to population dynamics was unique for its time, and his emphasis on *homeostasis*—or sustaining the condition of stocks manufactured or natural over the enlargement of flows as a determinant of human welfare—was and remains controversial within economics.

In his 1966 essay "The Economics of the Coming Spaceship Earth," he argued that standard economics texts failed to recognize the transition of Earth from an open system, a virtually limitless plane, from which humans can draw materials and into which humans can expel wastes, to a closed system in which "the outputs of all parts of the system are linked to the inputs of other parts." This tied back to the foundations laid in Reconstruction, which established a basic conflict between the consumption necessary to sustain full employment and the drawing down of stocks (in this case the natural environment) necessary to enrich human lives.

Boulding experienced success and recognition in mainstream economics for much of his career. The remarkable callout to Boulding in the title of Knight's 1936 article perhaps foretold Boulding's destiny as a 1949 winner of the John Bates Clark medal for an economist under the age of 40. Two generations of economists who were trained in the mid-20th century cut their teeth on his textbook *Economic Analysis*. He was voted president of the American Economic Association in 1968, and he was purported to be nominated for the Nobel Prize in both Economics and Peace. Yet it may also be fair to say that he was a man whose views were widely respected, but often ignored in the economics profession. His own writings suggest an awareness of this juxtaposition, but one that did not embitter him so much as motivate him to push the boundaries of economic thought and application. In later life, he still viewed himself as an economist, even if there were some within the field who may have assumed he had launched to another intellectual island. Despite any questions about the extent of Kenneth Boulding's acceptance by the economics mainstream, his influence on the development of environmental economics on topics such as sustainability, population, and green national accounts is both clear and profound.

BUDGET

A *budget* is the document that categorizes income received into spending, saving, and investing categories. Individuals, organizations, governments, and corporations all use budgets to monitor their income and expenses. The budget creation process is similar for all entities and involves several discrete stages.

The Consumer Budget

Creating a budget or a spending plan may be the consumer's most important money management activity. A *budget* is the spending plan that integrates the consumer's income and expenses and earmarks funds for the important spending, saving, and investing categories. The consumer creates an initial budget by tracking and analyzing spending habits so the amounts for each category can be accurately predicted. After the budget is created and expenses are recorded, the consumer compares actual spending with the budgeted amounts for each section. Adjustments are made so that the spending plan is realistic and meets the targeted spending and saving classifications.

Pre-Budget: Track Expenses

To develop a budget accurately, it's helpful to keep track of one's expenses for a few weeks; otherwise, the budget category estimates will likely be inaccurate.

Maya, a recent college graduate, gets her first job and wants to create a budget. After tracking her expenses for a few weeks, she finds that her $2,700/month salary doesn't last very long. Federal, state, Social Security, and Medicare taxes eat up $700, leaving $2,000 to cover rent, food, utilities, car payment, gas, entertainment, phone, eating out, charity, saving, buying clothes, and investing for the future.

Maya spent $750 on rent and utilities. She paid $500 for groceries, eating out, and entertainment. Her car payment and insurance were $325 per month, and gas consumed another $200. That added up to $1,775, with just $225 remaining for charity, clothes, and saving. By tracking her expenses for a month, Maya understood why her savings account was low and her credit card bill was not paid in full at the end of the month.

Creating the Budget or Spending Plan

Once a consumer has that knowledge of prior income and spending in hand, step two of preparing a budget involves financial goal setting. Before creating the spending plan, decide upon saving and spending financial goals. These might include saving for retirement, saving to buy a home, going out for entertainment several times a month, saving for a vacation, buying a car, buying new clothing, and so on. To decide how to allocate limited personal income or corporate revenue, both individuals and corporations must prioritize their wants and needs.

After financial goals are decided on and prioritized, the working budget creation begins. The budgeter reviews prior income and spending data and financial goals, and then uses the information as a guide for the budget.

Maya created a few goals, including saving for retirement, taking a vacation, and buying new clothes. She also wanted to save several months' worth income for emergencies. In the first example above, it was clear that Maya didn't have enough room in her budget for her newly outlined goals. She needed to reduce spending to make room for her future expenses.

By integrating all of her prior spending and goals, she came up with a working budget. This is a flexible document that she will try out and amend as needed.

Maya decides to contribute $200 per month to her workplace 401(k) retirement account. Her boss contributes another $135 per month, or 5 percent of her pretax income. This retirement account contribution is made before taxes are taken out, so it reduces her taxable income. In spite of contributing $200 per month to a retirement savings account, her taxable income declines only $69, which leaves $1,931 for the month's remaining spending and saving. Maya's rent and utilities remain at $750, but she reduces her spending on food and entertainment to $425. After shopping around for more economical auto insurance, she is able to reduce her monthly auto-related payments to $290. She decides to carpool, which cuts her gas spending down to $100.

These small changes leave Maya $366 to spend on charity, clothes, vacation, and emergency savings.

That's how the budgeting process works, for individuals. Organizations receive revenue instead of income, and they spend on different categories than individuals, but the budgeting process is similar.

After trying out the budget for a month or so, the budgeter reevaluates the spending and saving to make sure the benchmarks are accurate.

Common Budget Guidelines

There is no hard and fast rule about how much of one's income should be allocated to various budget categories, although recommended guidelines exist. In particular, savings and housing guidelines are widely accepted. Federal, state, local, and other taxes cannot be overlooked.

In general, the following approximations are guidelines to help allocate personal income. In order to have money for future expenses such as retirement and long-term goals, individuals are advised to save 10 percent of their *gross* income (that is, before taxes and deductions are subtracted from the paycheck). It is widely accepted that housing costs should require no more than 30 percent of one's income. It's preferable to keep housing costs closer to 20–25 percent if possible. Taxes take up to 25–30 percent of one's income. This figure varies based upon many factors, including whether one has children or other dependents. Taking the most conservative estimate, after housing, tax, and savings goals are deducted, 30–40 percent remains for food, clothes, insurance, transportation, entertainment, and miscellaneous expenses.

This hypothetical budget scenario illustrates the importance for consumers to consider their expenses carefully, so that they are able to live within their means and avoid excess credit or debt.

Monitoring the Budget

There are many ways to keep track of a budget, including online tools, computer programs, paper and pencil, and envelopes.

The envelope system—one of the oldest methods of budgeting—consists of placing each category's monthly funds in a separate envelope. For visits to the supermarket, money is taken from the Food envelope. When that envelope is empty, the spending for that category should end for the month.

Another traditional approach is to record income and expenses in a ledger and compare the actual spending with the predetermined budgeted amounts.

Online tools allow the consumer to input or even download income and expenses from the bank, credit card, or debit card. The actual spending is compared with the targeted spending, and adjustments are made as needed.

A unique budgeting strategy first described by the well-known financial journalist Jane Bryant Quinn suggests automatically deducting all saving and investing into the appropriate financial accounts. The individual is free to spend whatever money remains, confident that the future is provided for.

Regardless of which budgeting method is used, it is an ongoing process. As income and expenses evolve, the budget will change as well.

BUFFETT, WARREN

Born: August 30, 1930, in Omaha, Nebraska; Nationality: American; Professional Interests: businessman, investor, owner of Berkshire Hathaway, one of the wealthiest people in the world.

Warren Buffett is one of the wealthiest people in the world, a legendary investor, and the owner of Berkshire Hathaway. He is the son of Leila Buffett and Howard Buffett. His father was a stockbroker and a member of the U.S. Congress. Warren Buffett was born in Omaha, Nebraska, and he's the middle of three children and the only boy. It was evident from an early age that Buffett had an aptitude for investment; he likely was influenced by visiting his father's office. Buffett demonstrated his business acumen as a child and frequently resold items for a profit.

Buffett purchased his first shares of stock when he was only 11 years old. The stock he purchased, Cities Service Preferred, dropped after he purchased it. Buffett waited patiently for the stock to rebound, and when it did, he sold it. However, he immediately regretted the decision, since the share price of Cities Service increased even more in the time following the sale. That buy-and-hold lesson is still the crux of Buffett's financial philosophy.

Buffett did not want to go to college, since he already had made considerable money as a paperboy, work that he had been doing since age 13. He also purchased pinball machines with a friend, resold them, and within a few months reaped quite a profit. He eventually sold that business, and at his father's insistence he attended the University of Pennsylvania's Wharton School of Business. Unimpressed with his education, Buffett eventually transferred to the University of Nebraska, Lincoln where he finished his education. For graduate school, Buffett attended Columbia University in 1956—after being rejected by Harvard. At Columbia he met Ben Graham, who became his mentor and teacher.

After graduation, Buffett wanted to work for Graham, but Graham did not hire him, so Buffett returned home to work for his father. Shortly thereafter, he met Susie Thompson, whom he married in 1952. The young couple did not make a large income, so they lived modestly, even using a drawer as a crib for their first child. Eventually, Buffett was able to fulfill his dream of working for Graham, when Graham hired him and invited him to work at his firm in New York.

Buffett was extremely successful and hardworking, and he learned a great deal about the investment industry under Graham's tutelage. He eventually formed his own investment partnership, which proved immensely successful. Just before he liquidated that partnership, he became a major stakeholder in Berkshire Hathaway, which at the time was a textile company. It eventually morphed into a holding company, and Buffett began accumulating more stock and other companies: the luxury candy company See's Candies, GEICO, Nebraska Furniture Mart, Scott Fetzer, and Executive Jet. He also invested in the *Washington Post*. Perhaps his best-known acquisition was a large percentage of the Coca-Cola Company.

Buffett's investment strategy has changed over time, but overall his investment style can best be described as having patience in the market, studying the habits of business owners, learning from mistakes, and investing only in businesses that he truly understands. Buffett is also well known for going against popular opinion and for being frugal, even living in the same modest house that he has owned for many years.

Over the past few decades, Buffett has demonstrated a strong commitment to charitable giving. He has donated substantial amounts of money to many charities, and in 2006 he announced that he would give his entire wealth to charity ($62 billion).

Buffett has not written any books, but many people have written books about him. Of these, the best known is *The Snowball: Warren Buffett and the Business of Life*, by Alice Schroeder.

Over the years, Buffett's personal life was tumultuous. He and his wife Susie separated, and in an unusual move, his wife gave her blessing for Buffett to date other people. Buffett and Susie remained close, even traveling and spending Christmas holidays together. With Susie's knowledge and approval, a waitress named Astrid Menks moved in with Buffett.

Buffett's wife has since passed away, and Buffett eventually married Menks in 2006 in a modest ceremony. He has three children—Susie, Howard, and Peter—all of whom work in different fields and own their own foundations. Buffett has donated heavily to each of their foundations, and he recently donated $2 billion to the Bill and Melinda Gates Foundation. Although he is famous for not giving overwhelming amounts of money to his children individually, he has pledged to donate more to their foundations in the future so that they can continue their charitable work around the world.

Ultimately, Warren Buffett has had an extraordinary career thus far and is a prime example of someone succeeding in the pursuit of the American Dream. He will remain one of the most famous and most successful investors in history, inspiring millions of people along the way.

CANTILLON, RICHARD

Born: ca. 1680 in County Kerry, Ireland; Died: May 1734 in London, England; Nationality: Irish–French; Professional Interests: political economy; Major Work: *Essai sur la Nature du Commerce en Général* [Essay on the Nature of Trade in General] (1755).

Richard Cantillon was best known for his treatise *Essai Sur la Nature du Commerce en Général,* which was written in French circa 1732 and published anonymously in England 20 years after his death. Cantillon was an Irishman who moved to France and made a personal fortune in banking and investing in the British mercantilist John Law's Mississippi Company. Cantillon's *Essai* is considered the first dedicated treatise of economics as an analysis of the entire economic system. The broad scope of Cantillon's *Essai* implies that Richard Cantillon, not Adam Smith, is the rightful father of modern political economy and the true founder of modern economics. The Physiocrats and the French school of economics knew Cantillon's work; however, he was not viewed with the degree of fame as Smith until William Stanley Jevons, a cofounder of the marginalist revolution, rediscovered the *Essai* in the 1880s. Jevons writes that the *Essai* is "a systematic and connected treatise, going over in a concise manner nearly the whole field of economics. . . . It is thus, more than any other book I know, the first treatise on economics" (Jevons 1881). Cantillon died in 1734.

Richard Cantillon was born in the 1680s in County Kerry, Ireland, to a family of Catholic landlords who had fought for the Stuart cause and later lost their lands to Oliver Cromwell. Cantillon moved to France in 1708, and became a French citizen. Then he clerked as an assistant of the British paymaster general, James Brydges, in Spain where he organized payments to British prisoners of war during the War of the Spanish Succession. In Paris, Cantillon's cousin—who also went by the name Richard Cantillon—hired Cantillon to work in the family banking business. By 1716, Cantillon bought out his cousin and attained complete ownership of the Paris branch of the bank. He became very successful due to his contacts and connections throughout the major commercial centers of Western Europe.

Cantillon built a personal fortune by investing in British mercantilist John Law's Mississippi Company and profiting from the South Sea Bubble of 1711. Predicting an inevitable crash from Law's money-induced speculative bubble, Cantillon lent heavily to clients at high rates of interest that took future inflation into account. As a result, these clients owed Cantillon a significant financial debt, causing much animosity and enmity. Cantillon did not agree with Law's inflationist theories, but he understood their composition and the reasons for their eventual collapse. Until his death, debtors filed numerous lawsuits against Cantillon, leading to multiple murder plots and criminal accusations.

Cantillon's *Essai* is significant as it was the first *general* inquiry into economic theory and was quite different from the pamphlets of the day. As such, the *Essai* played a role in the early development of modern economic thought, and it influenced such thinkers as Adam Smith, many of the Physiocrats, A. R. J. Turgot, and Jean-Baptiste Say. The treatise is one of the few referenced in Adam Smith's *Wealth of Nations*. The document's extensive range and influence led Jevons to call the *Essai* "the cradle of political economy."

Cantillon's *Essai* is distinctive for its organization; it uses cause-and-effect methodology. Cantillon also wrote of positive economics only, excluding his own ethics or value judgments. He also used the *ceteris paribus* assumption, as well as a small isolated state to eliminate extra complications within the model. This scientific approach and logical-deductive reasoning is impressive and unique when placed in context historically.

Significantly, in the *Essai* Cantillon introduces and explains the concept of the "entrepreneur" as a risk-taker who balances supply and demand in a market while bearing the risk of uncertainty. These entrepreneurs—farmers, independent craftsmen, merchants, and manufacturers—are different from "hired men" who earn a fixed income.

Cantillon also writes that demand and relative scarcity determine market price. Price as "intrinsic value," or price based on opportunity cost and the factors of production, may differ from actual market price due to the forces of supply and demand. Intrinsic value is a measure of cost, yet it is important to note that Cantillon considered all resources to be heterogeneous. It becomes nearly impossible to determine their respective intrinsic value, because each piece of land or each worker is of a different quality. In addition, Cantillon explains the value of the alternative uses of land and labor, thus introducing the concept of opportunity cost to determine choice.

Cantillon wrote of monetary theory and the microeconomic aspect of monetary inflation. He explained how an increase in the volume of money in circulation will lead to an increase in the price level of goods and services where it enters the economy, as opposed to general inflation. He also explained that the forces of supply and demand of new money would influence the interest rate in the hands of money-lenders. In addition, Cantillon disagreed with the mercantilist–monetarist goal of continual increases in the money supply. Except as a result of extenuating circumstances, the money supply should remain stable. Cantillon was also the first to clearly outline the creation of the spatial theory of economics, the population theory (which later influenced Malthus and Smith), and the business cycle.

Richard Cantillon played a significant role in the history of economic thought, although his *Essai* was visible to only a few for a long period after its publication. Jevons served as a catalyst for renewed interest in the *Essai*, and Higgs's translation to English allowed significantly more readers to study the beginnings of modern economic thought. Unfortunately, Cantillon's discharged cook ultimately murdered him and set Cantillon's house on fire to cover the crime.

Richard Cantillon died in his London home in May 1734.

CAPITAL GAINS AND LOSSES

Capital gains and losses refer to an increase or decrease in value of a capital asset when compared with its purchase price. A *capital asset* refers to an investment in such financial assets as stocks, bonds, mutual funds, or other investment vehicles. Real estate is also considered a capital asset. Additionally, today's definition of a *capital asset* might also include precious gems; gold, silver, and other metals; a car used for commuting; or a stamp collection.

Imagine that someone bought a home for $250,000. The next year, a change in position at work caused the home buyer to be transferred to a city across the country. The person sold the home for $200,000—resulting in a capital loss of $250,000 less $200,000, or $50,000. The reverse holds true for a capital gain.

There is a long history behind the tax treatment of these capital gains and losses. The tax treatment of capital gains and losses had financial implications in the past, just as it has today. These tax treatments are important to savers and investors.

History

In the 1900s, the income taxes on gains from capital assets were the same as those from ordinary income (Auten 1999). The definition of a *capital asset* along with the capital gains and losses applied almost exclusively to fixed (capital) assets (Arnett 1967). A *fixed capital asset* is a building or equipment that is used in business production and is not "used up." At that time, capital losses were deductible only if losses were associated with the taxpayer's trade or business, and they were deductible only up to the amount of any capital gains.

The Revenue Act of 1921 changed the capital gains and losses tax treatment by dividing assets into short-term and long-term. Simply, a *short-term gain and loss* is the profit or loss that is garnered when an asset is sold within one year of purchase. Assets held longer than one year are subject to long-term tax treatment. Normally, taxes are lower and investors benefit by owning assets longer than one year.

World War Two and the Revenue Act of 1942 changed the capital losses treatment and consolidated the tax treatment of short- and long-term losses. A five-year carryforward was created so that net capital losses could be used to offset capital gains and up to $1,000 of ordinary income in succeeding years. A *loss carryforward* is an accounting term that allows prior years' losses to be used in subsequent years to offset profits, thus reducing taxable income.

During the 1960s through the 1970s, new tax laws affecting capital gains and losses were enacted. The Revenue Act of 1964 repealed the five-year loss carryover for capital losses and replaced it with an unlimited loss carryover. Net losses, however, were still deductible against only $1,000 of ordinary income in any given year.

From 1986 to 2002, previous tax treatment laws over capital gains and losses were amended once again. One legal change during that 16-year period included the Taxpayer Relief Act of 1997, which changed the capital gains tax treatment by lowering the maximum tax rate on long-term capital gains income to 20 percent (and creating a 10-percent maximum capital gains tax rate for individuals in the 15-percent tax bracket). The capital loss treatment remains unchanged.

Present

At present, under current income tax law, a capital gain or loss is the result of a sale or exchange of a capital asset. Property held for less than a year is considered short-term, otherwise the gain or loss is considered long term.

Any short-term gain in excess of a short-term loss is taxed at ordinary income tax rates. Assets held for longer than one year are subject to long-term capital gains and losses tax treatment. The long-term capital gains tax rate is usually lower than a taxpayer's ordinary income rate, and it can range from 15 percent to 20 percent, depending upon the taxpayer's marginal tax bracket. In certain instances, the capital gains tax rate may be higher.

Capital losses offset capital gains, eliminating any tax implications. Long-term capital losses that are not offset by gains may be used to reduce taxable income up to $3,000 ($1,500 if the taxpayer is married and filing separately), with additional losses carried forward indefinitely into later years.

As mentioned earlier, short-term capital gains are taxed at the individual's tax rate and long-term gains are taxed at 15 percent, in most cases. For example, if an investor buys stock for $15,000 and sells it after seven months for $20,000, the $5,000 short-term capital gain is taxed like any other taxable income. However, if the stock was sold more than a year later, the capital gain will be taxed at the 15-percent long-term capital gain rate (depending on the individual's marginal tax rate).

Taxpayers can elect to avoid taxes entirely on capital gains by holding the securities until death. Then the value of securities is taxed as part of the deceased's estate, and the asset is transferred to the individual who inherits with the cost basis value for the asset equal to current value. This is favorable for taxpayers who want to avoid capital gains tax on the appreciation.

CAPITAL MARKETS

Capital markets are institutions that channel surplus money into medium- and long-term productive investments—investments that last at least one year. Domestic capital markets include such institutions as commercial banks, stock and bond markets, and insurance companies. Some capital markets are designed to supply investment capital mainly to borrowers in global markets. Examples include the international bond market, the Eurodollar market, and such international financial institutions (IFIs) as regional development banks and the World Bank. Further, transnational corporations (TNCs) are a major component of today's capital markets. TNCs are the source of most foreign direct investment (FDI). Well-functioning capital markets are essential to productive investment in individual countries and in the larger global economy. As the wellspring of investment funds, capital markets enable business firms and governments to raise needed money for private sector and public sector investment. Productive investments, in turn, promote economic growth, job creation, capital formation, and higher living standards for the peoples of the world.

Access to capital markets in the global economy is uneven. The advanced economies of the Northern Hemisphere typically have highly sophisticated domestic capital markets, which have evolved over time. By the early 2000s, 19,000 depository institutions in the United States had amassed over $9 trillion in assets. About 80 percent of these assets were held by commercial banks, and the remainder was held by savings banks, savings and loan associations, and credit unions. Other features of U.S. capital markets were sophisticated stock exchanges, such as the NASDAQ stock market and the New York Stock Exchange; active computerized bond markets for corporate and government securities; multibillion-dollar insurance corporations and pension funds; and a variety of smaller institutions, such as venture capital funds.

Key reasons for the stability of domestic capital markets in the advanced economies are transparency in rules-based financial dealings, effective regulation and supervision of financial institutions, accurate and timely reporting of financial information, and a modern infrastructure for information and communications technologies (ICT). In addition, investors from the advanced economies are generally perceived to be creditworthy, and they are better connected to international capital markets. This connectivity gives investors from the rich countries easy access to funds in global capital markets.

The Eurodollar market is one popular source of funding for well-connected investors. Eurodollars are U.S. dollars deposited in any foreign bank. Wealthy individuals, corporations, central banks, and governments make these dollar-denominated deposits. In the Eurodollar market, foreign banks loan U.S. dollars to investors such as TNCs. Interest rates on these loans are generally lower than rates in the United States because Eurodollar loans are not regulated, and the Eurodollar deposits are not subject to Federal Deposit Insurance Corporation (FDIC) fees or Federal Reserve System reserve requirements. Governments and corporations can also sell bonds in the international bond market to raise needed capital for public and private investments.

Capital markets in most emerging market and developing economies are less sophisticated than those in the advanced economies. Underdeveloped domestic capital markets stem from a number of factors related to the history and development status of countries. For example, poorer countries have a low gross national income (GNI) per capita, which reduces people's ability to save money. Low domestic savings retards the development of depository institutions such as banks. Other limitations include capital flight, as domestic funds are whisked away to more secure institutions abroad; poor management, due to limited experience in forming viable financial institutions; and the absence of good governance and the rule of law. These factors reduce the creditworthiness of investors from the Southern Hemisphere, and they limit their access to funds in global capital markets.

IFIs are able to pick up some of the slack by extending development loans to emerging market and developing countries. For example, regional development banks provide billions of dollars in development loans to regional member countries. The four main regional development banks are the African Development Bank Group (ADB Group), the Asian Development Bank (ADB), the Inter-American Development Bank (IDB), and the European Bank for Reconstruction and Development (EBRD). The World Bank Group also provides a variety of development loans to support government and private development through the International Bank for Reconstruction and Development (IBRD), the International Development Association (IDA), and the International Finance Corporation (IFC).

In recent years, capital markets have been at the center of a firestorm in the global economy. Core concerns include how to promote efficient capital markets in the developing countries, and how to level the playing field for poorer borrowers in global financial markets. Often, the reform of capital markets is lumped together with other reforms in the global financial architecture—the sum total of all types of financial transfers between nations. Several major proposals for reforming capital markets and the overall global financial architecture are under discussion. First, uniform rules for borrowing, and TNC investment, are essential. Second, corruption and cronyism in developing countries must be curtailed. Third, additional funds are required in order to deal with liquidity crises in poorer nations. Fourth, external debt rescheduling and other debt relief is necessary for heavily indebted countries. Fifth, additional development loans to poorer countries are needed in order to complement the work of the World Bank and other IFIs.

Microfinance, a nontraditional source of development financing, is another promising source of development funds. Microfinance, also called microcredit, is a means by which the poor obtain small loans, called microloans, to start or expand a small business. Microfinance institutions accept deposits and grant loans, some as small as \$50–\$100, to support entrepreneurship. Thus, microfinance institutions represent a more grassroots capital market. Microloans are made to poor people who are routinely excluded from traditional financing by banks because they do not meet established lending criteria, such as income level and collateral requirements. Microfinance is not a new idea in the realm of development financing, however. The Grameen Bank of Bangladesh has made microloans to the poor of Bangladesh since 1983. Under the direction of its founder, Muhammad Yunus, the Grameen Bank has made nearly 4 million microloans to local entrepreneurs—mainly women. Since the 1970s, major international organizations, such as the United Nations and regional development banks, have recognized the importance of microfinance and have developed programs to expand microcredit in the global economy. Today, thousands of microfinance institutions operate in the global economy, some offering related services such as insurance.

CAPITAL RESOURCES

Capital resources, sometimes referred to as productive capital or capital goods, are durable goods used to produce other goods; they can be in the form of equipment, tools, or machinery. These resources are necessary to the manufacture of consumer goods and services, as well as for a country to achieve economic growth.

The use and implementation of capital resources was impacted by the Industrial Revolution and the Transportation Revolution. As countries industrialized, the production of goods became more mechanized and efficient. Furthermore, the more specialized these economies became, the more subdivided the production of capital resources became. Eventually, businesses were also able to take advantage of economies of scale as they produced more of a particular good. In addition, an increase in capital resources led to labor-saving methods as manufacturing became more machine-based. Finally, as transportation methods also became more efficient, it cost businesses less money to ship and transport their goods to the market.

Businesses use capital resources based on the notion that those resources will be useful for more than one year. Businesses invest in the resources that they receive the most marginal benefit from and that are the most cost-effective. Businesses must decide whether to purchase or lease capital resources, and many external factors play a role in this decision. First, some capital resources, such as heavy machinery, need periodic maintenance in order to last a long time; business must take this additional cost into consideration. Second, access to money, interest rates, technological innovation, and the current economic situation are also important factors in this decision.

A business decides whether to acquire capital resources based on a number of factors: (1) whether it can acquire the capital resources at a lower price; (2) whether it has the appropriate money for more capital goods; and (3) whether it needs the additional resources to maintain the its projected growth, or to support a new business venture, or to stay competitive in a particular market.

Capital resources are also closely tied to technological innovation, and this places new demands on capital goods. Specialized machinery is important for facilitating technological change. This specialization and use of technology increase economic growth, and they lead to more capital resources being used efficiently. There is another side to innovation, which focuses on workers' resistance to new ways of doing things. Innovation may require workers to learn new skills and increase their human capital in order to use equipment or resources efficiently. In addition, as workers adapt to new production or manufacturing techniques, they may need to unlearn the previous way of doing things. Potential or future technological innovation also plays a role in whether or not a business will purchase or lease specific capital resources.

In many cases, capital resources are also affected by fluctuations in the business cycle. When the manufacturing sector of an economy suffers, there is less demand for capital resources. When economic times are prosperous, there is an increase in demand for capital resources and large-scale projects that require their use, such as improvements to bridges and highways. The state of the global economy also affects capital resources, as countries are more hesitant to invest in additional resources when the economic outlook is uncertain.

Countries with a lower level of economic development often lack adequate capital resources. Developing nations may also have a difficult time increasing their infrastructure, and because of a lack of specialization and human capital they often choose to import capital goods. The internal development of capital resources is crucial to a country's economic development and independence.

The future of capital resources seems to be in technological advancements—and in how goods can be used in new, more efficient ways in areas such as energy and telecommunications.

CAPITALISM

Adam Smith is credited with synthesizing the tenets of capitalism in his book *The Wealth of Nations* (first published in 1776), which has become the classic reference for capitalism's underlying theories and principles. Capitalism is related to personal finance and money management in several ways. First, it is important to understand the basis for the economic environment in which people live and work. In capitalistic nations, individuals compromise between the benefit of (traditionally) lower taxes and the disadvantage of less social welfare and a smaller public safety net.

Capitalism is a type of economic system in which the majority of property, resources, and means of production are owned privately rather than by the government. More generally, capitalism is based on individual rights and political freedom. In contrast, an economic system based on communism supports public (government) ownership and control of all property and production. In capitalistic nations, the government and the economy are separated such that the government has limited control over businesses and the market. The role of the government is to enforce private property rights, support competition through antitrust laws, and create a stable political and fiscal environment. Decisions concerning the production, distribution, and pricing of products and services are market-driven rather than being governmentally determined. Advanced economies are usually based on capitalism.

The underlying philosophy of capitalism contends that individual entities, such as people or businesses, have the right to own property and earn profit from their efforts and investments. Proponents of capitalism argue that since people and companies can own property such as land, equipment, and homes, they can influence their own well-being. Thus, capitalism allows for the incentive of personal wealth accumulation, which drives people to work harder if they want to improve their economic situation.

In contrast, in communistic societies, where the government accumulates funds from the owners and producers of goods and services and then allocates the funds evenly across citizens, neither individuals nor businesses have the incentive to work harder since their end rewards do not change.

Advantages of Capitalism

Similarly, under capitalism, individuals are able to choose their professions based on their skills and preferences instead of being assigned jobs by the government. In order to maximize individual wealth, people can pair their careers with their expertise. As such, people and businesses are motivated to make the most efficient use of resources, which can result in specialization. Both individuals and businesses can focus on doing the activities to which they add the most value, which increases value creation for the entire economy.

Additionally, individuals have free choice, such as options for what to purchase. Businesses decide what to produce and in which markets to compete. The prices of goods and services change in response to supply and demand fluctuations. In turn, businesses must compete for the purchasing decisions of their customers. Thus, businesses have the incentive to match their products and services to the needs and wants of consumers. This competition drives innovation that brings new products and services to the market, increases product quality, and improves the standard of living. Competition between businesses also compels the optimization of production and the reduction of pricing. Capitalism also encourages entrepreneurship as people seek to improve their living standard by meeting market needs. It is argued that capitalism is the economic system that supports market growth, since it advances the competition, innovation, and entrepreneurship that drive economies.

Another foundational tenet of capitalism is the minimization of government intervention in commerce. As such, businesses in capitalist countries usually have fewer regulatory constraints than in other nations. This type of government–economy relationship is called *laissez-faire*, translated from the French to mean "let do" or "leave to do." Today, the *laissez-faire* term is an accepted name for a government with minimal government intervention. On the one hand, this means that the governments of capitalistic countries have less ability to coordinate national economic goals. In practice, businesses optimize performance based on their market environment, not government intervention.

Disadvantages of Capitalism

While capitalism has many benefits, disadvantages are evident. It has been argued that in capitalistic nations, "the rich get richer and the poor get poorer." The ensuing income inequality occurs because the wealthy do not need to overcome the same hurdles as the poor in order to increase their assets. Additionally, just as individuals in capitalistic nations have incentives to work harder for material rewards, individuals without the ability to do so are left behind, which can result in higher income inequality than is found in other types of economic systems. Unlike economic systems in which the government distributes wealth evenly, capitalism does not redistribute assets. Similarly, capitalistic economies tend to have less social welfare to help citizens in need.

In wealth maximization, businesses direct resources to the opportunities with the most profit-earning potential. This improves the efficient use of capital and assets, but it may not meet the needs of the society. For example, under capitalism pharmaceutical companies may focus on developing drugs with the most lucrative market potential, while ailments without such high profit potential are ignored, even though the ailment's influence on society may be much worse.

Another weakness of capitalism is the potentially negative effects of competition. Firms that operate in price-sensitive industries are incentivized to reduce costs to further increase their margins and competitive advantage. The drive to reduce costs increases the potential for workers' rights violations and product quality concerns. For example, firms that find cheaper labor in other countries with fewer workplace safety or child labor regulations may exploit those workers. Businesses may use the least expensive materials to minimize costs even though those materials reduce the performance of the product.

A system that promotes individual parties maximizing their own well-being also increases the likelihood of negative externalities (e.g., pollution, traffic, or noise). For example, a farm must choose between using pesticides that pollute the groundwater of nearby residents and using farming methods that take more time and money but do not harm the environment or health of those nearby. Profit maximization rewards the use of the lower-costing materials, regardless of the effect that this use has on society.

Capitalism, like any economic model, has its advantages and disadvantages. U.S. workers and managers prize their freedom and independence from extensive governmental regulation. And entrepreneurs are influenced by the economic system in which a firm is started, since tax rates and autonomy are greatly influenced by the government's level of intervention.

CARLYLE, THOMAS

Born: December 4, 1795, in Ecclefechan, Dumfriesshire, Scotland; Died: February 5, 1881, in London, England; Nationality: Scottish; Professional Interests: British historian and essayist; Major Works: *Sartor Resartus* (1831), *The French Revolution* (1837), *History of Friedrich II of Prussia* (1858).

Thomas Carlyle was a Scottish-born historian and essayist. He was given credit for coining the term "the dismal science," referring to economics or the political economy. The term had nothing to do, however, with the topic of economics as a miserable or dull discipline. The phrase actually was a rebuttal to John Stewart Mill's *Principles of Political Economy* (1848). Carlyle held the view that humans from all races were not the same. Three ideas were prominent in Carlyle's political beliefs. He protested against the doctrine of laissez-faire, he supported the organization of labor, and he advocated for emigration. Carlyle died in 1881.

Thomas Carlyle was born in Ecclefechan, Dumfriesshire, Scotland, on December 4, 1795, to James Carlyle and Margaret Aitken Carlyle. As a member of a family strict in its adherence to Calvinist views of religion, discipline, and prudence, Carlyle seemed destined to join the ministry. He attended the village school at Ecclefechan and then attended Annan Academy. At the age of 14, Carlyle entered the University of Edinburgh to study mathematics and the classics, and he graduated with a bachelor of arts degree. He prepared to enter the ministry at the Church of Scotland, yet to his family's dismay he lost his faith in Christianity and decided against a career in theology. Instead, he became a schoolmaster for Annan Academy and then for Kirkcaldy Grammar School. With the help of his friend and mentor Edward Irving, in 1820 Carlyle landed a position as a tutor for Charles and Arthur Buller (sons of a wealthy Scotsman). Carlyle eventually moved to London, where he met some great literary figures, including Samuel Taylor Coleridge and Matthew Arnold.

By 1824, Carlyle was a full-time writer and a dedicated student of German idealism. In 1826, Carlyle married the writer Jane Baillie Welsh. They moved to Craigenputtock, where he wrote *Sartor Resartus, or* "The Tailor Retailored" (1831). The book was a general view about life, part autobiographical and part philosophy. *Sartor Resartus* was originally released as articles in *Erasers Magazine* between November 1833 and August 1834. Even though *Sartor Resartus* was not well received by the press, it would eventually become one of Carlyle's most notable writings. Carlyle had a difficult time finding a publisher, and *Sartor Resartus* was not published as a book until 1838.

Carlyle's next challenge—and his first real, successful accomplishment—would come in the form of his three-volume work *The French Revolution* (1837). In *The French Revolution,* Carlyle focuses the reader's attention on the egotism of the nobility and of the monarchy. The manuscript of the first volume was accidentally burned by a maid of John Stuart Mill, to whom Carlyle had loaned the original. Carlyle wrote the second and third volumes, then rewrote the first volume. When *The French Revolution* was finally published in 1837, Carlyle's fame as a leading writer of the era was solidified.

In 1840, Carlyle published *Chartism,* taking a stance against the conventional economic theory of the day. Chartism was a working-class movement that was made up of groups such as miners, factory operatives, rail makers, carpenters, handloom weavers, and artisans. It was primarily an urban and industrial phenomenon, not very well known in agricultural areas. The theory of Chartism reflected the contradiction in society between the rich and poor. It gave a voice to many people who had a grievance about their own situation or a complaint about the current disorder. Carlyle's response to the question of the English condition was that an active government and a responsible social and political order could elevate Britain out of its slump.

Carlyle's book drew much attention. *Chartism* expressed his opinion that England lacked a mental or spiritual vigor and enthusiasm. Carlyle's beliefs brought about his next two works. His lecture *On Heroes, Hero-Worship, and the Heroic in History* showed his respect for strength, especially when combined with a God-given mission. *Past and Present* embodied his detailed vision of a hero.

By 1857, Carlyle wrote a history of Frederick II of Prussia called *Frederick the Great.* This six-volume biography is considered Carlyle's greatest accomplishment in writing, because it showcased his exemplary talent at recounting character skillfully and constructing language beautifully. Frederick the Great was one of Carlyle's heroes as he admired Frederick's everlasting strength, discipline, leadership, writing abilities, and his hand in creating the Diplomatic Revolution. Carlyle called this masterpiece his own "Thirteen Years War." Writing *Frederick the Great* consumed much of his time, and took a toll on his health.

Carlyle lived his last 15 years as a recluse. Two events did spark his interest in his final years. One was his defense of Edward Eyre, the British governor of Jamaica, who was dismissed for brutally putting down a rebellion of black peasants. The other cause was the Franco-German War, in which Carlyle claimed Germany should be the leader of Europe.

Thomas Carlyle died on February 5, 1881, in London. Westminster Abbey was offered for his burial, but he requested to be placed beside his parents in Ecclefechan, Scotland.

CARNEGIE, ANDREW

Born: November 25, 1835, in Dunfermline, Scotland; Died: August 11, 1919, in Lenox, Massachusetts; Nationality: Scottish-born, United States citizen; Professional Interests: industrialist and philanthropist; owned Carnegie Steel Company; Major Work: *Gospel of Wealth* (1889).

Andrew Carnegie, a Scottish-born industrialist and philanthropist, lived from 1835 to 1919. He became the wealthiest man in the world in 1901 when he sold his company, Carnegie Steel Company, to J. P. Morgan for $480 million. In today's dollars, that would be equivalent to $310 billion. To put that number into perspective, it is more than the projected gross domestic product of Israel, Denmark, or Ireland in 2015. This astronomical deal makes him the fourth wealthiest man of all time. Throughout his lifetime, he wrote many influential books. *Gospel of Wealth*, arguably his most famous publication, reflects his views on philanthropy. In it, Carnegie theorizes that any man can achieve wealth by putting in hard work; if the government does not interfere in business, then Darwin's theory of survival of the fittest will play out and the strong will prosper, while the weak will eventually cease to exist. Another example of his philanthropy is through the Carnegie Corporation, which gives grants to a variety of causes, from the discovery of insulin to the funding of Sesame Street.

Through the Carnegie Steel Company, Andrew was able to use efficient and innovative technology to produce steel at an affordable price. Producing steel at an affordable price led to high demand, because the steel could be used to create skyscrapers and bridges at a reasonable price. This fueled the Industrial Revolution that was occurring at this time. Building these bridges and skyscrapers called for many new jobs. So through his innovative way of cheaply producing steel, he helped accelerate the already booming economy. As a result, this raised the national prestige and improved many people's lives.

Although his business was booming, not all was well at the Carnegie Steel Company. While he ran a very efficient mill that produced a great amount of steel at a very low cost, he ran a dangerous sweatshop. His workers were paid extremely low wages, and the working conditions were less than desirable. For working in mills where accidents occurred regularly, the workers were equipped with only two pairs of wool long johns. The beliefs he wrote of in *Gospel of Wealth* are exhibited in the way that he treated his employees. He (the stronger party) prospered, while the workers (the weaker party) were suffering and not succeeding. So while there were many upsides to the Carnegie Steel Company, there were also many negative sides.

Andrew Carnegie is known as one of the most influential people of the 20th century because of his influence in the Industrial Revolution, which helped to accelerate the economy. Through his business, the Carnegie Steel Company, he was able to revolutionize the way that people look at business, because of his unconventional ideas involving efficiency in production.

CENTRAL BANK

A *central bank* is an independent institution that has been granted legal authority by a government or group of governments to manage a nation's or region's money supply and regulate its credit markets. A central bank can also be the legal authority for a group or region of nations—for example, the European Central Bank for the European Union's eurozone.

Dating back to at least 1668 with the founding of Sweden's Riksbank, central banks initially loaned governments funds for commerce and wars, or to quell recurring monetary crises. In the beginning, central banks were privately owned.

It can be argued that modern central banking in the United States had its genesis in 1913, when the Federal Reserve ("the Fed") was formally established as a private institution owned by member banks, yet authorized by Congress to create and destroy currency in order to maintain an appropriate money supply to facilitate daily economic transactions without significantly affecting prices. The Federal Reserve was formally charged with regulating and safeguarding the nation's banking system and employing monetary policy with a dual mandate: price stability (maintaining the real value, or purchasing power, of the currency) and high and sustainable economic growth (noninflationary full employment). Implicitly, a central bank is thus expected to maintain financial stability by offsetting economic shocks and crises and smoothing out greater business cycles.

Learning from the Great Depression, which ensued from a financial panic generated by banks' inability to meet depositors' immediate demands for withdrawals, the Fed subsequently required member banks to hold a percentage of all deposits in reserve, unavailable for loans. This would greatly reduce the likelihood of future panics.

Within this fractional reserve banking system, a central bank employs monetary policy in three primary ways, and many lesser ones. First, a central bank can manipulate the required reserve ratio. This action would legally change the amount of funds available for banks to lend. In reality, the Federal Reserve rarely uses this tool. If the reserve ratio is lowered, banks can make more loans, which eventually become deposits in other banks. New money, or reserves, is created for further loans (and so on), thus increasing the money supply by a multiple of the original deposit. A higher reserve ratio will require greater reserves, thereby reducing funds available for loans, and thus restricting the supply of money.

Second, a central bank can alter the discount rate, which is the interest rate the Fed directly charges banks for overnight loans in order to maintain legal reserve requirements. If the discount rate is increased, banks must pay more for short-term loans, thus requiring them to charge more for their own longer-term lending to customers.

Third, a central bank can influence the key interest rate and implement policies for the interest rate to remain within a preferred target range. This can be accomplished through open-market operations of buying and selling government securities. This key interest rate is the market-based interest rate charged to banks for overnight loans by other banks with excess reserves. If the rate strays too low, the central bank will sell government securities, which requires payment, thereby reducing funds available for other interbank loans, and thus pushing the rate upward. On the other hand, the central bank will purchase government securities (largely held in members' reserve accounts) and inject new money into the economy, thereby pressuring rates lower, incentivizing more borrowing.

Monetary policy intended to stimulate an economy is termed "easing," while restrictive policy (generally meant to combat inflationary forces) is referred to as "tightening." Other significant monetary tools that central banks might employ include raising or lowering capital requirements for bank lending and margin requirements for investing. Additionally, money can be created through the purchase of foreign currencies with new reserve dollars, or it can be withdrawn from the economy's circular flow through sales (requiring payment in dollars). There are limitations to monetary policy. Like the metaphorical horse that can be led to water but not forced to drink, banks can be incentivized to loan (or borrow) through interest rate policies, but they cannot be forced to actually loan.

CENTRAL PLANNING

Central planning is a type of economic system in which a central authority is in control of the nation's economy. Centrally planned economies are also referred to as command economies. The central authority of the nation answers the three basic economic questions: (1) What to produce, (2) How to produce goods and services, and (3) For whom should goods and services be produced. This type of system does not allow the market interactions of consumers and producers to decide the three basic economic questions. The central government makes all economic decisions for the nation.

The answer to the "What to produce" question determines the allocation of an economy's resources. It is the central government's responsibility to provide enough raw materials and workers to ensure that the goods and services get produced. In this economic system the central government owns and controls the allocation of the land, the capital, and the labor force. Since the government is in complete control of land and capital, the government decides where individuals work and what wages workers will be paid.

The "How goods will be produced" question is an economy's efficiency question. Typically, the top bureaucracy decides the needs of society and then determines how those needs will be satisfied. The bureaucracy determines how the available resources will be used to fulfill these needs. The government, in control of all resources, provides the resources to the factories in which the workers assigned to this task by the bureaucracy will produce the goods. Consumers' wants are not considered in this type of structure.

The central authority determines "for whom the goods and services will be distributed" in the economy. Under market conditions, this question is answered by the determination of private versus public goods and services, or the interaction of buyers and sellers in the marketplace. In a command economy, the central authority decides the distribution of the final goods and services; this decision is made through any number of random variables, such as geography, income level, political affiliation, or even gender.

Several terms are closely associated with centrally planned economies: socialism, communism, fascism, and authoritarianism. Even though these terms are often used interchangeably, there are distinct differences between them.

Socialism

In this political structure, even though there is democracy the belief is that economic equality is the only way to achieve true equality. Wealth should be distributed (or redistributed) evenly throughout society; therefore, the public controls economic power. In order to achieve this fundamental goal, socialism requires a high level of central planning and authority.

In socialist nations, the government usually owns major industries, even though the people can control property and capital. Citizens have a great degree of freedom, but usually they pay high taxes to ensure wealth redistribution and to ensure that all citizens receive equal amounts of public goods, such as health care and education.

Communism

The philosophy of socialism, in which all people should equally share in the distribution of resources, led to the political system of communism. Under communism, all economic and political power lies with the central government. A distinct difference between socialism and communism is the issue of freedom. Socialism allows some freedoms, while communist nations believe in an authoritarian type of government.

Typically, in a communist nation the authoritarian government owns all of the resources, capital, and land. Communist nations are ruled by a single person or political party. That authoritarian government exerts strict order and rule over its citizens, and there are few, if any, freedoms.

Fascism

Fascism is different from socialism and communism in that most of the land, labor, and capital resources of the economy are privately owned. However, the central authority (the government) controls the use of private resources and property through its laws, rules, and autocratic answering of the three basic economic questions. Representatives of the central government determine what will be produced, how, and for whom. Fascism sets all prices, wages, and money supply, but it maintains the outward appearance of a market economy.

Positives and Negatives of Central Planning

Equality for all is a noble cause. The guarantee of a job, income, education, and health care for all citizens is very appealing. To maintain this type of structure and provide these types of services to all citizens, however, is extremely difficult.

One of the most difficult issues to solve in a centrally planned economy is lack of motivation. When citizens are given a job and are provided housing, education, and health care, the motivation to progress individually disappears. When people do not own their own property or control their own ideas, incentives to improve disappear. This causes diminishing production and eventually a shortage of goods and services, as production goals determined by the central authority are never achieved.

Another major issue under central planning is lack of freedom. To pursue societal goals, citizens must sacrifice personal freedoms and ownership of resources. It is hard to maintain motivation and progress in a system that does not reward innovation. Eventually, consumers' economic wants are not fulfilled, increasing workers' lack of willingness to perform at their highest levels. Historically, centrally planned economies have eventually failed due to lack of motivation and lack of available consumer goods and services.

CHARITABLE DONATIONS

Charitable giving accounts for around 2 percent of the U.S. gross domestic product (GDP), and it has been steadily increasing in real terms, doubling over the past 20 years. This increase has been largely unaffected by economic turbulence, and it has allowed for the provision of many important public goods. What's more, economic research on charitable giving has enabled a clearer understanding of individual behavior, optimal fund-raising among charities, and government tax and spending policies. Each of these domains has received extensive treatment in the literature, often yielding substantial theoretical and practical insights.

The question of exactly what makes a donor say yes to a charity's solicitation presents a window into the economic behavior of individuals. While Adam Smith famously observed that people do not rely on the "*benevolence* of the butcher" for our dinner (Smith 1976), it is also true that people observe costly prosocial behaviors, like giving to charities across the globe. What accounts for this generosity? Two major possibilities that economists have considered include, first, that individuals give primarily to affect outcomes (Bergstrom, Blume, and Varian 1986) and, second, that there a "warm glow" to giving (Andreoni 1989), wherein people who contribute feel pleased to have "done their part." Beyond the internal psychological rewards of giving itself, donating to a charity is often a social activity: when groups are soliciting donations people are observing each other's giving decisions. Accordingly, those who donate may also do so because of external pressures, or because they have a desire for status.

Like individuals, charitable organizations also change their behavior in response to incentives. Andreoni and Payne (2003) document charities decreasing their fund-raising efforts due to increased government grant support. This fund-raising activity is itself the subject of extensive study focusing on its extent, methods, and effectiveness. Early field experiments on these topics evaluated the effectiveness of seed money (List and Lucking-Reiley 2002) and comparisons to others (Frey and Meier 2004) on individual donations, observing that both factors have an impact. Effective fund-raising activities can confer prestige on donors (Glazer and Konrad 1996) and can signal project quality (Vesterlund 2003, Andreoni 2006).

Governments often attempt to stimulate charitable giving by providing tax deductions, grants, and matching funds, as in the case of disaster relief. Research on changes in the tax deductibility policy tends to show that charitable giving is price-elastic, with a recent estimate placing the elasticity at –1.2 (Auten, Sieg, and Clotfelter 2002). That is, a small incidence of tax increase will lead to a proportionally larger decrease in charitable giving. Government grants to charities are shown to crowd out individual donations, but they also may signal quality and so may increase individual donations to a particular charity, counteracting the crowding-out effect to some degree (Andreoni and Payne 2011).

CHICAGO SCHOOL OF ECONOMIC THOUGHT

Those who adhere to the economic philosophy of conservative economics, free markets, and monetarism embody the key tenets emboldened by the economics faculty at the University of Chicago. The Chicago School of Economic Thought became especially popular during the 1970s, during the tenure of the late Nobel laureate Milton Friedman.

The Chicago School of Economic Thought became a mainstream economic philosophy as additional economics faculty joined Friedman as Nobel laureates. The list of Nobel laureates and their topics included George Stigler (deregulation), Merton Miller (financial economics), Ronald Coase (Coase theorem), Gary Becker (nonmarket behavior), and Robert Lucas (rational expectations). While not a Nobel laureate, George Shultz can also be added to this illustrious list and the influence of the Chicago School of Economic Thought when he served as Dean of the University of Chicago's Graduate School of Business from 1962 to 1969. His influence expanded further with his service to the country as Secretary of Labor, Office of Management and Budget, and Secretary of Treasury under President Richard Nixon, and Secretary of State under President Ronald Reagan.

Long before Milton Friedman or George Shultz, J. Laurence Laughlin served as founding professor of the University of Chicago's department of economics. From the department's beginnings in 1892, Laughlin emphasized free market economics and free trade. Early scholars of the University of Chicago's free market philosophy included Frank H. Knight, Henry Simons, and Jacob Viner. These men were supporters of limited government involvement in an economy, along with free and open competitive markets.

National notoriety came to the University of Chicago and its economic philosophy with the faculty addition of Milton Friedman in 1946 and George Stigler in 1958. Friedman became the leader of the minority voices for free markets and limited government during the dominance of Keynesian economic thought, which promoted expanded government involvement and economic planning. Stigler also took on government involvement, writing against government involvement in business regulation.

While much of the writing based on the Chicago School of Economic Thought was mathematical and quantitative in its analysis, the Chicago School also contained a strong philosophical strand of individual liberty. This strong philosophical strand was the basis for the strong belief in free markets and individual choice, and that only limited government involvement can assure these individual freedoms.

Later, in his popularly acclaimed *Free to Choose* (Friedman 1980), coauthored with his wife Rose, Friedman elaborated on the Chicago School of Economic Thought and its extension into the political sphere. He proposed that for political freedom to exist, economic freedom must first exist. With the Chicago School of Economic Thought as his foundation, Friedman went as far to submit that without a free capitalistic market influenced only by the interaction of buyers and sellers, political freedom cannot be a reality for any society. He continued his assault on socialism and planned economies, suggesting that tyranny is the sure result of political and economic power under one person's control.

CIRCULAR FLOW OF ECONOMIC ACTIVITY

Multiple, simultaneous economic actions and interactions make the circular flow of economic activity a beautiful piece of economic art. The circular flow of economic activity is the mosaic of macroeconomics. It reveals through its illustration how money, goods and services, scarce resources, exports, imports, loans and interest move from one sector to the other, including households (individuals), businesses (entrepreneurs), government, financial institutions, and companies in foreign countries. From the circular flow, most of life's macro-market mysteries can be explained.

Society sets the first set of rules by answering the three basic economic questions: what to produce, how to produce it, and for whom in society will the good or service be made available. The first question suggests how the productive resources will be allocated in the production of goods and services. The second identifies how efficiency of production will occur so the productive resources are used as efficiently as possible. The third question reveals societal choices on whether goods and services will be distributed privately or publicly.

The circular flow of economic activity can be compared to a board game. A game has a board and players; the circular flow also has two main fields of play: the markets and various players. The markets are as follows: the Product Market, where goods and services are bought and sold; the Resources Market, where natural resources, human resources, and capital resources are bought and sold; the Financial Markets, where money flow is controlled; and the Foreign Markets of exports and imports. The players include households (individuals), businesses (entrepreneurs), government, financial institutions, and foreign companies.

Government's primary and most essential role is to protect individuals' and businesses' property rights through the rule of law and a creditable court system.

Finally, a core principle of every economy is that individuals and businesses respond to incentives in predictable ways. Incentives affect behaviors and the exchange of resources from households to businesses.

The Rules: Command (Central Planning) or Market?

The circular-flow economic model also needs to define the rules of how the economic system will function. The first of two key questions that needs to be answered by a society regarding its economic system is this: Who owns the natural, human, and capital resources of the society?

The two continuum extremes of resource ownership of an economic system are a pure market economy on one end and a command central planning economy on the other. As mentioned earlier, there are three questions that must be answered: what to produce, how to produce it, and for whom. The basic economic question of every question society is, "Who will answer the three basic economic questions?" Whoever owns the resources controls the economy.

Ownership of an economy's productive resources is a foundational concept for all economic behavior. If a government or a central authority owns the resources, an economy is labeled a command economy or central planning economy. If the resources are owned privately (i.e., by the households), the economy is labeled a market economy.

Circular-Flow Phase 1

In a pure market circular-flow economic model, households (individuals) take their natural, human, and capital resources to the Resource Market and voluntarily

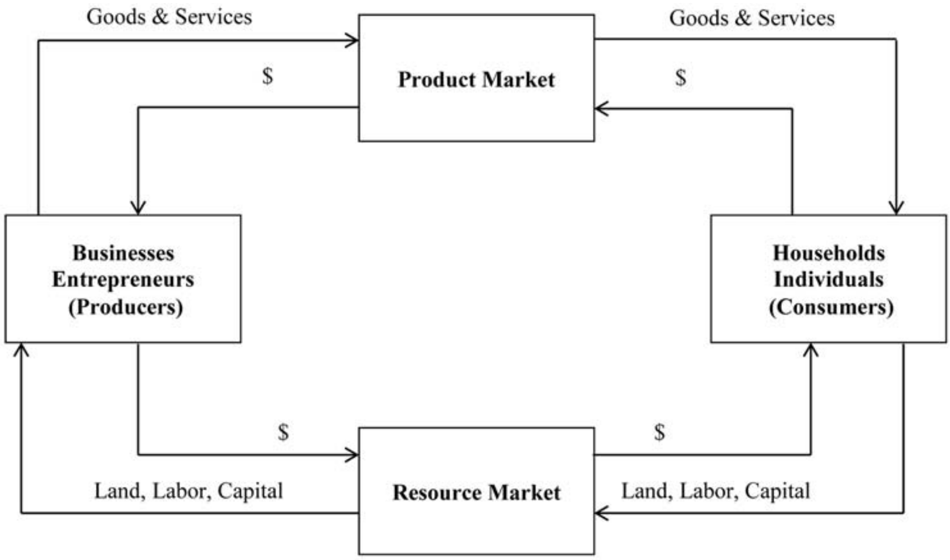

Figure 1. Phase 1: Circular flow of economic activity (businesses and households)

exchange their land, labor, and capital with businesses. In exchange, households receive wages, rents, and profits. The result of this voluntary exchange is that businesses have the resources to make and deliver goods and services in the Product Market, and households have the money to purchase goods and services in the Product Market.

So consumers take their money to the Product Market, and businesses take their goods and services there as well. When a market interaction occurs in the Product Market, businesses sell their goods and services to households (individuals) with the money the households earned in the Resource Market.

Phase 1 is the phase of "non-negotiable." Every market and component of Phase 1 is essential for the economy to operate.

Circular-Flow Phase 2 Adds Financial Institutions (Federal Reserve System, Banks, Credit Unions, etc.)

Financial institutions make loans to businesses and households for everything from homes and cars, to new machinery and equipment, to a college education. In return, the businesses and households repay the money they borrowed—with interest. Likewise, when businesses and households loan their money to financial institutions, they are rewarded by receiving interest from the financial institutions. For money to be a functional entity in the circular flow, financial institutions exist to perform central banking monetary and intermediary functions.

As a financial intermediary, an institution receives money from households and businesses, and in return the institution pays interest. It then reallocates the funds back into the economy to businesses and households. Households use the loans from financial institutions for purchasing such durable goods as homes, cars, washing machines, and college loans. Loans are made to businesses for buying

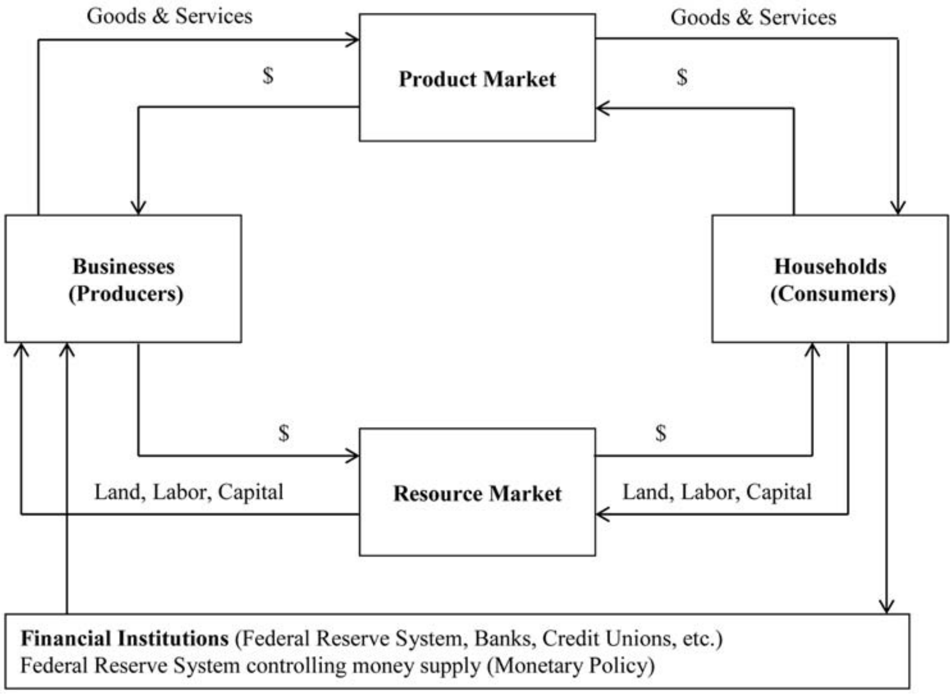

Figure 2. Phase 2: Circular flow of economic activity (Phase 1 + financial institutions)

new capital equipment, such as lathes and drills and real estate and for performing other expansion and start-up functions, such as hiring additional labor. In return, banking institutions receive money, in the form of interest, from the households and businesses to which they loan money. The net result is economic growth for an economy.

Circular-Flow Phase 3 Adds Government (National, State, and Local)

Governments at all levels (local, state, and national) are certainly direct, major participants in the Resource Market as users of human resources. As the view of the circular flow of the economy becomes more advanced, and economic "Who" questions are addressed by a combination of the market and the government, the government's role in the economy becomes more sophisticated. In addition to protecting property rights, governments provide public goods and programs that people are entitled to receive when they become qualified for a given program. Governments also provide contracts to businesses, and the businesses perform certain public services that the governments cannot perform or choose not to perform themselves.

Entitlements are payments to households from a government entity. A few of these programs are unemployment, housing subsidies for low-income individuals, food stamps, Medicare, Medicaid, and Social Security.

Public goods are those goods that society has deemed necessary for all citizens, not just those who are willing and able to pay for them. Examples of public goods include fire and police protection, national military, education for kindergarten through 12th grade and higher, roads and highways, and parks.

Some public goods, such as higher education, can also be provided as private goods. As a societal value, it has been determined that higher education should be available to any citizen who desires the service. That societal value does not preclude organizations or individuals from organizing their own private schools to operate under their own rules and values.

Contracts refer to the practice of privatization where arrangements between government and private businesses are made for the purpose of providing public goods and services. Government/business contracts include building military planes, tanks, and armaments; constructing public schools and roads; and, of course, buying the operational pen-and-paper goods that the government needs in order to function.

The full role of government in an economy becomes highly dependent on *who* answers the "what," "how," and "for whom" questions. The extent of government's role in our economic model will determine the set of rules of the economic sphere.

In a command economy, government is the "great provider" and answers the three questions. When government is involved to the extent that it answers the "what," "how," and "for whom" questions, incentives are shifted from the individual to the government. Command economy primarily exists to its fullest when government is singularly ruled (that is, by a dictator or a communistic government).

Government participates in a market economy through privatization contracts, loans, and subsidies to private businesses for the provision of goods and services

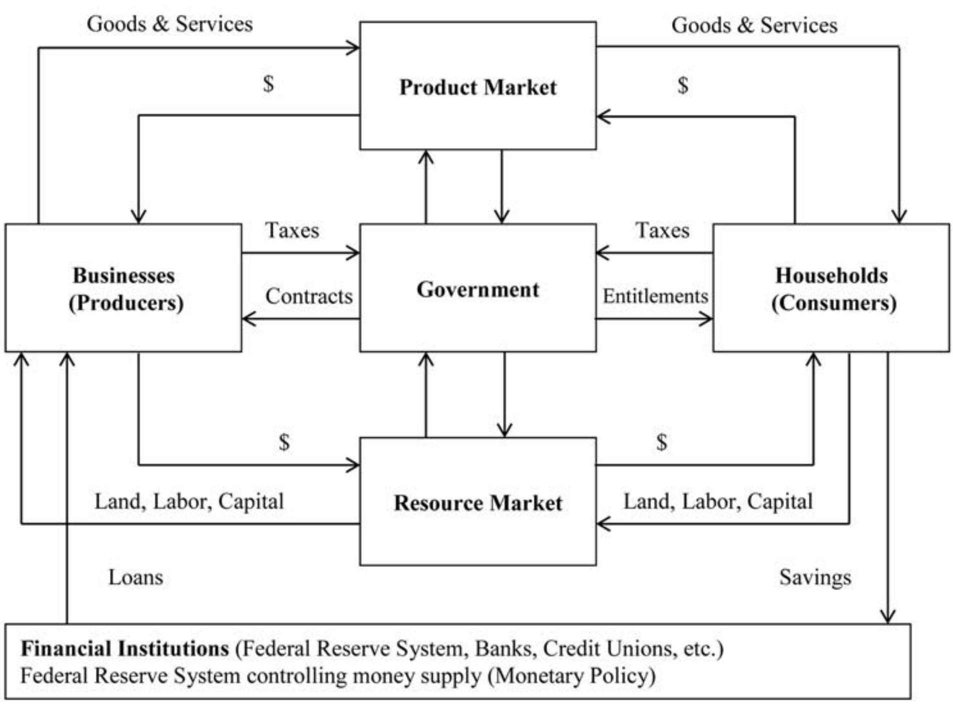

Figure 3. Phase 3: Circular flow of economic activity (Phase 2 + government)

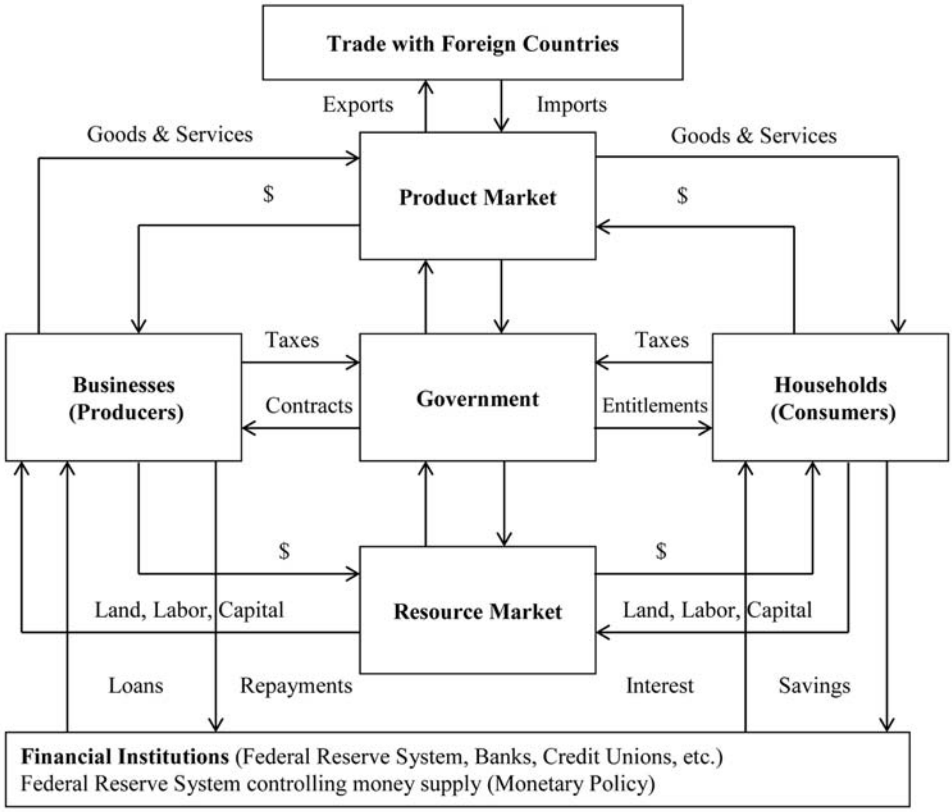

Figure 4. Phase 4: Circular flow of economic activity (Phase 3 + foreign markets and foreign companies)

such as roads, schools, military hardware, and bridges. It provides entitlements and loans to households to increase their participation in the Product Market.

Circular-Flow Phase 4 Adds Foreign Countries (Exports and Imports [X & M])

A growing component of most economies is the influence of foreign countries through exports and imports. *Exports* are those goods and services a domestic producer sends to other countries, while *imports* are those goods and services the domestic consumer can purchase which were produced in foreign countries.

Summary

Every society must answer three questions for their economy: what to produce, how to produce it, and for whom. The major question is the basic economic question: Who answers the three questions—the market interactions between producers and consumers or a central planning authority?

For every market economy, the fundamentals are private property and the presence of incentives. Private ownership of the productive resources by individuals (households) is a must. The second important concept, which affects the exchange of resources from households to businesses, is incentives.

When both households and businesses are better off, everyone wins. The households (consumers) have obtained the goods and services they desire, while entrepreneurs and businesses (producers) have reaped the benefits of good business decisions by efficiently and effectively using the productive resources they purchased in the Resource Market. Or they have suffered the consequences of bad decisions. Either way, society is better off.

CITIZENS UNITED V. FEDERAL ELECTION COMMISSION

Citizens United v. Federal Election Commission, 558 U.S. (2010) was a 2010 case in which the U.S. Supreme Court upheld the First Amendment rights of corporations, nonprofits, and unions to make unlimited financial contributions for the purpose of electioneering. The decision involved such key economic concepts as private property and economic rent.

Congress passed the Bipartisan Campaign Reform Act of 2002 (BCRA) in an effort to change the manner in which money is obtained and used for political campaigning in the United States of America, hopefully for the better. The focus in the *Citizens United v. Federal Elections Commission* case was on corporations, nonprofits, and labor unions and their right, without government restraint, to contribute to political campaigns. However, when an individual votes or contributes to a politician's campaign, it is with the expectation he or she will be looked out for as a constituent.

Large corporations or unions are not like people who can cast a ballot. When they contribute to campaigns, the expectation is much different. The *quid pro quo* could include a corporation's receiving economic rent through special legislation that will benefit its business; less severe regulation; tax credits; or perhaps some political appointments. In an effort to adjust this imbalance and limit the contributions these organizations could make toward getting leaders elected to political office, Congress in effect abridged the organizations' First Amendment right to free speech. The constitutional question before the Court was whether or not Congress had the authority to stifle free speech by these legal organizations, whose contributions could have external economic effects on the nation.

Following this decision, changes did indeed take place in the manner in which money was channeled toward and spent on political campaigns in an effort to obtain economic rents. Large firms, sensitive to government policies, are able to contribute unlimited assets to the political economy with few restrictions. The economic and political results of this case still remain to be seen. Nevertheless, it can be argued that the impact of this case has altered the finances of the political landscape more than any other case in recent history.

Case Summary

The race for the White House is the most expensive political race in the world. Some people have suggested that presidential candidates should wear outfits like race car drivers do, with corporate support advertised openly and no sponsor secrets hidden. These garments would make more than just a fashion statement. In the case of race car drivers, their right to wear such apparel is protected by the First Amendment to the Constitution. In *Citizens United v. Federal Election Commission*, the First Amendment, politics, and economics collided over a film produced by Citizens United that criticized candidate Hillary Clinton during her 2008 presidential campaign.

In 1905, in his campaign for a second term, President Theodore Roosevelt called for Congress to ban corporate contributions for political purposes. The evolution of regulatory policies aimed at limiting the richest Americans' influence on the outcome of federal elections has continued.

In February 1972, the Federal Election Campaign Act (FECA) was passed, designed to focus on disclosure of contributors. In 1974, FECA was amended to tighten limits on these contributions. In addition, this amendment created the Federal Election Commission (FEC). The FEC is an independent regulatory agency led by six members, appointed by the president and confirmed by the Senate; by law, half of the members must be Republicans and half must be Democrats. The members' duty is to disclose, enforce, and oversee federal elections legislation passed by Congress.

During the 2008 presidential campaign, Citizens United, a wealthy nonprofit corporation that runs a political action committee (PAC), produced a 90-minute movie (*Hillary: The Movie*) about Senator Hillary Clinton. The film listed character traits and background evaluations, and it scrutinized her political *vita* in a manner that would discourage voters from casting their ballot for her as the next president. Citizens United paid over a million dollars from funds in its general treasury to have the film aired on pay-per-view cable television within 30 days prior to the primaries. However, according to the amended section of BCRA, no electioneering communication that clearly identifies a candidate could be funded by the general treasury of a corporation and broadcast 30 days prior to a primary election. The law made it a felony, punishable with up to five years in jail, for corporations to violate this law. When the FEC banned Citizens United from airing the broadcast, the corporation filed suit in the Federal District Court of Washington, D.C., to obtain an injunction (put a legal stop to an action) to lift the ban. The District Court denied the injunction based on *McConnell v. FEC,* 540 U.S. 93 (2003), in which the Supreme Court upheld BCRA, stating that not all political speech was protected by the First Amendment.

The plaintiff appealed the case to the Supreme Court. The Roberts Court heard the first round of arguments in March 2009. Theodore Olson, arguing on behalf of the petitioner, claimed that political speech was a core principle guaranteed in the First Amendment. The punishment for a corporation that expressed its political opinion in film was five years in jail. Olson argued that the First Amendment exists to guarantee intense political debate and participation. He claimed that the process of expression is fundamental, and that government limitations on corporate political speech are therefore a violation of the Constitution.

Olson noted the fact that there was an exemption for media corporations added to the unconstitutionality of the issue; for example, corporations such as Disney and National Public Radio did not have to follow the same rules. In addition, the 90-minute documentary speech was not only offered by the speaker but also invited by the listener, who had to choose to hear it, and was thereby entitled to heightened First Amendment scrutiny.

On behalf of the defense, Malcolm Stewart countered with the legislative statutes included in BCRA. Congress did not ban political corporate speech; rather, it banned how the speech was funded and in what time frames it was to be presented. The law was not intended to take away constitutional freedoms, but rather to level the playing field of political influence in a democracy, where corporations did not get the high ground simply because they could afford it. Stewart argued that whether the subject is a book, a newsletter, a sign, or a film, the ban on using corporate treasury funds is a clear violation of the law and within the constitutional powers of Congress to enact. It was also within the power of Congress, according to the McConnell case (which upheld BCRA and claimed that not all political speech is protected), to grant exemptions to media corporations. In fact, the media exemption for publishing corporations is an effort to safeguard First Amendment rights.

The Supreme Court heard arguments a second time on this case in September 2009. Again, Olson brought forth the argument that this fundamental right to free political speech was denied to corporations, even the vast number of small, single-shareholder-owned businesses. However, Solicitor General Elena Kagan, who a year later would be an associate justice on the Supreme Court, contributed to the government's defense, stating that there was great concern about the overall corrupting influence that campaign finance had on the political system, and that BCRA may well have been the most unselfish act of Congress in a very long time. To this she added that there had been compiled before Congress a great number of records indicating the validity of this corruption and the need to address it through legislation regulating political expenditures, particularly by corporations. Seth Waxman spoke as well, on behalf of Senator John McCain and others as *amicus curiae* (friends of the court) in support of the government. In his brief time, he reminded the Court of the historical dangers involved in allowing corporations to contribute to and spend within political elections without regulation.

In January 2010, the Court decided 5–4 for Citizens United. The Court overruled *Austin v. Michigan Chamber of Commerce,* which had upheld a restriction on corporate speech and portions of the *McConnell* case. The conservative justices John Roberts, Antonin Scalia, Samuel Alito, Clarence Thomas, and Anthony Kennedy, who wrote the opinion, held that the First Amendment supports corporate funding of independent political broadcasts in elections and cannot be limited. The more liberal Justice John Paul Stevens dissented, and he was joined by Justices Ruth Bader Ginsburg, Stephen Breyer, and Sonia Sotomayor, all of who maintained that narrow disruption to a corporation's right to free speech was the lesser evil, considering the danger it posed to the political process.

Nevertheless, the majority also held that the BCRA's disclosure of contributors' identities was constitutional because it served a justifiable government interest in educating the people as to resources behind the spending. In addition, the Court maintained the ban on direct contributions to candidates from corporations and unions with regard to the appearance of impropriety.

Between the original oral arguments and the second round of oral arguments, the Court saw the retirement of Justice David Souter and the addition of Justice Sotomayor. Since the outcome was divided on ideological lines, changing one liberal justice for another did not change the end vote. Nonetheless, anyone who listened to the oral arguments would have heard the passion with which these principles were discussed. This case revealed a true concern for the electoral process—a desire to balance rights with guidelines, and a deep respect for judicial and legislative traditions—and it had a dramatic effect on the political economy of U.S. democracy. The decision is new, and more time is needed before its impact on the relationships among the political power of wealthy corporations, free and fair elections, and First Amendment free speech rights is fully understood.

CIVIL WAR ECONOMICS, SHORTAGES, AND INFLATION, 1861–1865

One cause of the Civil War was the difference between the economies in the North and South, and these economic differences continued to play out during and after the war. The Civil War would bring the North prosperity and a major advance in industry. It also brought an end to the long recession after the panic of 1857. Both sides suffered shortages during the war, but those experienced by the South were extreme because of naval blockades of foreign goods and because it had no access to northern manufacturing. The South also had labor shortages throughout the war. The South had been fighting for lower tariffs for decades, but though the war brought the desired removal of tariffs, the Union naval blockade prevented the South from benefiting. Shortages of clothing were worse in the South than in the North; although the South had the cotton, it depended on New England and Europe to convert it into cloth. After the war, inflation increased prices in the North and the South by about 75 percent.

During the war, labor shortages were less problematic in the North because the flood of Irish immigrants into New York, Boston, and Philadelphia was a source of soldiers and cheap labor. Young male immigrants were barely ashore before they were enlisted and marched off to train. On both sides, the average recruit earned about $13 a month, with a reenlistment bonus as high as $200. Both sides instituted a draft to fill their army's ranks. In the North, a draftee could purchase a substitute for $300. With the average wages in the North being $500 a year, however, substitution was mostly for the wealthy. The draft would eventually lead to riots in New York and other cities; the 1863 Draft Riot in New York took 150 lives. The Union was forced to withdraw battle-hardened troops from Gettysburg in order to stop a week of riots and the burning of whole city blocks.

The cost of the war resulted in the first direct taxation of Americans on both sides. Before the Civil War, most of the government income came from tariffs. The North used a package of excise, direct, and income taxes to finance the war. Excise taxes, which were imposed on the manufacture and purchase of all products, were the most effective in raising funds. As the war progressed, the North imposed a 5 percent tax on incomes over $600 and a 10 percent tax on incomes over $10,000. The income tax, at best, accounted for 20 percent of the war funding and required a new federal agency to collect the taxes. The Confederacy initially applied direct taxes on agricultural products, but it lacked the administration to fully collect taxes. Later in the war, the Confederacy imposed an income tax, but it lacked the administrative power to fully enforce this tax as well.

Currency was a major problem for smaller businesses, even in the North. The strong northern banking system was able to support manufacturers, but the government stopped minting coinage at the start of the war. The supply of coins in circulation dried up, and the federal government began issuing paper money. The general public lacked confidence in these "greenbacks"—with good reason. By the end of the war, the paper bills were worth only 39 percent of their original value. In total, the government issued $500 million in greenbacks. Many merchants, however, reverted to bartering and IOUs. The government issued fractional paper money and glueless stamps, to be used as a replacement for coins.

The Confederacy had even greater problems with its currency. Initially, the Confederate paper dollar was valued at 95 cents in U.S. dollars. By 1863, the Confederate dollar was worth 37 cents. At Lee's surrender, a Confederate dollar was worth 1.6 cents, and a month later it sold in bales of 1,200 dollars for one U.S. dollar. By 1863, a Confederate soldier could not feed his family on the pay he earned, forcing wives to move into the labor force.

Lincoln also used tariffs to raise money for the war (war had been a basic use of tariffs for decades). Protectionism remained the core policy of the Lincoln administration, and it provided a solid income stream for the North during the war. Lincoln's economic adviser, Henry C. Carey, was a huge supporter of Clay's American System and a strong supporter of tariffs throughout the prewar period. Tariffs would drive up production of pig iron, and there is no demand for iron like the demand created during war. As much as 25 percent of the union's artillery (15 percent at Fort Pitt Foundry alone) was made in Pittsburgh, creating a boom previously unseen in the industrial North. At least 80 percent of the Union's naval iron plate for ships was made in Ohio and rolled in Pittsburgh. Most of the Union's armor plate was rolled in Pittsburgh. All of the artillery carriage axles and most railroad axles were also forged in Pittsburgh. Most of the raw pig iron, however, came from southern and eastern Ohio. Cleveland, Ohio, which had no iron foundries in 1860, had more than 50 after the war.

CLASSICAL ECONOMICS

The term *classical economics* denotes a philosophical system that dominated economic thought and policy from the end of the 18th century until the middle of the 19th century. This system, with many contributors and characteristics, was influenced most especially by the writings of Adam Smith (1723–1790), Thomas Robert Malthus (1766–1834), David Ricardo (1772–1823), Jean-Baptiste Say (1767–1832), and John Stuart Mill (1806–1873).

Sometimes referred to as a "system of natural liberty," classical economics described government as having a circumscribed role in the economy. Classical economics emphasized the importance of natural law, natural rights, and a Newtonian order of society. The essential features of classical economics include the following concepts: laissez-faire, economic growth and competition, value and utility theory, the population principle, and Say's Law. Economic growth and competition are additional cornerstones of the system, incorporating private property rights, arguments in favor of free trade, the encouragement of emerging markets, and an expanding division of labor and a wage-earning class. As the factory system developed and manufacturing began to exert a greater influence on the economy beginning in the 18th century, use and exchange value of a good or service was incorporated in the classical theory of value. This theory, which maintained a "paradox of value"—an expression that stressed the dichotomy between "use" value and "exchange" value for each good or service—would be subsequently replaced by a more complete value analysis. This change would be spearheaded during the latter half of the 19th century by three important marginalist writers: William Stanley Jevons (1835–1882), Leon Walras (1834–1910), and Carl Menger (1840–1921). *Utility*, the idea that value comes from the pleasure or benefit produced by a good, and not the good itself, was refined throughout the classical period. The population principle, which later led to the notion of a "Malthusian trap," provided the classical paradigm with subsistence wage rates and a stationary state, leading many later writers to label economics as the "dismal science." Finally, the general acceptance of Say's Law, or the law of markets, also pervaded classical discussions. Although Say's Law is controversial and somewhat limiting in its description, it implies that in a state of equilibrium, and generally in the long run, goods and services are simply bought with other goods and services.

Adam Smith, the first major classical writer, was born in Kirkcaldy, Scotland. Smith entered the University of Glasgow at the age of 14 and also studied at Oxford. In 1751, he was appointed a professor of logic at Glasgow, and in 1752 he was appointed chair of moral philosophy. Smith's first publication, *Theory of Moral Sentiments* (1759), was a widespread success. In 1776, Smith's seminal work, *An Inquiry into the Nature and Causes of the Wealth of Nations*, was published. The global success of *The Wealth of Nations* was the beginning of the classical period. Smith's focus on growth and development exemplified the ideas of the Scottish Enlightenment. In *The Wealth of Nations*, Smith attacked mercantilism, the popular economic system of his day. As the originator of the classical school of economics, Smith developed the theory of value, wages, rents, and profits. Smith promoted the natural liberty of the individual and the free enterprise economic system, making him the originator of classical economics philosophy.

Smith identified three roles for government: national defense, the maintenance of law and order, and the building and maintenance of a public infrastructure and public institutions. Smith is arguably most popular for his economic concept of the invisible hand, the idea that individuals promote the general welfare by seeking to advance their personal welfare.

Thomas Robert Malthus, born in Surrey, England, studied at Cambridge and became a clergyman in the Church of England. He later assumed the post of professor of history and political economy at the East India College. His most famous work, *Essay on the Principle of Population as It Affects the Future Improvement of Society* (1798), was initially published anonymously and created a controversy in the academic community of his day. While many contemporary writers asserted the inexorable ascent of human happiness and prosperity, Malthus's work denied this claim. He argued instead that ultimately a country's population would outstrip its food supply, thereby dampening future economic growth and development. The policy implication of this population principle, even with positive and preventive checks, was an eventual subsistence wage rate and economic stagnation.

David Ricardo, born in London, England, entered his father's brokerage firm at the age of 14 after a short business education in Holland. He left the firm when he was 21—after his marriage and subsequent conversion from Judaism to Christianity. With the financial support of numerous members of the exchange, he eventually became extremely wealthy on his own as a trader and stockbroker on the London Exchange. He retired from business in 1814. He later became a member of Parliament, and it was in this capacity that he took an active part in the public policy debates of his day, including bank reform, tax proposals, the resumption of specie payments, and the national debt. Ricardo contributed numerous articles and pamphlets pertaining to various pressing issues in monetary and fiscal policy of the early 19th century, especially his spirited debate with Malthus regarding the repeal of the Corn Laws. His most important work, however, was *On the Principles of Political Economy and Taxation* (1817).

Improving and borrowing from classical rent theory, Malthus's population theory, and the wages-fund doctrine of Adam Smith, Ricardo forged a highly abstract analytical system that focused on the problem of income distribution. Additional insights included his recognition of an imperfect measure of value, a long-run stationary state, and an analysis of comparative advantage.

French-born Jean-Baptiste Say was a businessman in England before he returned to France. Upon his return, he edited a magazine promoting ideas of the French Revolution. In 1799, when he was appointed to the Tribunate, he promoted his laissez-faire philosophy publicly. Say was later relieved of his duties by Napoleon, who did not agree with his views. His *Treatise on Political Economy* was published in 1803. It was widely read through many editions in both the United States and Europe. While the phrase "supply creates its own demand" is incorrectly attributed to Say, the book is credited with spreading the ideas of Adam Smith to continental Europe.

John Stuart Mill, the oldest son of James Mill, published his *Principles of Political Economy with Some Application to Social Philosophy* in 1848. *Principles* was the most-used economics textbook in the English-speaking world until the late 1800s, when it was replaced by Alfred Marshall's *Principles of Economics* (1890). Mill's philosophy was a combination of the utility theory of Jeremy Bentham and the intellectual ideas of David Ricardo. Mill addressed many of the microeconomic topics and public policy issues of his day. He supported social change through his support of inheritance taxes, women's suffrage, and compulsory education.

Although classical economics had declined in importance as a system of thought by the end of the 19th century due to the rise and importance of marginalism, the emergence of socialist and historicist critics, and its inability to adequately answer some of the great policy debates of the day, it continues to be the starting point for modern micro- and macroeconomic analysis.

COLONIALISM

Colonialism is the control by one nation over another territory through unequal annexation, procurement, exploitation, and profiteering. It also involves a transfer of people from the conquering nation to the conquered territory. Colonialism dates back to the late 15th century, when Europeans began partitioning the world. From the early 16th century to the middle of the 20th century, European settlers and exploitative colonies were established in the Americas, Africa, and Asia. At first, mercantilist policies were instituted to benefit the home country at the colony's expense, and later, free market policies were established to justify further colonization.

Settler colonialism is often motivated by the need for land acquisition as well as religious, political, and economic considerations. Imperial motives compel large groups of immigrants to move into a region. Often, depopulation or dislocation of indigenous inhabitants is a prerequisite, as the colonizing people play the vital role of bringing "civilization" to the territory. Moreover, Social Darwinist theory and the idea that Europeans are racially superior to native peoples appear to have justified expansion. As an example, after the United States became independent of British rule in the late 18th century, the British sought out a new colony in Australia to exploit its resources by resettling some of their skilled prisoner population there. A type of indentured servitude agreement allowed convicted prisoners to serve out their sentences by building the infrastructure needed for a long-term sustainable colony. As a result, aboriginals were pushed out of their ancestral homelands as white settlers colonized much of the continent.

Exploitation colonialism usually entails intense resource extraction by native labor under the supervision of settlers; the resources are often sent back to the colonizers' homeland or to a major trade center. Financial and governmental administrative bases serve to further the interests of the colonizing nation while relying on indigenous expertise, resources, and labor. Commodities such as agricultural products, precious minerals, timber, and other goods are extracted mostly for the benefit of the colonizing nation while a limited infrastructure is built for the colonized territory. During the slave trade era, slaves were used in the Americas largely as a result of the Atlantic slave trade. This was chattel slavery. Slavery in Africa was a different form of slavery. In Africa slavery was instituted to pay off a debt or punishment for a crime.

Mercantilism was at the forefront of the early economic policies of colonizing nations from the 1500s to the 1700s. In promoting mercantilist policies, individual European nations sought to strengthen their positions vis-à-vis other competing nations by forcing their colonized territories to trade only with them. This ensured a favorable balance of trade, an increase in bullion reserves, and high-value commodities obtained at the expense of the colonized regions. Mercantilism encouraged colonialism by giving many nations a need to expand overseas to extract minerals, raw resources, and labor to compete for economic and political prestige.

Free market policies took a dominant role at home for many European nations, while the lack of free markets abroad continued to make colonies an expensive enterprise. During the mid-1800s, the most dominant European power, the British Empire, relinquished mercantilist and trade restrictive policies but did not fully employ free market principles in its colonies. The resulting British monopoly over Indian industry caused Mahatma Gandhi to seek India's political and economic independence from the European empire. Nations throughout Africa and Asia were the last to declare their sovereignty from the influence of European nations.

COMMAND ECONOMY

In a command economy, also known as a centrally planned economy, the factors of production or resources are owned by a central authority, usually the government. Government has the responsibility to determine how to solve the economic problem of scarcity. Government planners or central committees answer these economic questions: What to produce? How to produce? For whom to produce?

Command economies are usually combined with a highly authoritative political system. The ideas of socialism and communism are most often used in reference to a command economy. *Socialism* is an economic theory in which most resources are publicly owned, and general assemblies along with workers and consumers make economic decisions. *Communism* refers to a centrally planned economy in which the government maintains all economic and political power. Communist nations have an authoritarian government or a single political party or dictator.

Central planners try to allocate the best use of land, labor, and capital to provide a basic standard of living for all peoples within the society. Central planners create production and hiring targets to achieve such economic goals as price stability, economic growth, and full employment. To achieve these goals, the planners determine the levels of production for capital goods and consumer goods.

A command economy functions on short- and long-term goals devised by the central authority. Often, plans are set to achieve objectives over five-year periods, with additional smaller targets. In contrast to a market economy, where the interactions of consumers and producers establish prices and determine signals, planned-economy prices do not signal the value or distribution of goods or services, as the central authority has already established the prices and allocations within its plan.

Advantages

Due to the central decision-making process, a centrally planned economy is usually able to mobilize economic resources for large-scale projects with relative ease. Historically, this has allowed such economies to transform large societies and encourage rapid industrialization, especially in developing a military complex. A short-term advantage is the emphasis on full employment and equitable distribution of goods. This advantage is very appealing to the voters of developing nations when it is proposed by their populist politicians. A second advantage is the emphasis placed on economic security, with promises that all citizens will have jobs and that basic needs as such medical care, housing, and education will be met. Societies that do not normally practice command economies have also found a centrally planned economy useful and advantageous during wartime, as it allows focused production on those goods and services deemed necessary for success during the conflict.

Disadvantages

Consumer sovereignty does not play a role in a planned economy. In a command economy, it is common for production targets to not be clearly communicated between the government and the manufacturer, leading to a lack of coordination and resulting in low product quality and inaccurate production quantities. This coordination problem highlights the emphasis of quantity over quality. Five-year plans and smaller target goals make consumer wants and needs difficult to predict, leading to market misallocations and frequent shortages. Personal limitations and a lack of consumer goods facilitate the rise of shadow economies and/or political corruption.

In addition, a goal of full employment may force people to work in an industry or at a job they did not choose. There is a loss of individual innovation and incentive, as all effort is focused on the production target or the five-year state goal, rather than on market interactions between business and labor or producer and consumer.

History and Examples

Planned economies existed as long ago as the Incan empire of 16th-century Peru. The Viennese economist Otto Neurath used this method to control hyperinflation after World War I. The Mormons in 19th-century Utah, Maoist China, Castro's Cuba, and the United States during World War II mobilization have all used planned economies. The former Soviet Union is considered the essential case study.

The story of the Union of Soviet Socialist Republics (USSR) begins with German economist Karl Marx and philosopher Friedrich Engels. The two wrote *The Communist Manifesto* in 1848, after observing the numerous, deplorable working conditions common during the Industrial Revolution. Marx and Engels wrote of an alternative system in which the *proletariat*, or working class, would rise up and overthrow the *bourgeoisie*, or factory owners; society would form a classless society—which Marx and Engels would be a "utopia."

Vladimir Lenin led the Bolsheviks to try this great social experiment upon the overthrow of czarist Russia in 1917. The new state claimed ownership of the means of production, and government committees began planning and performing the prior functions of the market. Lenin quickly realized that some ownership of private property (the New Economic Policy) was necessary for a smooth economy, yet the government would maintain control of what Lenin termed the "commanding heights" or major infrastructure industries, such as coal, steel, and transportation.

After the Bolshevik Revolution and the communist consolidation of power following the Russian Civil War, Soviet leaders decided to move away from Lenin's New Economic Policy. Stalin rose to power upon Lenin's death in 1924, and in 1928 the USSR embarked on a rapid industrialization movement known as the First Five-Year Plan. A number of other five-year plans followed, with differing amounts of success. However, the Soviet Union was successful in becoming one of the major industrial and military powers in the world in the 1930s.

While the Soviet Union put an emphasis on the production of capital goods in the industrial sector, it moved toward collectivization in the agricultural sector. From 1927 to 1937, the state took control of the country's agricultural inputs. These collectivization efforts led to a famine in 1932–1933, resulting in millions of deaths due to starvation. The production of agricultural goods was slow to recover, and for years afterward the Soviet Union was forced to import large quantities of these goods.

After World War II, the Soviet Union exerted its influence over the nations of Eastern Europe by creating Soviet-style governments throughout the region. The Soviet Union forced the economies of these nations to specialize in the creation of certain goods under the Council for Mutual Economic Assistance (COMECON). Under both Nikita Khrushchev and Leonid Brezhnev, the Soviet Union placed emphasis on creating more consumer goods than it had in the Stalin era.

By the 1980s, the inefficiencies of central planning were having disastrous effects on the Soviet economy. When Mikhail Gorbachev took the reins of leadership in the Soviet Union in 1985, he embarked on a policy called *perestroika*, which introduced more market principles into the Soviet economy. Still, crippling shortages and massive military spending because of an arms race with the United States helped contribute to the end of the Soviet Union in 1991.

COMMUNISM

Communism is a type of economic system based on government ownership and control of the factors of production—natural resources, human resources, and capital goods. A communist economy relies on centralized, public-sector decision-making. Thus, central planners within the government answer the basic economic questions of what, how, and for whom to produce. Modern communism is based on the theories of Karl Marx, a German-born philosopher, economist, historian, and revolutionary. The 20th-century applications and adaptations of Marxist thought, often called Marxism, reshaped the economic landscape of the global economy.

Communist economies during much of the 20th century were inward-looking, choosing to isolate themselves from most forms of connectivity in the global economy. For instance, communist confiscations of business firms in Russia, China, Cuba, and elsewhere terminated many economic or financial contacts with outside firms. Government-imposed restrictions on international trade and foreign investment also limited most cross-border flows from noncommunist nations. From 1949 to 1991, the Soviet Union stressed economic cooperation and economic integration only among the COMECON countries. COMECON, the Council for Mutual Economic Assistance, was a type of economic alliance to promote economic, scientific, and technical cooperation among member nations. Its original members included Bulgaria, Czechoslovakia, Hungary, Poland, Romania, and the Soviet Union. Over time, additional nations joined, including Albania (from 1949 to 1961), East Germany (from 1950 to1990), Mongolia (since 1962), Cuba (since 1972), and Vietnam (since 1978). As the dominant economic and military partner in this economic alliance, the Soviet Union thwarted most outside contacts through its inward-looking policies. COMECON, and the Union of Soviet Socialist Republics, formally disbanded in 1991.

The theoretical underpinnings of modern communism are found in the writings of Karl Marx, the acknowledged founder of communism. Many of the basic principles of modern communism are explained in *The Communist Manifesto* (1848), co-authored by Marx and his lifelong friend Friedrich Engels. A more exhaustive treatment of Marxist theory is outlined in Marx's three-volume tome, *Das Kapital*. The first volume of *Das Kapital* was published in 1867. The final two volumes were published in 1883, shortly after Marx's death. During the 20th century, the writings of Marx fueled the fires of revolution in Russia, China, Cuba, and elsewhere. During much of the 20th century, communism posed a formidable challenge to capitalism in the global economy.

Marxism is built on several core principles: the theory of surplus value, dialectical materialism, and the inevitability of communism. First, *surplus value* is the gap between the monetary value of the worker's output and the monetary value of the worker's wage. In Marx's view, the capitalists, who owned the factories and other businesses, confiscated this surplus value to enrich themselves. The common workers were doomed to lives of poverty. Marx's second principle, *dialectical materialism*, explains how history progresses from one stage to the next. Marx believed that all history was a matter of class struggle between exploited and exploiter classes. He predicted that the injustices during the capitalist stage would eventually boil over into revolution, pitting the *proletariat*, or propertyless laboring class, against the *bourgeoisie*, or capitalist owners of society's wealth. The proletariat's victory would create a new stage in humankind's evolutionary history, called socialism. Third, the "inevitability of communism" theorized that perfect communism was the natural culmination of past class conflicts. Marx believed that, under socialism, classes would be eliminated through the abolition of all private property, private profits, and other capitalist "baggage." The gradual perfection of socialism would lead to the ultimate goal—communism. Under communism, people would be willing to work for the common good and would be willing to distribute society's output according to people's need. The government, which was itself viewed as an instrument of oppression, would eventually "wither away" during the transition.

The Soviet Union, the People's Republic of China, Cuba, and other countries adapted communism to support revolutions and to organize economic activity during the 20th century. The first communist government was formed in Russia. Russian revolutionaries, under the leadership of Vladimir I. Lenin and Leon Trotsky, brought communism to Russia in 1917. The Bolsheviks, one branch of the Russian communist movement, had long favored violent revolution as a means of creating a communist state in Russia. As a tight-knit band of professional revolutionaries, the Bolsheviks were also quick to seize opportunities. In the fall of 1917, Lenin and Trotsky pounced on the teetering Russian provisional government, which had just been formed in the spring of that year. The provisional government was unable to defeat Germany in World War I, and unable to quell the chaos caused by wartime shortages of food and other essential goods. A disciplined Bolshevik assault on the weakened provisional government put the Bolsheviks in the driver's seat with Lenin at the wheel. Communism had arrived, but with a Leninist twist. While Lenin accepted the traditional Marxist proposition that the urban proletariat would be in the vanguard of the revolution, he also stressed the importance of the peasantry in transforming the agricultural sector along communist lines. Thus, Marx's vision of revolution by an urban proletariat was adapted to include a revolutionary rural peasantry.

The Russian brand of communism vacillated between the theoretical and the practical during the 1920s. Under war communism (1917–1921), Russia's resources were mobilized to win a fierce civil war. During this period, the communists expropriated domestic and foreign-owned banks, manufacturers, mines, railroads, and other industries. Crops were confiscated. Forced labor was instituted. By the close of the civil war, Russia's economy was in shambles. To jump-start economic activity during the post-war years, in 1921 Lenin immediately introduced the New Economic Policy (NEP), a program of small-scale private enterprise. Under the NEP, the government permitted peasants to own and farm private plots of land, and to sell their surpluses—the amount left over after an assigned quota had been delivered to the government—on the open market. The positive results of the NEP were felt almost immediately. Production of most goods and services rose to pre-war levels, and the economy stabilized under the watchful eye of the Bolshevik leadership, the Red Army, and the Cheka (secret police).

Joseph Stalin jockeyed for power after Lenin's death in 1924. Under Stalin's tyrannical rule, from 1927 to 1953, the Soviet economy was redesigned to stamp out the remnants of private enterprise. Stalin created a command economy, built on a foundation of public ownership of the means of production and central planning. Entire villages were absorbed into massive state-owned farms. Millions of rich peasants, or *kulaks*, were slaughtered, many of them dying from famine or disease in the countryside or in Siberian slave labor camps. Smaller industries were again expropriated. Stalin also introduced the five-year plan to the Soviet economy. Five-year plans, which began in 1928, established priorities for national production and set specific production targets, called production quotas, for state-owned industries. Gosplan, the state planning agency, created and implemented the five-year plans. The concept of centralized decision-making was transplanted by the Soviet Union into the communist-occupied countries of Eastern Europe after World War II. These occupied countries, called the Eastern Bloc, included Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, and Romania.

By the late 1960s and 1970s, the Soviet economy began to unravel, and by the mid-1980s, the Soviet economy was in crisis. Premier Mikhail Gorbachev attempted to rescue the faltering economy with a series of economic and political reforms. Economic reforms were packaged under the banner of *perestroika*. Perestroika restructured the Soviet economy along more market-oriented lines to promote economic growth and modernization. Under perestroika, limited private enterprise was encouraged, many wage and price controls were lifted, subsidies to state-owned enterprises (SOEs) were reduced, commercial contacts in the global economy were expanded, and individual plant managers were empowered to make many production decisions. Gorbachev also introduced national campaigns to reduce corruption, alcoholism, and other drags on the fragile economy. Political reforms, under the heading of *glasnost*, were also instituted to support a more open political process and individual freedoms.

The inherent weaknesses of the communist system overwhelmed the Soviet Union. Severely limiting the effectiveness of Gorbachev's reforms were bloated and corrupt government bureaucracies, obsolete capital goods, low worker productivity, weak incentives, and the lack of entrepreneurial skills and business expertise. International stresses also weakened the faltering Soviet economy. Government coffers were drained by the unsuccessful Soviet invasion of Afghanistan from 1980 to 1989, and by an ongoing arms race with the United States. Festering resentments by people in certain Soviet republics and in the Soviet-occupied Eastern Bloc nations also boiled over into the streets. By 1991, the Baltic republics of Lithuania, Latvia, and Estonia had declared their independence from the Soviet Union. Poland, under the leadership of Lech Walesa and the Solidarity Movement, openly challenged the communists' monopoly on political power in the Eastern Bloc. By the early 1990s, communism in the Soviet Union and Eastern Europe had collapsed. The Soviet Union was formally dissolved on December 26, 1991, and the 15 former Soviet "republics" became independent countries soon thereafter.

Communism came to China in 1949, the result of decades of armed struggle between the Chinese Communist Party (CCP), headed by Mao Zedong, and the Kuomintang Party (KMT), headed by Chiang Kai-shek. During the bloody Chinese civil war, Mao skillfully built alliances, especially with the peasantry. He promised the peasants land reform, an attractive pledge in a country where large landlords dominated the agricultural sector and dictated the conditions of life for millions of tenant farmers. In 1949 the KMT, or Nationalists—weakened by corruption, military defeats, and sagging popular support—fled to the island of Taiwan. Chiang Kai-shek established a separate Chinese government on Taiwan: the Republic of China. Meanwhile, on the Chinese mainland, Mao and the CCP triumphantly established the People's Republic of China in October 1949.

Chinese communism, often called Maoism, wavered between the pragmatic and the dogmatic from 1949 to Mao's death in 1976. Under Maoism, the CCP held a monopoly on political power, and the party permitted no opposition to policies emanating from Beijing, the nation's capital. Under its "people's democratic dictatorship," the CCP controlled the government and dictated China's economic course. The path toward communism was pitted with unrealistic "leaps" and painful retrenchments throughout the 1950s, 1960s, and 1970s, however. Production in agriculture, industry, and commerce were disrupted by unrealistic economic goals, faulty five-year plans, and widespread resistance to change.

Collectivization was the centerpiece of the government's agricultural policy from the 1950s to 1970s. The first step in the collectivization process was to rid the countryside of rich landlords and to redistribute land to the peasants in small private plots. This goal was achieved between 1949 and 1952. The second step was to introduce cooperative enterprise into the countryside. In 1953, small "collective farms" were created by government decree. The land on these collectives was still privately owned, but it was worked by several families, called mutual-aid teams. Soon, larger "cooperatives" were formed, with land, tools, draft animals, and other possessions owned by the cooperative enterprise rather than by individual peasants. Finally, in 1958, the "people's communes" were introduced, marking a radical leap toward communism. Almost overnight, over 100 million households were absorbed into people's communes. Now, the CCP leadership in each commune dictated the allocation of resources, including labor, to build the region's infrastructure, work the farms, and attend to other business activity in industry and commerce. The communes also controlled education and law enforcement, and they administered punishments for counterrevolutionary activity or dissent. All private property and private incentives were banned.

The negative reaction to the communes in the countryside was swift. Some peasants refused to plant or harvest crops without an incentive system, while others sabotaged farms and other businesses, destroyed their herds, or otherwise disrupted production. Widespread opposition by the peasants, and a serious drought, reduced crop yields. Faced with the specter of famine, the government restored limited incentives, including small private plots of land, to the peasantry from 1959 to 1961. The functioning of the commune system, with its limited and uncertain incentive system, fluctuated greatly during the 1960s and 1970s. Selective implementation of government policies by local CCP officials, economic chaos caused by the Great Proletariat Cultural Revolution during the 1960s and early 1970s, and the inevitable internal power struggles—all of these added to the confused state of Chinese agriculture and industry during the period.

Reform in China's industrial sector followed a similar course during the Maoist era. The 1950s witnessed the systematic dismantling of private enterprise and the rapid rise of SOEs. To coordinate the government's expropriation of private firms in industry and commerce, China embarked on its first five-year plan in 1953. By the end of this five-year plan in 1957, virtually all of the country's industrial and commercial firms were in government hands. Buoyed by its success in reigning in privately owned firms, the government imposed a second five-year plan (1958–1962), promising a Great Leap Forward to double the nation's industrial production. Under this plan, peasants in the people's communes were expected to contribute to China's rapid industrialization by constructing and operating "backyard furnaces" to increase China's production of steel and other heavy industrial products.

Inadequate capital goods, the lack of technical expertise, and nonexistent private incentives transformed the "Great Leap" into an economic freefall. By the early 1960s, the government was forced to retrench in the industrial sector, just as it had already done in agriculture. The crippled Chinese economy was given another negative jolt by the excesses of the Great Proletarian Cultural Revolution in the 1960s and 1970s.

The Cultural Revolution was meant to be a purification campaign to identify and punish counterrevolutionaries. Youthful militants, called the Red Guard, purged scientists, engineers, party officials, and other well-educated professionals to stamp out lingering capitalist ideas among China's elite. These purges destroyed important elements of China's human capital, however, a tragedy that rippled through China's already stumbling economy. After Mao's death in 1976, reform-minded leadership began a series of cautious, methodical experiments in free-market, incentive-based enterprises—China's first steps toward a market-oriented economy.

Communism came to Cuba in 1959 through revolution. Under the leadership of Fidel Castro, Cuba's dictatorship was toppled and the Republic of Cuba was established. Castro instituted a series of socialist reforms, including the expropriation of private enterprises and the elimination of dissent. He also introduced Soviet-style central planning to dictate the use of Cuba's resources. In response to Castro's aggressive seizure of private assets, including American-owned plantations and other businesses, the United States imposed a total embargo on Cuba in the early 1960s. This embargo halted U.S. trade, foreign investment, and other economic ties with Cuba. Castro turned to the Soviet Union for economic and military assistance, which the USSR generously supplied to its new friend in the Western Hemisphere.

Cuba instituted economic reforms during the 1990s, particularly after the collapse of its most important benefactor, the Soviet Union, in 1991. In 1993, the Castro dictatorship dismantled its cumbersome central planning agency, the Central Planning Board, in favor of more specialized planning ministries. This reshuffling within government was designed to promote tourism, industrial development, agricultural development, foreign direct investment, and other economic activity. During the 1990s, Castro also legalized many small-scale private enterprises, mainly in the services-producing sector. In agriculture, some large state-owned farms were divided into smaller producer cooperatives. These cooperatives were required to sell a portion of their output to the state for a set price, but they were encouraged to sell the remainder for profit in farmers' markets. The Cuban government also courted foreign investment and legalized the use of the U.S. dollar in most types of transactions.

By the early 2000s, the Castro regime had reversed course and abandoned some of the market reforms of the 1990s. The government reasserted its control over SOEs and cracked down on fledgling private sector business activity. In November 2004, Castro banned the use of U.S. dollars in Cuba and required citizens to convert dollars into pesos. Today, the vast majority of Cuba's human, capital, and natural resources remain firmly under the government's thumb. In addition, the communists retain a monopoly on political power, ruthlessly suppressing dissenting viewpoints.

COMPOUND INTEREST

Compound interest is created when interest that is added to the principal of a deposit or loan also earns interest. Over a period of time, compounding can greatly magnify the amount of debt owed or savings accumulated. An understanding of this principle will help investors and consumers appreciate the importance of saving and the need to avoid debt.

Importance of Compound Interest

Compound interest is widely believed to be "one of the most powerful forces in the universe." Indeed, some claim that Albert Einstein described compound interest as the eighth Wonder of the World and remarked, "He who understands it, earns it . . . he who doesn't . . . pays it."

When people invest money, they receive interest on the original amount they invest (known as the principal). If they choose to add the interest to the principal (rather than withdraw and spend it), it also earns interest along with the interest paid on the principal. This is known as compounding. It is an important concept to understand, because it shows the importance of investing early and the power of reinvesting the interest earned. Money subject to compound interest will grow to a large sum over a long period of time. When it comes to deciding whether to postpone saving, compound interest is particularly important; if individuals delay, they may not enjoy the full benefits of this powerful force.

Suppose you invest $1,000 at 10 percent interest. At the end of the first year, you will receive $100 interest on your $1,000 investment. If you reinvest the interest, the $100 interest is added to your original investment of $1,000, so your investment at the start of the second year is now $1,100. In the second year, the interest on your investment is $110 (10 percent of $1,100), and you earn $10 more interest because your investment is worth $100 more than the amount in the first year.

In the third year, your investment will grow to $1,210 and the interest earned is $121. With compounding, the interest earned grows with time—$100 in the first year, $110 in the second year, and $121 in the third year. Consequently, the value of your investment grows exponentially with the passage of time. The money value of the increase is not so large in the early years, but it is very large in the later years.

In contrast, if you choose not to reinvest the interest, your original principal will earn *simple* interest of only $100 each year. A $1,000 investment will grow by just $100 each year. After two years, your investment will be worth only $1,200 (compared to $1,210 with annual compounding). It's over a long period of time that the differences between simple and compound interest can become enormous. Another simple example can demonstrate this: At 15 percent simple interest, $100 grows to $550 in 30 years, while at 15 percent interest compounded annually, $100 grows to $6,621 in 30 years, a difference of $6,071.

The frequency of adding interest, or compounding, can affect the amount of interest accrued. Interest can be added more frequently than once a year—it can be monthly, quarterly, semiannually, or annually. This is known as *compounding frequency*. The greater the frequency, the higher the amount of interest earned.

Suppose two banks offer two interest options: Bank A pays interest monthly and bank B pays interest annually. With interest added monthly, $1,000 at 10 percent will give you $104.71 of interest in year 1, while $1,000 at 10 percent with interest added annually will you $100 of interest, a difference of $4.71. However, over 30 years this can lead to a huge difference: $1,000 with 10 percent added monthly grows to $19,837, while $1,000 with 10 percent added annually grows to $17,449, a difference of $2,388.

Compound interest richly rewards those who invest early. The benefit of investing early can be illustrated by the story of twins: Hannah and Ellie. Hannah started work after leaving university at the age of 21, and she began investing $1,000 per annum with compound interest of 8 percent per year. Ellie also left university and started work at the same time, but she failed to set up a saving plan because she liked to party and buy clothes. Hannah stopped saving at age 30, when she left her job to have a baby. She left her savings to grow but did not invest any more. Ellie, on the other hand, started saving $1,000 per year earning 8 percent compound interest per year.

By age 65, Hannah has accumulated a bigger pot of savings. Although she has paid in only $10,000 over 10 years, her investment is now worth $231,324 because her investment has had 44 years of growth. Although Ellie has paid a total of $35,000 over the 35-year period, her investment is now worth less than Hannah's ($186,102) because of the shorter period of investment. The lesson is clear—the sooner you start saving, the better.

People often think that investing makes sense only if you have a lot of money to begin with. This is not true; compounding works on any starting sum. Whether the sum is large or small, compounding gives the same impressive percentage increase.

Borrowing and Compound Interest

While compound interest can work miracles when you save, it can have a ruinous effect when you borrow. For example, if you borrow $1,000 over 30 years at 10 percent per annum, the total amount you will have to repay is $17,449, which is more than 17 times the original amount borrowed.

Here, it might be worthwhile to distinguish between good debt and bad debt. People often borrow money to buy real estate, and this is perceived as good debt because the value of real estate is likely to grow over time. Although borrowers will have to repay more than the amount they owe, they take the risk in the hope that their asset will grow more in value and they can still make a profit. Bad debt, on the other hand, refers to assets whose value depreciates over time (e.g., cars, vacations, paying off other debts); money borrowed to acquire these types of assets will not enable individuals to accumulate wealth.

Compound interest, then, is a double-edged sword: It can help those who invest early to build a significant sum of money over a long period of time, and it will punish those who borrow money for a lengthy period. The lessons are clear: When it comes to saving, save early and leave the money to grow for as long as possible. When it comes to borrowing, borrow as little as possible, and repay it as quickly as possible.

COST-BENEFIT ANALYSIS

Cost-benefit analysis, or benefit-cost analysis, is the economic process of analyzing all costs and benefits associated with a decision. People should use this type of analysis to make good economic decisions, and they should do something only if the benefit outweighs the cost. Generally, this type of decision-making is applied to public programs and projects, where costs, including opportunity cost, and benefits of the project are weighed. Cost-benefit analysis was first used in the United

States in the 1930s as it related to water allocation. The concept was also applied to transportation in the United Kingdom in the 1960s.

Cost-benefit analysis is credited to the French economist and engineer Jules Dupuit. The concept was first applied to public works and transportation projects in the 1840s. Dupuit examined the costs of public projects differently than other economists had, and he first applied his reasoning to a canal project. He also favored charging people a toll to use the canal, with the price of this toll to be determined by an examination of the canal's utility to consumers as well as by price discrimination. Later, Dupuit extended his idea of cost-benefit analysis to examine who owns the good or service: the individual or the government.

Dupuit's contributions led cost-benefit analysis to be based on the following: identifying the costs and benefits associated with a project, measuring benefits based on both supply and demand prices, and determining tolls or any related costs by taking utility and potential deadweight loss into consideration. He also applied the terms *consumer surplus* and *producer surplus* to determine what the benefit would be to society, or the government, as well as to the people. Dupuit also examined what the effect of a tax would be, and he stated that taxation would decrease consumer and producer surplus. Dupuit also discovered that there would be a societal loss resulting from imposing a tax; today this is called deadweight loss.

One of the first steps in cost-benefit analysis is to identify the costs and benefits of a particular project. This also includes potential future costs of the project as well as external costs (or benefits) to society. Another area to be examined is how the project will affect supply and demand and the price of related goods. Some groups would lose utility due to this, while others would gain utility.

Cost-benefit analysis evolved to also include the tradeoffs of making a decision, or what is being given up to make a specific decision. The amount of alternative choices can also play a role in this analysis, as can the anticipated utility, or satisfaction. Behavioral economists believe that in some cases, people fail to use cost-benefit analysis because they postpone making a decision or they accept an option without weighing the true costs and benefits of the decision. It must also be considered that the "best decision" for one person may not the same for the next person.

Cost-benefit analysis also involves projects that maximize societal benefits and welfare, and it is not the same as examining only the financial costs and benefits of a decision or a project. It also contains analysis of external costs and benefits to society. Cost-benefit analysis does not include sunk costs, the costs incurred by society even if something is not implemented.

Cost-benefit analysis is increasingly used in environmental policy and behavioral economics, as well as in welfare economics.

CRAFT GUILDS

Craft guilds are associations of craftsmen that formed an alliance for their mutual aid and protection and to further their professional interests. Craft guilds were created soon after merchant guilds started to form, and their history can be traced back to the 10th century.

When labor began to divide and specialize, the craftsmen banded together to help regulate their trade. Years ago, these guilds were usually set up by families or towns that had specialized in a trade and were seeking to regulate their craft for their own best interests. This allowed the guilds to regulate their trade by setting quality standards and establishing basic rules. These standards set up expectations for the quality of the goods or services that the craftsmen were providing, which allowed the craftsmen to set prices that were stable and that reduced the competition among craftsmen of the same trade. The guilds helped to increase integrity in the trading process, since craftsmen of the same guild were not undercutting each other and providing inferior services. This helped to reduce competition among those in the same trade, and it added organization to trading processes. Craftsmen who did not adhere to the guild's rules and standards found themselves facing fines that were imposed by the officials within the guild who were responsible for investigating complaints.

While guilds have become rarer than they were many years ago, they still exist today for tradesmen such as plumbers, electricians, and carpenters. The guilds are structured so that people start their on-the-job training as apprentices, become journeymen, and eventually become masters. Apprentices start work with little or no experience in the particular field they have chosen. They are provided an education on how to perform the labor in a profession, and in exchange they agree to work for their employer for an agreed-upon period of time after they achieve a certain level of competence. Apprenticeships typically last for three to six years, depending upon the difficulty of the profession, the skill of the apprentice and the trainer, and the state of the overall economy. Apprentices learn their trade or profession from the master craftsman whom they were assigned to at the start of the program. They learn the majority of their chosen trade or profession through on-the-job training, but this is often supplemented with classes sponsored by the guild or company that the apprentice is affiliated with.

Once the guild deems that an apprentice has learned the craft but is not yet a master, the apprentice is promoted to journeyman. As a journeyman, the person can be certified and, if required by law, become a licensed journeyman. A journeyman's education depends largely on the field the person has chosen and the requirements of the laws governing the field. For some journeymen, their education continues for one to three years after they graduate from their apprenticeship. This additional training can be informal, on-the-job training, or it can be formal training with additional classes required in order to move to the level of master.

Journeymen typically are responsible for supervising the apprentices who are assigned to the master that the journeymen usually are working under. Journeymen have a greater knowledge of the industry than apprentices do, but they may not have the same knowledge as those who are considered masters. Journeymen often specialize in one area of their trade, but they are unable to offer their services in all areas of the trade like many masters are able to. Depending upon the trade and the profession, as well as the laws that govern it, "journeyman" may be the highest rank that is achievable in the guild.

For guilds that offer it, trainees can achieve "master" status after taking additional classes, passing various exams, and obtaining further licensing. Tradesmen who achieve master status can generally command higher pay than journeymen, since they have a greater knowledge and have faced more difficult requirements to achieve their status.

Many years ago, to start a business, a craftsman had to have achieved master status. For most people today, this does not apply; journeymen can open their own businesses and provide services to the public.

Some countries require that a person that has achieved master status must be involved in a trades business in order for the business to operate legally without fines. Many countries have eliminated this requirement in an effort to make it easier for people to start new businesses and drive the economy. Businesses that are still subject to these rules will often hire just one master tradesman in order to meet the requirements set forth in the laws. These requirements can be met even if a company has multiple locations and hundreds of employees; this requirement has led many countries to eliminate the requirement of having a master tradesman at each site.

The majority of guilds are no longer informal groups that are joined together by family; instead they are now formal unions that are representatives for their members. Many of these guild unions have joined the American Federation of

Labor and Congress of Industrial Organizations (AFL-CIO), the largest federation of unions in the United States.

CREATIVE DESTRUCTION

In *Krieg und Kapitalismu* (War and Capitalism), Werner Sombart (1913) originally brought *creative destruction* into the public sphere as an economic concept. Reinart and Reinart (2006) argue that the concept is actually attributable to the influence of Friedrich Nietzsche. Nietzsche interpreted creative destruction in attempts to remedy the need to create a new moral system and the subsequent need to dismantle the previous schema. This theme of the morality of innovation can be traced back even farther, to Hindu principles of creation and destruction. Creative destruction, however, is largely attributed to the work of Joseph Schumpeter—specifically, through his expansion of earlier works by Karl Marx and Friedrich Engels. In Marxist thought, *creative destruction* refers to a paradox in the nature of capitalist systems whereby capitalistic societies are being destroyed by capitalism's own creative success.

In their writings, Schumpeter and Marx both envision capitalism as a main creator of the socialist system. Furthermore, they both claim that capitalism will inevitably fail and give way to socialism. They differ, however, in that Marx pictures capitalism as failing as a result of economics, where Schumpeter postulates that capitalism will fall victim to its own incessant need for growth and expansion. This was the genesis of creative destruction, which is sometimes referred to as Schumpeter's Gale.

Capitalism as a system is fueled by growth and profits, especially those associated with new technologies and advances in business thinking. As a result, the system is supported by continued growth, which means it is ever-expanding. Therefore, new technologies frequently require the clearing of both physical space and market space, which will compete and subsequently destroy previous, outdated productions—or even existing, capable productions. To that extent, Schumpeter argues that any enterprise is threatened and put on the defensive as soon as it comes into existence. To exist, capitalism requires continual creation of growth and increasing wealth. This creation of new wealth requires the repurposing, or even the complete destruction, of past wealth. This is the core principle of creative destruction, and it can be applied to other aspects of capitalist societies, such as property, intellectual intelligence, and innovations. More modernly, it can be seen as a large factor in modes of globalization.

In *Grundrisse* (1939), Marx takes a much more critical look at the destruction of capital and other systematic apparatus as a necessity for the self-preservation of capitalism. He describes the end product of capitalism as cyclically growing into conditions of overreliance on the system and overdevelopment, bringing the immediate need for either destruction within its own system or expansion into dominance of other markets. Essentially, the overdevelopment and inevitable stagnation of growth within a given system leads inevitably to a recession. Sometimes, a more controlled or manipulative device within an economy—such as war, labor conflicts, and subsistence restrictions—may also be a by-product of the needs of preserving capitalism via the degradation of quality of life. Essentially, wealth, capital, subsistence, property, and markets all must continually grow. If there is not room for that growth, but there are vast technological improvements, they may be destroyed.

Wiggins and Ruefli (2005) assert that there are three key predictions of Schumpeter's theory. First, as time progresses, maintaining strategic competitive advantages becomes more difficult. Second, the paradox of creative destruction is increasing its reach to affect more industries. Third, competitive advantage is becoming more reliant on multiple advantages developed over time rather than a singular force. This increase in competition seems to lead the way for shorter cycles of creation before the inevitable counterbalance of destruction. It means the exponential precipitation of the needs of capitalism. It also means that established businesses are gaining advantages in their experience and utilization of past wealth for the creation of new wealth. As a result, the wealth gap between poor and rich is ever-expanding.

CREDIT REPORT

A *credit report* is a tool that lending institutions such as banks use to determine if you are a good credit risk and will pay back the loan you are applying for. The credit report contains information about your past and current financial transactions that involve debt (such as credit cards) and loans. Additionally, it includes information on judgments and past credit inquiries from credit-granting institutions. You are allowed one free credit report a year from each of the reporting agencies. You may also request a report when you are denied credit.

Credit-reporting agencies are companies that, for a fee, will compile the data for your credit report and provide the information to banks and other institutions.

What Is on a Credit Report?

A credit report contains information related to your ability to pay back money that you borrow. It includes the following items:

Personal Identification Information—This includes your name, address, Social Security number, and phone number. It may also contain information from your past, such as former names, addresses, employers, and people you have a credit relationship with, such as your spouse.

Outstanding Debts—These are debts that you have not paid off in full. Examples are mortgages, car loans, student loans, and credit cards.

Past Debts—Any debts that you have finished paying off will continue to show on your credit reports. For example, once you have paid off a car loan, it will remain on your credit report as a debt paid in full. If you do not pay it in full, and instead use a settlement, then the credit report will indicate that the debt was settled and closed.

Payment History—Your credit report will show if you made your payments on time, or late. Typically, it will show On time, 30 days late, 60 days late, and 90 days or more late. After that point, the information typically will be moved to a collection status, such as "Referred to collection," Repossession, or Charged off. These last classifications indicate that you have not paid the debt as you originally agreed to do.

Your positive information on your payment history will typically stay on your report indefinitely, and your negative will be removed after seven years. Bankruptcy will stay on your report for 10 years.

Available Credit (Utilization)—Your report will show how much you have available on revolving credit. Available credit is considered the available credit line minus your outstanding balance. Thus, if your credit line is $20,000 and your balance is $5,000, you have available credit of $15,000.

The lower your utilization, the better your credit score appears; lenders look upon this favorably. If you are maxed out on your credit cards and are applying for more credit, lenders see this as a bad sign.

Public Records—Your credit report will also include any items that are on the public record, such as tax liens, court judgments, and bankruptcies.

Credit Inquiries—Anytime someone checks your credit, that request will show up on your credit report.

Dispute Statements—If your report contains an item that you disagree about, you can file a dispute statement; this will show up on your credit report. The credit-granting company you have the dispute with may also include a statement on the credit report detailing their version of the reason for the disagreement.

Types of Debt

Three types of credit will appear on your credit report:

1. *Revolving Credit*—This type is when you don't have a final end date for paying off the debt; you are allowed to continually use the credit, pay it off and then take out more. Examples of revolving credit are credit cards and home equity loans.
2. *Installment Loan*—This type of loan has a fixed loan amount, a fixed payment, and a fixed payoff date. Examples are auto loans and mortgages.
3. *Open Debt*—This is the least common among the types of debts, but it includes debts that must be paid in full every month. An example of this is some of the cards offered by American Express®; they have no credit limit, but you must pay the owed amount in full every month.

Purpose of a Credit Report

The purpose of the credit report is to help companies determine if you are good credit risk.

Credit reports are also used by insurance companies, some employers when you are applying for a job, landlords, and when granting military security clearance. These companies and institutions typically use the information to determine if you are responsible and will pay your debts.

Some employers, such as in the banking industry, want to learn whether you are able to handle constant interaction with money and will manage money responsibly for others. In the military, it has been shown that most unethical or illegal acts are perpetrated in order to gain money to pay off debts.

Credit Score

The credit report itself does not say whether you are a good or a bad risk. It is up to lending institutions to take the information from the report and make their own decisions regarding your credit-worthiness.

In an attempt to make this easier, the "credit score" was created to attempt to summarize your ability to pay; this is also known as your FICO score. This score is not part of your credit report. Companies pay extra to have this score given to them, in addition to your credit report.

When you get your annual free report, it will not include your credit score unless you pay an additional fee for access to the score.

Reporting Agencies

Your credit report is compiled by a credit reporting agency, also known as a credit bureau. The three major agencies are Experian, Equifax, and TransUnion.

To compile your report and score, each agency gathers information from lending agencies and and public records. While each company typically has obtained very similar information about you, there may be small differences between each of the agencies reports and the scores that they report to lending institutions.

These agencies are for-profit companies, and they make money by selling your reports to lending institutions and others that want the information. Companies requesting the credit report must get you permission to access your report. For example, if your landlord wants to run a credit report on you, you must sign an authorization form for the landlord to make the request and receive the information.

While lending institutions are not required to report any information on an individual's debts, they do so voluntarily to help create a complete picture of the person's credit.

The reporting agencies are monitored by the Federal Trade Commission (FTC).

Disputing Information on Credit Report

If you pull your credit report and determine that some information on it is false, then you can request that the reporting agencies remove that information from your report.

In order to have it removed you must submit a request. Then the agency has 30 days to verify the information or to remove the information.

It is possible, however, that the information may show up again at a later time. This occurs when a bank or lending institution has wrong information in its files. After the agency has removed the incorrect information, the bank may re-report the data and it will show up again on your report.

To guarantee that this incorrect data will not show up again, you must work with the lending institution to remove the bad information from the files they retain for you.

CRONY CAPITALISM

A capitalist market is in force when individuals choose their roles as producers and consumers in an economy. Producers succeed or fail based on their skills and their ability to participate in the market and successfully conduct market transactions with buyers. In contrast, the transactions of a crony capitalist system are based on government officials selecting who will participate as producers by providing special treatment to a select group or groups—usually political allies and the friends of government officials. Crony capitalism is a form of capitalism in which government officials have chosen certain market participants to receive special favors such as subsidies, grants, or special payments to give a chosen business preferential treatment and an extra advantage over its competitors.

The bigger a government's budget and regulatory powers, the greater the potential for crony capitalism to occur. Crony capitalism exists even in democracies, as those with financial means seek to influence the government. The more the government becomes involved in the selection and designation of certain businesses, the more those businesses depend on government favors and support in order to be successful. This leads to a system of bribes to government officials and increased government corruption, as businesses and special interest groups vie for the government preferences. This often leads to instability in the government, sustaining a system of bribes and corruption. Because the participants—government officials and businesses receiving the special favors—have no incentive to change the system, crony capitalism reinforces the current corrupt political and economic structures and provides no incentives to change.

Crony capitalism often results in the misuse or misallocation of resources. It also emphasizes the use of economic rent (or rent-seeking behavior), which will be higher than necessary, leading to inefficiencies. *Economic rent* is a system in which the government grants favors to businesses while businesses must devote some resources to obtaining those favors. For example, a business, might ask the government for tariffs or quotas in an effort to protect domestic manufacturers; in exchange, the business supports the politicians who are providing the favors.

Crony capitalism perpetuates the influence of the political elite. The system also gives immense power to bureaucrats who make decisions on how to spend money that can benefit some people or groups over others. Even when the government seeks to provide public goods, such as roads, crony capitalism is present, as private interests seek to benefit. Crony capitalism threatens the distribution of income, as profits remain high for the few at the expense of both producers and consumers.

This system favors and benefits smaller groups of people, and the burdens of this favoritism are placed on the rest of society. In addition, those who are better off may be against projects that assist the poor, because the wealthier people would then be faced with higher taxes.

When crony capitalism has a strong presence in an economy, the country's legal system and the agencies that regulate markets are likely to be less strong. Lenders assume more risk as they interact, and have close relationships, with their borrowers.

Corruption is much more common in economies with a strong crony capitalism component. It disrupts the efficient allocation of resources in an economy, and it may affect both foreign and domestic investments.

There are some advantages to crony capitalism: It encourages investment in growth within an economy even when economic times are not especially strong. The presence of crony capitalism has also helped different world economies grow in the short run, including those in Asia. Many stakeholders, such as banks and businesses, can remain insulated from economic problems as a result of crony capitalism.

Crony capitalism is prevalent in developing nations where populist political leaders dispense political and economic favors to maintain control and power. Crony capitalism has been blamed in part for the economic problems of developing nations such as those in sub-Saharan Africa and South America. The Asian economic crisis of 1997 has also in part been blamed on crony capitalism. A close relationship among business, the government, and banks may have caused the crisis that affected Thailand, Indonesia, and South Korea and several other Asian countries.

In the United States, the Federal National Mortgage Association (Fannie Mae) and the Federal Home Loan Mortgage (Freddie Mac) are organizations established by the government but operating in the private sector. As private businesses established by the federal government, they often take their business mission, direction, and role in the housing market from Congress. As a result of this close relationship between government and a private sector business, with the special preferential treatment they receive from government, they have often been labeled as the result of crony capitalism behavior. They benefit from their relationship with the government, which allowed them to promote and purchase below-market, substandard mortgages. Many consider this to be the primary cause of the housing bubble that led to the 2008 financial crisis. To avoid a potential financial collapse, the federal government bailed them out by purchasing some of their stock and guaranteeing loans to prevent homeowners from foreclosures; a private business without preferential government benefits would have been allowed to fail.

As mentioned, when both businesses and government officials benefit from crony capitalism, there is no incentive to change the structure. Additional government intervention and regulation can make the situation worse, which often leads to another government problem—moral hazard. Private businesses decide that it is not a problem if they fail, for the government will bail them out as it did Fannie Mae and Freddie Mac. It is difficult to prevent or even regulate crony capitalism.

CULTURAL ECONOMICS

Cultural economics is a field of economics that relates to the arts and heritage of cultural industries. Cultural economics covers several areas of cultural goods: the performing arts, which includes music, theater, dance, and opera; cultural heritage, which includes museums and other artifacts; and cultural or creative pursuits, such as broadcasting, film, sound recording, and software. Producing cultural goods is initially expensive, as fixed costs are high; but as subsequent units of the good are produced, the marginal cost decreases. A topic of frequent political debate is whether or not the cultural arts should be considered public goods and publicly funded.

Cultural economics began as "economics of the arts" in the 1960s, and it expanded in the 1970s. An influential book, *Performing Arts: The Economic Dilemma*, published in 1966 by William Baumol and William Bowen, led the way in the field of cultural economics. Baumol and Bowen asserted that as people earned more income, the arts, paradoxically, would face more financial difficulties. Furthermore, the rising cost in the wage of performers and artists would lead to a decrease in the demand for a performance yet an increase in the overall price of a performance. Therefore, a lack of revenue would lead to the subsidization of the arts to make up the needed revenue. Baumol and Bowen also believed that society as a whole benefited from the arts. This proposition ties cultural economics to the idea of welfare economics.

Cultural goods and artistic labor differ from other labor and do not necessarily grow due to technological change or advancement. The arts depend on public and private contributions for their maintenance. Conflicting ways of preserving the field of cultural economics also existed. Baumol and Bowen argued for subsidies to keep the arts alive so that there would always be financial support for it. Alan

Peacock, tied to cultural economics in the 1970s, felt differently; he was in favor of subsidies only to preserve the arts in schools.

Peacock developed a system to determine the output of an orchestra in order to determine the appropriate level of costs. This became known as cultural accounting, and it was used to standardize the approach to the financing of the arts. Peacock also explored how to make the arts more affordable for all citizens, and he examined a voucher approach, which would operate much like a subsidy.

Peacock contributed to cultural economics further through his work on museums and the "building of heritage," or the preservation of generational artifacts. Peacock examined the idea of charging visitors a fee to enter a museum, holding that these fees could help preserve the museum and provide for its restoration in the future.

Peacock was also a contributor to the field of broadcasting, studying how this public good would be financed. He applied economics to the field, through the idea that listeners (or viewers) should receive maximum satisfaction from the programs being broadcasted and also that a competitive market should exist.

Copyright is yet another area of cultural economics that is meant to protect the creativity and originality of artists' works of art, music, or literature. The current concern has to do with how digital versions of artists' works will affect copyright laws and regulations. Digitalization allows works to be shared for free in many cases, and this means many cultural goods are becoming public goods.

Cultural economics has made use of welfare economics and cost-benefit analysis to determine if new methods or techniques make economic sense for financing specific cultural industries. The field of cultural economics also looks to public finance, and it seeks to determine if the arts should be financed publicly since they contain the features of public goods.

The field of cultural economics has evolved beyond attending the theater, the opera, or a ballet; today it can be broadened to include many social media elements and pieces of technology. The field has expanded to include Facebook and its millions of users, as well as YouTube and everyone's immediate access to culture. The iPhone and iPod have revolutionized cultural economics, as songs can be downloaded quickly and inexpensively. Kindle and other e-readers have changed the face of culture, as people can download and read current bestsellers or classic works with just a few clicks. The field of cultural economics will continue to evolve and will change with the times and the technology.

CULTURE AND BEHAVIORAL ECONOMICS

Culture is generally defined to mean the shared beliefs, values, and attitudes that influence the formation of people's preferences and their choices for goods and services. In a way, human actions are imprinted by their history. Conceptualizations of culture vary across disciplines. But culture, as a system of shared beliefs, values, and attitudes, provides collective understandings in forming people's choices.

According to Richerson and Boyd (2005), *culture* is information that individuals acquire from other members through teaching, imitation, and other forms of social transmission—information that then has the ability to affect individuals' behavior. By *information*, Richerson and Boyd mean any kind of mental state, conscious or not, that is acquired or modified by social learning and affects behavior. People are likely to perceive bits of information that is germane to existing schemata.

Culture can be understood as heterogeneous. Cultural differences are, to a large extent, due to environmental differences. Humans acquire large parts of their behavioral repertoire via forms of social learning (basically, through imitation). Therefore, patterns of social interaction affect the structure of cultural systems. Culture can be the mechanism that reduces "intra-group" differences and maintains "inter-group" differences, by biasing individuals in favor of copying the common beliefs, values, and attitudes.

In addition to being a source of preferences, culture can be introduced as a deviation from conventional economic predictions. Roth et al. (1991) published the first cross-cultural comparison study of an ultimatum game, conducted in the industrialized cities of Pittsburgh (U.S.), Tokyo (Japan), Ljubljana (Slovenia), and Jerusalem (Israel). Subjects were first assigned a role: proposers or responders. The responder could accept or reject a proposal. If the responder accepted the offer, the proposer got the demanded amount and the responder got the remainder. If the responder rejected the proposal, neither player received anything. In the test, modal offers by proposers generally approached 50 percent of the total stakes, with the mean offer ranging from a low of 37 percent (Israel) to a high of 47 percent (U.S.). Rejection rates by responders varied between 19 percent and 27 percent, with offers below 20 percent commonly being rejected. In contrast to these results, which were obtained in relatively industrialized settings, those of Henrich's (2000) experiment with the Machiguenga of the Peruvian Amazon nearly approached conventional economic predictions. That is, Machiguenga proposers seemed to possess little or no sense of obligation to provide an equal share to responders, and responders seemed to have little or no expectation of receiving an equal share. The modal offer of 15 percent seemed quite fair to most Machiguenga. Culture may have played a profound role in determining what was perceived as fair.

Cultural differences can affect economic behavior and, therefore, economic performance. In his classical work *The Protestant Ethic* and the *Spirit of Capitalism*, Max Weber (who lived from 1864 to 1920) saw culture as the driving force behind differences in economic development. Weber argued that the rise of the Protestant work ethic led to economic development of the Protestant regions of Europe, starting in the 16th century.

There is some evidence to support the argument that culture plays a fundamental role in explaining the wealth of nations (Tabellini 2010). Culture is measured to a degree by indicators such as trust, respect for others, and confidence in individual self-determination. Indeed, trust is a crucial factor for fostering cooperation among people, and trustful relations reduce transaction costs in economic interactions (Teraji 2008). If societies differ in their degree of trustworthiness, one would expect this variation to be reflected in economic performance. Also, differences in culture can affect decision-making processes and choices, resulting in different economic outcomes, which are stable over time. The outcomes can range from economies that are economically highly efficient to those that are highly inefficient (Altman 2001; Harrison 1993). According to Jones (2006), however, cultures seem sticky but can be fluid. Cultural change reflects better knowledge of alternative cultures, and such knowledge leads to cultural merger.

DECISION COSTS

The terms *decision cost*, *optimization cost*, and *deliberation cost* have all been used to describe the value of resources a decision-maker uses to sort through a set of alternatives and choose the one that best accomplishes the objective. *Decision cost* includes the cost of concentration, attention, thinking, checking, and deciding. As it is most typically conceived, decision cost does not include information cost. *Information cost* is the cost of gathering the information necessary to define the set of alternatives, while *decision cost* is the cost of sorting through the set of alternatives.

Decision costs arise because humans have limited cognitive capacities. It takes time, concentration, and effort to compare alternatives. These resources could be productively used in other ways, so there is an opportunity cost associated with any particular decision method. If human decision-makers had unlimited cognitive capacity, they could sort through a set of alternatives and without cost, but such is not the case. Thus, to say decision cost is positive is to say rationality is bounded.

Once decision-makers recognize that it is costly to make a choice, it becomes evident that it may not be best to consider all alternatives. One decision method may yield a choice closer to an optimum than another, but this benefit might be outweighed by a higher decision cost. This explains why people adopt a variety of decision-making modes—trial and error, imitation, obeying an authority, and habit—that fall short of comparing all alternatives.

It is tempting to think that decision-makers should optimally choose a choice method, but this line of thinking leads to a circularity problem that is most commonly referred to as the "infinite regress problem." If there is a decision cost to optimally solving the original decision problem, then the decision cost must be even larger when a decision-maker wants to also decide how to decide. Ultimately, the presence of decision cost implies that decision-makers must be arbitrary to some degree when adopting a decision method.

Because an optimal choice involves making a best choice with no decision cost, it is not possible both to make an optimal choice and to know with certainty that an optimal choice has been made. To the extent that decision-makers make optimal choices, they must find ways to limit decision cost. To the extent that they limit decision cost, they increase the likelihood the choice is not best.

A habitual choice may be near optimal, because it is reasonable to think the decision cost would be zero or near zero. Of course, the habitual choice could also be far from optimal, because it does not involve the consideration of alternatives. Therefore, occasionally deviating from a habit is reasonable. A deviation that leads to a significantly better choice indicates that the application of some other decision method should be fruitful. As trial and error, submitting to authority, imitation, and other more rational procedures lead the decision-maker toward the best choice, these methods become too expensive to further apply. Habit should then dominate. In summary, only a dynamic and evolutionary process can effectively lead a decision-maker to an optimal choice. Only such a process allows a decision-maker to balance the possibility of incurring too much decision cost against not using enough.

Competition in the marketplace incentivizes decision-makers to evolve their decision-making processes to effectively manage the trade-off between improving decisions by incurring decision cost and improving decisions by economizing on decision cost. It is hard to imagine optimal choices being achieved by any means other than conscious cognition. However, because conscious cognition is typically expensive, market competition will typically ensure that those who survive have developed habitual business practices that allow good choices to be made without much conscious cognition.

Decision cost has been offered as an explanation for a variety of important phenomena. Why pay human subjects in experiments? Answer: The instruction to "Do your best" is not enough to overcome the decision cost associated with performing the decision task. Why might having more alternatives not improve well-being? Answer: It may increase decision cost enough to discourage search sufficiently that a worse decision is made. Why might a decision-maker focus only upon similar probabilities or similar outcomes when considering uncertain prospects? Answer: The decision cost associated with the more complex approach of considering both probabilities and outcomes may be perceived to outweigh the potential usefulness.

DEMOCRATIC SOCIALISM

Democratic socialism is a type of economic system in which core socialist beliefs guide national economic policy, and democratic institutions govern the nation. Democratic socialism is most concerned with creating an environment conducive to social and economic justice. Democratic socialism became a major player in the global economy during the post–World War II period by claiming electoral victories in many advanced countries. Democratic socialism is sometimes referred to as the "third way" to distinguish it from capitalism, which leans heavily toward the market model, and communism, which leans heavily toward the command model.

Democratic socialism in the post-war world was non-Marxist and gradualist, preferring to work within existing political institutions rather than toppling them from without. Its stronghold was in Scandinavia, Western Europe, and several regions of the British Commonwealth such as Australia and New Zealand. Democratic socialism in these regions embraced policies to bring the commanding heights of the economy under government control, create consensus-based economic plans, and construct comprehensive social-welfare programs. Further, democratic socialism invited open discussion of economic and political issues, guaranteed free elections, and protected the civil and human rights of citizens.

Once the electorate handed the reins of power to the democratic socialist governments, the new leadership moved to nationalize elements of the economy's commanding heights. The commanding heights of an economy represent key industries, including transportation, communications, energy, health care, and finance. Nationalization occurs when the government assumes ownership of an important firm or industry, but compensates the previous owner. Nationalized businesses were organized and managed in different ways. Most were restructured as public corporations, run by a government-appointed board of directors. Others were jointly owned and operated by public and private interests, or operated as appendages of certain government agencies. Democratic socialists supported nationalization to guarantee an adequate quantity and quality of essential goods and services. Nationalization also gave the government some control over prices and employment. In the post-war United Kingdom, a number of key industries were nationalized, including coal and steel, railways, docks and harbors, some public utilities, and the health care system. Similarly, in France, the government nationalized some public utilities, mining, banking, and insurance.

Another pillar of the democratic socialist agenda was indicative planning. *Indicative planning* is a collaborative economic planning process that gives a meaningful voice to labor leaders, business leaders, academicians, and public officials. Indicative plans establish national production goals, targets for inflation and unemployment, guidelines for public expenditures, and so on. The overriding goal of planning was to improve the standard of living and quality of life for the people, not to meddle in the affairs of private firms. France pioneered indicative planning at the close of World War II. By the 1960s, most other European countries—socialist and nonsocialist alike—adopted some form of economic planning. Not surprisingly, developing countries mimicked this European planning model even after these poorer countries achieved independence.

The final cornerstone of democratic socialist policy was the welfare state. In a *welfare state*, government programs redistribute some of society's wealth to promote people's economic well-being. By the 1950s, Sweden was the world's preeminent welfare state. It created an extensive network of mutually supporting social-welfare programs, which, over time, were woven into the fabric of Swedish society. Included were national health care, national accident insurance, unemployment insurance, job training programs, paid childbearing and childraising leaves, subsidized higher education and housing, paid vacations, and retirement and other pensions.

Challenges to democratic socialism stiffened over the last quarter of the 20th century. For example, by the late 1970s and 1980s, many governments moved to denationalize or privatize state-owned businesses. *Privatization* is the process of selling state-owned enterprises to individuals or firms. In the vanguard of privatization was Britain's Conservative prime minister Margaret Thatcher, who privatized telecommunications, coal, and some railways. In France, Prime Minister Jacques Chirac initiated privatization in many large industrial corporations, banks, and insurance companies by the late 1980s. At roughly the same time, enthusiasm for economic planning was waning. Led by Great Britain, most advanced countries shifted toward market-oriented solutions to economic problems. The welfare state concept was also under siege by the 1980s and 1990s. Many European nations dismantled elements of people's cradle-to-grave security blankets during this period. Even in Sweden, critics argued that heavy taxes, which financed the welfare state, were a disincentive to work, save, and invest. In the early 1990s, Swedish voters bumped the socialists out of office in favor of a more conservative administration. Soon, market reforms capped certain taxes on investment income, privatized some industries, and nurtured entrepreneurial activity. While elements of the social safety net remained in Sweden and other former socialist countries, it was clear by the 1990s that the economic pendulum had swung decisively toward the free market.

DEMOGRAPHICS IN ECONOMICS

Demographic economics is the study of economic decisions based on populations, ranging from residents of a small town to a population cohort such as the "baby boomers." College towns anywhere in the United States contain no shortage of fast-food restaurants. Burger King and Taco Bell not only sprinkle the streets in the Western world, but they can also be found crowding the university neighborhoods of Seoul and Tokyo. One is unlikely to find as many high-end automobile dealers in these areas, but drive through an upscale suburban neighborhood outside of Boston or New York, and a Lexus, BMW, or Volvo dealership will surely be among the town merchants.

There are reasons why various economic enterprises locate in some places but not others. These reasons range from the assumed income and educational levels to the ethnicities and financial priorities of residents of these neighborhoods. Knowing the ages, cultural backgrounds, and educational levels of people allows businesses to make informed decisions about where to locate and what to offer customers; this is known as demographic economics. The study of *demographics*, the science of population and it subsets, has long been employed by governments in order to meet the needs of their constituents. Similarly, businesses and economists use this information in order to determine and predict customer and societal needs and to understand the different choices that different groups of people make.

The term *demographics* originated in the Greek word *demos*, meaning "people." A *census*, a counting and cataloging of a society's populace, has historically been the method by which governments—and, more recently, other interested parties—learn who is where. Civilizations from the biblical era conducted censuses, and the ancient Romans held one every five years for tax purposes. Perhaps the earliest and most famous collection of demographic data that endures is the Domesday Book. Commissioned by William the Conqueror (1028–1087) of England in 1085, the Domesday Book catalogued all the citizens, their land, and their livestock in

William's realm of England at the time. The first census of the United States of America was conducted in 1790. It was the growth of this young nation that inspired a groundbreaking economic direction by one entrepreneur nearly a century later. As settlers populated the American West, store owner Richard Sears (1863–1914) of Chicago came up with a method of alerting consumers about his store's products, regardless of where they were living. The first Sears catalog, the *Book of Bargains: A Money Saver for Everyone*, was distributed in 1895 with a specific demographic in mind: namely, a widely dispersed population endeavoring to build and furnish homes far from Richard Sears's retail space in Chicago (Sears Archives n.d.). Even before to this, enterprising businesspeople were known to tailor their services to the demographics in the vicinity. Historically, the movement of military forces and the establishment of mining communities were quickly followed by businesses plying liquor and females offering paid companionship to the largely young, single males at hand.

A plethora of examples of demographic economics can be found after 1945, when the post-war baby boom gave rise to a mushrooming toy industry. Understanding this explosion, the Hassan brothers, founders of Hasbro, Inc., aired their first TV commercial in 1952 for the puzzle toy Mr. Potato Head.

Three years later, the Mattel company began advertising its wares on a new Disney program segment, the Mickey Mouse Club—spending $500,000 the first year. The spots paid off, boosting the sales of Mattel's previously unpopular toy the Burb Gun to $14 million annually in three years (Sears Archives n.d.).

Greater proliferation of the automobile and growing families around this same time led ice cream entrepreneur Howard Johnson to expand his New England-based operations nationwide. His chain of family-friendly hotels with their iconic orange roofs stretched as far as the Bahamas. This newfound mobility and explosion of youth in the United States was not lost on the technology sector of the economy either. With the introduction of the transistor into electronics, in the1960s young people were able to use battery-operated radios to enjoy their music independent of their parents.

The entertainment industry is also a keen barometer of demographics, which should not come as a surprise since the goal of its producers is to make a profit. Reflecting the surging push for racial equality in United States by 1965, the National Broadcasting Company (NBC) debuted its light-hearted espionage buddy show, "I Spy," which paired white and black leading men—the latter played by Bill Cosby (born 1937)—as globetrotting intelligence operatives. An effort to capitalize on the women's movement of the same era could be found in the Philip Morris tobacco company's introduction of a women's cigarette, Virginia Slims. As the baby boom generation came of age and a sexual revolution began, the reconsideration of traditional social values was also reflected in certain demographics. A Centers for Disease Control report illustrates that the number of divorces and annulments in the United States doubled between 1965 and 1975. This came after an era—the 1950s—that actually saw a decrease in this rate over various spans of time (NCHS 1987).

Marital status is another demographic factor, and the personal care industry was happy to exploit this increasing singlehood. Men's magazines were filled with advertisements for grooming products with names like Score, while television ads reminded viewers that "There's something about an Aqua Velva man."

The evolution of the American family has more recently been reflected in network television as well as advertising. By the end of the first decade of the 21st century, the American Broadcasting Company (ABC) network featured an openly gay male couple in its series "Modern Family." During commercial breaks in the show in 2013, viewers could have seen a commercial for Cheerios featuring an interracial couple. Such realities would not have been part of the commercial realm a generation earlier. In the interests of appealing to a wider audience by attracting viewers and customers from new, diverse demographics, ABC and General Mills made business decisions to adapt.

The demographics of various regions are often grist for a comedian's mill, and the economics of the state of Florida has surely been part of that mix over time. However, for all the references to golf courses and "early bird" specials in restaurants in the Sunshine State, it is worth noting a reality of the demographics there—namely, a senior citizen population that is quite sizable relative to other areas of the United States. Such a population came of age when American cars were the norm on U.S. roads, unlike today when Honda, Toyota, and BMW often outnumber GM and Ford in certain northern enclaves. The number of auto dealerships representing various makers in Florida reflects this older demographic, which is more accustomed to American brands; while 23 Volvo dealerships could be found across Florida in 2014, DealerRater listed 66 Buick dealerships statewide (DealerRater 2014).

Just has a clothing retailer seeks to offer what potential customers would like to see themselves in, any enterprise endeavoring to succeed in today's changing society should also bear in mind how its target market and society has its own look and way of thinking. The travel website TripAdvisor counts 954 establishments where one might find Indian food in a city far from India: London, England (TripAdvisor 2014).

For reasons ranging from global immigration to personal relationships that bridge ethnicities, races, and cultures that were seldom joined in an earlier time, most societies in the world today look very different from how they looked two generations ago. And many will look very different 20 years in the future. In order to succeed in an economic sense, one cannot afford to ignore this reality.

DISCRIMINATION AND BEHAVIORAL ECONOMICS

In economics, *pay discrimination* is measured by differences in pay per unit of time worked that cannot be explained by traditional variables such as education and work experience. This translates into lower wages that are independent of a person's productivity—that is, unequal pay for equal work. Another aspect of discrimination is individuals being segmented in specific jobs independent of their qualifications. This can result in one group of individuals being paid less than another. Discrimination can take place against any group of individuals, but the largest group of people with documented economic discrimination is women. Women are and have been paid less than men throughout the world, although this pay gap has diminished in many countries. Currently, in developed economies the average gender pay gap is around 10 to 20 percent. Economists have attempted to explain and measure the extent of the gender pay gap and other pay gaps in order to determine the contribution of labor market discrimination to this gap.

Not all of this pay gap can be attributed to discrimination. Education levels, experience, age, and career choice also matter. Discrimination appears to play an important role in explaining about 50 percent of the gender pay gap in developed economies. In these economies, women are equal before the law, and there are strong social norms favoring nondiscriminatory behavior.

A classic argument in economics, pioneered by Gary Becker of the University of Chicago, is that preferences or a taste for discrimination can produce and help sustain, in the short run, a discrimination-based pay gap. Employers are assumed to maximize their level of utility of well-being, not simply their profits. Given their strong dislike for female employees, for example, employers feel a need to pay women less than men, even when women are as productive as men. This generates a pay gap measured by the preference-based coefficient of discrimination. Absent this pay gap, employers' utility is lower than it might be otherwise.

But conventional economics maintains, consistent with Becker, that market forces can be expected to eliminate the discriminatory portion of the gender pay gap. Nondiscriminating employees, with no taste for discrimination, should hire the lower-priced female workers. This should drive the discriminators, who employ high-wage males, into bankruptcy or force them into changing their discriminatory ways, ultimately equalizing male and female wages. But the evidence suggests that this evolutionary process, eliminating pay inequality, has not taken place.

One possible reason for sustainable discrimination-based gender pay inequality relates to the fact that productivity is a function of effort inputs, among other variables. And contrary to the conventional wisdom, effort typically is not at a maximum and typically is affected by the work environment, inclusive of wage rates. This relates to X-inefficiency theory. Effort might be less for women since they do most of the housework, including childcare, even in the most economically advanced and democratic societies. This is often a product of socialization. To the extent that household work absorbs effort from these women, they have less effort available for doing their paid work than men have. This can result in lower productivity and lower pay. This is an important example of how off-the-labor-market discrimination affects the gender pay gap.

On the labor market, X-inefficiency and efficiency wage theory suggests that workers who are paid less for discriminatory reasons retaliate by working less hard, thereby reducing their productivity. In this case, cheap female workers would no longer provide the nondiscriminators with a competitive advantage over the discriminators. Low wages, based on discrimination, become sustainable among firms that have a taste for discrimination.

Relatively low wages can also be a product of discrimination in the household—and also in the larger society, which socializes girls into taking jobs that are relatively low-paying. Once women are socialized, as children and young adults, into targeting low-wage careers, it is very costly for women to change their choices. They are locked into these choices even if they might regret past decisions. In addition, if women expect that training for certain jobs will not pay higher wages, due to discrimination, they will not prepare themselves for these types of potentially high-paying jobs. Thus, even pay gaps that do not appear to be discriminatory in nature might very well be so. Off-the-labor-market discrimination can be as important as on-the-market discrimination in generating a gender pay gap or a discrimination-based gap against other groups in society.

ECOLOGICAL ECONOMICS

In the course of the raised social awareness in the West during the 1960s and 1970s, the concerns of those who publicly demonstrated unhappiness with government policies were made clear in demonstrations and various expression of pop art. An appreciation for ecosystems emerged—*ecosystems* being systems of different biological entities in which organisms interact with each other as well as their surroundings. As the 20th century came to a close, certain segments of societies around the globe became more concerned with the impact that unrestrained economic development was having, and an appreciation for an accommodation of area ecosystems became a greater part of discussions and planning with regard to development. To be *green*, which is to think and act in ways that accommodate, respect, and preserve the environment in its natural state, became a priority with people worldwide, and their sentiments frequently included criticism of business and governmental policies that they deemed less respectful of the natural world in its still unspoiled state. This sentiment has been known to spawn the rebuke to development that "The greenest house you can build is the one you don't build."

Although a relative newcomer to the subdisciplines of science, the concept of *ecology*, the realm of biology that involves relationships between organisms and their surroundings, can be traced back to 19th-century Europe, where German zoologist Ernst Haeckel developed the term based on the Greek term *oikos*, meaning "place to live" (Mounce n.d.).

In terms of another discipline, it can be thought of as the economics of nature, for reactions to demand and scarcity dictate what happens with regard to organisms and drives the actions of those who can impact them. Currently, there actually exists an International Society for Ecological Economics, which portrays itself as "a not-for-profit, member-governed, organization dedicated to advancing understanding of the relationships among ecological, social, and economic systems for the mutual well-being of nature and people" (ISEE n.d.). This topic is often seen as a transdisciplinary subject, with content in the realms of the ecology, history, and economics. It is important to realize a distinction between this subject matter and that of *environmental economics*, which considers the impact of the human on the world, with regard to matters such as waste and pollution and extending to the realm of climate change. In their book *Ecological Explanations: Principles and Applications*, Herman Daly and Joshua Farley suggest that the goal of teaching this topic is to "help the next generation of economists take proper stock of nature and nature's limits" (Daly and Farley 2001, xxi).

An awareness of the need to be cautious regarding the ecological interactions around us was most publicly raised by a 19th-century Scottish American named John Muir, whose appreciation for the natural beauty all about led him to found the Sierra Club in 1892.

The following decade, President Theodore Roosevelt signed legislation preserving large swaths of land in the western half of the nation with the intention of their eventually becoming national parks. The increased industrialization of the 20th century and the general mobilization necessitated by two world wars kept ecological and environmental concerns from being major political and societal priorities for more than half of the 20th century, but the emerging youth culture of the 1960s adapted an awareness of issues involving the well-being of nature and the larger planet.

As ecology involves the interaction of organisms, the materialism of the post–World War II era can be seen as an economic era with one-sided ecological priorities; the baby boom and accompanying commercialism spawned industrial production that accommodated social whims such as a national love affair with the automobile and governmental policies fostering the military industrial complex. The impact of these developments as well as less obvious creations such as Styrofoam and plastics in many consumer products posed ecological challenges as various consequences became clear. Although such items are not organisms, their use and disposal by an organism—people—impacts other organisms.

The economics of the most ubiquitous ecological relationship about us involve a genuine paradox. The basic human need for sustenance and nutrition drives the food production industry in the developed world and parts of the developing world. According to the United States Department of Agriculture's Economic Research Service, total costs for food consumption nationwide in 2012 were $1,375,516,000,000, nearly double the $791,862,000,000 spent in 1999 (ers.usda.gov). In spite of this increase, one economic reality of this growth is that a smaller percentage of the American workforce is involved on the agricultural end of this production. At the close of the 20th century, 3 percent of the nation's workforce was employed in some aspect of farming, but by the second decade of the 21st century, less than 1 percent of American workers were employed in agriculture. In spite of this fact, this same era involved oft-publicized medical concerns over the increasing numbers of obese Americans, with many scientific pronouncements claiming that up to one-third of Americans could be classified as obese. Industrial farming and genetically modified organisms (GMOs) help to explain this increased production to meet apparently equivalent demand, but the ecological impact of these economics is less visible. The ability to produce more food with a smaller percentage of the workforce has economic appeal to certain interests, such as those concerned with the costs of production. As regards the agricultural ecosystem and the cultivation and consumption of genetically modified crops and livestock products, by the second decade of the 21st century the ultimate results remain unclear.

A key requirement for healthy ecosystems to persist is *sustainability*, which can be defined as the use of a resource or system at levels that assure its continued viability and productivity. Various organisms threaten and diminish others within certain systems, such as invasive species that prey on other species. The Asian Black carp (*Mylopharyngodon piceus*) was accidentally introduced to waterways in the North American Great Lakes when ships discharged ballast water that had originated in the Pacific Ocean; the species was also intentionally introduced for phytoplankton control (USDA NISC n.d.).

Black carp are believed to "negatively impact native aquatic communities by feeding on, and reducing, populations of native mussels and snails, many of which are considered endangered or threatened"—to the point that in 2010, President Barack Obama signed the Asian Carp Control and Prevention Act to limit the transport of the species across state lines (NISC n.d.). This is a case where the introduction of a new species into the ecosystem has some major economic dimensions. The National Wildlife Federation has estimated that the fish's devouring of other species in the Great Lakes could cost the region more than $200 million in damage annually (NWF n.d.). The U.S. Army Corps of Engineers estimates that the cost of containing the carp to its present areas would run between $15 and $18 billion (GLMRIS 2014). Given the shared nature of large bodies of water, the latter expenses would be shared by governmental entities at the state and federal levels. Another ecological reality with a different economic dimension is the interaction of the Japanese beetle with fauna in North America. A 2014 Penn State study of the issue estimates that this species feeds on "nearly 300 different host plants," causing more than $460 million in damage annually in the United States, to the point that the U.S. Department of Agriculture published a pamphlet, "Managing the Japanese Beetle: A Homeowner's Handbook" (USDA APHIS 2004). Governments will contract pest control and tree removal services to deal with this organism, but so will businesses and private property owners. As the 2014 Penn State report suggests, the commercial exchanges involving these two multi-million-dollar industries clearly have an economic impact wherever this organism exists. Well-balanced ecosystems can yield a variety of economic benefits, but when human interaction is employed to restore such balances or to work towards their preservation, the economic impact of this course can also be significant.

ECONOMIC ANTHROPOLOGY

Economic anthropology can be defined formally as the discipline in which societies determine how to produce and distribute goods and services in a way that makes the society's lives and economies more productive, while also making the individuals of that society as well off as possible.

Economic anthropology began as a subfield of anthropology, founded by the anthropologists Bronislaw Malinowski and Marcel Mauss. Both scholars were interested in bartering and gift exchanges as a means of acquiring goods and services—rather than a traditional market exchange method that relied merely on the transfer of traditional valued money. After World War II, the discipline would be highly influenced by Karl Polanyi. Polanyi was already a popular economic historian, but he would later become known for his work in economic anthropology. Exchange and bartering as a means of progress is the real focus of the discipline, which is why both anthropologists and economists are intrigued by it. Economic anthropology tries to describe economic behavior in the broadest way possible, whether historically, geographically, or culturally.

Economic anthropologists are best known for their specialized research and study, which includes three different sectors: (1) how social groups produce the things they want, need, and desire; (2) how those goods and services are exchanged; and (3) how those goods and services are consumed. The economic anthropologists' job is to study how humans provide the goods and services they need to make life possible. Economic anthropologists study the processes of production and the movement and consumption of all types of goods in different social settings. These goods and objects range from obvious material items, to less tangible objects, and to services that individuals perform in exchange for other goods or services. The social settings where these tasks are performed also vary greatly—from households, to villages and markets, and even on to firms.

Economists are mainly concerned with how societies and economies manage scarce resources. As early as the 1920s, Malinowski studied ceremonial exchanges of Kula bracelets in Milne Bay, a province of Papua New Guinea. This system, which was incredibly complicated and involved visits and exchanges, was one of Malinowski's primary areas of research. While the bracelets had no value of their own, they served as a social connection that continued throughout a recipient's life. Another example is cowrie shell money, which was used in ancient societies beginning in approximately 1200 BCE. At that time, the shells served as a medium of exchange and store of value worldwide, and they remain the most widely used and longest-used currency in history. Methods such as these have huge economic implications, as they are more difficult to measure, compare, predict, and understand.

The goal of economic anthropology is for people to recognize that all economies vary in the way they decide to make the best use of their resources and the way they conduct the exchange of goods and services that lead to progress and better, happier individuals. This can range from exchanging services for services, to bartering, to using commodities and objects such as shells and bracelets as a system of exchange.

ECONOMIC FREEDOM

Economic freedom is the ability of individuals and businesses to freely choose how to use their private property in an economy. Consumers exercise freedom of choice in determining which goods or services to purchase. Workers express economic freedom by preparing for and securing gainful employment in an occupation, and by freely changing jobs or careers. Savers and investors freely select savings or investment instruments best suited to their financial situations. Businesses exercise freedom of enterprise to employ the best mix of resources in a production process. Economic freedom is embodied in the free enterprise system, or capitalism.

One of the world's most widely recognized measures of economic freedom is *Economic Freedom of the World* (*EFW*), an annual report published by the Fraser Institute in Canada. In the *EFW*, the policies and institutions of individual countries are evaluated, and a freedom ranking is compiled. The *EFW* considers five main categories of data to assess a country's degree of economic freedom: size of government; legal structure and property rights; access to sound money; freedom to trade; and regulation of credit, labor, and business. Generally, a country's freedom ranking is enhanced when policies and institutions support personal choice, individual initiative, good governance, macroeconomic stability, voluntary exchange, private property rights, and competitive markets. A country's freedom ranking falls when excessive government intervention or a negative business environment limits personal freedoms and distorts market incentives to work, save, invest, or produce.

In *Economic Freedom of the World: 2015 Annual Report*, 157 countries and territories were ranked by level of economic freedom during 2013. A nation's ranking is expressed in the freedom index, which is derived from a variety of reliable data. The top 10 countries for economic freedom in 2013 were Hong Kong; Singapore; New Zealand; Switzerland; United Arab Emirates; Mauritius; Jordan; Ireland; Canada; and the United Kingdom and Chile, which were tied for tenth. The 10 lowest-rated countries for 2013 were Angola; Zimbabwe; Central African Republic; Algeria; Argentina; Syria; Chad; Libya; the Republic of Congo; and, in last place, Venezuela. The United States was ranked 16th, Mexico was ranked 103rd, Canada was ranked 9th, and China was ranked 111th.

Another leading measure of economic freedom in the global economy is the *Index of Economic Freedom*, an annual publication of the Heritage Foundation and *the Wall Street Journal*. The 2016 *Index of Economic Freedom* evaluates economic conditions in 178 countries against 50 criteria. The 50 criteria, which are categorized under 10 headings, include trade policy, fiscal burden of government, government intervention in the economy, monetary policy, capital flows and foreign investment, banking and finance, wages and prices, property rights, regulation, and informal market activity. Like the *EFW*, the *Index of Economic Freedom* analyzes factors that affect economic growth. High country rankings in the *Index of Economic Freedom* are earned when countries support free trade, responsible and nonintrusive government policies, healthy financial institutions, and well-defined private property rights. In the 2016 *Index of Economic Freedom*, the Hong Kong SAR earned the highest freedom ranking. After Hong Kong, the remaining top 10 countries were Singapore, New Zealand, Switzerland, Australia, Canada, Chile, Ireland, Estonia, and the United Kingdom. The United States was 11th. The 10 lowest-ranked countries were Argentina, Equatorial Guinea, Iran, Republic of Congo, Eritrea, Turkmenistan, Zimbabwe, Venezuela, Cuba, and North Korea.

Research by credible think tanks and foundations suggests that economic freedom is an important determinant of investment, economic growth, and per capita income. Researchers at the Fraser Institute, the Cato Institute, the Heritage Foundation, and elsewhere have identified a series of causal relationships between economic freedom and the overall performance of economies. *Economic Freedom of the World: 2015 Annual Report* argues persuasively that there is a direct causal relationship between high levels of economic freedom and positive economic growth rates. *EFW* also correlates high freedom rankings with high per-capita incomes, high life expectancies, high adult literacy, low infant mortality, low corruption, greater political rights and civil liberties, and low rates of business activity in the extralegal or informal sector. The 2016 *Index of Economic Freedom* arrives at similar conclusions. The study of economic freedom and its impact on the wealth of nations is still in its infancy. The topic will likely provide fertile ground for further research in the coming years.

ECONOMIC GROWTH

Economic growth occurs when the value of a nation's output increases over time. Economic growth is mainly concerned with long-term trends in national output, rather than with annual fluctuations in business activity. Economic growth is typically measured at the national level, but it can also be calculated for groups of nations, such as world regions or regional trade blocs, or for the entire global economy. Economic growth is sometimes confused with a broader term, *economic development*. Economic development deals with economic growth and with measurable improvements in people's quality of life. Economic growth and sustainable economic development are important goals for all countries.

The two most widely used measurements of economic growth are real gross domestic product (GDP) and real GDP per capita. The first measure, real GDP, calculates the dollar value of newly produced national output each year, after adjusting the data for inflation. The real GDP is a convenient measure of economic growth, enabling cross-border comparisons of total output and, thus, the overall size of an economy. From 2006 to 2016, the average growth rate for the United States was below 2 percent.

The determinants of economic growth are varied and often complementary. At the heart of long-term economic growth is higher productivity. Productivity measures the amount of output that is produced per unit of input, such as labor inputs or capital inputs. Economists typically measure productivity gains in terms of labor inputs. Key economic factors that support the growth of national output and productivity include (1) heavy investment in the factors of production, including capital goods, human resources, and natural resources, and (2) investment in research and development (R&D), information and communications technologies (ICTs), and entrepreneurship and innovation. The maintenance of formal economic institutions, such as capital markets, and informal institutions, such as profit incentives, is also critical. Good governance, the honest and competent administration of government, creates a pro-growth environment. Key government responsibilities include the building and maintenance of an economic infrastructure, legal protections for property rights and the sanctity of contracts, and responsible macroeconomic policies. Democratic political institutions, based on broad citizen participation, a free media, and an independent judiciary, also support a pro-growth national agenda.

Economic growth is illustrated by an outward shift in a nation's production possibilities curve (PPC). A PPC shows the range of possible production choices for a nation at a moment in time. In the illustration below, the inner PPC, AB, shows the original range of output for two types of goods, investment goods and consumption goods. At point A, all of the nation's resources are devoted to investment goods; hence, zero consumption goods are produced. At point B, all resources are used to produce consumption goods; hence, no investment goods are produced. In reality, a nation would likely choose to produce at a point between A and B, perhaps at point C. Economic growth is represented by a shift of the curve AB to YZ. Note that at every point along the curve YZ, more investment goods and consumption goods are produced. The outward shift of the PPC from AB to YZ illustrates economic growth.

The benefits of economic growth are readily observable. First, economic growth improves people's standard of living. Today, the most common standard of living measure is the gross national income (GNI) per capita. Most people who live in countries with a high GNI per capita are able to satisfy their economic needs for food, clothing, and housing. They also consume many types of luxury goods, such as automobiles, personal computers, televisions, artwork, vacations, and a wide variety of consumer durables. Second, economic growth improves people's quality of life. A higher quality of life implies a higher standard of living plus other

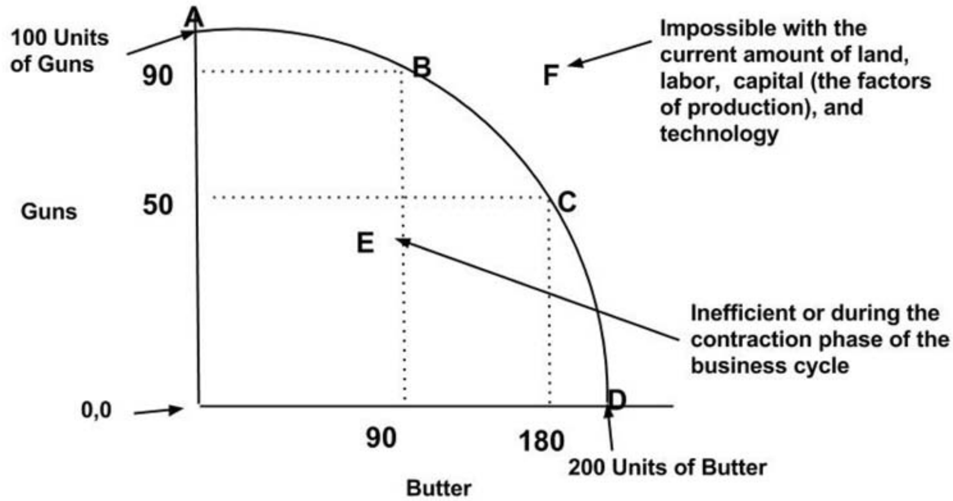

Figure 1. Production possibilities curve

improvements in the human condition, including access to education, health care, personal security, infrastructure, and social programs. Third, economic growth fuels the virtuous cycle of development. Economic growth promotes national savings, as well as productive investment in research and development, private and social capital, human capital, and entrepreneurship.

The costs of economic growth are also apparent. One cost is environmental degradation, an inevitable result of production. The severity of degradation varies widely among regions, yet the drive to increase national output fouls the air, water, and land with pollutants. This drive sometimes creates wastelands due to strip-mining and aggressive timbering, overgrazing, and overplanting. Toxic emissions into the atmosphere cause global warming, ozone depletion, acid rain, and other harmful effects on the global commons. A second cost of economic growth is resource depletion. *Resource depletion* occurs when resources are used in production but are not replaced. Nonrenewable resources, including petroleum and natural gas, are in finite supply. Finite resources are consumed in the production process and cannot be reclaimed for further use. A third cost of economic growth is a decline in some people's quality of life. For instance, the widening digital divide creates unequal economic opportunities in the global economy. People in the advanced countries receive far more benefit from global economic growth than do people in the world's poorest regions.

ECONOMIC HISTORY

Economic history is the chronology of events involving exchanges of goods, services, and currencies, as well as an understanding of the incentives and meanings of them and an appreciation of the different economic systems that societies have adopted over time and the theories involving money that have emerged as a result.

The term *economics* has its origins in the Greek word *oikos*, relating to "household management"; the term *history* comes from the Greek word *historia*, which means "learning by inquiry." In the 1960s, the term *cliometrics* was coined to describe "economic history," and it used quantitative methods to understand the past through statistics and models (Cliometric Society n.d.). In ancient Greece, the figure *Clio* was known as the "muse"—the inspiration—of history, and *metrics* comes from the Greek word for "measurement." The Cliometric Society reasons that *economics*, the "science of how choices are made regarding resources and their scarcity resulting in exchanges," has etymological roots in Greek, as the basics of this social dynamic were evident in ancient Greece during the final centuries BCE.

The Greek society, like the Roman Empire, was agrarian and employed slave labor for much of its development. Both civilizations developed currencies in the form of coinage to facilitate exchanges and allow for "tribute," today called "taxes," to be paid to the governing interests. In Roman times, these coins were produced in a temple dedicated to the goddess *Moneta*, causing the commodity to be called money, with each unit produced being a store of value.

The coinage was made of silver and gold, valuable units of exchange that are thought to date back to 2000 BCE. Owing to limited technology, it was common for agrarian societies to use slave labor. In the Judeo-Christian Bible, the New Testament tells that, upon finding "money changers" conducting business within Herod's temple, Jesus "overthrew the tables of the moneychangers, and the seats of them that sold doves" (Matthew 21:12–13).

In the absence of currencies, practical commodities that could provide food, such as livestock, were commonly used in exchanges. Negotiations between parties aimed at agreeing on how many cows might be exchanged for land or for coins was known and continues to be known as bartering. With exceptions such as the travels of Marco Polo and the religious Crusades, well into the early second millennium most people lived their entire lives in the hamlets, villages, and regions where they were born. This allowed the barter system to endure at the local level for centuries.

As early as the seventh century CE, the Tang dynasty in China, proficient with woodblock printing, began issuing receipts for amounts of heavy coinage; these receipts evolved into paper bills. During Roman times, the nature of local relationships and the urgent need to secure one's staples produced the concept of credit. *Credit* is a relationship of trust that allows one party to commit a transaction, with a promise to compensate another party for it at a later time. Credit furthered the commerce of the day.

This tool of economics was especially useful as the age of exploration dawned in the late 1400s, allowing adventurous individuals to secure the resources needed for their journeys—based on promises that they would have newly found riches with which to repay the amounts upon return. The Roman era coincides with biblical accounts of various events, however, and guidelines for lending with interest were explained in the religious context of the day. The book of Deuteronomy explains that if Hebrews lent money to non-Hebrews they were to charge interest (Deuteronomy 23:19–20). Although charging interest has become a staple of successful banking, the requirement to repay an amount provided on credit with interest added on top of the original sum has fueled anti-Jewish sentiments throughout history that still persist. Transactions continued to be made with coinage of precious metals into the second millennium, and as the fruits of these endeavors were reaped, new trades emerged in Europe—and guilds grew as well.

Guilds were associations of artisans and merchants who protected the secrets of their trade in order to assure their prosperity. Guilds first appeared in Europe in the 15th century, and while they were made up of independent craftsmen, they are frequently thought of as a precursor to unions. Although seafaring trade among empires and civilizations along the Mediterranean Sea had been taking place since the final centuries BCE, developments in transportation technology were the catalyst for the emergence of mercantilism in Europe by the 1600s. *Mercantilism* is the effort to create wealth on a national scale by having the state foster efforts and policies that will further its commercial interests—most notably, trade.

Because technology in Asia, Africa, and the Americas did not afford it and as national governments in the Far East looked inward rather than abroad, Western Europe alone took to the seas in the interests of exploration and commerce. As noted in *The Economist* (2013), "The best way of ensuring a country's prosperity was to make few imports and many exports, thereby generating a net inflow of foreign exchange and maximizing the country's gold stocks."

Much of this mercantilist activity was conducted by the British, the Dutch, and the French as they ventured west and claimed land in North America for their governments, while Spain and Portugal established outposts to the South. Traders from these nations also made it to Africa, where they encountered the practice of slavery and themselves began to capture, transport, and trade people from the Gold Coast of the continent to the Western Hemisphere as slaves. This workforce was largely set to work in agriculture, which ranged from tobacco and cotton in North America to sugar cane in the West Indies to rubber and dye plantations in South America.

To protect its interests as trade grew, Britain adopted the Navigation Acts of 1651 in an effort to keep other nations from trading with its colonies in North America. To further enhance its economic welfare, Great Britain ventured to China in 1793 with an overture to establish trade with the Qing government. The United Kingdom was turned away, but it pushed its point again in the mid-19th century; the result was two Opium Wars with China. Britain won both, allowing it to establish itself at several treaty ports in East Asia. By this time, the former British colonies in North America had established their independence, and the United States was also pursuing trade opportunities across the seas.

The late 18th century saw the publication of a landmark book on economics. Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations* suggested that individual interests, which he referred to as "the invisible hand"—better than the mercantilist practices of the day—would drive economic decisions toward improving an economic society for everyone.

In 1848, Karl Marx published his *Communist Manifesto*, in which he theorized that, owing to the inequalities of the capitalist system, political and social upheaval would soon emerge. By the midpoint of the 20th century, major nations such as the USSR and China had formed governments with an eye toward implementing Marxist ideas.

Industrial revolutions in Europe and the United States led to previously unseen growth through new technologies, such as the factory system and the forging of iron into steel. Immigration fueled by population growth also helped the U.S. economy to eclipse Britain's by the end of the 19th century.

Economic speculation and entrepreneurship led to the creation of stock exchanges in Western economies. Owning stock meant owning shares in a firm; with an eye toward growth, the firm would use the funds that were raised from the sale of those shares; the profits from the growth were shared with the stockholders. This stock speculation and growth afforded more industrialization and the creation of vast fortunes, particularly in the United States in the late 19th and early 20th centuries.

Inventions such as the combustion engine and the vacuum tube fueled the creation of automobiles, radios, and numerous other appliances that became staples of daily life in developed nations in the 20th century. Realities such as overproduction and overvalued stocks led to less demand for products and a lack of liquidity, which contributed to a stock market crash in 1929 and a worldwide depression for years afterward.

When nations on both sides of the Atlantic endeavored to generate business by erecting tariffs (taxes on imports), matters only worsened. Many economic historians submit that it took the general mobilization of World War II to fully restore economic health in the West.

The second half of the 20th century saw the communist world and the developing world lagging behind Western Europe, the United States, and some capitalist economies on the Asian Pacific Rim. As the USSR and China embraced free-market systems and as new technology and the Internet reached around the world, previously unseen levels of prosperity emerged in the West and even in some former

Communist countries. With the 21st century, globalization had truly arrived, enhancing trade worldwide.

ECONOMIC PSYCHOLOGY

Economic psychology is the study of economic behavior from a double-handed perspective: how the economy influences the feelings, thinking, and behavior of individuals and groups—and vice versa. The focus is on economic behavior, decision-making, and anomalies. Literature in the area is vast, with books and articles published in many different countries. Research areas include savings; the psychology of money; the psychology of debt; household decision-making; taxation; economic socialization; experimental economics; behavioral economics; environment, sustainability and consumption; heuristics and biases; intertemporal choice; economic and financial crises and their psychological underpinnings; risk; consumer behavior; lay economic theories; and work.

This area has been experiencing much growth, and it overlaps with behavioral economics in its focus of study and some methodologies, such as experiments, surveys, longitudinal studies, with findings routinely expressed in descriptive models. For their research on the intersection between economics and psychology, Herbert Simon and Daniel Kahneman were awarded the Nobel Prize in Economics.

One major difference between the two disciplines is that economic psychology has always been a branch of psychology, broadly holding to the same principles, approaches, and methods as traditional psychology, whereas behavioral economics is somewhat distinct from traditional economics in terms of assumptions and methodology. As a result, economic psychology's toolbox study of economic behavior and decision-making is largely housed in psychology, while behavioral economics often imports tools from psychology, neuroscience, sociology, and other disciplines in order to pursue similar objectives.

Another difference between economic psychology and behavioral economics relates to their respective treatments of rationality. Economic psychologists often avoid attributing irrationality to humans (all decisions have some rationale behind them, even if they may appear otherwise), while many contemporary behavioral economists consider anomalies to represent irrational behavior.

There is also an overlap between economic psychology and consumer psychology. However, they are different in their traditions, their principles, their breadth of scope, and especially in their goals. *Consumer psychology* investigates human responses to information and experience related to products and services, encompassing affective, cognitive and behavioral aspects. *Economic psychology*, while doing likewise, goes beyond market research; informed by both psychology and economics, it studies how economic issues impact actual economic behavior of individuals and groups. This may include such topics as work and unemployment, personal finance, inflation, and poverty. Economic psychologists are also increasingly focused on public policy, with a significant emphasis on such topics of financial education as investment, retirement, and financial planning and on issues related to consumer debt.

Economic psychologists are mostly psychologists, but these scholars also include experimental economists; finance, environment, information, and communication specialists; and public policy experts. They are usually members of the International Association for Research in Economic Psychology (IAREP), with some of them also belonging to Division 9 of the International Association of Applied Psychology (IAAP). A list of institutions that do research and provide opportunities to study at the intersection between psychology and economics is available at www.iarep.org/graduateprograms.htm.

Economic psychology is thought to have originated in the late 19th century; the expression was first used in 1881 by French jurist Gabriel Tarde (1843–1904). Around this time, American economist Thorstein Veblen (1857–1929) argued for a broader approach—to incorporate biology, sociology, history, and other disciplines in economics studies.

At first opposed vigorously by economists, economic psychology started taking root after World War II, when Hungarian-born psychologist George Katona (1901–1981), who had been living and working in the United States since before the war, published *Psychological Economics* in 1975. This remains one of the main publications in the area, along with *The Individual in the Economy* (Lea, Tarpy, and Webley 1987). For decades, it was one of the most cited publications in the main journal of the discipline, the *Journal of Economic Psychology* (Kirchler and Hölzl 2006).

ECONOMIC SCIENCE ASSOCIATION

The Economic Science Association (ESA 2013) is "a professional organization devoted to economics as an observational science, using controlled experiments to learn about economic behavior. The ESA welcomes participation by economists interested in the results of such experiments, as well as scholars in psychology, business, political science, and other related fields." It serves as a forum for economists around the world who use experimental methods to study economic phenomena under more controlled conditions than are possible in naturally occurring environments. The ESA was founded in 1986, and it became fully international in 1997.

Since its inception, the ESA has been active in promoting the usage of experimental methods in economics. In contrast to many other economic fields, which are defined by the topic of inquiry, experimental economists define themselves based on the experimental tools that they use to collect the data in the laboratory and the field. Many behavioral economists doing empirical research use experimental methods to collect data in order to test the predictions of theories, analyze the effect of public policies, test new markets and institutions, and investigate regularities and anomalies in individual and group behavior. The main advantage of experimental methods is the ability to keep "other things constant" while determining the effect of one variable of interest on another. Controlled laboratory and field experiments allow researchers to create and replicate a specific situation or a context that may not be possible in the field.

The ESA sponsors several conferences, including the International ESA Conference /World Meeting (June–July), the ESA European Conference (September), the North American ESA Conference in Tucson (November), and the Asia-Pacific ESA Conference (Winter), as well as sessions at the Southern Economic Association, the Allied Social Science Associations and other meetings.

In addition to the website, www.economicscience.org, the ESA maintains two Google Groups discussion boards: "ESA-discuss," on which the members can post their inquiries regarding various topics related to conducting experiments, and "ESA-announce," on which the members can post announcements of general interest of experimental economists.

Three members of the ESA have received the Nobel Prize in Economics: Vernon Smith, in 2002, "for having established laboratory experiments as a tool in empirical economic analysis, especially in the study of alternative market mechanisms"; Elinor Ostrom, in 2009, "for her analysis of economic governance, especially the commons"; and Al Roth, in 2012, "for the theory of stable allocations and the practice of market design" (Nobelprize.org 2012).

As of June 2013, the ESA has had 15 presidents: Vernon Smith (founding president, 1986–1987), Charlie Plott (1987–1988), Ray Battalio (1988–1989), Elizabeth Hoffman (1989–1991), Charles Holt (1991–1993), Robert Forsythe (1993–1995), Thomas Palfrey (1995–1997), James Cox (1997–1999), Andrew Schotter (1999–2001), Colin Camerer (2001–2003), Ernst Fehr (2003–2005), John Kagel (2005–2007), James Andreoni (2007–2009), Tim Cason (2009–2011), and Al Roth (2011–2013).

In 1998, the ESA started the journal *Experimental Economics*, which publishes high-quality papers that advance experimental research in economics and such related disciplines as accounting, finance, political science, and the psychology of decision-making. The journal also publishes cutting-edge theoretical and econometric work motivated by experimental data and papers focused on methodology or replication of controversial findings. *Experimental Economics* is known for its rigorous review process and the highest standard of experimental procedures. Every year the journal selects a best published paper for "Editor's Award for Experimental Economics,"

ECONOMIC SOCIOLOGY

Within economics, William Stanley Jevons conceived the concept of *economic sociology* as an integral branch of economics, alongside economic theory and other branches. In his work on the subject, he proposes that "it is only by subdivision, by recognizing a branch of Economic Sociology [and other branches], that we can rescue [economic] science from its confused state" (Jevons 1965, 20–21). Following Herbert Spencer's definition of *sociology*, Jevons understands *economic sociology* as "the Science of the Evolution of Social Relations" and the influence that social relations have on the economy, including the market. Notably, he implies that economic sociology observes and studies real-life economic processes and behaviors in their social relations and environments, thus being a socially and behaviorally realistic branch of economics. To illustrate, he suggested that economic analysis should take account of the fact that market processes and behaviors (the "influence of the future supply and demand") often "depend on the political information of the moment" (Jevons 1965, 182).

Moreover, Philip Wicksteed (1933, 784) suggests that economics "must be a handmaid of [economic] sociology" as an observation and study of the real-life economy on the ground that the market in reality "never has been left to itself" due to multiple social influences and interferences. Vilfredo Pareto (1932, 1317) suggests the concept of *economic sociology* as a realistic analysis of the social context of the economy; he proposes that the "study of many [economic] facts cannot be made without the help of sociology" and hence economics should "consider not just the economic phenomenon taken by itself, but also the whole social situation, of which the economic situation is only a phase." Pareto implies that economic sociology is a more realistic or complex discipline than pure economics, because the "social system is much more complicated" than the economic system and "there is much more complication in sociology where, to logical actions, the only [actions] considered by economics, are to be added non-logical actions, and to logical reasoning, derivations" (Pareto 1932, 1315, 1594–95).

Max Weber (1968, 68–79; 1949, 45) identifies and defines *economic sociology* as the "sociological theory of economic action" and the "sociology of economic action"—specifically, an analysis of the "various ways in which non-economic social events influence economic events." Influenced by Weber, Friedrich von Wieser (1967, 152–53) considers *economic sociology* (or "social economics") to be an investigation of the "sociological problems of economic theory" or the "social relations of the economy," thus being socially grounded and realistic. Frank Knight (1958) registers *economic sociology* or "sociological economics" within the Historical School of Economics—mentioning Werner Sombart—as well as in French sociology (Émile Durkheim), but this discipline is not limited to the two traditions. Joseph Schumpeter (1949, 60) identifies "the economic sociology of Adam Smith," characterized as the study of the "social framework of the economic course of events." Specifically, Schumpeter defines *economic sociology* as the "analysis of social institutions," namely, those "institutions and [social] forces which shape economic behavior," thus as institutionally grounded, behaviorally realistic, and interdisciplinary endeavor ("no man's land, or every man's land") (Schumpeter 1954, 9–22; 1956, 134). Further, Schumpeter incorporates economic sociology into the branches of "economic analysis," alongside economic theory and others (1954, 9–22). In particular, Kenneth Boulding (1970, 153–55) emphasizes the "economic sociology of the market" as a realistic analysis that takes account of the real-life "process of development" of markets involving "total society," which causes the "purely economic models" to be of "very limited value."

In modern economics, since John Maynard Keynes's *General Theory*, the term *economic sociology* has constituted a sociological version or proxy of social behavioral economics (Etzioni 1999). George Akerlof (2002, 411) implicitly identifies elements of economic sociology and psychology in Keynes's behavioral economics. He detects in Keynes's *General Theory* an emphasis on the role of such psychological and sociological factors as cognitive bias, reciprocity, fairness, herding, and social status, including "animal spirits" (Akerlof and Shiller 2009). In general, Akerlof (2002, 411) emphasizes that, like economic sociologists, behavioral economists, "incorporating realistic assumptions grounded in psychological and sociological observation, have produced models that comfortably account for [various] macroeconomic phenomena." Such assumptions of economic sociology relevant in behavioral economics involve "adherence to group norms"; "reference group theory"; the "sociological" version of efficiency wage theory based on gift exchange (Akerlof 2002, 415); the general theory of social norms and ideals, including "Weber's analysis of the relation between religion and savings" and Pierre Bourdieu's analysis of the "consumption of cultural goods"; the "sociology of the corporation"; and others (Akerlof 2007, 15). In particular, with respect to motivations Akerlof (2007, 29–31) emphasizes that economic sociology is a realistic discipline depicting human motivation from "close observation," just as Keynesian early and present behavioral economics is "reflective of reality" by virtue of being based on "experience and observation." In sum, in terms of empirical realism and emphasis, *economic sociology* is a sociological variant of and name for social behavioral economics.

ECONOMIC SYSTEMS

An *economic system* determines the way in which a country manages the production and distribution of goods and services. Every economic system functions by answering three basic questions: what to produce; how to produce; and for whom the goods and services will be distributed. The more fundamental economic question is "Who will answer these three questions?" One option is the interaction of buyers and sellers in the marketplace. A second option is a central authority or government. Third is some combination of the two.

The "what to produce" question is a matter of the allocation of resources. One decision by a society in determining the economic system is what goods and services will be produced for the marketplace. However it is defined, "what goods and services will be produced for the marketplace" suggests the allocation of an economy's land, labor, and capital—that is, the resources available for producing the goods and services. The entity (market, government, or combination) that answers the first question will determine the uses of an economy's resources.

The "how to produce" question is about efficiency. It defines the rate of innovation and change in the ratios of land, labor, or capital used to produce the goods and services. Will the economy use a horse and plow in the field or a tractor? Will manufactured goods be made by labor-intensive industries or capital-intensive industries? The answer lies in the decisions of the individuals, the government, or some combination of the two.

The "for whom" question applies to the distribution of goods and services and who should receive those goods and services. Will the goods and services of an economy be distributed to those who are willing and able to pay for them, or to a select few, or to everyone regardless of ability to pay? Answering this third question ultimately defines the distribution of goods and services in the market as private, public, or selective. Again, the answer lies in who makes the decision: individuals, the government, or a combination.

There are several ways to answer the basic economic system questions. They can be answered based on cultural or historical traditions within a culture or society. They can be answered totally in the marketplace, through the interaction of buyers and sellers. At the other extreme, they can be answered by one central authority making all the economic system decisions for the entire economy. The fourth alternative falls somewhere between market decisions and a central authority; there are numerous combinations of a mixed economy.

Traditional Economic System

In a traditional economic system, the three questions are answered by a long-standing tradition in a culture or society. This usually means one vocation or type of work is handed down from generation to generation. If one's great-grandfather was a farmer, in a traditional economic system one's grandfather and father were also farmers. One can count on being a farmer. The tradition would continue, as one's son and any future generations will also be farmers.

Traditional economic systems are generally subsistence economies, and they do not experience economic growth. Since there is no mobility in labor or resources, these economies are stagnant, and standards of living do not change from generation to generation. They are often very isolated and do not trade with others outside their traditional system. The lack of mobility also makes the future of a traditional economic system very predictable. The interests of the whole often supersede the interests of the individual. As a result, property rights are often absent or lightly regarded.

Historically, traditional economic systems were a major form of economic organization. The feudal systems of early Europe, as well as the economies of many towns and regions in the early United States, were traditional in nature. Today, traditional economic systems are confined to isolated tribes and cultures such as the aborigines in Australia.

Market Economic System

In market economies, the three economic system questions are answered by individual producers and consumers. The "allocation" component of the question of what to produce is answered by the interaction of producers and consumers in the product market. Buyers (consumers) determine what they are willing and able to consume, and it is up to the sellers (producers) to adequately provide those goods and services at both a price and a level of quality that the buyers desire. If buyers demand three-legged stools, producers have an incentive to supply three-legged stools at a price the buyers are willing and able to pay for the quality they want.

The "efficiency" question in a market economy is answered by the interaction of producers and consumers in the resource market. Businesses need land, labor, and capital (resources) to produce the goods and services that consumers desire. In a market economy, private property and property rights are paramount to the proper functioning of a market economic system. Individuals decide their level and participation in the economy through education, and individuals decide how to invest their resources in land and capital. All the resources are privately owned.

Privately owned resources are then sold to the businesses in the resource market, so the businesses can produce goods and services for the product market.

In the resource market, the producers are private individuals and the consumers are businesses. Businesses respond to the incentives of producing goods and services by using resources most efficiently. They also have incentives to innovate and invent new ways and methods of using resources more efficiently in order to be more competitive in the production of goods and services.

In a market economic system, the "for whom" question is also answered in the marketplace. In a purely market-driven economy, the question of who is going to receive the goods and services is based entirely on who are the willing and able buyers. A central authority, like a government, is not involved in any economic decisions. While historically pure market economic systems existed during certain eras, such as the late 19th century, pure market economic systems do not exist today.

Command (Planned) Economic Systems

At the other end of the range of economic systems is the economy in which the three basic economic system questions are answered by one single authority, usually the government. The government decides what will be produced, how it will be produced, and who will receive the economy's goods and services. In so doing, the government regulates prices, distribution, and allocation of the economy's resources. In a pure command economy, the resources are not privately owned; they are owned by the government. The government makes all decisions regarding the allocation of resources, including designation of labor. That is, one's job selection is determined by the government, not by the individual.

Command economies have existed throughout history. Vladimir Lenin introduced a command economy to Russia based on the writings of Karl Marx. A command economy in Russia eventually led to the Soviet Union and to the command economies of Eastern Europe. North Korea and Cuba continue to be model examples of command economies.

Mixed Economic Systems

Pure market economies and pure command economies are rare in today's global economy. Today, most economies answer the three basic economic system questions as some combination of market and command. These are known as mixed economies, and the questions of what, how, and for whom are answered by either individuals in the market or by the government. How the questions are answered also determines whether an economy's goods and services are either private goods and services or public goods and services.

In today's global economy, most economies—including the economy of the United States—are mixed economies. The major question for most mixed economies is the degree of private influence versus the degree of public influence is in play in answering the three economic questions. Economies such as Russia today have a high degree of command economy; they also include a degree of market economy decisions. Economies such as that of the United States have a high degree of market economy decisions, with the inclusion of command economy decisions. Regardless of where each economy currently is along the economic system spectrum, all economies are in a dynamic state of change. Some economies are transitioning from a primarily command economy to a more market-oriented economy, with some transitioning from a primarily market economy to a more command economy influence.

EKELUND, ROBERT, JR.

Born: 1940 in Galveston, Texas; Nationality: American; Professional Interests: political economy, economic theory, economic history; Major Works: *A History of Economic Theory and Method* (with Robert F. Hébert, 2007), *The Economics of Edwin Chadwick: Incentives Matter* (2012).

Robert B. Ekelund Jr. taught economics for more than 30 years at Louisiana State University, Texas A&M University, and Auburn University. He has written dozens of books and journal articles on a variety of topics in economic and political theory, such as micro- and macroeconomics, mercantilism, and even the economics of the American Civil War and the economics of religion. Through his research and knowledge, Ekelund has made a major contribution to the economic community. During his career, he also has a contributor to both the Heartland Institute and the Mises Institute. Much of the progression and development of economics over the past 40 years has come as a result of his work and collaborations.

Robert Burton Ekelund Jr. was born in Galveston, Texas, in 1940. He attended St. Mary's University in San Antonio, where he earned a bachelor's degree in business administration (a BBA) in economics and art history in 1962 and a master's degree in economics and history in 1963. After graduating from St. Mary's, Ekelund accepted a teaching position at Louisiana State University (LSU). While teaching and studying at the same time, he earned a PhD in economics and political theory from LSU in 1967.

Ekelund left LSU in 1967 after accepting a teaching position with Texas A&M University in College Station, Texas. At Texas A&M, he began his prolific writing career by coauthoring *A History of Economic Theory and Method* with colleague Robert F. Hébert in 1975. In their book, Ekelund and Hébert explained the growth and development of economic behavior from ancient Greece through the late 20th century. They used mathematical and statistical analysis and inquiry to explore how market behavior impacts modern economic theory. Comprehensive analysis and an easy-to-read writing style made *A History of Economic Theory and Method* a textbook favorite in the academic community. Ekelund and Hébert have collaborated on several major contributions to the history of economic thought.

In 1977, Ekelund accepted a position at Auburn University and moved from east Texas to east Alabama. He wrote a majority of his books and publications over the next 25 years while at Auburn. Ekelund's writings cover a wide array of topics, from micro- and macroeconomics to the specifics of economics and how the subject of economics relates to 19th-century France, to the American Civil War, and even to religion.

During his graduate studies, Ekelund developed an interest in the work of French engineer and economist Jules Dupuit. His fascination with Dupuit continued through his professional career. In 1999, Ekelund and Hébert cowrote *Origins of Modern Microeconomics: Dupuit and the Engineers*, in which they analyzed how the 19th-century French engineers used daily experiences to arrive at solutions and how that methodology can be used in addressing economic problems today. Ekelund and Hébert were commended by the economic community for their dedication to their work. Many of the sources from both before and after the French Revolution had yet to be translated, and some were not accessible. Ekelund credits Dupuit as one of the founders of formal economic theory and reasoning.

After retiring from Auburn University in 2003 as the Catherine and Edward Lowder Eminent Scholar Emeritus, Ekelund continued to write. In 2004, he and Mark Thornton coauthored *Tariffs, Blockades, and Inflation: The Economics of the Civil War.* The authors investigate the American Civil War, interpreting data from the time period and organizing it into an interesting, easy-to-read format from the standpoint of contemporary economic theory. In 2006, Ekelund teamed up with Hébert and fellow economist Robert D. Tollison to write *The Marketplace of Christianity.* The book explores Christianity as an industry filled with intense competition dating back to the Protestant Reformation of the 16th century; it offers an intriguing look into how religion relates to such economic concepts as self-interest and individual choice. The book provides interesting insights into a variety of topics, and Ekelund's writing ability brings economic concepts to life in different contexts.

Ekelund's contributions to economic thinking are far-reaching and extensive. His teachings—through his instruction and his writing on economic and political theory—are both inspired and influential from the Austrian-style economic perspective. He is renowned for both his expertise and his writing style, and his works are widely publicized and circulated throughout both the academic and economic arenas.

EMOTIONS AND DECISION-MAKING

In *Theory of Moral Sentiments*, Adam Smith noted that "emotions . . . discolor our view of things, even when we are endeavoring to place ourselves in the situation of another" (Smith 2000, 221). Notwithstanding his appreciation of the impact of emotions on behavior, he concluded that these effects are disruptive and a "fatal weakness of mankind." For decades, economics held onto this view, partially because of the inability to classify, measure, and understand emotions. Today, however, research in affective sciences teaches us that emotions serve a very special purpose and can be logically linked to behaviors. Still, emotions are complex and might relate to multiple motives and evaluations. Most of the time, emotions also involve bodily reactions. Since bodily reactions are not always required for emotions, *emotions* are sometimes defined as complex reactions to external (or internal) events that will lead to changes in readiness (or "action tendencies"). Meanwhile, these changes in readiness do not necessarily imply actual actions. Different emotions can thus be defined through their associated action tendencies. Fear, for example, is associated with the tendency for the action of flight, while love is associated with the tendency for the action of approach.

The specific action tendencies associated with each emotion have most likely evolved to enable us to automate our reactions to certain situations, crucial for survival. When we analyze the impact of emotions on behavior, it is thus important to differentiate between different emotions. However, due to the large number of emotions, in many cases simplified categorizations of emotions are applied. A two-dimensional model is frequently used, since many emotions can be differentiated by the two dimensions of pleasure (good versus bad) and arousal (calm versus agitated). However, in such a representation some emotions cannot be distinguished. For example, both anger and fear are unpleasant emotions that lead to medium levels of arousal.

Emotions can also be grouped into "basic" and "higher." *Basic* emotions are emotions that are present in all humans and also in other mammals. Examples are fear, anger, and anxiety. *Higher*, moral or social emotions are emotions that are shaped and defined by culture, education, and society. Examples include envy, shame, and guilt. However, moral emotions can overlap with what other people considered to be basic emotions. Anger, for example, is a moral emotion that is also widely seen as a basic emotion.

Which decision situations will be influenced by which emotions also depends on how possible outcomes are determined. Ortony, Clore, and Collins (1988) categorize emotions according to causes and consequences. Emotions caused by our own actions (regret, anxiety) can be important for understanding individual decision-making when we're facing risk. The importance of emotions for risky decisions has been theoretically modeled and experimentally observed in economics. Anticipating regret, for example, might lead us to make choices to help ensure that we will never experience regret; we might achieve this by avoiding information about things that are happening in other parts of the world.

Emotions caused by the actions of agents can be important for game situations. For example, anger is always related to the actions of another "agent," even if this agent is an object. Anger is particularly important for reciprocity in social dilemmas. Participants often incur costs to punish norm violations by others, and this is linked to how much anger they feel. Other emotions can modulate this reaction. When we feel angry, for example, accompanying feelings of guilt and shame can inhibit the tendency to punish. This is important for situations where agents receive some penalty due to norm violation. This penalty might be considered to be "unfair" and to elicit anger, but when the anger is considered to be justified, it can lead to changes in behavior. Observing anger in others can further lead to strategic considerations; the anger can be seen as a signal that this person will not only maximize his own payoff but will also react to actions considered as unfair or unjust. In an ultimatum game, for example, expecting anger in second movers will lead first movers to propose an equal split. Honest smiles—signals of positive emotions—are another way of signaling intentions in interactions. In trust games, for example, observing honest smiles in others leads to more trusting behavior.

ENDOWMENT EFFECT

An *endowment effect* (Thaler 1980) exists if the subjective value of an item depends on whether it is owned or not. This phenomenon has frequently been found in bargaining contexts with items such as coffee mugs, pens, wine bottles, and lottery tickets. In this vein, Kahneman, Knetsch, and Thaler (1990) report experimental results showing that the average of buyers' willingness to pay for a coffee mug was only half of the average price that sellers who owned the same mug were willing to accept as minimal price for giving it up.

The standard economic explanation for this difference in valuations is based on two features of prospect theory (Kahneman and Tversky 1979)—namely, reference dependency and loss aversion. *Reference dependency* refers to the notion that the subjective value of an item depends on the current reference point of the decision-maker. From the reference point of a seller owning an item, a transaction is framed as a loss, whereas from the reference point of a buyer attempting to get an item, a transaction is perceived as a gain. Since losses are known to have a greater psychological impact compared to gains of the same magnitude, sellers should accept losing an item only for a higher price than buyers are willing to pay in order to get it.

This difference in valuation between sellers and buyers of the same good can also be observed with entrance tickets. To illustrate, Carmon and Ariely (2000) showed that people holding a ticket for a sold-out basketball game requested on average $240 to give up that ticket, in contrast to a mean price of $170 that potential buyers were willing to pay. Research has also shown that merely touching an object results in increased perceived ownership of that object. Similar effects can be achieved through the presentation of imagery encouraging touch of an object, because the valuation of an object is said to be jointly influenced by both: perceived ownership and valence of the touch experience (Peck and Shu 2009). A so-called quasi-endowment effect seems to play an important role in online auctions and explains such often-observed behavior as multiple bidding and *sniping*, or placing a last bid just seconds before the end of an auction.

Different lines of predominantly more recent research on the endowment effect offer alternative explanations with regard to *loss aversion* as the main source of the endowment effect. The choice heuristic assumes that people typically own things that they have chosen beforehand and they infer that if they have chosen something it must be more valuable compared to nonchosen alternatives (Brehm 1956). Another line of research emphasizes that chosen items are associated with the self, and people tend to value things more when they are associated with the self (Beggan and Scott 1997). Furthermore, the confounding of ownership and bargaining role in standard buyer–seller tasks investigating the endowment effect might be problematic, since people typically sell only things they own and buy only things they do not own. Experimental evidence un-confounding ownership and the bargaining role suggests that the endowment effect disappears when buyers are owners and sellers are not. Thus, ownership rather than loss aversion may cause the endowment effect in the standard buyer–seller paradigm (Morewedge, Shu, Gilbert, and Wilson 2009).

Aside from the bargaining context, endowment effects are often studied within a lottery setting, where participants are endowed with a ticket and get the possibility to trade the endowed ticket for another one. People show a strong reluctance to trade a ticket in possession in these situations. It is controversially discussed whether this phenomenon can be explained by prospect theory or newer versions of prospect theory, respectively, since this effect might follow as well from anticipated regret by the owner imagining that an exchanged ticket might win, especially if this ticket was in possession before.

ENTREPRENEURSHIP

Entrepreneurship represents the actions of entrepreneurs in developing new products, processes, or businesses. Entrepreneurs are innovators and risk-takers. They tend to see commercial opportunities, and they then seize the initiative to transform commercial ideas into commercial enterprises. Entrepreneurs are sometimes individuals who start a new business, a process called venture initiation. Entrepreneurs might also be innovators within an existing business enterprise, such as scientists, engineers, or managers. Entrepreneurs operating within an existing business are sometimes called intrapreneurs. *Intrapreneurs* adapt or improve existing products, or they introduce new product lines to the firm. Entrepreneurship is an agent of growth and change in an economy. Because of the vital role of entrepreneurship in business activity and production, it is sometimes viewed as a factor of production, joining human resources, natural resources, and capital goods.

In recent years the role of entrepreneurship in the global economy has received additional attention by development economists and policymakers. Renewed interest in entrepreneurship was sparked by the launch of the *Global Entrepreneurship Monitor* (*GEM*), an annual publication of Babson College and the London School of Business. The *Global Entrepreneurship Monitor 2015 Global Report* measured entrepreneurial activity in 62 advanced and developing economies. One *GEM* measurement of entrepreneurship is the Total Entrepreneurial Activity (TEA) Index. The TEA Index evaluates the entrepreneurial performance of 31 *GEM* countries based on business start-ups and the competitiveness of these business ventures.

The financing of entrepreneurship in the global economy combines informal and formal mechanisms. Informal methods dominate the financing of global entrepreneurial activity. Informal financing taps the personal assets of entrepreneurs, their families, and their friends to start a business. Venture capital, also called risk capital, is money invested in new and promising businesses, mainly by venture capital firms called venture capitalists. Historically, venture capitalists were instrumental in launching some of today's technological giants, such as Microsoft, Intel, and Google.

There are different motivations and support structures for entrepreneurship in the global economy. *GEM 2003* reports that "opportunity entrepreneurship" is prevalent in richer countries, and among wealthier people. Opportunity entrepreneurship is based on personal choice, and it often utilizes the higher educational level and personal assets of individual entrepreneurs to jump-start an enterprise.

"Necessity entrepreneurship" is more common in the world's poorer regions, and among poorer people in general. Necessity entrepreneurship is based on the need for additional household income to purchase such necessities of life as food, clothing, and housing. Among the more important factors that encourage entrepreneurship in both rich nations and poor nations are personal contacts with other entrepreneurs, a younger labor force, fewer burdensome government regulations and taxes on businesses, less central planning by government, more cultural acceptance of business risk-taking, and less government support for a safety net of social programs.

Entrepreneurship has a major impact on economic growth and development in countries, regardless of their income status. First, entrepreneurship creates new firms and makes existing firms more innovative and competitive. Second, entrepreneurship creates new jobs. Third, evidence continues to mount pointing to a positive correlation between increased entrepreneurship and higher rates of economic growth over time. *GEM* research shows that necessity entrepreneurship in the world's poorer regions boosts economic growth at an even faster rate than opportunity entrepreneurship does in the wealthier nations.

Entrepreneurship has taken center stage in the realm of development economics in recent years. Since the 1990s, prominent development economists such as Hernando de Soto have stressed policies of inclusion to promote sustainable economic development in the world's poorer regions. At the heart of de Soto's message is the belief that entrepreneurial activity in countries' informal sector must be harnessed and brought into the formal economy. De Soto and other like-minded economists believe that the merger of the extralegal and legal sectors would vastly accelerate *capital formation*—the process of expanding a nation's total amount of productive capital. Private property rights for the poor, the reduction of excessive business regulations and taxes, and access to credit are key incentives for entrepreneurs to join the formal economy. Major multilateral organizations such as the World Bank and the International Monetary Fund, as well as numerous private foundations and national governments, have voiced support for reforms to bring entrepreneurs into the formal sector.

ENVIRONMENTAL ECONOMICS

Environmental economics considers the impact of human activity on the world with regard to matters such as waste and pollution, and it extends to the realm of climate change in the context of economic realities such as scarcity and development. The term *environment* emanates from the Old French and an even older English word from the 14th century that refers to a circle, with "the world that surrounds us" in mind. The biggest impact on the natural world around humans is the development of that world in the form of using its resources to enhance people's quality of life. As such, economics has impacted the environment since trees were first felled and land was cultivated for food. The environment has impacted economics via the resources that people have found useful for their purposes, be it for sustenance or for commerce.

By the 21st century, initiatives for preserving the environment (or at least harming it less) were ubiquitous. Recycling, reusing, and being green—which is to think and act in ways that accommodate, respect, and preserve the environment in its natural state—had become a priority for people worldwide.

While all of human existence has involved economic choices and efforts to raise the quality of life for various societies, the effect that doing so has had on the environment did not register as a concern until the 19th century. The Industrial Revolution in the West spawned factories all around Britain, primarily in the cities; the fouling of air, water, and public ways caused poet William Blake to call attention to the problem in his work *Jerusalem*, referring to the factories as "those dark, satanic mills." Blake's principle inspiration was the Albion Flour Mill of his youth in London. In *The Engines of Our Ingenuity*, John Lienhard explains how by the early 19th century, "the new factories were providing goods and implements by which people could live more amicable lives. The problem is, those works started obscuring nature" (Lienhard 1999). An awareness of the need to be cautious regarding the environment was most publicly raised first by naturalist John Muir, whose appreciation for all of nature led him to found the Sierra Club in 1892.

President Theodore Roosevelt later preserved large swaths of land that eventually became national parks, but industrialization and the general mobilizations of two world wars kept environmental concerns from being major political and societal priorities until the1960s. The publication of Rachel Carson's *Silent Spring* and the emerging youth culture of the decade brought environmental concerns into common public discourse, and they increasingly were seen as in conflict with economic principles that foster growth. At the start of the decade when *Silent Spring* saw print, 8.3 percent of the American workforce was involved in some aspect of agriculture, in which the pesticide DDT was commonly used (agclassroom.org).

Ten years after Carson's book came out, the U.S. government banned the domestic use of DDT, and it could be expected that removing this means of keeping pests from crops would stunt agricultural production. Conversely, farm production has continued to increase steadily on a yearly basis. A U.S. Department of Agriculture report at the end of the first decade of this millennium noted that total agricultural exports from America rose from $39,495,000,000 in 1990 to $115,809,000,000 in 2010 (U.S. Census Bureau 2012). With no control group to allow an assessment of what this growth might have been if DDT had still been in use, it is impossible to consider such a comparison. During this same period, the share of the American labor force involved in agriculture dropped from 3 percent to less than 1 percent. It is difficult to conclude that this environmentally sensitive development had a negative impact on the economics of farming or the food supply.

Another realm where economics and the environment intersect is the air we breathe. As concern grew in the new millennium over the impact of greenhouse gas emissions on the earth's climate, discourse on the matter included resistance from those interests tied to industries that contribute greenhouse gasses as externalities. Responding to news in 2014 that the Barack Obama Administration had concluded a deal with China to reduce such emissions, Senator Mitch McConnell from the coal-producing state of Kentucky announced that he was "particularly distressed with the deal [Obama] has apparently reached with the Chinese" (Drucker 2014).

Perhaps the most pedestrian and ubiquitous action taken by people every day with an eye toward protecting the environment is the recycling of various materials that two generations ago would have simply found their way to local dumps. It seems clear that in terms of economics, this shift in society's approach toward waste has resulted in considerable job creation, for machines are needed at establishments and individuals are required at the municipal level to oversee these operations.

There are those, however, who question the net environmental effect of recycling. A 2010 report in *Congressional Quarterly* noted that due to the industrial efforts involved in collecting and transporting used drink containers and paper, the environmental results of this approach "outweigh the pollution saved by recycling" (Cooper 1998). Nevertheless, the intention to act prudently in terms of the environment has led to new economic opportunities, and a market for "green" or greener products now exists—such as packaging made with recycled materials.

ENVIRONMENTAL PROTECTION AGENCY

The Environmental Protection Agency (EPA) was created on December 2, 1970, through an executive order signed by President Richard M. Nixon. The EPA reorganized the federal government's environmental programs and agencies under one entity. The EPA was created as an independent organization with the directive to supervise and control pollution, waste, air and water quality, pesticides, hazardous waste disposal, toxic substances, and wildlife in the United States. It was believed that as the country's population grew, these issues would become increasingly important and that a regulatory agency was needed to implement policies and regulations.

Before the EPA was created, only sporadic attention was paid to the environment. President Theodore Roosevelt was a conservationist, and during his presidency he set aside lands for national parks. In 1916, President Woodrow Wilson oversaw the creation of the National Park Service. The Tennessee Valley Authority was established in 1933, authorizing the construction of dams to generate hydroelectric power. Under Franklin D. Roosevelt's New Deal, soil conservation measures were put into effect with the creation of the Civilian Conservation Corps.

Rachel Carson's 1962 book *Silent Spring* drew widespread attention to the effects that the use of pesticides were having on the environment. Carson's work helped increase public awareness of the need for environmental protection, which led presidents John F. Kennedy and Lyndon B. Johnson to include the environment as part of their legislative agendas.

President Nixon took things further and expanded the nation's environmental policy. In 1969, he established the Environmental Quality Council to oversee issues related to the environment as part of the National Environmental Policy Act (NEPA). NEPA made the government the protector of earth, land, air, and water. This act established a national environmental policy and set goals for protecting and maintaining the environment through federal agencies. In July 1970, President Nixon announced his desire to create an independent regulatory agency to oversee the implementation and enforcement of environmental policy. This agency would be called the Environmental Protection Agency, and its duties would include the following:

1. Recommending environmental policies to the president for implementation;
2. Enforcing environmental standards;
3. Researching pollution and its effects, and recommending policies to reduce pollution;
4. Working with state and local agencies as well as federal agencies to coordinate pollution policies;
5. Assisting other federal organizations that deal with environmental quality–related issues; and
6. Developing reports for the president and Congress regarding the environment.

Furthermore, the EPA sought to identify potential pollution problems by investigating factories and manufacturing facilities. The EPA pursued an examination of agricultural pesticides and their effect on the environment. The agency also wanted to locate and address pollution in cities, rural areas, oceans, and lakes.

Countries around the world are also concerned with environmental standards. Britain's Environmental Protection Act of 1990 sought to update and refine pollution controls and standards as well as implement harsher penalties for violations. In 1998, Canada sought to strengthen its Environmental Protection Act by making it more stringent as well as providing a review of the act every five years.

Today, the EPA employs over 17,000 people—from scientists to engineers. The organization has changed with the environmental issues of the time. Most recently, the EPA has focused its attention on greenhouse gases and fuel emissions standards, as it continues to be concerned with its original charge for air and water quality.

ENVIRONMENTALISM

Since its inception, the environmental movement has had an uneasy relationship with economics. The environmentalism that arose in the 1970s relied almost exclusively on command-and-control regulations that mandated certain actions by polluters, with little attention paid to issues of economic efficiency, business incentives, or how markets are likely to evolve over time. The movement was populated largely by scientists, lawyers, and activists, many of whom believed that the U.S. capitalist system was the main driver of environmental degradation and that economics was little more than capitalism's enabler.

This skepticism, and sometimes outright hostility, toward economics stemmed from some firmly held beliefs: that the quest for economic growth by definition resulted in the exploitation of the natural world; that private entities, with their focus on profit, will always degrade the environment; and that assigning dollar values to nature was counterproductive, and was one of the main drivers of the unhealthy relationship between humans and the environment. The overarching position of the environmental community for much of its first 20 years (roughly 1970 to 1990) was that markets could not be harnessed to benefit the environment, and that instead they needed to be suppressed and reined in to promote environmental values.

This position still prevails in some environmental circles, but the profound distrust of economics has largely given way to a more balanced and realistic assessment. Environmentalists have discovered that the theory of market failure (the foundation of much of microeconomics) contains a powerful environmental message: Private markets alone will not fully account for the costs they impose on the environment and human health, nor under many routine circumstances will they promote the sustainable use of natural resources. Environmentalists can now point to classical economic theory for one of their strongest arguments in favor of government action to protect the environment.

This theory not only provides diagnostic criteria to determine when markets work effectively and when they do not; it also offers prescriptive action on how to make markets function better. For example, the rationale for greenhouse gas taxes comes directly from the economic theory of *Pigouvian taxation* (named after the English economist Arthur Pigou), which posits that polluters should be charged on a per-unit basis for the damages they impose on society. Microeconomics can also provide insight into the best stage of the production process to levy the taxes (in order to maximize their efficacy), as well as methods to redistribute the tax revenue to reduce any regressive impact and help transition to cleaner modes of production.

The primary alternative to direct emissions taxation is *emissions trading*, which allows the government to set an overall cap on total pollution while allowing firms to achieve emissions reduction by buying and selling pollution permits. “Cap and trade” was successfully implemented in the United States in 1990 for sulfur dioxide emissions (and was adopted by the European Union in 2005 for greenhouse gas emissions), with cost savings to the industry in the hundreds of millions of dollars per year, without compromising the target reductions. Environmentalists used to fret about the moral implications of giving polluters a right to pollute; now that cap and trade has a demonstrated record of success, there is growing acceptance that the method can be a powerful environmental policy mechanism.

There is also growing recognition that in places where property rights are nonexistent and natural resources are being exploited unsustainably, assigning property rights and limiting access can help reverse the damage. The principle has been applied with significant success in many ocean fisheries; it is also being put into practice to help reverse deforestation in areas where ownership is currently contested.

Sometimes, markets fail in subtle ways that have major environmental implications. For example, private entities have little incentive to provide the public with information about their toxic emissions. Consumers, therefore, make purchasing decisions with limited information about what types of production processes their purchases support. Policies that force firms to provide complete information on their toxic emissions can empower users to make better-informed purchases, and to more knowingly express their preferences for greater environmental quality.

The examples provided earlier are only a few of the ways in which environmental goals have been advanced by addressing market failures. Assigning dollar values to ecosystems has also been accepted by many environmental organizations, and these organizations now view this valuing as an essential ingredient in making sure policymakers and businesses do not overlook, and underestimate, the benefits that nature provides.

New York City decided to purchase its upland watershed because forests could provide water filtration more cheaply than a sanitation plant could. Costa Rica elected to pay private landowners for the forest ecosystem services their properties provide to the general public. These are just two real-world examples of how placing a dollar value on ecosystems led directly to increased preservation.

The ability of economic theory to advance environmental goals has helped the economics profession win over many once-skeptical environmentalists. The environmental community has come to recognize that market failures are to blame for much of our environmental degradation, along with market distortions—for example, subsidies, tax breaks, and the right to pollute without accountability. These market failures and distortions are the antithesis of healthy capitalism, and most economists oppose them.

Summing up, over the decades environmentalists have become far more sophisticated in their understanding of economics. Economic theory provides many important tools with which to analyze when markets work and when they do not, as well as ways to use that knowledge to benefit the environment. Most important, there is a growing recognition that well-functioning markets are not the enemy of the environment, but in fact may be one of its greatest allies.

ESTATE PLANNING

Estate planning is the roadmap for distribution of one's financial and personal assets upon death. An individual creates an estate plan while living. The estate-planning strategy makes it clear and easy for the surviving family or other beneficiaries to carry out the wishes of the deceased with respect to financial and property holdings.

Understanding Estate Planning

First, let's briefly review the legal terms that are used when an estate plan is being set up. The *deceased* is the individual who has died. The *beneficiary(ies)* is the individual who is to receive the deceased person's possessions. The *will* is a document that the individual created, while still living, to describe his or her wishes upon death. The *executor* of the estate is an individual who carries out the directives of the will. *Probate* is the court process of proving the validity of a will. A *lawyer* usually draws up a will and creates an estate plan.

For individuals with few assets, estate planning is simple; usually, it involves completing a will and having the will signed, witnessed, and possibly notarized. In the simplest cases, an individual may create his own will by hand or with an online program.

Individuals with greater amounts of wealth or assets and more complex finances usually have complicated estate plans. In order to ensure that the assets are distributed the way the deceased prefers, these plans involve not only a will but also trusts.

Estate-Planning Functions

An estate plan can have narrow implications or broad ones. The estate plan lays out how assets are to be distributed upon an individual's death. Estate plans have various goals. The simplest estate plan is a will, which gives instructions for distributing the deceased's assets.

More detailed estate plans can be structured to smooth out the legal probate process. The estate plan simplifies the legal process by using trusts and other legal tools. In this way, the plan protects an individual's wealth from undue taxes and expenses. In other words, the individual's money, property, and financial assets can be maximized, while the estate tax burden on their heirs is minimized.

If minor children are involved, an estate plan usually names a guardian. If a mother and father both die and leave behind young children, the estate plan tells the court who should care for the children. This section of an estate plan is very important, because without it the courts must decide who should care for the minor children. Without a named guardian, there is no assurance that the court-appointed guardian is one whom the deceased parents' would have desired.

Another function of an estate plan is to address medical issues. A living will/advance health care directive addresses end-of-life medical treatment wishes. This document instructs medical providers and family members regarding end-of-life care. For example, if an elderly individual cannot breathe on her own, the medical directive within the estate plan might advise a doctor to remove the breathing assistance. A "Do Not Resuscitate" directive is common for the elderly as well. This means that if the individual suffers a heart attack, or if some other medical procedure stops the heart, the individual does not wish to be revived.

The durable medical power of attorney is sometimes referred to as a "health care proxy" or "health care surrogate." This document, contained within an estate plan, names an individual to make medical decisions in the event the individual is not able to make those decisions for himself.

The power of attorney is another document included in an estate plan. The power of attorney gives someone else the power to act on an individual's behalf. The power of attorney responsibilities may be limited to specific circumstances; or they may be more comprehensive and cover all decisions. For example, when an elderly person loses mental functioning, or under certain prescribed circumstances, the power of attorney document names someone to act in that person's stead. Frequently, married couples name each other in their power of attorney documents.

What Happens If Someone Dies Intestate (Without a Will)?

If a person dies without having a will, the state has laws of descent and distribution to map out who receives the deceased person's property. The chain of distribution usually begins with the spouse and/or living children; if there is not a living spouse or children, the state turns next to other family members. For the property to pass according to the deceased person's wishes, clearly it is preferable to have a will.

How Does an Estate Plan Impact Probate?

Probate is a two-part process. First, the will is submitted to the probate court in order to be proved valid. Second, the court appoints an estate administrator to collect the assets and distribute them to the designated heirs.

The probate process has disadvantages, and some individuals use estate-planning strategies in order to avoid probate. There are several reasons to attempt to avoid probate. First, the legal probate process is publicly recorded. Many individuals don't want public disclosure of the details of their estate. Further, in some states the probate process can be slow and expensive.

There are legal techniques and instruments available to avoid probate, although applying these strategies can be expensive. For example, trusts can be set up to pass assets to beneficiaries without going through probate.

How Do Trusts Fit into an Estate Plan?

A *trust* is a legal entity that "holds" assets on behalf of its beneficiaries. The trust has rules or provisions that define the document.

Estate planning uses a variety of trusts, such as testamentary trusts, living trusts (either revocable or irrevocable), and generation-skipping trusts. A lawyer can explain the advantages and disadvantages of each type of trust. In especially complicated situations, life insurance, charitable trusts, and other more sophisticated tools are used.

Although frequently considered a tool only for the wealthy, trusts are also useful in estate planning. For example, a young couple with children could create a trust for the benefit of their children, in case they die while their children are minors. This trust could describe how their assets would be handled and who would attend to the parents' affairs and the care of their minor children.

Estate planning is not a one-time activity. As individuals and families evolve, so must their estate plans. As families grow and age, their estate plans need to change.

ETHICAL CONSUMPTION

Ethical consumption reflects our concern about the past and the future of a good, in addition to its present properties. The *past* of a good has to do with how the good was produced. Those of us who choose to be vegetarians may object to the conditions in the factory farms and the slaughterhouses. The *future* of a good has to do with the consequences of consumption. Many of us find it morally abhorrent to litter the land and pollute the air with the wastes from what we consume today.

Ethical consumption was not much of a personal or public issue until the age of industrialization. Before then, even with the domestication of animals and plants, consumption and production were largely integrated: People grew their own crops, raised their own animals, and made most things themselves. If they needed things that they did not make themselves, they bought from people they knew well, so they had a good idea of how those things were produced. There was also little waste from what people consumed, so environmental pollution was not a major issue except in densely populated areas.

Industrialization drove a wedge between consumption and production. Many of the things people bought came to be "manufactured" by people about whom the consumers knew little. Two developments helped separate consumption from production. First, increasing specialization meant that the most ethically questionable tasks could be done by specialists in ways and at locations hidden from the public view. This isolation helped people become callous or oblivious about those tasks. Second, producers used mass media and advertising to create images of the wholesome, the ethical, and the trustworthy. These developments effectively silenced consumers well into the 20th century, as this was the best information that most consumers had available to them at the time.

Still, ethical consumption is deep-seated in our psychic. We are witnessing a resurgence of it. For example, there is strong evidence that we are willing to pay more for something if we perceive that it was produced ethically, or at least we prefer to pay less for something that was produced unethically. There is also strong evidence that we attach a higher value to a good in our possession that we intend to "consume" than the same good in our possession that we intend to "sell." Behavioral economists call this "the endowment effect."

Ironically, the resurgence of ethical consumption is being propelled by the same media technology that helped producers build the public trust in their presumed ethical practices. Media technology is making it possible for consumers to network, to share ethical concerns, and to become aware of breaches of the implicit contract they have with producers. The environment-protection movement, the animal-protection movement, and the fair-labor movement all began at about the same time as the Internet. More and more consumers are asking if the paper used to make a book has with a connection to deforestation in Indonesia, if the eggs in grocery stores come from laying hens confined in wire cages, if the workers who make their shoes have no human rights, if the coffee they drink comes from beans picked by small children in Africa, and if the strawberries they're eating are grown using chemical insecticides and fertilizers.

The ethical issues driving these movements are not new. What is new is an awakening to our own foibles—in particular, our naïve assumption that the things we buy are produced in the "right" ways. Behavioral economics can help us understand how all this came about, by better modeling information asymmetries, social norms, preference formation, and the significance of such non-material concerns as ethics and morals to an individual's well-being and preference function.

ETHICAL PRODUCTION

Ethical production has to do with the methods of making things and providing services. We consider a firm to be engaged in ethical production when the manager treats employees fairly, pays bills on time, and uses low-pollution technology. In this case, the manager takes into account the interests of workers, investors, and future generations.

Ethical production and business ethics may sound like the same thing. Both are concerned about producers' ethical behaviors. But they are very different in approach. Business ethics is about how producers should behave, while ethical production is about how producers actually behave. Therefore, business ethics deals with abstract principles of rights, obligations, social welfare, and justice. Ethical production, in contrast, uses behavioral economics to understand decision-making in the real world.

Like ethical consumption, ethical production was not much of a problem before industrialization. In agrarian societies, even with the domestication of animals and plants, production and consumption were integrated to a large extent. We mostly consumed what we ourselves produced. We took care of our immediate environment because we lived in it and because we knew we depended on it. We often treated well people who worked for us, because they were family members. We paid off our debt because the creditors were our friends and neighbors. When we wanted things that we did not make, we bought from reputable traders whom we knew personally.

During industrialization, we were confronted with goods that had much lower prices but were produced by processes about which we knew little. How we overcame that blind spot is a subject of active research. It is clear, however, that we began to think that we had entered a new era, that our earlier concerns were old-fashioned, and that we needed to let go some, if not all, of them. This moral weakening created what we now know as "negative externalities." Pollution is a prime example of negative externality. From the polluter's point of view, much of the social cost of pollution is born externally—that is, by others.

Producers do what they can to promote the public's trust in their moral character. Advertising is symptomatic. Advertising would not be necessary in a society where consumption and production were integrated. Producers also do what they can to remove ethically offensive practices from public view. Thus, smoke is collected through pipes rising high into the sky so we cannot smell it, chemical wastes are sent by underground sewers into rivers so we cannot be burned by them, and animals are killed in featureless and windowless buildings far from urban areas so we cannot see them. Finally, as producers make goods and services more complex, consumers understand them less and become more vulnerable to media advertising. Complexity is a means of concealment.

Another development in modern times that has exacerbated unethical production is the ascension of professional managers. This phenomenon, also known as "the separation of ownership and control," has contributed mightily to mass production, in both capitalistic and socialistic systems. Professional managers are fundamentally different from equity owners. Professional managers desire growth, while equity owners desire profit.

The rising dominance of professional managers has been a precipitating factor in global financial crises in recent decades. Most economists regard financial crises as a serious problem of the modern economy, and they believe that a decline in ethics among professional managers has a lot to do with it.

There are forces that have always constrained the degree to which producers can ignore ethics. First, there is strong evidence that consumers are willing to pay much less for a good that is produced by means of an unethical method. Second, according to X-efficiency and efficiency-wage theories, productivity is higher when production is ethical. When workers and investors perceive that the manager treats them ethically, workers are more productive and investors demand lower returns on investment. Revenue rises and cost declines. Thus, ethical production can be economically sustainable, while meeting the demands of ethical consumers.

EVOLUTIONARY ECONOMICS

Evolutionary economics is a research tradition that aims to explain dynamic socio-economic phenomena on the basis of realistic assumptions about the nature of human behaviors and institutions. This tradition goes back to the early 20th-century work of, among others, Thorstein Veblen on institutional change and Joseph Schumpeter on economic development. Modern evolutionary economics is often associated with the work of Richard Nelson and Sidney Winter, who studied innovation and economic growth by combining Schumpeter's interest in economic development with insights from the behavioral theory of the firm developed by Herbert Simon, Richard Cyert, and James March.

Modern evolutionary economics is most easily understood by contrasting it with neoclassical economics. Three distinguishing features are its behavioral assumptions; its view of organizations; and its emphasis on the dynamic, path-dependent, and historically specific nature of such economic phenomena as economic and institutional change. First, the main behavioral assumption of evolutionary economics is bounded rationality, Simon's concept to distinguish real-world human decision-makers from the hypothetical fully rational *homo economicus* of neoclassical models. Second, in contrast to the neoclassical view, in which firms are seen as unitary agents that pursue the interest of shareholders, evolutionary economics acknowledges the political dimension of organizations and considers the decisions of firms as outcomes of collective decision-making processes in which multiple interests compete and in which various forms of (coalitional) power play an important role. Third, evolutionary economics takes issue with the neoclassical tradition to capture economic phenomena in equilibrium terms. Evolutionary economics holds that the essence of theorizing about economic phenomena is not to predict outcomes under a given set of conditions at any one point in time, but to explain how economic systems are able to change themselves from within over time.

In the work of Nelson and Winter, these three characteristics result in a theory that employs a biological metaphor to model economic change. At the heart of economic change is competition between firms: a dynamic process driven by innovation and selection. Routines, understood as learned collective action patterns, are seen as the "genes" of organizations. They represent a "truce" among the stakeholders associated with the firm (they are the result of balancing conflicting interests), and they allow the members of the organization to save on cognitive resources by repeating behaviors that worked in the past. Firms compete on the basis of operating routines, and their relative profits are a feedback signal of the adaptive fit of their routines. If profits fall below aspiration levels, this will trigger innovation through higher-order "search" routines that will lead to the introduction of variations in operating routines. These variations are subjected to the selection pressures of markets. Successful variations are retained and become the new routines. In this way, successful firms adapt to changing environmental conditions through a process of variation, selection, and retention, while unsuccessful firms are selected out.

There is an ongoing debate among evolutionary economists about the specific meaning of the label "evolutionary" and the appropriate link of the field to theories of biological evolution. In this debate, the field has moved beyond Nelson and Winter's metaphorical use of biological evolution. Two approaches stand out. The first, which is relatively uncontroversial, has been labeled the "continuity hypothesis." It proceeds from the core idea of evolutionary psychology that human cognitive and social psychologies are the product of an evolutionary history of living in small-scale tribal societies. These psychologies in turn both enable and constrain the processes of cultural evolution that drive economic development. The second approach, known as "generalized Darwinism," accepts the continuity hypothesis and adds the more controversial claim that an understanding of the commonalities between biological and cultural evolution can help unravel the general logic of an evolutionary explanation, which in turn can inform better economic theories of dynamic phenomena like economic growth.

Recent work on the basis of the continuity hypothesis, either with or without also accepting generalized Darwinism, has led to a naturalistic perspective on economic behavior and institutions. This perspective links up with other behavioral work in economics (such as the work of Samuel Bowles, Ernst Fehr, Simon Gächter, Herbert Gintis, and Robert Frank) and elsewhere (evolutionary anthropology and evolutionary social psychology), and it recognizes that human behaviors ultimately must be understood in the context of gene-culture coevolutionary processes. A central theme in this work is that human behaviors are driven by both competitive and cooperative tendencies. Empirical studies of these two tendencies inform two more behavioral assumptions (in addition to bounded rationality) that deviate from neoclassical orthodoxy. The first is that, especially in cooperative situations, the majority of individuals display "bounded self-interest"; that is, rather than being purely self-regarding, many people also act on other-regarding (social) preferences. The second is that, especially in competitive situations, utility is often driven by differences among individuals: many people seem to care more about their relative payoffs than about maximizing their absolute payoffs.

EXPERIMENTAL ECONOMICS

Experimental economics is a comparatively recent addition to the economist's toolbox. In fact, until a couple of decades ago, at a time when experimental economics was already reasonably established (Davis and Holt 1993; Friedman and Sunder 1994), standard textbooks still maintained that economics could not be an experimental science. Plott (1991) famously begged to differ, predicting that economics would in fact become an experimental science. It is hard to argue with this prediction today, given the growing number of textbooks and the growing percentage of articles in top economics journals reporting on experiments (Ellison 2013), the increasing importance of experiments in policy design, and the award of the Nobel Memorial Prize in Economic Sciences to Vernon Smith in 2002 and Al Roth in 2012. Previously, the Nobel Prize Committee had already acknowledged Reinhard Selten's experimental work (Selten 1999).

Experimental economics is the application of experimental methods to answer questions that economists ask. It seems fair to say that experimental economics started out as an undertaking mostly dedicated to testing economic theories. Today it is hard to think of any economic theory, or any economic topic for that matter, that has not been investigated with experiments. Individual decision-making, competitive and oligopolistic markets, matching markets, bargaining, auctions, political and other institutions (such as common pool resources or public good provision mechanisms), the internal dynamics of firms and other organizations, learning, and social preferences have all been studied with experimental methods. Even such macroeconomic phenomena as bubbles or bank runs are now also studied with experimental methods. Almost 20 years after its publication, the *Handbook of Experimental Economics* edited by Kagel and Roth (1995) remains an excellent read on several of these topics, while Duffy (2008) provides a substantial on macroeconomics-related experiment. Kagel and Roth's book also contains a lengthy introduction to experimental economics by Roth. (Publication information about a short version of this introduction is given in "Roth, Alvin E." under "Further Reading" at the end of this entry.) Likewise, the *Handbook of Experimental Economic Results* edited by Plott and Smith (2008) contains 115 chapters on the subject. Camerer (2003) not only reports results but also is quite careful to describe how they came about.

A distinguishing characteristic of experimental economics is its methodology (Hertwig and Ortmann 2001), which distinguishes it from other social sciences such as psychology. Experimental subjects are almost always paid on a performance basis. And the use of deception is generally not accepted. Precise scripts are considered a necessity in order to facilitate replication. Decision-making is not studied as an "as if" proposition but in laboratory representations of the problem being studied. In such representations, subjects typically are instructed to enact a particular role—such as buyer or seller or voter. These different methodological practices are not quite as innocent as they may at first appear. That's because the way one does an experiment is crucially important: different choices of particular design and implementation details can significantly affect results.

Experimental economists' methodological practices have also influenced emerging experimental efforts in finance, political science (Morton and Williams 2010), and philosophy, and they have led to fruitful reflections in other social sciences. Increasingly, experimental economists also have had to share the limelight with scholars in behavioral economics and neuroeconomics. In fact, many prominent experimental economists straddle these areas and then some.

Insights from experimental economics also inform policy design in many areas—from telecom auctions (Binmore and Klemperer 2002; Klemperer 2002); to market mechanisms that match students with schools or colleges, and interns with hospitals or high-court judges; to emissions trading schemes and various strategies to nudge people in directions that policy-makers believe improve human welfare.

FACTORS OF PRODUCTION

Factors of production are resources used to produce goods or services, and they are often called productive resources. The three main factors of production are natural resources, human resources, and capital goods. Some economists list entrepreneurship as a fourth factor of production. At the microeconomic level, firms use the factors of production to produce goods efficiently and profitably. At the macroeconomic level, national output, employment, and sustainable economic development are heavily dependent on the efficient use of society's productive resources. The factors of production are unevenly distributed in the global economy.

Natural resources are the gifts of nature used in production. Natural resources include minerals such as bauxite, uranium, and nickel; primary energy sources such as oil, natural gas, and coal; water bodies such as oceans, rivers, and lakes; wildlife such as animals, fish, and insects; natural vegetation such as forests and plants; and naturally occurring forces such as wind and sunlight. Natural resources provide many of the raw materials needed to produce goods and services. Some nations, such as the United States, are well-endowed with a wide variety of such natural resources as mineral deposits, navigable rivers, and arable land. Other nations may be rich in a single resource, such as oil or timber. Still others lack essential natural resources. Resource-poor Japan acquires natural resources through international trade and foreign direct investment, but poorer, land-locked countries have limited access to essential natural resources.

Human resources are people who are engaged in production. Human resources include assembly line workers, miners, and contractors in the goods-producing sector; teachers, doctors, and engineers in the services-producing sector; and farmers, loggers, and ranchers in the agricultural sector. Education, training, apprenticeships, and other investments in human resources create a skilled workforce, often referred to as human capital. Human capital development increases the productivity of labor. The advanced economies finance comprehensive public education, and they support higher education and worker training programs to create human capital. The emerging market and developing countries value human capital, but they have fewer resources to support its development. In addition, the dearth of financial incentives, uncertain property rights, and low quality of life contribute to a "brain drain" in many poorer countries. This *brain drain*, or a migration of professionals and other skilled workers from poorer nations to greener pastures in richer countries, depletes the stock of human capital in poorer regions.

Capital goods are items used to produce other products, rather than to satisfy an immediate consumption need. Capital goods include bulldozers, cement mixers, and automated assembly lines in the goods-producing sector; communications satellites, subway trains, and engineering design software in the services-producing sector; and mechanical harvesters, fishing boats, and fertilizers in the agricultural sector. Investment in new capital goods is a prerequisite for capital formation, the increase in a nation's capital stock. In the advanced economies, capital formation has sharpened their competitive edge over other emerging market and developing economies. For instance, U.S. investment in information processing equipment, such as computers and software, has improved the product quality in information technology (IT) firms.

Sophisticated IT also increased the productivity and connectivity of firms that are using this technology. Similarly, capital formation in the newly industrialized economies (NIEs)—including Chinese Taipei, the Hong Kong SAR, Singapore, and South Korea—accelerated their economic development over the past several decades. Low domestic savings, poorly developed capital markets, and capital flight slowed capital formation in many poorer nations.

Entrepreneurship is the process of transforming innovative business ideas into viable commercial enterprises. Entrepreneurs develop new products, production methods, or business ventures. Entrepreneurship is often considered a fourth factor of production, joining natural resources, human resources, and capital goods. Entrepreneurial activity involves risk-taking, as well as a visionary zeal to succeed. Entrepreneurs like Thomas A. Edison and Henry Ford helped create the modern industrial age. Similarly, Steven Jobs, cofounder of Apple Computer, and Bill Gates of Microsoft fame, helped jump-start a global information revolution.

The widely respected *Global Entrepreneurship Monitor 2003* (*GEM 2003*) makes a compelling link between entrepreneurship, business and jobs creation, and economic growth. *GEM 2003* also concluded that entrepreneurship supported economic development in all classifications of countries: low-income, middle-income, and high-income.

FASCISM

Fascism is a term coined by Benito Mussolini in 1919 when he organized veterans and other Italians into the Fascist Party. He took the name from the Latin word *fasces*, which means "a bundle of sticks wrapped around an ax." In ancient Rome, the fasces symbolized unity and authority. Historians still debate the real nature of Mussolini's philosophy and intent. In the 1920s and 1930s, fascism meant different things in different countries. Today, we generally use the term *fascism* to describe any centralized, authoritarian government that is not communist and whose policies put emphasis on the state over the individual. People today also use the term to describe actions of nations that are destructive to basic human rights.

Shared Characteristics of Fascism

All forms of fascism, whether past or present, share some basic features. They are all rooted in extreme nationalism. Fascists glorify action, violence, discipline, and, above all, blind loyalty to one's nation. Fascists also pursue aggressive foreign expansion and glorify warfare as a noble cause for survival. The political theory of fascism is antidemocratic. It rejects faith in reason and the democratic concepts of equality and liberty.

From the perspective of fascism, democracy leads to corruption and weakness. Fascists also believe that national goals should always be put before individual goals and class interests. Supremacy of the state is a main priority of fascism. Another common feature is a single-party dictatorship with full obedience to a single leader. Full control of the economy should be in the hands of the state, and the use of spies and terror to enforce the will of the state is common.

A further common characteristic of fascism worldwide occurs through government use of the media, which the government has control over; the government uses the media to disseminate propaganda to persuade and mobilize citizens. The use of schools and youth organizations to spread ideology to children and the strict censorship of artists and intellectuals who have dissenting opinions are also features of fascism. Finally, fascism supports a society with defined classes, not the ideal of equality for all that is found in communism.

Historical Background of Fascism

The Italian Fascist party was created in 1919, and within it, Benito Mussolini rose quickly to power. In 1922 King Victor Emmanuel III asked him to form a government as prime minister, and so he obtained a nominally legal, constitutional appointment to lead Italy.

At first, fascists held only a few cabinet posts in the new government. However, by 1925, Mussolini has assumed more power and taken the title of *Il Duce*, "The Leader." Under Mussolini's rule, rival parties were suppressed, the press was muzzled, elections were rigged, and elected officials were replaced with Fascist supporters. In theory, Italy remained a parliamentary monarchy, but in fact it was a dictatorship upheld by terror. Critics were thrown in prison, forced into exile, or murdered.

To spur economic growth in Italy and end conflicts between business owners and workers, Mussolini brought the economy under government control. Under Mussolini's economic state structure, representatives of business, labor, government, and the Fascist party controlled industry, agriculture, and trade. Mussolini's system favored the upper classes and industrial leaders. Although production increased, success came at the expense of the workers. Workers were forbidden to strike, and their wages were kept low.

In Mussolini's new system, loyalty to the state replaced conflicting individual goals. To Fascists, the glorious state was all-important, and the individual was unimportant except as a member of the state. Men, women, and children were bombarded with propaganda glorifying the state and Mussolini. Men were urged to be ruthless, selfless warriors fighting for the glory of Italy. Women were pushed out of paying jobs and called upon to "win the battle of motherhood." Those who bore more than 14 children were given a medal by Mussolini himself.

Another of Mussolini's major goals was to mold the minds of the children. Fascist youth groups toughened children and taught them to obey strict military discipline. Boys and girls marched in torchlight parades, singing patriotic hymns and chanting "Mussolini is always right." By the 1930s, a generation of young soldiers stood ready to back Mussolini's drive to expand Italian power.

In addition to Mussolini's reign in Italy, fascism spread throughout Europe in the 1920s and 1930s. Even though the types of fascism may have varied a bit, the primary fundamental characters still remained in such places as Germany under the rule of Adolf Hitler (1933–1945) and Spain under Francisco Franco (1939–1975). Even Japan fostered fascist beliefs in the uniqueness of the Japanese spirit, and from 1936 to 1945 its government taught subordination to the state and personal sacrifice.

Fascism in Spain under the dictatorship of Francisco Franco (1939–1975) was a unique example of how fascism can fluctuate in its characteristics. One of Franco's first actions as leader was to kill or imprison thousands of Loyalist Party members; this was the political party in Spain that wished to preserve the republican government. Spain, much like Italy, was ruled as a strict fascist state until after World War II. After World War II, Spain became anticommunist and aligned with the United States. Even though independent political parties and trade unions continued to be banned, by the late 1950s pressure for economic stabilization forced Spain to open its doors for massive foreign investments, thus loosening some government control. With foreign influences pouring in, social and ideological influences from the West soon followed. This gradual change of beliefs and the simultaneous economic windfall led to extraordinarily rapid economic growth and a less strict form of fascism.

The Appeal of Fascism

Given its strong restrictions on individual freedoms, the reason fascism appealed to so many Italians and Germans was its promise of a strong, stable government and an end to the political conflicts that had crippled democracy in Italy and brought economic crisis in Germany. Mussolini's image was of a strong, confident and powerful leader in a time of disorder and despair. His unmatched nationalism also was a source of rekindled national pride.

Much like Mussolini, Adolf Hitler relied on the economic crisis of Germany during the Great Depression and his powerful speaking ability to influence the German population to believe in this fascist ideology. As unemployment rose throughout Germany and a financial crisis spread due to Germany's massive World War I debt, Hitler promised to end reparations, create jobs, and defy the Treaty of Versailles. His primary focus was on creating a great, united nation that must expand for its people. He appealed to nationalism by recalling past glories, and he boasted of a master race that would dominate Europe for a thousand years.

Whether in Italy, Spain, or Germany, the nationalism and patriotism of fascism partnered with a strong, driven, influential leader who promised people he would make their nation the greatest in the world. This made the ideology of fascism very appealing to those in need and hopeful for change.

FEMINISM AND BEHAVIORAL ECONOMICS

Feminists and behavioral economists have common interests, and they have made long-standing research contributions in power, fairness, altruism, trust, and institutions. However, only a small existing literature explicitly draws on both feminist and behavioral approaches to economics. Part of this literature links gender with different levels of risk aversion, often in the context of research on pension fund membership and accumulations. A further part identifies future research agendas that combine insights from both feminist and behavioral approaches. Achieving a closer integration of feminist and behavioral economics will involve more than simply "adding women" to existing studies in behavioral economics. It will require critical observation and concern for behaviors and outcomes that are defined by women as relevant to their social and economic experiences.

Risk aversion as a sex-linked trait is commonly inferred from lottery experiments and pension fund studies showing statistically significant gender differences in specific decisions and behavior. The conclusions have been challenged by feminist economists, who argue that inferences are likely to reflect the researchers' own (tacit and perhaps culturally-specific) beliefs about the underlying natures of men and women. While feminist economists do not deny differences between men and women, they emphasize the need to explore a range of possible explanations for observed differences in behavior by sex, including pressure to conform to prescribed social roles or relative positions in hierarchies. Feminist economists also emphasize the harm that can be caused by the perpetuation of false stereotypes about men and women.

Behavioral approaches that emphasize the importance of social categories and prototypes in economic decision-making will be an important area of future research overlap for feminist and behavioral economists. Kahneman's work on intuition is relevant to findings and interpretations of gender and risk aversion, in addition to a range of other phenomena. He argues that the mention of a familiar social category will increase the accessibility of the traits associated with the category stereotype, many of which have a gender dimension. Kahneman also emphasizes the influence of social structures and contextual factors on decision-making. This accords with feminist perspectives that highlight the role of social institutions in shaping men and women's "preferences" and in defining their feasible behaviors. Gender prototypes influence voting patterns, the perceptions of likely success in "masculine" or "feminine" tasks, and employment selection. Reskin shows how cognitive processes cause people to constantly categorize individuals and attribute to them certain stereotypical behaviors. Thus, while our conscious self may find discrimination abhorrent, our unconscious mind may attach specific behaviors to individuals because we identify them as part of a particular group or category. As a result, we may think and ultimately act in ways that privilege some individuals and disadvantage others.

Behavioral approaches to studying motivations other than material self-interest will be a further important area of research overlap between feminist and behavioral economists. Emerging research on altruism and reciprocity may contribute to studies of women's disproportionate involvement in paid and unpaid care roles and the poor material rewards for the performance of these roles. Thus far, rational behavioral choice theory has mostly been applied to social and economic experiences that appear relevant for large numbers of men, such as the fairness of wage relativities in internal labor markets. In comparison, issues and activities that are relatively more important to women, such as the wage gaps between caring and other types of paid work, have received little attention. Given that caring situations are characterized by a relatedness between care giver and care receiver participants, by an asymmetry between these participants, by dependence on the part of care recipients in particular, and by the importance of inherent power structures, it is likely that feminist economists will use theoretical approaches other than rational behavioral choice theory to examine issues of motivation and reward for large groups of women.

FINANCIAL LITERACY

Financial literacy—alternatively referred to as financial education or financial capability—analyzes several issues related to money management in different settings, such as savings, loans, budgets, investment, planning, and pensions.

Among the general goals of this process are understanding consumer financial decision-making; improving consumer education, awareness, and transparency of financial services; helping consumers make informed decisions about their finances and raise their financial capability; making financial matters understandable to the general public; and developing the capability of ordinary people to make risky financial decisions.

Although some countries—like the U.K., which launched the world's first comprehensive national strategy early in 2000s—have already delved into issues related to financial literacy, the issue has gained relevance and visibility mainly after the economic and financial crisis of 2008. The crisis and the efforts that governments carried out to cope with it have raised the question of whether that financial crisis could have been prevented or mitigated if people had been better informed about financial topics and, in particular, about risks.

Several challenges must be tackled by financial literacy, two of which are key. First, most people tend to believe they know more than they do about financial matters, and therefore they believe they do not need further knowledge in this domain. The focus here would be to convince this target audience that they need and would benefit from financial education, and then to design and effectively deliver that financial education. A more challenging task is to change the financial and economic behavior as a result of programs. Also of consequence is to improve the information available to individuals and improve their ability to understand this information, facilitating improvements in financial decision-making.

There has been intense debate around the efficacy of financial education programs. Some experts argue that the process ought to begin at childhood, while others claim that goals such as educating, raising awareness, and empowering large audiences are doomed to failure. To the latter group, offering technical information on finance would stop short of effectively helping people handle their money in a way that is more beneficial to themselves. Information might go as far as changing beliefs, values, attitudes and intentions—but not necessarily to changing behavior, with a great distance lying between intentions and actions.

With behavior quickly becoming the key element in the financial education agenda, economic psychology and behavioral economics have been called on to participate in this debate and in the design of programs and policies. Researchers in these disciplines, along with behavioral finance, with input from neuroeconomics, have been investigating economic behavior and decision-making for decades and have already accumulated a significant body of pertinent findings. Contrary to traditional economics, our choices and behavior are not always consistent; they can be strongly influenced by any of the following: mood, emotions, irrelevant details in the environment, the framing of information, excessive confidence and optimism, loss aversion, relatively heavy discounting of future income earlier in one's economic life cycle (hyperbolic discounting), poor or inaccurate information, and inadequate capabilities to process and understand available information. This results in errors in decision-making.

These decision-making characteristics need be recognized in the design of any financial literacy programs. Moreover, programs should be designed for each specific target audience. Testing strategies and programs with samples is ideal to further evaluate their efficacy before increasing their scale, with the researchers bearing in mind the decision-making insights from economic psychology and behavioral economics. Some scholars suggest using choice architecture and nudges, instead of expensive programs, to help people to make the choices they consider best. However, the researchers have trouble accomplishing it due to psychological and context limitations. Also recommended are improvements in the quality of the information that is made available to decision-makers.

FORD, HENRY

Born: July 30, 1863, in Dearborn, Michigan; Died: April 7, 1947, in Dearborn, Michigan; Nationality: American; Professional Interests: U.S. industrialist whose automobile manufacturing techniques included the assembly line, specialization, and division of labor.

Henry Ford had an innovative engineering mind even early in his career. He used this gift to perfect the assembly line and create a company that has stood the test of time. Another Ford contribution to the economy was strengthening the middle-class through higher wages. This increase in pay benefitted Ford's own company as well as others by mobilizing America.

Henry Ford was born on July 30, 1863, near Dearborn, Michigan. Raised on a successful farm, he was constantly intrigued not by the fields or horses of farm life but by watches, specifically the mechanism of a watch. When Henry was 13, he had his first exposure to a portable steam engine. The idea of a self-propelled object stuck with Ford for the rest of his life. This intense interest in machinery is what spurred him to live a life full of learning and perfecting. At age 33, he had become the chief engineer at the Illuminating Company, creating the Quadricycle. His Quadricycle was a fulfillment of his dream to build a machine that would move itself. By 1906, he started the Ford Motor Company.

Before the Ford Motor Company opened its doors, automobiles were made one at a time, which meant they were very expensive and only the wealthy could afford them. The Ford Motor Company did not invent the automobile, but it was the first to introduce an affordable car to the ordinary wage earner. The assembly line was just one factor that made Henry Ford's vehicles more accessible to a wider group of people. Ford's assembly line was a moving belt upon which a worker would complete a specific task as the body of a car came to him, resulting in increased production. The assembly line also required less-skilled workers. Thus, regardless of skill level, any person could be hired, given a specific task, and earn a decent wage with essentially no skills.

This sounded fine, but because the tasks were extremely repetitive they quickly became tiresome. Ford's solution was to create an irrefutable incentive for workers. He upped the pay to five dollars a day. This was more than double the average factory salary in 1914. People were now eager to work for Ford, despite the monotonous labor.

With an extremely efficient moving assembly line, and workers who were eager to do the job, Ford was able to produce 9,000 Model Ts a day. At the height of the Model T's production, a car was completed every 24 seconds. Ford focused on mass-producing this model, because he wanted his automobile to be affordable enough for his employees to be able to own one. He was once quoted as saying, "One's own employees ought to be one's own best customers."

This way of thinking was a huge change; with their increased wages, the working class grew. By increasing his workers' pay, in the end Ford made more money for himself: His workers could turn around and put the extra money they were making at the factory right back into the factory by purchasing their very own Tin Lizzy. The mass production of the Model T also drove the price down. In 1922, a person could purchase this vehicle for only $269 and have the same car as half of all other cars in the United States.

Henry Ford transformed the automobile and the automobile industry from a luxury good enjoyed only by the wealthy into an integral part of the American life. Ford was not the only one benefitting from his mobilization of America. Because they now had a means of easily transporting themselves longer distances, people spent more money at places they could travel to, such as restaurants or other businesses. This increase of consumer spending helped the economy further by creating a stronger tourist industry. People also needed fuel to fun their cars and roads on which to reach their destinations; the roads and gas stations needed to satisfy these needs created even more jobs.

Henry Ford left his mark on America by making it more mobile. He helped strengthen the middle class by paying livable wages that would benefit not only his company, but also the entire economy.

Henry Ford died from a stroke April 7, 1947, in Dearborn, Michigan.

FORECASTING AND MODELING

Forecasting is making a hypothetical claim about the future. It is a common human behavior that can be observed at every level of society. For example, a senior in high school may use job-growth statistics to determine which occupation to pursue. A firm may determine the level of production by forecasting the demand for its product. Political candidates forecast the outcome of an election based on polls and surveys. As such, forecasting varies in complexity. *Modeling* is simply a tool used to test or measure the forecast. Forecasting and modeling are important instruments that economists used to measure developments in an economy.

There are two different approaches to economic forecasting: quantitative and qualitative. However, both are used to predict or estimate events in the future. The rudimentary difference between quantitative forecasting and qualitative forecasting is the research method (the way in which data is measured) and data collection. Quantitative forecasting generates a predicted outcome based on historical, mathematical, and statistical data. For example, economists may quantify data to present the correlation between greater financial income and higher education. Qualitative forecasting generates a predicted outcome based on opinion, judgments, or expertise.

Before economists can engage in forecasting and develop an economic model, they are faced with two truisms. First, life is uncertain. Economists do not have the luxury of using a crystal ball to predict the future. Second, life is nonstationary: it changes over time. Individuals are constantly making decisions. These two points limit or constrain forecasting. As a result, economic forecasting is based on two key assumptions: representation and stability. The economic model should be an accurate characterization of the economy being measured, and the economic framework must be comparatively stable. The objective of every economic model is to have its outcome match its forecast. For an economist to make valid forecasts, the variables, math, economic models, and other collected data types used must be credible. In addition, the data must be closely measured. Otherwise, the forecast may be deemed inadequate and irrelevant.

Forecasting models are mainly generated in universities, financial institutions, government committees, and think tanks. There are a number of types of forecasting tools, including guessing, expert judgment, extrapolation, indicators, surveys, time series models, and econometrics. Additionally, economists use past relationships—such as consumer spending, household income, tax rates, interest rates, or employment—as variables. They then try to forecast how changes in some variables will affect the future course of others. A forecast tool widely used by economists is the time-series model. The *time series model* is a sequence of observations over time. Historical patterns are analyzed to forecast the future; the goal is to predict, within reason, how the sequence of observations will continue to behave. Examples of time series models are the price of a stock over successive days, a company's annual profits, and a department's quarterly sales.

G

GOLD RUSH BOOM AND BUST, 1848

The California Gold Rush saw a mania similar to that seen in bank panics, but it proved more deadly. The Gold Rush created a regional economic boom—featuring high inflation, acute shortages, crime, city fires, and disease—that would eventually burst with a regional bank panic.

On January 24, 1848, James Marshall discovered about 50 cents worth of gold near Coloma, California. This small nugget would eventually lead to the discovery of almost $970 million in gold. The rumors of a major gold find spread across the United States, but it was not until President James Polk announced the discovery in his inaugural speech that waves of would-be miners headed for California. Polk had hoped the gold found in California would replace the gold drained from the United States Treasury by the U.S. war with Mexico. The costs of the war had started to pull the country into recession, because banks lacked the gold reserves needed to expand credit. Polk also hoped to justify the cost of the Mexican–American War (1846–1848), which secured California for the United States, by the great gold resources mined from the new state. Some 85,000 "forty-niners" would rush to California in 1849, overwhelming cities such as San Francisco.

The Gold Rush of the late 1840s encouraged hopeful miners with their supplies to travel from the East Coast to San Francisco. Most ships took six to eight months to make the journey, but faster, more expensive clipper ships were the favorite mode of transportation. The clipper voyage took 90 days around Cape Horn, or about half the time of other vessels. At $300 (the equivalent of about $8,000 today), one-way travel for the 18,000-mile trip from the East Coast to San Francisco was not cheap. The other available transportation was by pack or wagon train, which was much cheaper but took six months. These trips cost about $200, which included the cost of a wagon and supplies. However, these trips had their own problems, such as major cholera outbreaks at wagon assembly points like St. Louis. In 1849, more than 1,500 people died of cholera in Sacramento alone.

The fastest (and most dangerous) way to travel to California was to take a ship to Panama, cross 30 miles of Panamanian jungle, and take a second ship to California. This cut 10,000 miles out of the trip around Cape Horn, but the cost was as much as $1,500, and thousands died in the jungles of Panama. Those who survived often brought disease with them to the cities of the West Coast.

As hopeful miners poured into California, prices on everyday necessities increased tenfold. Flour had to be shipped from the East Coast, where it cost $5 barrel; in California that same barrel of flour could cost as much as $50. The clipper business created an economic boom in New England and New York. Profits were so high that the investment that went into building a clipper ship was paid off in less than one year. The clipper trade in and out of California replaced the old triangular trade of the East Coast in profitability. Brandy, whiskey, and other agricultural products were shipped to China from San Francisco. Spices, coffee, and tea from the Far East were carried back to California and were welcome products for the mining camps. Clippers also brought Chinese laborers to San Francisco to help build the railroads and to provide cheap labor. Clippers also found a good business in moving the British to Australia and New Zealand and returning to California with much-needed lumber and wool.

Although some miners did strike it rich, most could barely meet their expenses because of the wild inflation in the prices of goods. Within a year, lumber went from four cents a board foot to more than a dollar. Wages for general work and construction labor soared from $1 a day to $20 a day; by comparison wages on the East Coast were around 50 cents a day. The high cost of labor fueled the use of cheaper Chinese laborers. Small building lots in San Francisco went from $30 to thousands of dollars in a few months. Rent for small rooms in large dorms went from $37 a week to $42 a week. Private mail companies charged as much as $16 a letter. A miner's pick cost $10, a simple shirt was $20, and eggs cost $10 a dozen. Miners put their underwear on ships to Hawaii, where it was cheaper to get it laundered.

The high prices in California and its gold fields spawned the rubber industry in New England, as rubberized clothing, belts, boats, pontoons, tents, and hoses were essential to the miners. The Union India Rubber Company was formed in New York with a factory in Naugatuck, Connecticut, to supply and equip thousands of forty-niners going west for gold. Clipper ships carried rubberized products to the miners of the West Coast, so ports in New York and New England became the logical locations to make rubber products. The Union India Rubber Company also established its own major retail stores in California to cater to these gold miners. Rubberized cloth for tents and blankets sold at high premiums.

Social problems soared in the main cities in California. One merchant made a fortune shipping in stray cats and selling them at $10 apiece to control rats. By 1852, merchants were selling goods at 20 times the East Coast prices. At mining camps, prices ran as high as the market would bear. Shortages of necessities were common. Saloons and gambling houses took the miners' money faster than they could mine or pan gold. New England rum sold for $20 a bottle, and a shot glass of cheap whiskey cost $1. Nativists and local politicians imposed a $20 tax on foreign and immigrant miners.

San Francisco's economy enjoyed the boom, but the city was regularly hit by major fires, and the destruction of city blocks was common. Oddly, the fires actually helped limit the deaths from cholera by destroying the breeding places for the disease. Crime was out of control, and the city lacked the police force do anything but watch. Neighborhoods formed their own vigilante groups to protect life and property. Lynchings were common.

By 1855, the great Gold Rush was over. The fields had been worked to the point that small miners could not even hope to pay their expenses. Merchants went bankrupt after becoming rich. Several banks failed. Many of the miners moved on to gold rushes in Nevada, Colorado, and Alaska. The mini boom–bust cycle would be repeated throughout the West over the next few decades. The end of the California Gold Rush brought an economic downturn in New England, as trade declined and merchants lost their most profitable business. In the emerging rubber industry, many companies went bankrupt, unable to find the needed profit margins in other markets.

GOLDEN RULE AND BEHAVIORAL ECONOMICS

One important finding in game theory is that rational or smart people with common knowledge and expectations of another individual's preferences will behave strategically such that a Prisoner's Dilemma outcome arises—the worst possible outcome for both individuals. In the original manifestation of this narrative, two individuals are arrested for a crime and interrogated in separated rooms. There is no communication between these two people. If no one confesses, both individuals are sent to prison for a short time, given the evidence. If both persons confess, they each receive a lengthy sentence. In one person confesses and the other does not, the silent one gets the shortest possible sentence or is released, while the other person gets the longest possible sentence. If the first person anticipates that the second person will confess, it is in the first person's interest to confess, because if the first person does not confess and the second person does, the first person will end up with the worst possible outcome. Rational strategic behavior results in the worst possible outcome given common knowledge of the other's behavior and no communication. Moreover, this Prisoner's Dilemma outcome is considered to be a stable equilibrium outcome.

This modeling can be imported into the realm of production. When groups of firm members such as workers and management are characterized by conflicting preferences, this can result in a Prisoner's Dilemma solution to the productivity problem yielding a minimal level of productivity and high level of X-inefficiency. If workers and managers maximize their efforts in a cooperative fashion, in the interest of the firm's productivity, firm productivity is maximized. This is sometimes referred to as the Golden Rule outcome. This occurs when workers and firm managers and owners treat each other as they each would want to be treated, bounded by the constraints of remaining competitive and earning normal profits. On the other hand, if workers and managers each minimize their effort inputs in a narrowly self-interested manner, hoping that the other party will maximize their effort inputs, one arrives at a Prisoner's Dilemma, with X-efficiency and productivity being minimized.

In this productivity narrative, unlike in the traditional Prisoner's Dilemma game, the different members of the firm can communicate with each other. But the Prisoner's Dilemma arises because the parties do not trust each other to maximize their effort inputs. Only joint effort maximization results in a Golden Rule productivity and X-efficient outcomes. In this narrative, economic incentives and behavioral norms and conventions determine whether a Prisoner's Dilemma outcome arises and to what extent it arises. Appropriate incentives and behavioral norms or conventions can resolve the Prisoner's Dilemma problem.

Unions, for example, can serve to enforce conventions that result in X-efficient behavior, providing workers with a trust mechanism in larger firms and providing managers with an efficient means to monitor and achieve X-efficiency among workers. Worker cooperatives have the same effect. So can norms of fairness and trust among firm members. Critical to achieving Golden Rule solutions are such incentives as higher wages and/or competitive pressures. If workers feel they are treated poorly, they will not produce X-efficiently. Also, if managers or firm owners see no benefit from increasing the level of X-efficiency—if all benefits accrue to workers—they might oppose the mechanisms that would achieve Golden Rule outcomes. It is possible for the Golden Rule option to generate the same benefits to managers and owners as the Prisoner's Dilemma option does. But even if managers and owners don't benefit from increasing X-efficiency in production, this Golden Rule can still be achieved if their preferences include improvements to the well-being of their employees or if higher wages are constraints that must be overcome, by increasing the level of X-efficiency for the firm to remain competitive. But in the absence of appropriate incentives, norms, and conventions, given the absence of trust among firm members or groups of members, a Prisoner's Dilemma is the natural consequence of strategic behavior among rational individuals.

GOMPERS, SAMUEL

Born: January 27, 1850, in London, England; Died: December 13, 1924, in San Antonio, Texas; Nationality: English, U.S. immigrant; Professional Interests: U.S. union organizer and leader, first president of American Federation of Labor (AFL).

Samuel Gompers was an English immigrant who led the labor reform movement in the late 1800s and early 1900s. He began as a cigar-making worker, and he worked his way up to being president of the American Federation of Labor. He fought and negotiated for the rights and welfare of American workers. During the First World War, Samuel Gompers was appointed to the Council of National Defense.

Samuel Gompers was born 1850 in London and raised in a Jewish family. Gompers quit school at the age of 10 and began working for his father as a cigar maker. After the family immigrated to New York City, he continued to work with his father in the cigar-making business. Finding work at a local cigar shop, he joined United Cigar Makers Local 15. In his new job, he was introduced to a group of socialist and labor reformers. Samuel Gompers was elected president of Cigar Makers' International Union Local 144 at the young age 25.

Gompers was an influential leader, and he gained the trust of many of his fellow workers. He was a leader in the creation of a new union—the Federation of Organized Trades and Labor Union (FOTLU)—which later became known as the American Federation of Labor (AFL). For his trust and leadership, Samuel Gompers was elected the AFL's first president.

As president of the AFL, Gompers continually fought to strengthen the power of the labor unions and improve the reform movement in order to increase the prestige of his fellow union members. Gompers' interests in upgrading union prestige extended beyond economic status. He wanted the AFL to have political status as well, but not at the expense of economic reform. Economic reform and member rights for the workers were always at the front and center of his platform.

Samuel Gompers continued to fight for workers' rights. One issue he worked hard for can be seen in the nationwide strike that took place on May 1, 1886. The main issue of the strike was to shorten the workday to eight hours.

Notably, not all workers were in favor of the union. While the pro-union movement continued to grow, an anti-union movement was also on the rise.

As the union continued to rise in power and prestige, Gompers retained his position as its president, serving for almost 40 years (the longest term of any AFL president).

Gompers became an adviser in the administration of President Woodrow Wilson. He was appointed to the Council of National Defense, where he played a key role in mobilizing the labor support for World War I. He was instrumental in the creation of the International Labor Organization (ILO) at the Versailles Peace Conference. Samuel Gompers was one of the most influential leaders in the early labor reform movement.

Samuel Gompers passed away on December 13, 1924, in San Antonio, Texas.

THE GREAT DEPRESSION AND WALL STREET CRASH, 1929

Although the stock market crash of 1929 did not cause the Great Depression that followed, it was the end of a bubble and the end of economic expansion. When the stock market crashed, its value dropped more than 50 percent. The depression that followed would bring years of unemployment and hard times. Unemployment became a way of life for as many as 25 percent of the American workforce. Gross national product dropped by 30 percent, and industrial production dropped by 40 percent. The nation's steel mills worked just two to three days per week for years. Corporate investment was negative, and capital investment was below the level of depreciation. Unemployment from 1929 to 1941 was higher than 10 percent, and underemployment was as high as 50 percent. The estimated number of homeless people in New York City alone was 15,000. The number of homeless people in the nation was estimated at more than two million. The Depression also exhibited a double dip, returning in 1937 after some improvement. The Great Depression was also a truly global depression, which prolonged the slow pace of the recovery.

The U.S. stock market had been building a speculative bubble on the back of a booming economy. The beginning of 1929 saw a nation in a boom economy with a record gross national product. Unemployment averaged a mere 3 percent. In 1929, car production was double the 1923 level. Real income per capita had reached new highs, and newspapers were filled with stories of excessive spending. Speculation was also at an all-time high. Margin leveraged accounts for stock trading were at record highs as well. To facilitate investment, the Federal Reserve, for years, had been following a strategy of easy money. Consumer credit was rising dramatically because cars and mass-produced goods were in high demand. Interest rates for stock margin accounts were moving higher, however, reaching more than 20 percent. Just as during the Mississippi bubble of 1719, many small investors rushed in at the end of the investment bubble, hoping to make millions by speculating on stocks that were selling at over 30 times earnings. Economists at the Federal Reverse were very concerned.

On September 3, 1929, the Dow Jones industrial average hit a record high of 381. The Federal Reserve had issued warnings against overspeculation and had started to tighten the money supply. Unfortunately, the New York Federal Reserve broke ranks, injecting massive amounts of cash for margin stock accounts. (This type of rogue behavior would be addressed after the Depression.) The availability of call money for margin stock accounts made big investors overconfident about the stock market's setbacks in September 1929 and pushed the bubble to the breaking point.

The stock market started to show true signs of instability in October 1929. On Black Thursday, October 24, the market moved lower on record volume with 13 million shares traded. The biggest and mostly widely traded companies lost an average of more than 10 percent, triggering the first wave of calls on margin loans. The U.S. president and major industrialists jumped in with positive public statements to try to calm the markets. Then on Black Tuesday, October 29, 1929, the market fell to 40 percent of its high a month earlier. As banks recalled loans, panic set in, and the great stock market crash entered into American legend. The Federal Reserve, business leaders, and politicians made the right moves to stop the economy from going over the cliff.

The stock market crash resulted in more than $2.2 billion being called on stock loans. Stock market losses put many people in desperate financial positions. The crash was not directly followed by a depression, but it did signal the end of a huge expansion and bubble in the economy. By the end of 1930 and into 1931, bank failures, panics, and runs started, with the now-famous lines of panicked depositors. Bank failures were 659 in 1929, 1,350 in 1930, and 2,293 in 1931. The banking problems spread in 1931, with a doubling of bank failures and mortgage bankruptcies. By 1933, 11,000 of America's 25,000 banks had failed.

The money crisis soon spread to other parts of the economy. The building of new homes dropped by 80 percent. Deflation rapidly lowered food prices and reduced grain prices, which hurt farmers. Farm prices dropped 40 percent from the 1926 high. Factories cut back to a schedule of two to three days a week, effectively cutting wages 50 percent. The government tried to pour money into the economy to create demand. Social problems started to mount, as unemployment hit 17 percent in 1931; ultimately it would peak at over 25 percent of all workers and 37 percent for non-farm workers. Even these estimated unemployment rates understated the panic, as most Americans were working short weeks. The unemployed clustered on the outer borders of major cities in boxes, tents, and shacks known as "Hoovervilles." President Hoover, who left office in 1933, was justifiably blamed for his failure to properly manage the U.S. economy. As the crisis spread across the world, countries raised tariffs to protect domestic production. Still, it was not the American tariff rates so much as a rush by all countries to protect their home markets that caused the Depression to deepen. The combination of deflation, low farm prices, and tariffs cut imports 40 percent. In 1932, as the Dow hit 95, the United States looked for a political solution with the election of Franklin Roosevelt and the progressive Democrats.

In 1933, Roosevelt imposed a bank holiday to stop panics and build new confidence in the banking system. More dramatic was the creation of the National Recovery Administration (NRA), which had sweeping powers to control wages and prices. The NRA created a national industry, similar to what Stalin implemented in Russia. From 1933 to 1934, Roosevelt tried a long array of approaches: moving off and on the gold standard, credit regulation, mortgage aid, work projects, trade laws, reduced tariffs, increased taxes, new banking regulations, and expanded credit programs. The government looked to put people to work. The NRA would be found unconstitutional in 1935, but while it was in effect it stabilized unemployment and restored some confidence. The Dow moved up from a low of 58. The Civilian Conservation Corps hired more than 250,000 young men and prevented social unrest during the worst of the Depression. In 1935, the New Deal Democrats, looking for a long-term social safety net, enacted the Social Security program. The National Labor Relations Act of 1935 allowed the unionization of the steel, rubber, and automotive industries and widespread collective bargaining. Economic improvement came, only to fall back in 1937.

The Depression changed the American psyche and economic thinking even to the present day. Despite the Depression, however, Americans remained patriotic and supported the government, whereas the poor economic conditions brought growing social unrest throughout Europe. The American family unit was key to America's weathering of the Depression. John Maynard Keynes's economic approach, which emphasized government spending and consumers, became the dominant approach to managing the economy before and during the Depression. Tariff policy would be changed after centuries of tariff protection because of the fear of trade wars.

The Depression also initiated a decade of social and economic legislation to build a safety net. Banking laws were strengthened to protect consumers, and the union movement was strengthened to help workers. Congress passed the Smoot-Hawley Tariff Act in June 1930, creating historic tariff rates at around 30 percent overall. Other countries also imposed tariffs in an effort to save domestic production, but the decline was well underway. Years later, however, many pointed to tariffs as a problem and used this theory to advance free-trade policies after World War II. An endless array of laws was implemented to address the causes and effects of the Depression, including stock market controls. Some of these have proved to be helpful, while others have been very costly to the economy. The analysis of the Great Depression and its causes and effects continues to this day. There is no question that it affected the psyche of Americans for decades.

In August 14, 1935, President Roosevelt signed the Social Security Act, which was a social insurance designed to pay retired workers age 65 or older a continuing income after retirement. Originally it was planned not to be a full retirement fund but to maintain income above poverty levels. In 1937, Social Security payroll taxes were 1 percent for the employer and 1 percent for the employee. Payroll deductions were mandated under the Federal Insurance Contribution Act (FICA). Today Social Security stands as the largest government program in the world and the single greatest expenditure in the U.S. federal budget. In 2009, more than 51 million Americans received more than $650 billion in Social Security payments.

GREAT MIGRATION

The Great Migration was the movement of African Americans from the South to the Midwest, West, and Northeast in the 20th century. Caused by economic and legal factors, the migration resulted in over six million African Americans leaving the South between 1916 and 1970. The shift brought many of these people from rural areas to cities, leading to overcrowding and housing shortages and to the development of an urban African American culture. The movement vastly increased racial tension as an increasing number of blacks and whites lived in close proximity to each other.

Economic conditions initiated the migration. African Americans often were uneducated and held unskilled and agricultural jobs. As mechanization of farm labor progressed, a significant number of these jobs were eliminated, forcing workers to find new occupations. Many traveled to other regions of the United States, where they found work in the industrial sectors.

While these economic conditions initiated the movement, legal factors amplified the scale of the migration. Jim Crow laws in the South were much more discriminatory than those in the North. Though prejudice and inferior treatment of African Americans were still present in the North, they were not as rampant as in the South. Many African Americans sought the less threatening North.

As the Great Migration progressed, millions of African Americans came from all across the South, generally settling in concentrated numbers in a few large cities. This change led to widespread housing shortages, amplified by the fact that most of these migrants could afford to live only in poor neighborhoods. Eventually, neighborhoods such as Harlem, which initially attracted African Americans, become centers of black culture. Harlem's renaissance of poetry, song, dance, and art allowed African American self-expression to blossom.

Another effect of the Great Migration was an increase in racial tension. About 90 percent of African Americans lived in the South before the movement, and less than 50 percent lived there afterward. This rapid increase in contact between blacks and whites led to multiple race riots, often in large cities. As the African American population in the North increased, so did the activities of the Ku Klux Klan.

In recent years, the Great Migration's effects on the concentration of African Americans in the United States have begun to reverse. Today more than 50 percent of African Americans live in the South—many of them in larger cities rather than in rural areas as was common before the Great Migration. In particular, in the late 1990s many African Americans with college degrees began moving to Southern cities.

GREEN NATIONAL ACCOUNTING

Current interest in green national accounting has its modern roots in the 1980s, when economists Michael Ward at the Organisation for Economic Co-operation and Development (OECD), Salahi El Serafy at the World Bank, and Robert Repetto at the World Resources Institute reflected on the future prospects for a nation, such as Kuwait, living on depleting natural capital (for a nation such as Kuwait, that capital was oil). Their thinking was that when the oil or other important stock of natural capital runs out, the nation will have become relatively poor, and this prospect should somehow be registered in its current measure of well-being. Current measures of national income, such a net national product (NNP), were failing to take into account large and inevitable future declines. The current NNP was somehow too large. The thinking was that there should be a depletion charge in current NNP to indicate that the productive base of the nation was being eroded year by year, since the capital stock was being drawn down year by year. A depletion charge in NNP would indicate that traditional NNP was unrealistically large. In short, greening the measure of national product for a nation would register changes in stock sizes, particularly drawdowns, of significant natural capital in a nation's national income.

This way of thinking about national accounting is sensible, and one could ask why thinking about adjustments for the current depletion in natural capital emerged only in the 1980s. Modern national accounting was developed in the 1930s in the United States and United the Kingdom, nations that were taken to be largely industrial, with fringes of agricultural activity and smaller fringes of mineral extraction. The treatment of mineral extraction in a national accounting framework was left to be handled in something of a back-of-the-envelope fashion. The size of the mineral extraction sector in, say, NNP was measured simply by the dollar value of its annual product. The depletion-of-stocks issue was left dangling. This is appropriate, of course, when the values of depletions are small relative to current NNP, but it is not a reasonable procedure when the values of depletions are large relative to current NNP—as is the case with Kuwait, a nation that is essentially living on the earnings from its annual oil exports.

Another dimension of greening the national accounts is incorporating adjustments for externalities—such as pollution in its many forms or excess entry to a fishing ground. Since the measurement of these externalities is so difficult, procedures for carrying out the adjustments have not been standardized. We will leave this class of adjustments aside here and focus our attention on adjustments for depletion of natural capital (disinvestments in natural capital).

Measuring depletions of natural capital in the national accounts is complicated by the fact that, for example, the cost of extracting a ton of oil from one deposit generally is different than the cost of extracting a ton from another deposit. The difference between market price and extraction cost is referred to as "rent per ton." Such rents include a dollar value for scarcity rent (user cost or Hotelling rent) as well as a dollar value for quality rent (Ricardian rent). A marginal ton from a deposit with high extraction costs will typically have only scarcity rent, while another ton (intramarginal) from a better-quality deposit will have the same scarcity rent plus some quality rent. Formal analysis suggests that scarcity rent captures the value of current depletion. However, simply summing up rents for each ton plus all other tons currently extracted generally overestimates the value of depletion, the dollar value we wish to use in adjusting for currently using up natural capital. To measure current aggregate depletion of oil, we want the rent on the marginal ton multiplied by aggregate quantity extracted over the year. In addition, though current oil extraction is a depletion activity, much activity goes on each year in adding new stock to the current known stock via exploration. The addition to new reserves represents gross investment (reverse depletion, so to speak) in natural capital, and the value of these additions to stock must be entered into the current depletion value as rent multiplied by quantity, with an opposite sign. Hence, adjustments for changes in the current value of natural capital can involve entries for investment in natural capital as well as disinvestment.

The sum of dollar values of natural capital is a nation's natural wealth and is typically more difficult to estimate than annual changes in the values of components of national natural wealth. The annual changes (investments and disinvestments) often have realizations in the marketplace and can, roughly speaking, be estimated directly, whereas the estimation of the values of stocks themselves usually involves numerous guesstimates.

H

HABITS

In ordinary parlance, *habit* can refer to repeated behavior. But scientific researchers most often treat habits as learned dispositions to behave in a particular way in response to a trigger or stimulus. Habits are formed through repetition of action or thought, and they have durable, self-sustaining qualities. Habits are the basis of both reflective and nonreflective behavior. They are economizers of scarce mental resources. If we had to deliberate fully upon everything, then our reasoning would be paralyzed by the weight of data. Habits overcome this problem.

The concept of habit was developed in particular depth by a linked group of "pragmatist" American thinkers in philosophy, psychology and economics, including William James, Thorstein Veblen, and John Dewey. A similar interpretation of habit as a disposition is found in the work of such contemporary psychologists as Wendy Wood and Ann Graybiel.

By contrast, *instincts* are biologically inherited reflexes, feelings, or dispositions that can be triggered by specific cues. Like habits, expressions of instincts can often be suppressed or diverted. The importance of socialization does not deny the necessary role of instinct. Instincts are necessary in order for socialization and habit to begin their work.

Habits are vital to all thought and behavior. Rational deliberation relies on habits. In turn, instinct is prior to habit, habit is prior to belief, and belief is prior to reason. That is the order in which they have evolved in our human ancestry over millions of years. That too is the order in which they appear in the ontogenetic development of each human individual. That too is the order in which they are arranged in a hierarchy of functional dependence, where the operation of reason depends upon belief, belief depends upon habit, and habit depends upon instinct. The lower elements are necessary but insufficient for the higher.

As Charles Darwin noted, human rational capacities are built on subconscious mechanisms inherited from our prehuman ancestors. We retain instincts and unconscious mental processes that can function apart from our conscious reasoning. As some animal species developed more complex instincts, they eventually acquired the capacity to register reinforced behaviors through the evolution of mechanisms of habituation. In turn, upon these mechanisms, humans built culture and language. Our layered mind, with its unconscious lower strata, maps our long evolution from less deliberative organisms. But when the human species evolved its capacity to reason, its dependence on instinct and habit did not decline.

Much social science takes it for granted—or by definition—that "action" is motivated exclusively by reasons based on beliefs. However, modern psychologies as well as the Darwinian evolutionary outlook undermine this proposition. Experiments show that conscious sensations are reported about half a second after neural events, and unconscious brain processes are discernible before any conscious decision to act (Libet 2004). This evidence suggests that our dispositions are triggered before our actions are rationalized: that is, we contrive reasons for actions already under way. It undermines the approach of explaining human action wholly in terms of reasons and beliefs.

But the "folk psychology" (Stich 1983) that beliefs are the source of intentions, choices, and actions still dominates social science. These "mind-first" explanations of human behavior are unable to explain adequately such phenomena as sleep, memory, learning, and mental illness, or the effects of chemicals or drugs on our perceptions or actions. Mind-first conceptions erect an unsustainable dualism or discontinuity between the mental and physical worlds, which is inconsistent with the fact of human evolution. Humans do act for reasons. But reasons and beliefs themselves are caused, and have to be explained.

A habit-based perspective implies neither stasis nor lack of choice. As Dewey explained, because of our engagement with diverse and changing contexts, we develop different habits of thought and action that sometimes come into conflict with one another. Such conflicts are opportunities for choice and change. Habit does not deny choice. On the contrary, the conflicting rigidities of different habits make choice inevitable.

Pragmatist and habit-based approaches can overcome the Cartesian dualism of body and mind, which still pervades the social sciences. Against dualism, intellect is not regarded as an independent and ungrounded causal power, but as an emergent and active property of already-engaged dispositions and unfolding actions. The reality and importance of human intentionality and creativity are reconciled with the Darwinian evolutionary legacy (Bunge 1980).

Once habit is seen as the foundation of preferences or beliefs, we can develop an enriched understanding of the interaction between individuals and institutions. Emergent institutions guide individual behavior. Individuals develop and reinforce habits consistent with that behavior, upon which revised beliefs and preferences transpire. These revised beliefs or preferences lead to further actions and form more habits, which may affect institutions, and so on. This gives us two-way mechanisms of reconstitute interaction, from individuals to institutions and back to individuals (Hodgson 2004, 2010).

The implications for social theory are profound, including a transcendence of the old debate between "bottom up" (methodological individualist) and "top down" (methodological collectivist) modes of explanation. In a fully fledged evolutionary view, causal influences have to be acknowledged in both directions. From such a perspective, we have to understand how individuals are affected by social structures, as well as how individuals constitute structures. Habit is a crucial mechanism in both cases.

HAMILTON, ALEXANDER

Born: January 11, 1755, in British West Indies; Died: July 12, 1804, in New York City; Nationality: American; Professional Interests: founding father of the United States of America; first U.S. Secretary of the Treasury.

Alexander Hamilton was a founding father of the United States. He lived from January 11, 1755, to July 12, 1804. He was born and raised in the British West Indies. His father was a Scottish trader; his mother, a Frenchwoman, was married to another man when Alexander was born. This man had cast her out for adultery, and Alexander's true father left them when he was an infant.

When Alexander was 11 years old, he went to work at a counting house. The owner was so impressed with his work that he sent the young Alexander to study in America. When he turned 16, Hamilton joined the King's college later known as Columbia. When he finished his studies, he joined the military and fought for the colonies in many battles along the East Coast. Proving great prowess in battle, he was promoted to the rank of lieutenant colonel in the army and attracted the attention of General George Washington.

He eventually became Washington's personal assistant and did much work for him. Bored with the menial tasks of a personal assistant, he went into battle one last time and was victorious at the Battle of Yorktown. When the war ended, he went back to being George Washington's assistant. During this time he realized some flaws in the legal system of the new nation. He believed the new government's

Articles of Confederation did more separating than unifying. After leaving his assistant job, he went on to study law and establish his own practice. Known as a Federalist, he advocated for a new constitution to replace the Articles.

Alexander Hamilton became our country's very first secretary of the Treasury. He constantly debated with Thomas Jefferson regarding the level of power that should be wielded by the Department of the Treasury. Hamilton focused on the dispersing of newly printed money and the growth of the economy. He took on the challenge of trying to get the new nation out of debt. An unexpected result was that he won the respect of the American people and of other foreign nations. He also planned out and created the first national bank in the United States in order to distribute the newly printed currency and assist the government with its financial transactions.

In New York City, on July 12, 1804, Alexander Hamilton was shot and killed in a duel with his political adversary Aaron Burr.

HAYEK, FRIEDRICH VON

Born: May 8, 1899, in Vienna, Austria; Died: March 23, 1992, in Freiburg, Germany; Nationality: Austrian, naturalized English citizen; Professional Interests: economic theorist, trade cycle theory, monetary theory, credit policy, Nobel Prize (1974); Major Works: *Profits, Interest and Investment* (1939), *The Pure Theory of Capital* (1941), *The Road to Serfdom* (1944), *The Constitution of Liberty* (1960).

Friedrich von Hayek was one of the most influential economists of the 20th century. He not only made many important theoretical contributions in his field; he blazed new paths in political theory, history, philosophy, and theoretical psychology as well. He accepted the Nobel Prize in Economics in 1974 for his penetrating work during the 1920s and 1930s in the area of business and trade cycle theory and the effects of monetary and credit policy. Hayek's prodigious output and legacy have helped to revived interest in and respect for Austrian and neo-Austrian economics. Hayek died in 1992.

Friedrich August von Hayek was born May 8, 1899, in Vienna, Austria, the eldest of three sons of August and Felicitas von Hayek. Not only was Hayek's father a medical doctor and later a professor of botany at the University of Vienna, but his brothers Heinz and Erich became professors as well—of anatomy and chemistry, respectively. In 1917, at the age of 19, Hayek served in an Austro-Hungarian artillery battery on the Italian front during World War I. After the war, Hayek entered the University of Vienna, receiving his doctorate in law in 1921 and a second doctorate in political economy in 1923.

At university, Hayek attended the *Privatseminars* of Ludwig von Mises; this later led to the two men developing a lifelong friendship and association. After attending New York University in 1923–1924 as a postgraduate research student, Hayek returned to Vienna and joined Mises as a legal consultant at the temporary *Abrechnungsamt*, or Office of Accounts. In 1927, they founded the Austrian Institute for Business Cycle Research in Vienna, with Hayek as its first director. In 1928, invited to a London Conference on Economic Statistics, Hayek met John Maynard Keynes for the first time. The two men would later become friends, as well as fierce intellectual critics of each other's economic positions.

In 1929, Hayek was appointed to his first academic post as a *privatdozent* in economics and statistics at the University of Vienna. That same year he wrote his first book, titled *Geldtheorie und Konjunkturtheorie*; it was published in 1933 in English as *Monetary Theory and the Trade Cycle*. Seeing a connection between business cycles and capital and monetary theory, Hayek saw the market as an unplanned, spontaneous order that coordinates the activities of all factors of production. Lionel Robbins invited Hayek to speak at the London School of Economics in 1931, leading to Hayek's publication of *Prices and Production*, which explained in greater detail his theory of *under-consumption*. Artificial increases in the money supply by central banks led Hayek to conclude that distortions between short- and long-term interest rates could create only "mal-investment." In that same year, Hayek assumed the Tooke Chair as professor of economic science at the London School of Economics, a position that he held for 19 years.

Between 1931 and 1937, Hayek was engaged in a number of anti-Keynesian critiques and essays, culminating in his 1938 work titled *Collectivist Planning: Critical Studies on the Possibilities of Socialism*. However, he never planned nor waged a full-scale refutation of Keynes's *General Theory of Employment, Interest and Money,* something he regretted later in life. In 1938 he became a naturalized British citizen. During these years his most significant works included *Profits, Interest and Investment* (1939); *The Pure Theory of Capital* (1941), which delved into the complex nature of capital as it relates to economic booms and slumps; *The Road to Serfdom* (1944); and *Individualism and Economic Order* (1948).

There was no work that took Hayek and the publishing industry more by surprise than *The Road to Serfdom*. Its unlikely success put Hayek back into the spotlight, warning his readers how the "ideal" of planning that was popular in Great Britain at the time could quickly turn into a totalitarian nightmare. Originally intended for a British audience, the *Reader's Digest Condensed* version gained him an audience in the United States and established him as the world's most celebrated classical liberal economist. In 1947, following the devastation of World War II, Hayek was anxious to revive classical liberalism in Europe. He convened the first meeting of like intellectuals at Mont Pelerin in the Swiss Alps. The organization that developed later became known as the Mont Pelerin Society.

In 1950, Hayek was appointed professor of social and moral science and member of the Committee on Social Thought at the University of Chicago. Over the next 12 years, Hayek produced some of his best and most diverse writings. These included *John Stuart Mill and Harriet Taylor: Their Friendship and Subsequent Marriage* (1951); *The Counter-Revolution of Science: Studies on the Abuse of Reason* and *The Sensory Order* (1952); *Capitalism and the Historians* (1954); and *The Constitution of Liberty* (1960), published on the 100th anniversary of the publication of John Stuart Mill's *On Liberty.* In this work, Hayek developed his view of the proper role of government, and his famous essay, "Why I Am Not a Conservative," was placed in the postscript.

In 1962, after 31 years away from his native Austria, Hayek left the University of Chicago and assumed a professorship at Freiburg University. In 1967, he published *Studies in Philosophy, Politics, and Economics*, which he dedicated to the philosopher Karl Popper. This work, unlike earlier studies, highlighted Hayek's outstanding breadth of intellectual knowledge. Although fighting ill health and irrelevance, Hayek published the first volume of his trilogy *Law, Legislation and Liberty: Rules of Order* in 1973.

In 1974, reinvigorated after being awarded, along with Swedish economist Gunnar Myrdal, the Nobel Prize, he completed the final two volumes of *Law, Legislation and Liberty,* subtitled *The Mirage of Social Justice* (1976) and *The Political Order of a Free People* (1979). By the late 1970s, as inflation ravaged the industrialized world and standard Keynesian prescriptions appeared to be ineffective, Hayek again found himself in great demand, speaking extensively about free-market solutions to audiences at packed lecture halls throughout the world. Approaching the age of 90, Hayek wrote his final book, titled *The Fatal Conceit: The Errors of Socialism* (1988). This strong critique of socialism would nearly coincide with the dissolution in 1989 of the former Soviet superstructure that was based on a collectivist foundation.

Friedrich von Hayek died on March 23, 1992, in Freiburg, Germany, at the age of 93.

HEALTH ECONOMICS

Health economics is concerned with the study of the allocation of resources to maintain and improve the health of individuals. This often includes the study of markets for health care services and health insurance as well as the role of government intervention in these markets. Since Kenneth Arrow's seminal paper on the economics of medical care (Arrow 1963), much of the analytical effort has been devoted to the market for health care services and health insurance, and this literature has paid a lot of attention to the peculiar characteristics of health care highlighted by Arrow. Comparatively less attention has been paid to the production and maintenance of health by individuals. Much of the analysis has taken a neoclassical approach, with health modelled as a capital stock yielding consumption utility, and income (Grossman 1972). While this is a useful modelling simplification, it essentially ignores the biology of human health—and the behavioral implications that follow from it. A careful examination of these, in the way Arrow disentangled health care, is a far more fruitful way of modelling health behavior than is a blind application of constrained optimization models to yet another dimension of human behavior.

All aspects of resource allocation to health are influenced by four features of health. The first and foremost is the centrality of health to human existence. No other aspect of a person's life is more critical than preservation of life itself. Even in a modern world of relative abundance, we remain concerned about threats to survival from hunger and germs, for example, and we've developed biological and psychological mechanisms to counter these threats. At an individual level, these threats influence the way we manage our health, and at a group level they influence our social and market interactions via (1) behavioral norms related empathy, trust, and fairness; (2) nonmarket institutions, such as the Hippocratic oath taken by doctors; (3) the centrality of emergency departments in hospitals; and (4) the public and charitable funding of ambulance services and rescue squads.

A second feature that requires attention is the paucity of information on health. As managers of our own health, we know very little about the status and functioning of our own biology. All we have to go on is observable markers (such as change in appearance or pain) and periodic measurements of biomarkers. It is changes in these that alert us to deviations from normality, and these—observable, nonclinical markers in particular—may not be very reliable indicators of what is really going on inside the body. In effect, there is an informational veil on the true status and functioning of our biology. Compounding this informational problem is the fact that while our biology is similar to that of other human beings, it is still individually unique and continuously changing. If our own health is essentially a black box, there is no reason to believe that we can allocate resources to health in an individually optimized way.

Physicians and health care providers know much more about human biology and medicine, and as a result there is asymmetry of information between patients and health care providers. This is well recognized in the health economics literature, and several studies have examined the implications of this in terms of the potential for physicians inducing the (unnecessary) use of health care services. Less appreciated is the fact that even a physician does not fully observe the details of a particular patient's biology, and the physician must base diagnosis and treatment on the limited set of information provided by the patient during presentation, patient history, previous clinical information, and current diagnostic data. None of these—individually, or even together—provide a complete picture of a patient's current condition or, more disconcertingly, the etiology of the presenting condition. As a result, diagnosis is typically algorithmic and experience-based; and except for surgery, treatment is often "average" treatment, conditional on what is known about the patient's condition.

The third feature is uncertainty with respect to the occurrence and severity of ailments and the effectiveness of treatments. Arrow (1963) highlights the role of uncertainty in health care markets and its implications for health insurance. Much of this uncertainty derives from the organic nature of the human body, and the organic environment within which it operates; downturns in the body's functioning can be entirely internal and due to wear and tear, but they can also be due to interaction with an environment full of microscopic organisms. It is important to distinguish between irreducible uncertainty, which is purely due to chance, and reducible uncertainty, which derives from lack of information. While advances in biological and medical knowledge and associated changes in medical practices (hand washing, sterilization, etc.) have greatly lowered the reducible uncertainty, some element of uncertainty remains.

A final feature is agency, or control over decision-making. As noted earlier, in a patient–physician interaction, there is asymmetry of information, and the patient transfers agency to the physician—expecting the physician to act in the patient's best interest. This is not very different from the transfer of agency that occurs in various service sectors, such as a car repair, where the mechanic knows more than the car owner and can use this power to increase the purchase of services. What differentiates the health care market from other markets is the fact that the service transacted (health care) is directly, or indirectly, linked to the patient's likelihood of survival. This adds a sense of urgency, which, along with the experience of pain and emotions such as fear, can imply substantial deviations from rational decision-making. Variations in health care systems—in particular, the extent to which they attempt to minimize such conflict of interests—attest to the critical role played by agency.

These four features—survival, information, uncertainty, and agency—yield a resource allocation problem that is truly unique and unlike any other human behavior. Not only do choices have to be made on allocating resources between health and other options, but also these necessarily have to be done with incomplete information about their appropriateness, and with the knowledge that more or less information may be needed at any point in the future. This would be difficult in itself, but then people must also rely on the judgement of others, who know more, but not everything relevant to a condition, and who also have their own interests to look after, but whose decisions are directly concerned with human survival itself.

HOBBES, THOMAS

Born: April 5, 1588, in Wiltshire, England; Died: December 4, 1679, in Hardwick, England; Nationality: English; Professional Interests: political economy, social contract theory; Major Work: *Leviathan* (1651).

Thomas Hobbes is best known as a political philosopher whose views on government would influence both the monarchy in England and the democracy of the United States. His role in economics is characterized as ranging from overly minimal to being the "father of political economy." While he never wrote specifically on economics, his view of man's relationship to his country and the country's role in promoting society opened up a world of connections to economic issues. Hobbes died in 1679.

Thomas Hobbes was born on April 5, 1588, in Wiltshire, England. His father was a vicar, but it was mostly support from his uncle that enabled him to enter Oxford at age 14. He studied scholastic logic and physics, graduating with a bachelor of arts in 1607. He served as a tutor for the wealthy Cavendish family, which allowed him to travel around England and throughout Europe. His service as tutor to the Cavendish family and, later, to other well-to-do families opened up doors of opportunity for him to study and formulate his own philosophy.

Hobbes was influenced by several people while working as a tutor. He was an acquaintance of Francis Bacon, who had an influence on Hobbes's pessimistic view that knowledge meant power. Hobbes was also fascinated by the mathematical field of geometry, seeing the proofs as groundwork for his later methods of philosophy. The idea of linking geometrical proofs with natural philosophy was proposed to Hobbes by Galileo in 1636.

Hobbes began his writing on political topics during the period in English history that featured much turmoil over the role of the king and Parliament. His writings mostly favored the king and were against democracy. To explain his stance against democracy was a major purpose of his translation of Thucydides in 1628. In 1640, he published *Elements of Law, Natural and Politic,* which angered many in England because it supported the authority of the king, causing Hobbes to flee to Europe. He wrote *De Cive* in 1642 in Europe on the theme of the church–state relationship.

Hobbes's most famous work, *Leviathan,* was published in 1651 while he was in exile during the English Civil War. While almost half of *Leviathan* was about religion, it did give new insight into the idea of social contract theory and absolute government. According to Hobbes, the idea of a social contract as presented in *Leviathan* deals with the twin issues of power and death. Because men fear death, they are willing to give up power to a government in order to secure their life. In this kind of situation the leader must be absolute, but the government can take on multiple forms of structure. Therefore, a democracy run by the people and an absolute monarchy can both be examples of a social contract, so long as they provide order.

Following *Leviathan,* Hobbes continued working out his philosophical ideas through a planned trilogy that dealt with the body (*De Corpore,* published 1655), man (*De Homine,* published 1657), and a more complete explanation of his thoughts on politics (which was never published). The first work of the trilogy was met with great criticism as Hobbes unsuccessfully attempted to square the circle.

De Homine ended up being his last philosophical book published while he was alive, because of controversy surrounding a book he published in 1656: *Questions Concerning Liberty, Necessity, and Chance* dealt with religious issues over free will in man, and it led to many debates with both religious and secular scholars. His *Leviathan* was condemned in the House of Commons in 1666 and was almost condemned by the House of Lords as well. He was forbidden to publish more philosophical literature from then on.

Hobbes did not write explicitly on economics, but the potential for economic application was present in his writing. Hobbes has been credited with influencing Adam Smith and other economic philosophers such as the Physiocrats and Bernard Mandeville. He wrote eloquently about the power of human free will to accomplish its goals. His emphasis on the self-interest inherent in men led other thinkers to expand on the role self-interest plays in economics. Despite Adam Smith's emphasis on free markets and Hobbes's emphasis on the importance of the state, both would agree that the state's main role was for ensure peace and provide common defense, which would allow for something of a free-market system in Hobbes' work.

Toward the end of his life, Hobbes was relegated either to writing works that would not be published until after his death or to writing nonphilosophical works. He wrote his autobiography in Latin verse in 1672, and he produced a new translation of Homer's *Iliad* and *Odyssey* in English rhyme in 1674. He wrote a history of the English Civil War, *Behemoth,* in 1668, but it would not be published until 1682, after his death.

Thomas Hobbes died on December 4, 1679, in Hartwick, England.

HUMAN CAPITAL

Human capital is the idea that intelligence and skillfulness makes a human beneficial. *Human capital* is also the concept that people or workers are a type of asset just like other types of capital. This implies that companies and even countries can invest in people just as they invest in other types of capital.

Early Human Capital Ideas

The United States of America at the start of the 1900s first saw expressed the notion that a country's people exemplify its prosperity. Near the conclusion of the 1900s, the world acknowledged that academia is important for technology implementation as well as economic expansion. The debate on whether people can or cannot be seen as capital continues to thrive, and the focus is changing from physical aspects to human features. As research and theories continue to evolve, some questions may rear their strange heads. Perhaps businesses have overlooked or underestimated the power of human capital, and with contemporary exposure human capital may override the strength of physical capital. In addition, an important question is whether the business world and other entities can find a sound balance in implementing both physical capital and human capital within their business realms.

Researchers can trace the notion of human capital back to the 1600s. In about 1691, Sir William Petty (1623–1687) assigned a worth to workers and assessed the worth of human capital to show England's strength. Petty appraised the price of lives taken in war and other deaths. In 1853, William Farr (1807–1883) described the current worth of an individual's net future profits as profits minus living expenditures. Farr then posited that the net future profits signified prosperity just as tangible possessions do—and that the government ought to tax them in a similar manner.

In 1867, Theodore Wittstein said that law courts ought to use Farr's current worth of net future profits to decide reimbursement for requests in terms of life that has been taken away. In 1930, two businessmen who worked in insurance—Alfred Lotka (1880–1949) and Louis Dublin (1882–1969)—became interested in Wittstein's idea as a way to determine how much life insurance a person should buy. The two men's study went beyond Wittstein's current worth of net future profits; they also contemplated death statistics (Kiker, 1966).

Human Capital and the Business World

The business world placed emphasis on human capital during the 1950s and 1960s, when labor economists started to view matters in reference to labor-force quality. Businesses spent funds on training and academic education. Business leaders pondered whether the training and education would positively enhance efficiency as well as incomes. Following these pioneers of human capital, other people developed the idea of human capital in terms of economics. They did this by considering the myriad ways that people are an investment that brings forth a return. Others also acknowledged the idea, but because of sentimentalism they did not want to think of people the same way they thought of physical commodities (Berry 2007).

Throughout the decades, many people have employed Human Capital Theory to tackle matters pertaining to civic courses of action. Many of these matters are still the focus of the theory. Such matters include the influence of countries, the outcomes of migration, investments in as well as supervision of well-being, well-being investing, economic expansion, and academic procedure and investing. Human capital economics, like other sciences, is mobile and continues to progress. During any period, it is the product of what occurred beforehand (Kiker 1966). In his essay "Human Capital in a Global Age," Nick Schultz (2012) notes that economists have been striving to evaluate the importance of human capital in the current time. One particular estimate was that the whole stock of human capital in the United States of America was worth more than $700 trillion. This number was far in excess of the estimate that physical capital stock was worth $45 trillion.

In *The American*, Gary Becker and Kevin Murphy (2007) maintain that greater rates of return on capital signify higher production in the economy. This inferred statement is valid for human capital just as it is for physical capital. The primary effect of greater returns on human capital is broader inequity in terms of wages. That influence has turned out to be more subdued, and young males and females may reverse this trend over time by investing more in their human capital.

In *Who Do You Want Customers to Become?*, Michael Schrage (2012) provides a wider viewpoint. Schrage stresses how inspiring creativity signifies a special type of human capital investment that people currently do not notice. He argues that innovators' main assets may be not their workers but their consumers. What matters is investment in terms of the consumer, which involves focusing on and elevating the consumer's proficiency level. Perhaps these attributes are the solution to whether an entity is going to prosper. Schrage continues by explaining that consumers' human capital plays a vital role in a business. Increasing the human capital of consumers and clientele is as cost effective, fiscally sound, and tactically important as overseeing the human capital of employees within the firm. Innovation creates a newfangled prosperity in terms of human capital. Consumers and clients obtain new abilities as well as new communication standards, causing an increase in value.

How Important Is Human Capital?

It is regrettable that formal economic theory as well as empirical studies have undermined and belittled the importance of the consumer's human capital in innovation achievement. Fruitful innovators have indulged in quality and quantity simultaneously, and this intertwining of the two has created an upsurge in human capital stock of consumers or clients. This is proof that these innovators have found success because their innovations make their consumers or clients indispensable (Salam 2012).

Currently, people emphasize the important nature of businesses in many ways. Research demonstrates that businesses that go from above-average to superior are able to do so because of the qualities and emphasis that the businesses place on the workers themselves. This is brought about through the all-inclusive business entity that involves leadership. Fortune's *World's Most Admired Companies* is an exclusive list, because the peer groups' ranks depend on their perception of human capital as the top aspect. These companies emphasize worker aptitude, management quality, and origination and civic obligation. The focal theme is that investors and business personnel adore entities that place prominence on the human capital aspects of their entities.

To many in the United States, the importance of human capital will continue to be controversial in comparison to physical capital. One question that may persist in contemporary times is the following: If all American business entities incorporated an identical model of the amounts of all measured input—including human capital—so that equality of work was acknowledged, would this action be considered a fair practice or a socialistic state of affairs?

HUMAN RIGHTS AND DECISION-MAKING

Human rights are rights everyone has, just by virtue of being human. Because they are rights, human rights entitle rights-holders to something. These special entitlements thus impose duties, most immediately on governments. Your human right to food obligates your government (1) to not interfere with your acquisition of food, (2) to prevent others from interfering with your acquisition of food, and (3) to provide food to you if you are unable to provide it for yourself.

Some people think of human rights as moral entitlements; legal positivists think of them as nothing if not legal entitlements. But of human rights are both. They are moral rights in the sense that they provide a normative compass, both for what is minimally good and also for what agents should and should not do.

The Universal Declaration of Human Rights (UDHR), which was adopted and proclaimed by the United Nations General Assembly (UNGA) in 1948 and now is endorsed by virtually all countries in the world, gives the fullest account of this moral framework. Human rights are also legal entitlements that can (or should) provide rights-holders with legal remedy when violations occur. While the UDHR has achieved the status of customary law, these legal entitlements find their highest expression in the International Covenant on Economic, Social and Cultural Rights (ICESCR) and the International Covenant on Civil and Political Rights (ICCPR), which entered into force in the UNGA in 1976. The ICESCR has been ratified by 160 countries, and the ICCPR by 167 countries. Together, the UDHR, ICESCR, and ICCPR are called the International Bill of Human Rights.

An increasingly dated division of human rights separates civil and political rights on one hand, and economic, social, and cultural rights on the other. *Civil rights* include nondiscrimination (the most fundamental of all human rights) and a host of rights associated with civil freedoms. *Political rights* include the right to a nationality, the right to equality before the law, and the right to vote by secret ballot in periodic elections. Economic, social, and cultural rights include rights to an adequate standard of living (including food, shelter, clothing, medical care, social services, and conditional social security), to work, to education, to freely participate in the cultural life of the community, and to a social and international order in which all of the rights and freedoms in the UDHR may be realized. Interestingly, while the UDHR includes the right to property, neither the ICESCR nor the ICCPR do.

What is the normative basis for human rights? After input from philosophers, scholars, and political leaders from around the world, the UDHR identified human *dignity*, which can be taken to mean intrinsic worth. Such worth is not contingent on having a particular skin color or nationality, or having a particular level intelligence or genitalia, or even having done the right things. Foundationalists source this kind of dignity in purposeful human action, and on the abilities of humans to form life plans and carry them out (agency/autonomy). In Kantian spirit, this is what distinguishes people from fish, trees, and rocks, and it is what entitles us all to the special protections and freedoms afforded by human rights. Whatever the justifications for human rights are, an overlapping consensus has emerged on its validity, in spite of the world's diverse views, religions, and cultures.

Of course, not everyone agrees. Some people believe that the human rights doctrine does not go far enough in ensuring social justice, or that it does not constitute a unified theory on the same level as Marxism or neoclassical economic theory. Others support some human rights but not all. While most countries of the world have ratified both covenants, the United States is the only rich Western country that has not ratified the ICESCR. Some countries are less enthusiastic about civil and political rights, citing cultural preferences for order. Developed countries often ignore the extraterritorial obligations associated with international human rights; seemingly all countries bemoan the costs. Nevertheless, human rights doctrine arguably contributed to the end of colonialism, the spread of democracy, the end of apartheid in South Africa, and the enactment of innumerable income security laws and policies throughout the world.

There are also good reasons for political decision-makers to support all human rights. First, all human rights together are necessary in order to ensure citizens minimally decent lives. Second, and often more convincingly, faithfulness to human rights provides a stamp of legitimacy to governments, which can help garner support for domestic policies and also help in international affairs: from successful negotiating loans and trade agreements, to enlisting allied assistance in times of conflict.

HUME, DAVID

Born: April 26, 1711, in Edinburgh, Scotland; Died: August 25, 1776, in Edinburgh, Scotland; Nationality: Scottish; Professional Interests: moral philosophy; Major Works: *A Treatise of Human Nature* (1739), *Essays, Moral and Political* (1741), *The History of England from the Invasion of Julius Caesar to the Revolution of 1688* (1757–62), *Dialogues Concerning Natural Religion* (1779).

David Hume is considered an Enlightenment author, but he did not believe in natural law and natural rights as John Locke, Jean Jacque Rousseau, or Adam Smith did. Hume advocated *utilitarianism*, the idea that goodness is the same as usefulness. He is remembered as an extreme skeptic. He held no belief as sacred; instead, he attempted to test every theory by observation. Hume died in 1776.

David Hume was born on April 26, 1711, in Edinburgh, Scotland. His father died when he was very young. Hume entered the University of Edinburgh at the exceptionally young age of 11. Although he started his studies intending to become a lawyer, he quickly found that he had a passion for philosophy. From an early age, Hume seems to have taken questions of morality, life after death, free will, the existence of God, and other philosophical issues very seriously; he pursued these questions in his studies and writing for the rest of his life.

Hume was a lifelong writer and philosopher. He published his first book, *Treatise of Human Nature,* when he was 28. In it, Hume challenges the notion that humans are guided by reason. Instead, he argues that people are driven by their desires, that they consistently seek to maximize their own happiness, and that a person's sense of "self" is simply a combination of sensations and choices. He draws a sharp distinction between the "is" of science and the "ought" of morality. The book was not well received at the time, to Hume's acute embarrassment, but it has since come to be recognized as one of the most important works of philosophy ever written.

His subsequent work was taken more seriously, but it also made him a notorious figure since it contained antireligious sentiment. Perceiving him to be an atheist, church leaders successfully denied his application to be a professor of moral philosophy at the University of Edinburgh and the University of Glasgow. Hume secured employment as secretary to a Scottish general, actually taking part in an attempted attack on French Canada that got sidetracked and was diverted to

France itself. He made his fortune when his eight-volume *History of England from the Invasion of Julius Caesar to the Revolution of 1688* proved to be a major success. He was able to devote the rest of his life to writing.

Hume's economic thought was dominated by utilitarianism; he believed that economic and social policies should be directed at producing the greatest possible value for the largest number of people. From this starting point, he defended private property not on the basis of natural rights (as John Locke did), but simply because of utility: Resources are scarce, and people use these resources most efficiently when they own them privately. Hume argued that if resources were unlimited, then private property would cease to be useful.

Hume pointed out flaws in the theory of mercantilism, an idea that discouraged free trade in favor of state-supported monopolies. In response to mercantilist claims that nations should seek to attract as much gold as they could through exports, he argued that this goal was impossible. He observed that if too much money was traded to one country, then prices in that country would rise due to inflation; this would cause people in that country to seek to buy imports from other countries that did not have an inflation problem, and therefore, in the long run, trade between nations would tend to balance. Furthermore, he pointed out, while trade promotes the economic development of a country, it also improves human capital—that is, the skills and knowledge of the population. It makes people more aware of the world, which in turn makes them more dynamic, imaginative, and productive. He went on to say that countries need not fear the economic development of their neighbors, as if one nation can flourish only at the expense of another. Rather, the economic growth of a trading partner makes for a more prosperous community of nations. Rich nations and poor nations have nothing to lose and everything to gain from trade. He even made the outrageous claim that trade could bring happiness and wealth to France—this was not a popular statement in 18th-century Britain! But Hume had made his point. To this day, economists still believe voluntary trade brings benefits to both sides.

David Hume, like John Locke, was a link in the chain from political liberalism to modern economic thought. He was friends with Adam Smith, and no doubt he shared with Smith his arguments against mercantilism and toward an economic philosophy driven by the decisions of individuals rather than the needs of the state. Hume's philosophy was first practical, and while this might not have won him the trust of the Church of Scotland, his writings have secured him a place among the most important of the world's philosophers.

David Hume died on August 25, 1776, in Edinburgh, Scotland.

HURRICANE KATRINA, 2005

Hurricane Katrina is considered one of America's greatest natural disasters. It was the third-strongest hurricane to make landfall in the United States. Hurricane Katrina ranks as the costliest hurricane, resulting in $81 billion in direct property damages and more than $150 billion in total costs. Private insurance claims paid an surpassed $41 billion, and federal insurance claims for flooding exceeded $16 billion. The death toll was more than 1,800 people, and more than 700 people are still missing. The main damage to New Orleans came from the failure of its levees, which is considered the worst civil engineering disaster in American history. Floods covered nearly 80 percent of the city of New Orleans.

Eventually, New Orleans would lose 50 percent of its population. More than 770,000 people were displaced, which was the largest migration of people since the Dust Bowl of the 1930s. On the Gulf Coast of Mississippi, hundreds of prime resorts were destroyed and beaches eroded. Oil and gas production in the United States was reduced by more than 22 percent for six months, as 30 oil drilling rigs were destroyed and nine refineries were shut down.

Katrina affected more Americans than any other hurricane. The gross national product, tourism, energy supplies, shipping, and imports all declined while gas prices and government relief costs increased. Costs continued to add up as money for reconstruction and to aid survivors was paid out. The federal government's response was highly criticized. Some of this criticism arose because no other hurricane in American history had received such real-time coverage; hundreds of reporters and camera crews were embedded in New Orleans.

Hurricane Katrina developed as a strong hurricane in the Gulf of Mexico on August 26, 2005. The sheer size of this slow-moving giant attracted much media attention. Although it strengthened to a Category 5 storm in the Gulf, it hit land as a Category 3. Katrina was one of the largest hurricanes in recorded history, extending more than 103 miles from its center and affecting more than 93,000 square miles upon landfall. Its size would create a large storm surge, to which much of the damage was attributed.

On August 28, New Orleans issued its first-ever mandatory evacuation. Voluntary and mandatory evacuations were also called for in large areas of Louisiana and

Mississippi. The Superdome sports stadium was designated a refuge of last resort for those left in the city. On August 29, Katrina made landfall and dropped eight to nine inches of rain. Many news channels had around-the-clock coverage of the event by reporters based in hotels in the French Quarter. Damage seemed light as the hurricane passed, but most observers missed the initial damage to the levee protecting New Orleans from storm-surge flooding. Flooding was the cause of 700 deaths. In total, New Orleans flooding accounted for 80 percent of the fatalities.

The storm surge of more than two feet breached the levee at New Orleans and flooded the canal system. As Lake Pontchartrain overflowed, the levee ruptured, flooding the sections of New Orleans below sea level. Counties in Mississippi were also flooded. Panic and looting began quickly in the streets of New Orleans. Guards abandoned prisons, with the result that hundreds of prisoners were unaccounted for. A number of people died in health care facilities that could not be evacuated. Some New Orleans police officers deserted their posts; others were overwhelmed by the flood, violence, and looting. The Superdome sheltering 26,000 people sustained heavy damage to its roof, making living conditions difficult. In the flooded streets, bodies were found floating. After a few days, the floodwater became a toxic mix of industrial chemical spills, raw sewage, and bacteria; the cleanup was expensive and took several months.

Throughout the Gulf Coast, the damage was extensive: More than 300,000 homes were destroyed, at a cost of $67 billion. Business property damage contributed another $20 billion to the loss, and the debris that washed ashore amounted to 118 million cubic yards. Major roads and bridges were destroyed. Short-term damage included the loss of electric power to 2.5 million customers and heavy damage to more than 170 water utilities. New Orleans Energy had to file for bankruptcy. For weeks, at least 60,000 people were trapped in New Orleans without fresh water, food, and medical supplies. The floodwater restricted the ability of federal agencies to provide aid. Americans watched in horror as timely help failed to address the problem. Finally, the Coast Guard was mobilized to rescue stranded residents. In addition, 58,000 National Guardsmen were activated. It took weeks to restore order in New Orleans, which had become a lawless zone of shootings, looting, and car-jacking.

Damage to the oil-refining industry, which was heavily concentrated around New Orleans, was extensive. For six months, 20 percent of the refining capacity was lost, causing increases in gasoline prices throughout the country. Nine refineries were closed for weeks as repairs progressed. More than 30 oil platforms in the Gulf were lost. The oil spills related to Katrina approached some of America's biggest, with a total of 7.4 million gallons lost. New Orleans was also a major U.S. port for crude oil, and its operations were disrupted for months. Crude oil hit a record high of $70 a gallon. Gasoline went from $2.50 a gallon before Katrina to more than $3 a gallon. In the South, some stations were selling gasoline for more than $6 a gallon, prompting federal inquiries into price-gouging. The South also reported long lines at stations and panic buying. The job losses in the oil industry contributed to a major increase in unemployment. President George W. Bush drew from the Strategic Oil Reserve to hold gasoline prices down.

This level of destruction from a natural disaster had never been seen. Congress appropriated $62 million in aid for the victims. Private organizations raised another $5 billion. At least 700,000 people needed housing assistance. More than half of the states provided help to evacuees. Some 80,000 people went to Houston, Texas, for temporary help. The major long-term costs were in the rebuilding of the levee system in New Orleans, which continues today and has cost more than $8 billion. In Mississippi, tourism was badly hurt as casinos and beaches suffered major damage. In all, even the initial relief aid took weeks to reach recipients, the cleanup took months, and the rebuilding has stretched into years.

HURRICANE SANDY, 2012

Hurricane Sandy, which had a diameter of more than 1,000 miles, was the largest Atlantic hurricane on record. It hit New Jersey and New York, just north of Atlantic City, on October 29 and ultimately affected over 24 states. Although it was only a weak Category 2 storm, it merged with a frontal storm, and newspapers gave it such nicknames as "Superstorm Sandy" and "Megastorm Sandy." Its low barometric pressure was just one of the records it set for an Atlantic storm. Its destructive damage cost $68 billion, an amount surpassed only by Hurricane Katrina. Hurricane Sandy passed through seven countries, leaving a total death toll exceeding 300; 117 of those deaths were in eight U.S. states. The low-lying areas of New York and the Jersey shore were hit with major storm damage. More than 6 million customers lost electricity in the wake of the storm. Because of the exceptional damage and the deaths caused by the storm, the World Meteorological Organization officially retired the name 'Sandy."

Sandy attracted major media coverage, as the slow-moving giant was predicted to merge with a surface low, creating a superstorm. Sandy was a hybrid of a hurricane and a winter storm. Headlines used terms like "Frankenstorm" as the merger took place a few days before Halloween. The meteorological term is the "Fujiwhara effect." On October 25, 2012, Hurricane Sandy hit Cuba and Jamaica as a Category 2 hurricane, killing 51 people. Sandy eased to a Category 1 hurricane as it approached the North American shore. As the storm approached, President Barack Obama signed an emergency declaration on October 25 to set up funds necessary for a potential disaster. The slowness of the storm allowed for extensive media coverage and reactions such as panic buying.

The reaction reached the crisis point on October 28, 2012, as New York City shut down its subway and commuter rail services. The city public schools were also closed, and the city's businesses started to shut down. Airlines on the East Coast started massive flight cancellations, running into the thousands. The New York Stock Exchange canceled its October 29 operations and remained down a second day after impact. Governors in New York and New Jersey mobilized the National Guard. Governors from the Carolinas to New England took emergency action. Similarly, Washington, D.C., shut down government operations. Amtrak closed down much of its East Coast operations.

When Sandy hit the coast on October 29, it was a Category 2 storm, but still it set several records. Its barometric pressure of 940 millibars (mbar) was the lowest ever recorded for an Atlantic hurricane. It also broke New York Harbor's surf record. The preparation for the storm's landfall had been extensive, including evacuations of residents in low coastal areas and cancellations of major events and transportation in the New York and New Jersey areas. Still, New Jersey reported 34 deaths and New York State reported 53 deaths. These two states took the brunt of the storm as the storm surge approached 15 feet.

In New Jersey, coastal cities had five feet of water in the streets. Hoboken, a city of 50,000, was flooded and had to be evacuated. Part of the boardwalk at Atlantic City was washed away. The damage in New Jersey was estimated at $30 billion. At the peak, more than 2.6 million electric customers were without power, and the neighboring Philadelphia area had more than 1.2 million without power. Gasoline shortages required rationing. The cost to state businesses also ran into the billions.

In New York, large sections of Manhattan were flooded. The New York subway system sustained the worst damage in its 108-year history. The total damage to the subway system exceeded $5 billion. More than 100,000 houses on Long Island were damaged or destroyed. Housing damage in the state of New York was estimated at $9.3 billion. As treatment plants were flooded, 10 billion gallons of raw sewage was backed up into the area's water systems. Area business came to a standstill. It was estimated that the cost to business in the state of New York exceeded $6 billion. The two-day closure of the New York Stock Exchange was the first since the Great Blizzard of 1888. Gasoline shortages caused panic buying for two weeks after the storm. The federal government had to truck gasoline into the city and set up mobile distribution centers. On November 8, the city mandated an odd–even rationing system. Estimates for the physical damage in the state of New York were estimated at more than $40 billion.

Sandy occurred in a presidential election year, which caused much debate about the costs to the public and the government's response to the storm. In addition, the idea of climate change was thrown into the mix. Still, private Americans pulled together with aid donations. After much debate, the federal government passed a $50.5 billion relief bill on January 28, 2013. To date, private insurance claims from the storm have passed $15 billion.

IDENTITY ECONOMICS

Identity economics is the study of economic behaviors that are shaped by social norms. Identities influence decisions, because (Akerlof and Kranton 2010, 13) "different norms for behavior are associated with different social categories."

Akerlof and Kranton (2010, 43) model the behaviors of "insiders" and "outsiders." "Insiders have an ideal of how they should or should not behave"; they "lose utility if they fail to live up to that ideal." One's identity then has a large impact on one's productivity and on a variety of other behaviors, holding many of the traditional economic variables constant. Akerlof and Kranton apply the model to the economics of organizations, education, gender, and race. The model points to policies other than standard economics.

Example 1: Akerlof and Kranton present the military as an example of an organization that casts civilians as outsiders. Rules of behavior create a culture of insiders. Short haircuts, uniforms, and oaths of office are means of creating a common identity. Officers must obey the rules of the organization and follow orders given in the chain of command. Harsh training is instrumental to creating self-image. Pride in being part of the organization and the sense of accomplishment gained from defending the nation are the rewards. Akerlof and Kranton (2010, 59) derive the result that "if employees think of themselves as insiders rather than outsiders, the pay differentials needed to induce high effort will be lower."

Example 2: With regard to the economics of education, Akerlof and Kranton (2010) analyze reforms in schools in New York City and in New Haven, Connecticut. They conclude that giving students the opportunity to choose what they wanted to study made the students feel like insiders and avoided disruption. "Life skills" curricula were introduced for non-college-bound students, and advanced placement classes and a chess club was introduced for people who wanted to be "nerds."

Example 3: About gender and work, Akerlof and Kranton (2010, 91) write that "The Supreme Court ruled in 1971 that it is illegal to treat individual women according to a group stereotype, even when on average women have attributes that make them undesirable employees." Nevertheless, studies indicate that people continue to view some jobs as appropriate for men and others for women. Akerlof and Kranton continue (2010, 92): "*Berkman v. City of New York* reinstated a woman firefighter who had been dismissed because of substandard work. The court ruled that harassment by her male co-workers made it impossible for her to perform her job adequately." Legal arguments defending Berkman were based on the Akerlof–Kranton concept of insiders and outsiders.

IDENTITY THEFT

Identity theft and *identity fraud* are terms used to refer to all types of crime in which an individual wrongfully obtains and uses another's personally identifiable information in some way that involves fraud or deception, typically for economic gain.

The terms *identity theft* and *identity fraud* are used interchangeably. *Identity fraud* is the umbrella term that refers to a number of crimes involving the use of false identification, though not necessarily using another person's identification. *Identity theft* is the specific form of identity fraud that involves using the personally identifiable information of another individual. Identity theft as a form of fraud may directly affect the life of the victim whose identity is stolen, in addition to defrauding that person as well as third parties (creditors, employers, insurance providers, etc.)

Current federal law defines *identity theft* as a federal crime in which someone "knowingly transfers, possesses, or uses, without lawful authority, a means of identification of another person with the intent to commit, or to aid or abet, or in connection with, any unlawful activity that constitutes a violation of Federal law, or that constitutes a felony under any applicable State or local law."

Identity theft is also defined by federal regulations as "fraud committed or attempted using the identifying information of another person without permission." Identity theft can therefore both facilitate and be facilitated by other crimes. For instance, identity theft may enable crimes such as bank fraud, document fraud, employment fraud, or immigration fraud. Obviously, identity theft may be furthered by crimes such as robbery or burglary.

Different Forms of Identity Theft

There are various forms of identity theft and identity fraud. *Financial* identity theft occurs when an identity thief accesses a victim's bank accounts and credit or debt account records. Individual victims are often protected under the Electronic Funds Transfer Act (EFTA), but financial institutions suffer billions of dollars in losses each year.

Medical identity theft and insurance identity theft are two types of identity theft that not only impact victims' finances, but also carry potentially life-threatening consequences. When someone receives health care using another person's insurance benefits, this may preclude the true insured from receiving much needed care in the case of an emergency. The World Health Organization has identified this as an information crime that can kill—and as one of the most difficult forms of identity theft theft to fix.

Criminal identity theft occurs when a thief uses a victim's identity during the committal of a crime and is subsequently caught and processed under the name of the victim. It becomes very difficult for such victims to eradicate their names from "the system." For example, the victim's credit record may be damaged due to the malfeasance of the criminal.

Driver's license identity theft occurs when a person's wallet or purse is lost or stolen and a thief sells the driver's license to someone who then continues to acquire other forms of identifications in the victim's name.

Social Security identity theft occurs when an individual uses someone else's Social Security Number in order to work legally. The thief may be an illegal immigrant or an American citizen who is trying to avoid detection by the authorities. The problem emerges when the victim tries to collect government benefits or file a tax return. To monitor this potential form of theft, individuals should review their annual Social Security Administration statement to ensure that only their wages are being reported to the Social Security Administration.

Child identity theft occurs when an adult, often a family member, uses a child's information to create accounts in the child's name. Child victims will not learn about this type of identity theft until they attempt to apply for student loans or other credit when they are older. Often, the information comes to light when a young adult is denied a loan request due to a bad credit history. Parents should begin monitoring their children's credit reports at age 16; this should give the parents time to repair any damage from an identity theft.

Impact of Identity Theft

According to a report prepared by the Congressional Research Service in 2010, over eight million Americans were victims of identity fraud, and the average victim incurred a direct cost of $631 as a result of the identity theft. The report found identity fraud costs to be at their highest level since 2007.

According to the Department of Justice, the total financial cost of identity theft over a two-year period covering 2009–2010 was nearly $17.3 billion, with almost 25 percent of identity theft victims suffering an actual out-of-pocket financial loss from their victimization. Almost half of the victims reported having to spend at least one full day trying to resolve the financial and credit problems associated with their identity theft, and 3 percent continued to experience problems related to the fraud more than six months after discovering it.

Victims of identity theft should immediately contact both their local police and the Federal Trade Commission to file a report. Next, they should contact all three of the major credit bureaus to report the fraud; ask to have a freeze placed on their credit report, which will warn any potential new creditors not to open a new account under their name; and ask for a copy of their credit reports. Victim should then contact the creditors and financial institutions that have been impacted by the fraud and inform them that an identity thief has taken over the account or that the account was created in their name but without their knowledge.

Identity Theft Prevention

The U.S. Department of Justice has created an education program called "SCAM," which stands for *S*tingy, *C*heck, *A*sk, and *M*aintain. Consumers should be *stingy* or cautious about whom they share personal identifying personal information with. They should regularly *check* their financial information, such as bank and credit card statements, for any unusual activity. Consumers should *ask* for a copy of their free credit report annually, which they are entitled to under the Fair and Accurate Credit Transactions (FACT) Act, and look for any accounts that are not theirs. Lastly, they should *maintain* careful financial records. All bank statements and credit card statements should be kept for a minimum of one year.

Consumers should keep all their important financial and legal papers secure, and they should shred documents that contain sensitive financial and personal information before disposing of them. It is also important for consumers to limit any personal information they carry in their purses or wallets; they should avoid keeping birth certificates and Social Security cards on their person in case of loss or theft.

IMMIGRATION: GLOBAL OVERVIEW

Immigrants are individuals who move to a foreign country. They may move to settle permanently, they may intend to return home after an extended settlement, or they may be undecided about the length of time they will stay in the foreign country when they arrive.

"Push" and "pull" factors are the driving agents that motivate immigration. Push factors include civil unrest or a bleak financial outlook in the migrants' home country. Pull factors include political stability or a strong economic infrastructure in the country to which migrants have chosen to immigrate. Often, both push and pull factors encourage people to immigrate to a given country. For example, people may decide to immigrate due to there being few economic opportunities in their home country, and they may choose to enter a country with a relatively high level of political stability versus a country that is wealthy but tumultuous. A country is more likely to encourage immigration from skilled or wealthy individuals than low-skilled and poor individuals.

Economic migration, also termed labor migration, is migration in which individuals leave one country for another due to perceived economic improvements in the country to which they are migrating. In order for migrants to leave their home country, the new nation's available earnings must be relatively high and the traveling costs minimally low enough to offset the necessary expenses of immigration. In the event that the appraisal of wages in the new nation does not surpass the estimation of wages in the nation of origin, immigrants may decide not to relocate, since the length of time spent in the new country may not be sufficient to help offset the costs. As a case in point, during the mid- to late 1800s the United States experienced high levels of immigration due to a rapidly expanding economy. Generally, low-skilled individuals in developing countries can improve their wages by transferring their labor to more developed nations.

The effects of economic migration are multiple. In the short term, a migrant's country of origin may experience benefits and incur costs but in the long run may stand to net a significant loss. This is generally true of highly skilled scarce workers. On the receiving end, the migrant's country of destination may benefit from an increased pool of highly skilled and previously scarce workers.

An increase in highly skilled laborers from generally developing nations, also known as "brain drain migration," might mean decreased wages for domestic workers. One of the undesired, unintended consequences of migration due to an overabundance of certain types of labor may be housing shortages in certain neighborhoods and segregated cities.

In the United States, the impact of immigrant labor on domestic labor has been to depress the wages of comparable domestic workers. The Brookings Institution finds that the recent wave of younger and relatively unskilled immigrants from developing countries has had a greater negative impact on similarly young and unskilled U.S. domestic laborers due to increased competition (Burtless 1996). The Center for Immigration Studies arrives at similar findings (Hirschman and Mogford 2009); according to this study, those who bear the brunt of direct competition with new immigrants are native-born workers lacking a high school degree, African Americans, and a broad base of Hispanic laborers.

INDUSTRIAL REVOLUTION

The 18th century is remembered for some of the most significant world events in all of history. The year 1776 especially stands out: 13 little colonies declared their independence from England, and a Scottish professor published a book that changed the world of economics. But prior to those two monumental events, another era began in the 18th century and continued to the middle of the 19th century. The Industrial Revolution changed the worlds of agriculture, transportation, textiles, manufacturing, and economic policies to new and higher achievements, innovations, and inventions that would change the world forever.

An era is labeled as a revolution when the old is permanently replaced by a new way of life. The Industrial Revolution definitely accomplished that feat. Yet, as opposed to revolutions like the American Revolution, which lasted several years, the Industrial Revolution replaced the old with the new over a period of nearly 100 years. The Industrial Revolution is generally considered to have begun in 1760 and lasted to 1850. Interestingly, the Industrial Revolution surrounded the new little country, the United States, from when it won its independence from England to just before it engaged in its own worst internal war, the Civil War.

The achievements and improved standards of living reached during the Industrial Revolution were the highest. New advances in industrial organization and technologies increased productivity and efficiencies. Profits increased, and manufacturing became an industry in its own right. New agricultural methods allowed more food to be grown and supplied by fewer farmers, while other agricultural advancements gave producers more efficient ways to obtain the earth's raw materials for production. Between advances in agriculture and advances in manufacturing, an interesting serendipity was occurring with regard to labor. As advances in manufacturing necessitated the need for more labor, advances in agriculture resulted in the need for less labor. While the transition certainly occurred over time, the agricultural labor that was no longer being used was gradually finding its way to the manufacturing sector. This also brought with it the demographic move of labor from rural areas to the cities, spawning significant growth in urban areas.

Some of the more notable achievements of the Industrial Revolution in agriculture included improved land use through crop rotation to improve soil fertility. Metal replaced wood in the making of certain farm equipment, and horses replaced oxen as the main source of power for plows. These improvements, as minor as they might sound, increased crop yields. The increased crop yields also led to increased livestock sustainability and growth for meat. This was especially important during the winter in England.

As manufacturing grew, the need for additional raw materials grew accordingly. One example of improvement in access to raw materials came in the coal-mining industry. Coal mining has always been a dangerous occupation. During the Industrial Revolution, coal mining was often a family affair, involving the women and children as well as the men. In the 18th and 19th centuries, several improvements made coal mining not only less dangerous (relatively speaking) but also more productive. Using ponies (and later carts on rails) as opposed to manual labor for transporting the coal to the surface made the mining process smoother. Other improvements, including better tunnel ventilation and lighting using safety lamps, improved the coal miners' ability to mine the coal. The miners also began using gunpowder to loosen the coal from the ground. By 1829, the coal-mining industry experienced a sevenfold increase in coal production. Similar to the improvements in coal mining were the improvements in the production of iron. Abraham Darby invented a way to make smelt pig iron using coke instead of charcoal. While the method was primitive and had its faults, it was beginning to future improvements and technologies for higher-quality iron.

As manufacturing continued to grow, improve, innovate, and produce more goods for market, transportation and communications became more important for getting the goods to those markets. Initial transportation improvements during the 1770s occurred in the use of canals. However, the railroad was right behind, and canal use was short-lived. Early railroads imitated the rail systems that had been designed for coal mining. A second improvement in railroad transportation was the use of the steam engine. The growth and dominance of railroads in England lasted for nearly 100 years, spawned by the need for better transportation to get the manufactured goods to market.

An industry closely associated with the Industrial Revolution is the textile industry. Before the Industrial Revolution, the entire textiles process was accomplished in the home by mothers and daughters. At that time, the goods produced in the textile industry consisted primarily of woolen cloth, cotton, and silk. The textile industry was truly a cottage industry, with much of the process outsourced across a locality. An invention "assault" took place during the 1770s that changed this industry forever. John Kay invented a new weaver that allowed individual weavers to double their workload. Lewis Paul invented a roller spinner to make spinning more efficient. James Hargreaves's invention allowed the user to spin literally dozens of threads at one time. Richard Arkwright perfected the roller spinner using a water frame. Arkwright's device was similar to the roller spinner, but it used water, not human labor, to generate power. Arkwright started his textile factory in Cromford, England, employing 600 people—mostly women and children who were already experienced in working with a roller spinner. Arkwright later invented a machine to comb the raw material to keep up the increased production of cotton in his factory.

Universally accepted as the greatest manufacturing achievement of the Industrial Revolution were the advancements in steam power. The invention of the steam engine is credited to James Watt, but in fact he was improving upon an earlier design by Thomas Savery and Thomas Newcomen. His many enhancements to the original design significantly increased steam engine efficiency. One of his secrets was to apply gun-making skills to making his cylinders for the engine. Manufacturing and transporting goods to market took a giant step forward as the steam engine operated more efficiently. The steam engine also freed up mill owners and factory owners to move their industries to more convenient, efficient locations.

Finally, during the 18th century the population grew faster than at any time in history. The birth rate increased, and the death rate decreased. The vast increase in food supply was evident in the health and well-being of the population, as they were now eating healthier foods. Healthier eating also led to the disappearance of plagues. Higher wages were being earned in the manufacturing sector. Consumption increased in clothing and housing, both of which showed marked improvement in quality.

The Industrial Revolution gave humankind many new inventions and processes through which to improve economic growth—and as a result to achieve a better standard of living. It began as people moved to where factories were located, away from the villages and rural agricultural areas. Of course, the population growth around factories and towns brought new issues and problems. But the Industrial Revolution was just as labeled: a *revolution* that replaced the old with the new and took humanity to a point from which it would never return.

INFORMAL ECONOMY

The *informal economy* consists of business activity that is not reported to the government. Many other terms are used to describe unreported business activity, including *underground economy*, *shadow economy*, *gray economy*, and *informal sector*. Just as there are competing terms for the informal economy, there are also competing definitions. To some economists, the informal economy consists of legal types of transactions that take place in an extralegal business environment. For example, unlicensed street vendors conduct legal business in many urban areas throughout the world, but for various reasons do not report business receipts or pay taxes to the government. Other economists include legal and illegal business enterprise in the informal economy. This broader definition accounts for financial and nonfinancial transactions of informal entrepreneurs, such as shopkeepers and craftsmen, and the criminal activities of drug traffickers, arms smugglers, and gambling rings.

Most informal economy business activity represents legal, if unreported productive enterprise. Business organization in the informal economy is diverse. One type of business structure is the informal *own-account enterprise*. Self-employed entrepreneurs such as street vendors, taxicab drivers, and repairmen own and operate own-account enterprises. These entrepreneurs sometimes work alone. However, these entrepreneurs often rely on paid or unpaid assistance from family members to run the business. Many of the businesses, such as street vendors, are mobile; others operate out of the entrepreneur's home. A second type of business structure is the microenterprise. A *microenterprise* typically employs several laborers on a regular basis. Employee compensation might include a wage or an in-kind benefit such as food or shelter. Auto repair shops and small-scale construction enterprises are sometimes organized as microenterprises. A third type of business structure is the established business firm that conducts a portion of its business in the *informal* economy. Production in the extralegal sector is usually a cost-cutting strategy. Low wages, tax avoidance, and the circumvention of government regulations motivate some established businesses to operate in the informal sector. In most parts of the world, people accept jobs in the informal sector to meet their subsistence needs for food, clothing, and shelter.

Informal economies operate beneath the layer of formal, reported business activity in all countries. The largest informal economies are found in the developing countries and in emerging market economies. The smallest informal economies appear in the advanced economies. A study by economists Friedrich Schneider and Dominik H. Enste, published as *The Shadow Economy: An International Survey* (2003), quantified the size of the informal sectors of 110 countries by estimating the value of unreported business activity as a percent of gross national product (GNP). Schneider and Enste concluded that the largest informal economies exist in Africa, South America, and the transition countries of Eastern and Central Europe. Smaller informal economies exist in North America, Oceania, and Western Europe. The survey also noted tremendous variation within world regions. In Asia, for example, informal sector activity accounted for more than 40 percent of GNP in the Philippines, Sri Lanka, and Thailand, but less than 15 percent of GNP in China, Singapore, and Japan. Key factors that increase informal sector business activity include high business taxes, stifling business regulations, low worker education and skills, and dire poverty. Factors that reduce informal sector business activity include high national income, universal public education, good governance and the rule of law, and property rights.

The existence of informal economies in the global economy is well-documented. The magnitude of the informal sector has stimulated serious discussion about how to improve the lives of people working in the extralegal sector. Hernando de Soto, a noted Peruvian development economist, supports the extension of private property rights for the poor as a means to harness the power of the informal sector in his homeland. The World Bank supports improvements in the delivery of basic services to the marginalized poor, regulatory reform to remove barriers to business formation, worker training programs, and expanded access to credit for start-up firms. The International Labor Organization (ILO) stresses the improvement of human capital in developing countries. In 2000, the ILO formally proposed education and training of workers and managers in the informal economy. Improved knowledge and skills were viewed as necessary to improve workers' immediate standard of living and to create new opportunities for workers in the formal economy. Grassroots initiatives, such as the Movement of Landless Rural Workers in Brazil, pressure governments to redistribute idle agricultural land and to grant property rights to the poor.

INSTITUTIONAL ECONOMICS

Central to institutional economics are the concepts of evolution (in contrast to equilibrium), learning (instead of fixed preferences), and bounded rationality. Institutional approaches have always been rooted in the behavioral/cognitive sciences. John R. Commons regarded the mind as a cultural product (socially constituted). Commons's insight was not that people are bound by custom, but rather that individuals are influenced by society and simultaneously exert influence on that society by creatively challenging and adapting to the culture that it generates (and is generated by it).

Thorstein Veblen made fun of outmoded consumer theory. "The hedonistic conception of man is that of a lightning calculator of pleasures and pains who oscillates like a homogeneous globule of desire of happiness under the impulse of stimuli that shift him about the area, but leave him intact . . ." (1898, 389). The "outmoded consumer theory" Veblen refers to assumes that people constantly calculate to their advantage as an axiom underlying all human behavior. Humans can and of course do, in some settings, calculate—but not all the time or across all types of decisions. Brain capacity is limited, and some scholars, such as Gerd Gigerenzer (known for "fast and frugal" heuristics) argue that these limitations provide valuable adaptive advantage without calculation or exhaustive optimization. Attention is also limited. One of Herbert Simon's important contributions was to point out and provide formal models of how perceptive scales and attention can be governed by threshold conditions rather than continuous relationships with cues in the decision-maker's environment. Humans constitute multiple selves. Which one dominates at a given time is contextual. Preferences are not given. Rather, they evolve. Whereas neoclassical economics treats preferences as a purely intrinsic attribute analogous to personality traits in the field of psychology, institutional economists propose that preferences themselves are a social phenomenon, as individuals learn from what others are doing.

Learning is central to the evolution of preferences. When prices change and choices adapt, consumption (and investment) may not return to the old equilibrium even after prices return to their initial values. For example, when new products are substituted for old ones, people may decide they like the new ones they did not seriously consider before. It cannot be assumed that consumers or businesses have a complete inventory of all possible products and have already attached an ordinal or cardinal weighting to these products. For example, when automobile manufacturers face mandates on mileage or pollution emissions, they may develop new technologies that they never bothered to investigate before.

People are emotional, and they do not like to admit their mistakes. In some domains, however, emotions can be a source of intelligence and a performance-improving cue for guiding decisions. An example of emotions hindering performance would be when the price of assets declines and unemotional analysis suggests little hope for recovery, but the owner of those assets still refuses to sell. The owner may reason that the loss has not occurred if the asset is retained. Contemporary institutional economists have embraced the insights of Daniel Kahneman, who observed behavioral regularities such as anchoring, defaults, availability, and regression to the mean.

The performance of an economy is not the outcome of a mysterious invisible hand, but rather the rules of the game: institutional choices. "Different laws lead to different markets and thus to different prices and resource allocations" (Samuels 2011, 295).

Hard moral interpersonal choices cannot be avoided, even with two widely agreed-upon policies—namely, competitive markets and democracy. There are still many details of markets and income distribution that affect performance. Likewise, simple voting ignores such details as agenda control and boundaries of voting districts. Kenneth Arrow stated, "Empirically we can reject the idea that consensus can be found in the expressed individual wills" (1986, vii). It does not take a formal model to see that each and every citizen cannot be sovereign if citizens have conflicting interests. Rules for making rules include both constitutions and everyday rules of legislatures and corporate boards of directors and committees.

Joan Robinson suggests that "The Keynesian revolution has destroyed the soporific doctrines, and its own metaphysics is thin and easy to see through. We are left in the uncomfortable situation of having to think for ourselves" (1979, 149). The popular demand for obfuscation and avoidance of responsibility is another behavioral regularity. Erich Fromm called it the escape from freedom. Institutional economics forces us to think through the multiplicity of variables—behavioral and other—that are required to understand the workings and evolution of economies.

INTELLECTUAL PROPERTY RIGHTS

Rights that refer to creations of the mind or creative processes are termed as *intellectual property rights*. These consist primarily of trademarks; patents; copyrights; and related items such as trade secrets to protect inventions, books, software, music, and numerous other products.

Internationally, the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) created by the World Trade Organization (WTO) came from the 1986–1994 Uruguay Rounds, multilateral discussions on international trade. This Agreement set the precedent for protecting the ideas and creations of innovators. relating those rights to the global trading environment (WTO n.d.). It allowed innovators to prevent their ideas or their products from being used without proper compensation.

The trademark is an often-used intellectual rights protection. A *trademark* is a distinctive mark, motto, device, or emblem that a manufacturer stamps, prints, or otherwise affixes to the goods it produces, to distinguish those good from those of other manufacturers (Miller 2013, 207–10). In the United States of America, trademarks can be registered with the U.S. Patent and Trademark Office, although they do not necessarily require registration to be protected. Courts generally use the rule of reason and likeness to determine whether an infringement has occurred. If another product copies a trademark to a considerable amount, the copying party can be charging. Common words cannot be trademarked, as their general use is not attributed to a specific party. A trademark is well protected if it is easily distinguishable with unique features. This can also apply to the appearance of an item, such as the old-fashioned Coca-Cola bottles. This right is commonly referred to as *trade dress*.

The copyright is another common intellectual property right. A *copyright* is an intangible right belonging to the originator of literary or artistic productions. A copyrighted item must fit a certain category, be fixed in a durable medium, and be original (Miller 2013, 219–21). To "fit a certain category" means that a production must be specifically musical, artistic, or any other specific field.

To be a "durable medium" requires the production to be in a format that can be seen, reproduced, or communicated. An infringement occurs when a substantial part of the original work is illegally reproduced. In 2009, the street artist Shepard Fairey and the Associated Press got into a legal battle over the artist's creation of the Barack Obama "Hope" poster. The poster appeared to have been an artistic reproduction of a photo taken originally by Mannie Garcia of the Associated Press. In 2010, the parties settled the civil suit amicably when Fairey agreed to acquire proper permission for future photos and the sharing of rights and reproduction of the "Hope" poster. They also agreed to share rights and work in tandem on future creative projects (Kennedy 2011). The original crux of the argument was the concept of "fair use" allowing for the use of a work for criticism, news reporting, teaching, scholarship, or research. An infringement may still occur based on the effect of the reproduction on the market for the original work (Miller 2013, 221).

For specific items of intellectual property, individuals or organizations can obtain a patent. Most patents applied for and granted are not for intellectual property. A *patent* is a granted exclusive right to make, use, and sell an invention for a period of 20 years. A *patentable item* must be an invention, discovery, or design that must be genuine, novel, useful, and not obvious in lieu of modern technology (Miller 2013, 215–18). A *patent right* is infringed upon when the product is used without the permission of the patent owner.

INTERNAL REVENUE SERVICE

History

In 1862, during the Civil War, Congress passed and President Abraham Lincoln signed a bill establishing the position of Commissioner of Internal Revenue. The commissioner was charged with collecting income taxes to help pay for the Union's war expenses. The income tax was repealed a decade later. In 1894, the income tax was again instituted, and a year later it was again ruled unconstitutional by the Supreme Court. The income tax did not become legal until the passing and ratification of the U.S. Constitution's 16th Amendment in 1913. The 16th Amendment made income tax a legal form of revenue collection for the federal government to authorize.

The first income tax, levied in 1913, was 1 percent on a person's net income above $3,000, and 6 percent on incomes above $500,000. The income tax was increased to 77 percent in 1918 to finance World War I, but it was dropped to 24 percent in 1929.

The federal government was also a victim of the Great Depression, and again it raised the income tax rate. Congress began payroll withholding and quarterly tax payments to raise revenue during World War II.

Over time, the Bureau of Internal Revenue had become a government agency of patronage. To move away from this, during the 1950s it was restructured and became the Internal Revenue Service, or IRS. The chief counsel and commissioner of the IRS were appointed by the president, with confirmation by the Senate. The IRS was significantly restructured again in 1998, with the Restructuring and Reform Act. The essence of this second restructuring was to create an organization focusing on its consumer needs as if it were a business in the private sector. One significant change to the IRS through the Act was the way in which it interfaced with taxpayers. In addition to modernizing itself as a federal institution, the IRS developed a system of taxpayers' rights. The new IRS was charged with assisting taxpayers with the preparation of their tax returns, helping with submission and compliance. The aim was for the agency to be more to the public than just a tax collector. For those who did not comply, the IRS was to enforce the laws and policies of the U.S. government.

The IRS Today

Headquartered in Washington, D.C., the IRS is the largest bureau of the U.S. Department of the Treasury. The IRS is responsible for assessing and collecting tax revenue for the federal government. The IRS collects not only personal income taxes but also corporate income taxes, estate taxes, gift taxes, excise taxes, and employment taxes for the Social Security Administration. The IRS today is considered by many to be one of the most efficient tax administrators in the world, processing over 220 million tax returns, based on 2004 IRS data. According to the *2012 IRS Data Book*, the IRS spends only 48 cents per $100 collected.

At the same time, many others have labeled the IRS the most mistrusted and unpopular federal agency of them all. As the federal government's tax collector, it often finds itself in the middle of, or a topic of, political debates over government funding or the roles and enforcement of IRS policies. When the IRS Restructuring and Reform Act of 1998 was passed, instituting a more comprehensive IRS philosophy, with an expansion of taxpayers' rights, it was hoped that the public's perceptions of the IRS would improve and the dealings between the IRS and the public would be less antagonistic.

IRS Enforcement

Even though the IRS depends on taxpayers to voluntarily provide information regarding their financial records and earnings, the IRS is charged with upholding the tax laws and policies of the U.S. government. To force compliance with tax laws and policies, the IRS has several options at its disposal—including audit, confiscation, criminal investigation, and prosecution. The IRS has the power to confiscate and auction a person's personal and real property, such as cars and homes. The money raised from an IRS auction of that property is used to recoup the tax liability and accrued interest created by the individual's negligence in paying taxes.

Criminal Investigation (CI) is the enforcement section of the IRS. It is the agency responsible for enforcing the Internal Revenue Code, and it is charged with investigating and prosecuting violators of the code. Special agents of the CI investigate money-laundering, tax crimes, and crimes related to the illegal sources of income, as well as Bank Secrecy Act laws. The CI is considered one of the most effective law enforcement agencies in the federal government.

Individuals can also participate in IRS enforcement through the IRS Informant Award. As a type of reward or bounty, the IRS will award up to 30 percent of the original tax owed to an individual who is a whistleblower and reports to the IRS those who have not paid their taxes.

The CI agency of the IRS is not without its critics. Complaints of power overreach are not uncommon for the agency. This criticism has escalated with the addition of CI's oversight of drug and narcotic financial investigations.

IRS and Its Critics

Reform of the IRS and reform of taxes in general are constant topics for debate, from the highest-level politicians to the friendly confines of the local pub. There are those who would like to reduce the tax collection process to a postcard-sized tax return and eliminate the IRS completely. There are also those who suggest that the IRS is not large enough, and that it should be expanded to accommodate and adequately regulate the tax policies of a growing economy that is producing greater personal and corporate wealth—and a global economy that offers newer ways to avoid taxes through technology.

In recent years, the debate has taken on a technological focus with the inclusion of the online filing process for tax returns. Critics of the IRS charge that the advent of online filing of tax returns has increased the agency's power and ability to invade the private space of individuals.

INTERNATIONAL ASSOCIATION FOR RESEARCH IN ECONOMIC PSYCHOLOGY

The International Association for Research in Economic Psychology (IAREP) is a scientific body that brings together economic psychologists and other researchers who investigate economic behavior and also the psychological effects of economic phenomena. Over the past decades, IAREP has been the leader in disseminating economic psychology throughout the world. Since 1976, a group of European researchers had been holding annual colloquia to discuss their findings. In 1978, they decided to create the Standing Committee of the European Group of Researchers, while keeping their regular meetings and exchanging ideas about their studies. In 1982, the organization was formally launched and took the name "IAREP."

Currently, members may be economic or social psychologists, behavioral economists, experimental economists, and other experts in fields related to the discipline, such as consumer behavior, finance, and information. One of the main purposes of the association is to be a network for international and interdisciplinary researchers, who may thus exchange ideas and mutually inspire studies on those ideas. As a result, research that originated and was developed in these meeting has been published and become available worldwide, further enhancing economic psychology.

IAREP operates in at least 30 different countries. Its representatives help disseminate the discipline locally as well as providing assistance to those who are interested in becoming members and attending the events.

IAREP and the Society for the Advancement of Behavioral Economics (SABE) had been collaborating in conferences and workshops for 20-odd years. In 2009, they established the International Confederation for the Advancement of Behavioral Economics and Economic Psychology (ICABEEP) in order to increase cooperation between the two organizations.

In 1981, IAREP founded the *Journal of Economic Psychology* (JoEP). Since then, IAREP has sponsored the journal and has been responsible for electing its editor(s). IAREP also publishes a regular newsletter for members, keeps a website (http://www.iarep.org/), and supports graduate-level summer schools in economic psychology and workshops on special topics in the area. IAREP also provides information on graduate courses related to economic psychology on its website: www.iarep.org/graduateprograms.htm.

Since 1976, IAREP has organized annual conferences, sometimes along with SABE, in different countries, covering different issues within the psychology–economics intersection. So far, these have been the dates and locations of the annual colloquia:

At these conferences, IAREP also sponsors the Kahneman lecture, with a notably relevant expert invited to be the keynote speaker (Daniel Kahneman himself inaugurated the series at the IAREP's Paris conference in 2006). Since 1984, it has awarded a prize, sponsored by Elsevier (JoEP's publisher) to the best student papers presented at the conference.

IAREP is not the only association for economic psychology researchers; the Ninth Division at the International Association of Applied Psychology (IAAP) is dedicated to the same field. However, IAREP has a much broader disciplinary focus.

The history of IAREP's creation, first years, and evolution can be found in the original documents (letters, memos, and proceedings of meetings), intended to become an official archive of the organization, and currently kept at the University of Exeter, in the United Kingdom.

INTUITION AND DECISION-MAKING

In its definition of *intuition*, the *Oxford English Dictionary* refers to a publication from the year 1659 in which *intuition* is part of "that Tree of Knowledge . . . which instructs not . . . by sad and costly experience, but by fair and safe intuitions." Economists would reject this, because the author mentions only the costs of experience while ignoring the benefits! Robin Hogarth, in *Educating Intuition*, lists the characteristics of intuition as speed of knowing, immediate cognition, and the absence of rational or deliberate thought. Mario Bunge (1962, 68) writes that *intuition* is "the collection of odds and ends where we place all the intellectual mechanisms which we do not know how to analyze or even name with precision, or which we are not interested in analyzing or naming." Joseph Schumpeter (1954, 41) says that *intuition*" is a "pre-analytic cognitive act that supplies the raw material for the analytical effort." Herbert Simon, 1978 winner of the Nobel Prize in Economics, thinks of intuition as an expert's skill for (unconscious) pattern recognition. Simon exemplifies this in his discussion of how chess grandmasters play intuitively (1996).

Intuition as a decision-making tool is difficult for traditional economics to comprehend, because it's inherently different from logic and analysis as a decision-making tool and because its nature escapes logical and rational analysis. Therefore, intuitive decision-making is often referred to as (unconscious) pattern recognition. Steve Sloman, in his article "Two Systems of Reasoning" (2002) distinguishes the Associative System of reasoning (intuition) from the Rule-Based system (analytical thinking). Daniel Kahneman (2011), winner of the 2002 Nobel Prize in Economics, refers to this as System 1 (intuition) and System 2 (analysis).

What about a role for intuition within behavioral economics? Intuition is considered a foundation for decision-making via heuristics—shortcuts in decision-making—because it bypasses all conscious thinking processes. But even as intuitions can and do yield accurate judgments, they can also create systematic errors in judgment.

According to Kahneman (2001) and Gary Klein (1998), intuition is at its best when we are solving (complex) problems on subjects about which we are knowledgeable and experienced, when we have a cue to help stimulate the knowledge in our subconscious, and when the environment is regular so as to be predictable. Under these conditions, we can learn about the regular aspects of the environment and develop expertise. Kahneman and Tversky refer to intuition as a "natural assessment" (1973). Both Kahneman and Tversky are psychologists, and so are less skittish about intuition. To dismiss intuition is inefficient, because it is the way the right hemisphere of our neocortex processes information.

According to Kahneman and Tversky, intuition leads to errors when the information is based on the representative heuristic. If you describe a person with the characteristics of a librarian and then ask someone if the person you described is a librarian or a salesperson, the person you are asking will tend to say a librarian. People choose "librarian" because the characteristics of the person you described are representative of a librarian, even though the essential piece of data in the conversation as a whole is that the number of salespersons vastly exceeds the number of librarians. Undergraduate students, weather forecasters, gamblers, and professional stockbrokers make errors in judgment via intuition.

Behavioral economics examines under what conditions people behave fully rationally (as defined in traditional economics) and less than fully rationally. It does not assume full rationality and ignore all of the elements that are inconsistent with this assumption. Intuitive decision-making plays an important role this behavioral economics narrative.

INVESTING

In economics, *investing* is defined as the act of purchasing goods that are not consumed today but will be used in the future to create wealth. In finance, an *investment* is a monetary asset purchased with the idea that the asset will provide income in the future or will appreciate in value and be sold at a higher price. In simple words, *investing* is how you make your money grow, or appreciate in value for long-term financial goals.

Examples of investments, in the economic sense, would include going to college to earn your degree, purchasing a computer for your business, or building a factory that will be used to produce goods. In the financial sense, investments include the purchase of bonds, stocks, or real estate property. There are many reasons to invest. Investing allows us to achieve such financial goals as buying a car, paying for college, beating inflation, and retiring comfortably.

The earlier you start investing, the more money you will accrue and the faster you will reach your financial goals. Investing garners the power of compound returns. Earning compound returns is the process of having money grow and making money on top of the original sum. For example, if you invest $2,000 a year for nine years starting at age 21 and you earn a 10 percent interest rate, when you reach age 65 your $18,000 investment will be worth around $763,000. On the other hand, if you wait until age 30 to start saving and you save $2,000 a year every year until you reach age 65, then you will have only $542,048.73, a difference of $220,000 from the amount you would have earned if you had started investing when you were 21.

Financial Market Investing Options

There are many investing options to choose from. A few are investing money in stocks, bonds, mutual funds, or real estate—or starting your own business. No matter what investment method you choose, the goal is always to put your money to work to earn additional income.

The stock market is one option for investing money. When you invest in stocks of a company, you're buying a share of that company. The value of each share depends on how profitable the company becomes. Compared with savings accounts, stocks tend to offer a higher rate of return on the initial investment. But stocks are relatively more risky, because stock is not insured by the Federal Deposit Insurance Corporation (FDIC) like a savings account is. The stock price of an individual company tends to go up and down based upon many factors, including the merits of the company, the psychological tenor of the overall stock market, and factors of supply and demand.

Buying bonds is another investing option. A *bond* is an agreement or a loan between the bond issuer (a company, municipality, or other type of entity) and the bondholder (the person buying the bond). The bondholder essentially loans out a certain amount of money to a government agency, municipality, or corporation and earns interest on the loan.

The term of a bond is given a fixed rate at the time of issue and expires on the specified maturity date. At that time, the issuer must pay the bondholder the face value of the bond. Throughout the term of the loan, the issuer also pays interest to the bondholder. The interest amount is set when the bond is issued. Bonds can vary in term length. The term can be as short as three months or as long as 30 years. Bond interest is also called a "coupon" payment. Usually, the longer the term on the bond, the higher the interest rate the bondholder receives.

Mutual funds are another type of investment. Mutual funds are created when money from many investors is pooled to create a large portfolio so everyone benefits from bigger profits. Most funds buy a variety of investments, like stocks, bonds, or other securities. Because one mutual fund can contain a variety of different investments, there is lower risk than investing in individual stocks and bonds: If one investment in a mutual fund has a poor return, another can make up for that loss.

When investing in the financial markets, investors make money when they sell a stock, bond, or mutual fund for more than they paid for it, as well as when they receive interest or dividend payments. If an investment does not increase in value, the investors may lose money when the stock, bond, or mutual fund is sold for less than the purchase price.

Real Estate Investing

Many individuals look to real estate as another investment in which to grow their funds for the future. Investors who do not want to buy an individual home or apartment building and rent that property to tenants may instead invest in real estate through a Real Estate Investment Trust (REIT). REITs are actually financial securities that combine the ownership of many real estate properties and then sell off individual slices of ownership, or shares, to individuals. REITs come in several varieties, including those that invest only in shopping centers, office buildings, or even just the mortgages of certain types of property.

For people who want to invest in actual real estate, buying, renting out, and managing the real estate investment requires a certain degree of knowledge, risk, and time. For example, if Kris wanted to buy a two-family apartment building as an investment, she would need to save up money for a down payment and then obtain a mortgage loan from a lender. Further, she would need to examine the rental income and expenses, as well as evaluate future rental income and expenses. Before purchasing the rental investment property, she would need to make sure that the amount she could charge as rent would be enough to pay for upkeep of the property, with some money left over for profit.

IRON AGE

The Iron Age is the final age in the sequence from Stone Age to Bronze Age to Iron Age. This sequence represents technological and cultural shifts in civilization. The beginning and end of the Iron Age differ depending on what geographic location is being considered. The Iron Age began in the Middle East and southeastern Europe around 1200 BCE. However, the technological advances of the Iron Age did not reach China until about 600 BCE.

The term *Iron Age* is used to explain the era in which iron replaced bronze in the production of tools and weapons. Iron is immensely more abundant than the elements that make up bronze, copper, and tin. Thus, the transition to the Iron Age was not due to the physical characteristics of iron compared to bronze, but rather to the availability of iron as a resource. The abundance of iron allowed for true mass production of weapons and tools. Given the uses of tools and weapons in society, both agriculture capabilities and warfare expanded due to the technological advancement.

Two subsections divide the Iron Age: Iron I (1200–1000 BCE) and Iron II (1000–550 BCE). Iron I represents the slow transition out of the Bronze Age into the Iron Age. The transition between the 13th and 12th centuries occurred without any significant cultural revolution, although the Bronze Age officially ended. Evidence suggests that as the Iron I era matured, the cultural transition away from bronze and toward iron began to take effect. Iron II is characterized by regional power struggles in the Middle East. Notable power shifts include the decline of Assyria and Egypt; the rise of Judah and Israel in the 10th to 9th centuries, followed by the re-establishment of power by Assyria in the 7th century; the destruction of Israel and the slow transition of Judah back to Assyrian rule; and finally the disintegration of Assyrian power yet again. The reign of Judah was short-lived, however, as the Chaldeans took over.

Armies within the Iron Age were the first to practice recruitment on a regular basis. For the first time, citizens were obligated to provide military service in times of war and peace. The Iron Age spawned the national strategy of providing a standing army based on citizen service. The Iron Age brought about a revolution in militaristic ideals. Militaries in the Iron Age increased in size, advanced logistics, and transportation, and they became more strategic and better organized. All of these improvements led to the creation of the military as an occupation. The constant increase in the size and the scope of militaries due to recruitment meant that professionals needed to be on hand to train the new citizen-soldiers and lead them into the fighting force. The weapons continued to be constructed of bronze throughout Iron Age I, although iron weapons began to appear. One example is iron knives with bone handles.

During Iron Age I, pillared houses and silos were constructed on top of the previous structures of the Bronze Age. By the time Iron II arrived, the pillared houses were the norm and the standard in domestic culture.

The Iron Age also brought about the creation of water systems—such as staircases to underground water, and large circular shafts within city walls—to provide access to underground springs. Moving away from the staircases, more-developed water systems emerged in Iron II. The staircases were shortened, and water tunnels were developed that would lead down to the underground spring. During the eighth century, tunnels were modified so that the water flowed into the cities.

While militarized citizens and agricultural advancements characterized much of the Iron Age, archeological discoveries have uncovered primitive board games, baby rattles, and slingshots.

Language and literature evolved in the Iron Age. While the Bronze Age produced the earliest alphabets, the Iron Age advanced the alphabet into written texts. Chinese and Indian literature and the Hebrew Bible were all products of the Iron Age. Poetry became popular, and language grew more complex, along with other emerging cultural dimensions of the civilizations.

One of the most notable characteristics of the Iron Age is its place in history as an era of transition. Technological advancements and the accessibility of iron spread throughout the Middle East, Asia, and Europe. While growth was specific and certain, it was slow and deliberate. Nations around the world slowly phased out bronze and introduced iron. Military advancements resulting from the use of iron allowed for the creation and destruction of new and old civilizations.

JOBS, STEVE

Born: February 24, 1955, in San Francisco, CA; Died: October 5, 2011, in Palo Alto, CA; Nationality: American; Professional Interests: inventor, technology entrepreneur and founder, chairman, and CEO of Apple Computer.

As founder of Apple Computer and inventor of the iPod, iPhone, and iPad, Steve Jobs greatly impacted the world of economics. While Jobs had a fairly normal upbringing, certain people in his life led him toward the path he created for himself. He experienced many struggles along the way, including being dismissed from the company he founded.

Jobs was born nameless on February 24, 1955, in San Francisco to Joanne Schieble, who immediately put the child up for adoption. He was adopted by Paul and Clara Jobs, and they named him Steven Paul Jobs. His adoptive father Paul taught him electronic tinkering. In school, Steve's classmates considered him to be something of a prankster.

While in high school, Jobs met an older student, Steve Wozniak, who was attending the University of California, Berkeley. Jobs looked up to Wozniak, and "Woz" impacted the path that Jobs would take. Jobs started at Reed College in Portland, Oregon, but soon dropped out. He did sneak into some creative classes, even though he was not a student.

In 1974, he was hired by Atari as a game designer. Soon he left the United States for India. When he returned to the States he turned his interests to physics. After some time he went to Wozniak, who helped him get back on at Atari. Jobs ended up making a lot of money working with Wozniak on an illegal device that emulated telephone tones, known as a "blue box." He began to believe that he could beat big companies.

Jobs and Wozniak attended a computer club that inspired them to build computers. In 1976, when Steve was 21 years old, he and Wozniak founded Apple Computer in the Jobs' family garage. They assembled the computers themselves and began selling the Apple 1. Eventually, Jobs asked Bill Gates to make a graphical user interface (GUI) for his company. A *GUI* is something that lets people communicate through graphic icons as opposed to words. Shortly after this, Jobs took his business to the Soviet Union to sell more of his Macs.

When Jobs was 30 years old, Apple CEO John Sculley phased him out from the operations of the company he had founded. Jobs responded by creating a new computer company: NeXT. He also bought George Lucas's computer graphics company, which would lead him to start Pixar with the animated motion picture *Toy Story*.

Jobs sold NeXT to Apple Computer, and as a result he rejoined the company he had founded. Not only did he rejoin Apple, but also he became CEO. According to his coworkers, when he returned he was much better at what he did. With his return, Apple released inventions like the iMac, iTunes, and iPod, which were huge technology breakthroughs. This had a massive effect on the technological economy, creating a demand for new technology.

In August 2011, Jobs resigned from Apple due to pancreatic cancer. He passed away on October 5, 2011, in Palo Alto, California.

KEYNES, JOHN MAYNARD

Born: June 5, 1883, in Cambridge, England; Died: April 21, 1946, in Firle, Sussex, England; Nationality: English; Professional Interests: macroeconomic theory; Major Works: *The Economic Consequences of the Peace* (1919), *Treatise on Probability* (1921), *Tract on Monetary Reform* (1929), *The General Theory of Employment, Interest and Money* (1936).

John Maynard Keynes, Baron Keynes of Tilton in the County of Sussex, was an English economist who impacted both political theory and modern economics. Keynesian economics promote a mixed economy, dominated by the private sector but with a large role for government and the public sector. Keynesian economics argues that at the macroeconomic level, the private sector is at times inefficient in its allocation of resources. When this occurs, the public sector needs to be actively involved in the country's fiscal and monetary policies to create stability of the business cycle. Keynes followed a legacy of successful nonconformists within his family, and he is revered as the father of macroeconomics. Keynes died in 1946.

John Maynard Keyes was born in Cambridge, England, on June 5, 1883. His father was a lecturer and the university's chief administrative official. His mother was an accomplished author, Cambridge's first woman councilor, and also its mayor. After enjoying an elite education at Eton College, Keynes completed his postsecondary studies at King's College in Cambridge and earned his degree in mathematics in 1905. He spent additional time studying under Alfred Marshall and Arthur Pigou, and he received a master of arts degree in economics.

Keynes started his career as a civil servant in London when he placed second on an examination—which cost him the job he desired at the Treasury Department. He was appointed to a position in foreign affairs at the Royal Commission on Indian Currency and Finance, a bureau that extended advice on the administration of India, one of England's dominions at the time.

Keynes accepted this foreign affairs job and learned how government departments operate. He soon developed an interest in Indian affairs and Indian currency; Keynes gained the attention of numerous government officials because he was able to apply economic theory to practical problems. His experience helped him write his first book in economics, *Indian Currency and Finance* (1913), a description of the Indian monetary system.

In 1908, Keynes returned to Cambridge to teach economics. Tired of the slow-moving departments of the Indian Office, he turned his attention to writing.

Based on his experiences in government, he composed an essay titled "Recent Economic Events in India" (1919), which was his first major article in print. In addition to being a journalist and a lecturer, Keynes was part of the acclaimed Bloomsbury Group of literary greats that included Virginia Woolf and Bertrand Russell. In 1911, Keynes was appointed editor of *The Economic Journal.* This was a prestigious honor and a significant accomplishment, especially given that he had few publications at this time.

World War I put a hefty burden on the British economy. In 1915, Keynes gladly accepted the offer of a job at the British Treasury, where he could actively participate in the war effort. Keynes served as the Treasury's chief representative at the Paris Peace Conference of 1919, since his division had done much of the work on preliminary reparations and war debts; however, its result was quite unfavorable to him. After returning to England, he resigned from the post and turned to writing a book. By the fall of 1919, Keynes had published *The Economic Consequences of the Peace,* which became an international best seller and a close foreshadowing of the immediate future. He predicted that the treaty's terms were too harsh and were aimed to cripple the people of Germany instead of punishing them. Keynes's contention was that the provisions in the treaty would hamper Germany's postwar economy, that Germany would eventually repudiate the treaty, and that a rearming of Europe would ensue. Just as Keynes had suggested, the German economy experienced hyperinflation in 1923, and only a fraction of the reparations were ever received.

After 1929, the economies of the entire world plummeted, and Keynes decided to take on the task of explaining and determining new ways to control trade cycles. This resulted in two books: *Tract on Monetary Reform* (1929) and *The General Theory of Employment, Interest and Money* (1936). Through these books, Keynes proclaimed that there needed to be both national and international programs that would lead to a cohesive monetary policy. He believed that a national budget should be used as a primary instrument in planning the national economy. Keynes asserted that policies were needed to regulate the ups and downs of the trade cycle. He firmly believed that it was the responsibility of government to regulate the levels of employment and investment. Keynes's solution to a depression or a recession is government actions designed to encourage spending and discourage saving, and a key component is that the government's central bank should lower interest rates when prices are too high and raise interest rates when prices fall.

Keynes made other important contributions to economics, one focused on the disorganization caused by World War I and the other on the deterioration in the balance of trade between Europe and the United States. He continued to help the British government, and he became an unofficial adviser to Germany. Keynes worked with Roosevelt and other writers of the New Deal, contributing directly to its implementation. By the time World War II began, Keynes was a famous and accredited expert on economics. He assumed a primary role in establishing the system envisioned at the Bretton Woods Conference, which would eventually lay foundations for the International Monetary Fund and the World Bank.

He strongly supported William Beveridge's proposal for an expansion of Britain's social services, which led to the United Kingdom's National Health Service. Keynes occupied a seat in the House of Lords as a member of the Liberal Party, and he supported equal opportunities for women in business.

John Maynard Keynes suffered several heart attacks before losing his life on April 21, 1946, in Firle, Sussex, England, due to heart failure. He was cremated, and his ashes were scattered on the Downs above Tilton.

KEYNESIAN ECONOMICS

Keynesian economics is the economic philosophy of John Maynard Keynes (1883–1946). Keynes has been considered by many as one of the most influential persons of the 20th century, due to his ideas about government playing a more expansive role as a means of influencing an economy. The central theme of Keynesian economics is that government can serve in leveling out the peaks and troughs of a business cycle by using taxes or government spending to eliminate the extremes of the business cycle. Keynes is credited with the "invention" of what is now called fiscal policy.

Keynesian economists believe in several ideas that are at the core of Keynes's economic philosophy. The key belief is that aggregate demand (total spending by consumers) has significant impact on an economy's output and inflation, and that it is influenced by many different economic decisions. Keynesians also believe prices are "sticky" downward, do not go down as fast as they rise, and do not respond predictably to conventional (classical) economic supply and demand models. This notion was quite unconventional at the time Keynes suggested it in 1936 with the publication of *The General Theory of Employment, Interest and Money*. Keynes also believed that wages, like prices, were "sticky" downward.

Keynesians believe that the wide variations of the business cycle negatively impact an economy, and that government involvement can improve a market economy. Keynesians are most noted for their belief that active government action can be used to stabilize the business cycle, minimizing recessions and downturns while also compressing excessive growth to stabilize an economy and avoid bouts of excessive demand-pull inflation (a concept proposed by Keynes). Finally, early on, Keynesian economists were more concerned with curing unemployment than inflation.

Over the years, Keynesians have debated and often changed their views on what essentially defined Keynesian economics. Most economists today question whether government can ever have enough knowledge to act as a fine-tuning instrument of the economy. This general agreement is based on the understanding that there are three policy lags that prevent governments from being successful:

1. the recognition lag between the time a policy is needed and the time that government realizes a policy is needed,
2. the implementation lag between when a policy is needed and when the new policy takes effect, and
3. the impact lag between when a policy is passed and when it becomes effective.

Each of these lags can be several months long, meaning that the time between recognition and impact could be quite long. These lags suggest that by the time a policy's impact is felt, the economy could in fact be in a very different position. The policy could be exactly what not to do, and could exacerbate a bad economic environment. Even though there is agreement that the lags exist, Keynesians today still believe government is the correct tool to stabilize an economy.

An additional concept related to the economic vocabulary and thinking promoted by the Keynesian position is the idea of a multiplier effect of fiscal policy on an economy. According to Keynes, government spending will increase GDP (Y* to Y**). (See illustration on facing page.)

Keynesians believe government spending has a ripple effect throughout an entire economy, not just at the point of infusion. This ripple, or multiplier, effect suggests an impact on economic growth. For example, if government injects a million dollars into the economy and the economy actually grows by 2 million dollars, it is said to have a multiplier of two. The increase could be as little as 10 percent, but the Keynesian economic model suggests that any multiple increase is a reflection of a multiplier effect on an economy.

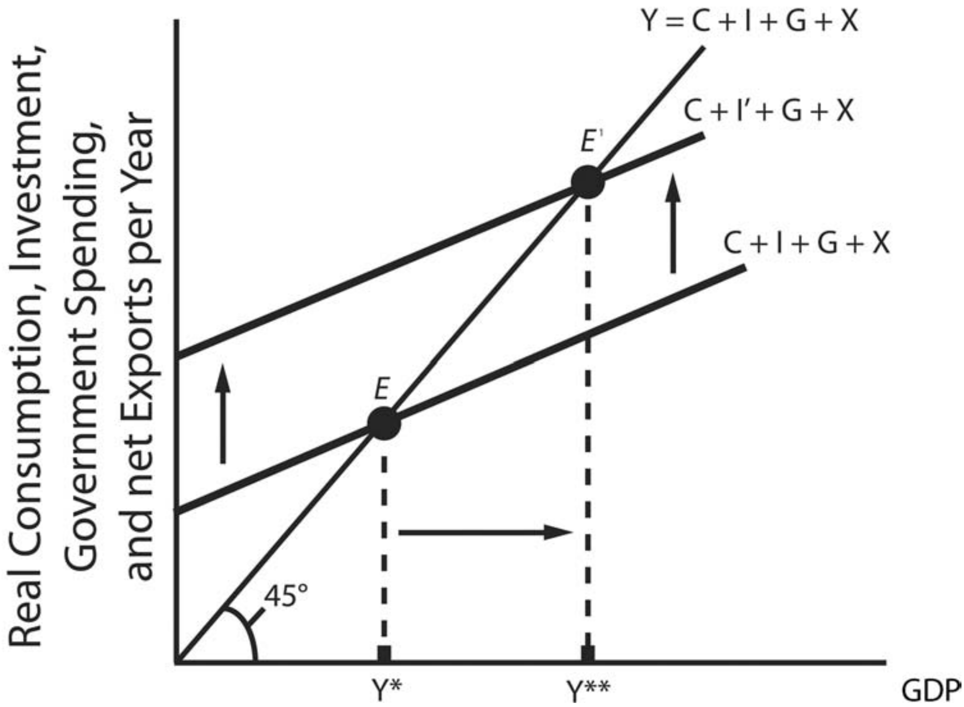

Figure 1. Keynesian government spending increases growth

Role of Monetary Policy

Another discussion between the Keynesians that has been debated over the years has been the role of monetary policy. Most, though not all, Keynesians believe that there is a role for monetary policy in stabilization, albeit a more minor role than fiscal policy. Monetarists focus on one of two metrics: the money supply or interest rates. Keynesians who hold a belief for monetary policy generally focus on interest rates as their key monetary policy metric.

Keynesians hold that low interest rates spur investment. Therefore, during times when expansionary monetary policy is the prescription, low interest rates will expand the money supply and spur investment and economic growth (GDP = C + I + G + X) (C = Consumption, I = Investment, G = Government, X = Net, Exports). History has shown this to be a valuable metric while an economy is either in a downturn or recession. Once an economy achieves full employment, however, history has shown this to be an activist position for inflation.

Keynesian theory is differentiated from other economic philosophies because of three distinct views:

1. Keynesians view unemployment as a function of aggregate demand—an economy's total demand for goods and services.
2. Keynesians advocate government being active to stabilize an economy and reduce the ultimate peaks or lows of the business cycle. This belief is the most distinguishing viewpoint of the Keynesians and the most important viewpoint for Keynesians to hold.

3. Keynesians generally believe that limiting unemployment is more important than limiting inflation, and is the key macroeconomic goal that will lead to economic growth. This view is much less universal, however, and many Keynesians today lean toward a more monetarist, low-inflation-first position, stressing low interest rates as the key monetarist goal.

Critics of Keynesian Economics

Every economic philosophy has its critics, and Keynesian economics is no exception. The criticisms of Keynesian economics were especially loud during the 1970s, when inflation and unemployment were both present in the economy. During this decade, several events were occurring in the economy that the Keynesians position could not defend. Keynesians believed that in the long run, unemployment and inflation could not occur at the same time and were therefore trade-off goals. Keynesians held the view that government stabilization policies would cure unemployment during economic contractions or halt inflation during periods of economic expansion in the short run, but did not have to be concerned about both simultaneously. A. W. H. Phillips (1914–1975) solidified this unemployment–inflation trade-off with his *Phillips curve*. Phillips showed that policies to achieve gains in reducing unemployment were met with only slight increases in inflation in the short run. In support of short-run policies over long-run policies, Keynes famously remarked, "[I]n the long run we are all dead." This position could not adequately explain the wage–price spiral and stagflation of the 1970s.

A second criticism of Keynes was the Keynesian monetarist view of focusing on interest rates instead of on the money supply as the more advantageous short-run monetary tool to control the money supply. To the critics, this view was especially flawed during the 1970s, as Arthur Burns and the Federal Reserve kept interest rates artificially low during a time of economic growth. Keynesianism's critics attribute this action as a major reason for the high inflation rates of the mid to late 1970s.

LAND USE

For almost as long as there have been urban areas in civilized societies, there have been efforts to preserve certain portions of these areas as parks and green spaces to provide amenities to local residents. It is the mix of land uses in urban areas that forms many of the amenities for local residents. For this reason, over the last century or so, most cities have adopted what are commonly known as zoning ordinances to regulate the types of land use and development allowed in a given area. A prime motivation for such regulation is to restrict private decision-makers from making land-use decisions that negatively impact their neighbors. In other words, these policies have been developed to reduce the impact of externalities.

Private landowners, like the owners of any other asset, have the incentive to maximize the value of their land. One way in which they do this is by converting it to its highest private value use. The value of a parcel in different uses is determined by market conditions. Areas seeing rapid population and/or economic growth, for instance, are likely to see values for developed land outstrip values for land in agricultural or other uses. In contrast, in areas experiencing slower population growth or economic growth, there may be little demand for additional development and, thus, relatively low values for developed land versus other uses. In any case, it is true that in many situations agricultural, forest, or other undeveloped land provides public-goods benefits to nearby residents that are not reflected in market prices. Unfortunately, private landowners will not take these public-goods benefits into account when managing their land—so it usually expected that much undeveloped land that, from a social welfare perspective, should remain undeveloped will, in fact, be developed to maximize the private benefits rather than social ones.

In addition to overconversion of undeveloped land, a number of other locally undesirable land uses (LULUs) also provide private benefits while imposing costs on neighbors. These include, but are not limited to, landfills, industrial sites, communication towers, and power facilities of all types. Measurement of the value of disamenities from changes in land use and the presence of LULUs is most often done using hedonic analysis.

To solve these market failures, governments at many levels have undertaken a number of policy approaches. The most basic of these is the public acquisition and preservation of land parcels as public spaces. Such acquisition takes many forms, but in urban areas it mostly takes the form of public parks, both small and large.

Instead of acquiring the land itself, authorities may separate the development rights from the land and acquire these rights, leaving the land with its existing owners, who are now prevented from developing the land they own, although they retain all other rights. Very often, the funds needed for such acquisitions are raised through increased local property taxes—or through local bond issues, which are approved by the public through voter referenda.

A second common regulatory approach is zoning, which creates zones of parcels designated to contain similar or compatible land uses. For instance, in residential zones, development may be restricted to residential uses of particular density as well as schools, churches, and other similar uses. Similar zoning-based policies have also been used to preserve green space and prevent the spatial growth, or "sprawl," of urban areas. These are often referred to as urban growth boundaries, or greenbelts. Such policies prevent further development of parcels in a region or belt around existing urban areas. Many other communities require that a certain portion of new development be left as open space. Unfortunately, these approaches may have unintended consequences: for example, increasing property values in the centralized urban area, which, in turn, may drive development to areas beyond those areas set aside, which will increase urban sprawl, commuting, and other costs.

The policies described are based on a command-and-control approach where government regulators dictate development patterns. However, there are also more incentive-based policies that also help to reduce the damages caused by overdevelopment in a more flexible framework. One such policy is development taxes. These taxes, which work like any other Pigouvian tax, charge developers a fee that increases as the amount of land being developed increases. Properly designed, such a fee would be set at a level that is equivalent to the social damages caused by the development and could be used to compensate those harmed. It also causes developers to internalize the externalities that development imposes on others, and thus it reduces the equilibrium amount of development. Another similar approach, which is most often implemented in more rural areas, is a tradable development rights system that separates ownership of the land from the right to develop the land. A set number of development credits are issued, and then developers buy and sell these credits as development happens. Such a program minimizes the costs of restricting development while it achieves the desired level of total development in an area.

If, as many predict, population growth in urban areas continues, concerns about land use can be expected to grow, as such growth will put additional financial pressure on property owners to sell their land for development. In this context, there will continue to be a policy debate about how best to preserve undeveloped land so as to provide the associated amenities.

LAW AND ECONOMICS

Legal constructs provide order and direction for society in the modern world. Economics is commonly thought of as the realm of financial and commodity exchanges, but it is more broadly explained as human behavior and interaction based on resources, interests, and needs. The law and economics can be seen to inform each other and evolve in response to each other. There are those who believe that one realm should exert greater influence over the other. Regardless of this contention, the symbiotic impact of law and economics on each other is undeniable.

Law in a society is any system of regulations designed to dictate human conduct in the interest of consistency and justice. As early as 1792 BCE, in ancient Iraq, the need for broadly understood guidelines for behavior was such that Amorite King Hammurabi established his famous code: over 200 laws that addressed a range of contingencies from trade to murder. Over millennia, successive attempts to improve various societies by creating order and fairness have been put forth, ranging from the Magna Carta and the Mayflower Compact to the Japanese constitution of 1947. *Economics* has existed in the broadest sense since individuals first devoted time to scavenge for food instead of another endeavor. History affords no shortage of examples in which humans and nations acted in their economic interests with no regard to law and order. England's Navigation Act of 1651 can be seen as a major touchstone of the interaction of law and economics. In the interests of English merchants, Parliament decreed the following:

> For the increase of the shipping and the encouragement of the navigation of this nation . . . be it enacted by this present Parliament, and the authority thereof, that . . . no goods or commodities whatsoever of the growth, production or manufacture of Asia, Africa or America, or of any part thereof; or of any islands belonging to them, or which are described or laid down in the usual maps or cards of those places, as well of the English plantations as others, shall be imported or brought into this Commonwealth of England. (Scobell 1651)

Adam Smith

In his treatise *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776), Adam Smith laid out the rationale for the relationship between nations and interests. But consider the actions of his home nation, the United Kingdom, in the case of the Opium Wars conducted against China in the 1800s; or the 1884 Berlin Conference, in which European nations colonized Africa according to their whims; or Japan's subjugation of Korea following the Russo–Japanese War, which led to political and economic depravity at the expense of that nation. These are just a few examples of how economic interests have trumped the rule of law between nations.

On a microeconomic scale, certain entrepreneurs regularly pursue economic interests, such as dealing in narcotics, contrary to the law. Conversely, certain communities impose laws to restrict or forbid the operations of businesses at certain times, such as on Sundays or after certain hours. As the law in a centrally planned economy—for example, in a totalitarian state such as North Korea—is understood to be paramount to the government's interest, it is practical to consider the interaction of the law and economics within the frameworks of the free-market system.

As economics considers how parties act and interact regarding their interests, the consequences of pursuing these interests without regard to the rule of law have littered history, with no shortage of misery when these interests are not considered. The understanding of property rights is the most universal point of the unspoken law that impacts economic interactions. This recognition is found in most assemblages of laws from the Magna Carta in 1215 to the U.S. Constitution in 1787; the Constitution articulates that "the right of the people to be secure in their persons, houses, papers, and effects, against unreasonable searches and seizures shall not be violated" (Tindall and Shi 2007, A7).

History, not documents, illustrates how, in the absence of the law, actions based on economic interests do not bode well for the human interests of absolutely everyone concerned. Once the rule of law in a jurisdiction reflects property rights, it is common for that legal framework to impose some levy upon various forms of property, be it real property or income. The Sixteenth Amendment to the U.S. Constitution confers that right on the government: "The Congress shall have power to lay and collect taxes on incomes, from whatever source derived . . ." (Tindall and Shi 2007, A74). Disagreement over the nature and amount of taxes levied by society on its subjects perhaps even predates the Roman adage of rendering unto Caesar that which is Caesar's, and the sources of these revenues are as varied as the municipalities that collect them. In the United States, the state of New Hampshire levies no sales tax on retail purchases, nor any income tax, while the state of Colorado collected $2 million in taxes on the sale of marijuana in the first month of its legalization in 2014 (Lobosco 2014).

In Colorado, the government enacted laws to take advantage of an economic reality—namely, scarcity and demand—and the expected increase in economic activity. By its nature, this activity benefits willing and able buyers as well as sellers and complementary interests. In doing so, the state has enriched its own coffers. In other cases, the law has been used to preclude an economic benefit resulting from an earlier illegal act. The state of New York enacted the so-called Son of Sam law—after a serial killer attempted to publish an account of his acts—to prevent purveyors of crime from benefiting economically from their exploits.

In spite of these examples, the world is more rife with cases of economics impacting the law than it is with cases of law impacting economics. Whether it has been the economic benefit of legalized prostitution in Nevada or the deregulation of the American airline industry in the 1980s, societal and commercial forces that recognized the prospects at hand successfully affected change in the laws that governed these realms. Various business interests touted the benefits of the North American Free Trade Agreement (NAFTA) in the 1990s, to the point that a Democratic candidate for the American presidency endorsed it in spite of objections from a traditional base of Democratic support: namely, organized labor. Individual workers—or in the case of unions, organized workers—have also been another realm where the law and economics have intersected. Employees and their organized representatives have frequently sought relief and protection of the law for their rights, wages, and assurances regarding their working conditions. How such protections impact the commercial interests involved—that is, how a firm's owners might respond, perhaps with higher prices or outsourcing—is an issue that the law has endeavored to move into its realm. In the United States, this has been attempted through the National Labor Relations Act, seeking to move such disputes from the picket line, where shoving might ensue, to the courts. Just as self-preservation, more than peace, is the foremost priority of most nations, history and the present both suggest that the economic interests of parties often dictate their actions more than the rule of law does. It is because of this truism regarding the former that societies enact the latter.

LENIN, VLADIMIR

Born: April 22, 1870, in Ulyanovsk, Russia; Died: January 21, 1924, in Gorki Leninskiye, Russia; Nationality: Russian; Professional Interests: Russian government leader 1917–1924; Major Works: *The State and Revolution* (1917), I*mperialism, the Highest Stage of Capitalism* (1900), *April Theses* (1917).

In 1917, imperial rule in Russia came to an end in what is known as the October Revolution, led by the Bolshevik leader Vladimir Lenin. A three-year civil war in Russia ended with the Bolsheviks victorious and taking control of the newly created Soviet Union. Once Lenin was in power, the Bolsheviks renamed themselves the Communists. Besides a new name, many additional changes came to the Soviet Union under Lenin's rule.

Vladimir Ilich Ulyanov was born April 22, 1870, in Simbirsk (later named Ulyanovsk), Russia (he would change his name to Lenin in 1901). Vladimir was the third of six children in a well-educated and close household. He loved education and reading, but his future was highly influenced by two incidents. First, the Russian government grew suspicious of public education, and his father, who was a school inspector, became the focus of a government investigation of public schools. Second, in 1887 his older brother, a university student, was executed by the government for being part of a plan to assassinate Emperor Alexander III. The same year of his brother's execution, he enrolled in Kazan University as a law student. Like other members of his family, he was a revolutionary against the government, and he was expelled during his first semester. He did eventually complete his law degree, in 1892.

Lenin became quite impacted by Karl Marx's *Das Kapital*, and in 1989 he declared himself a Marxist. After receiving his law degree, he eventually moved to St. Petersburg and began the Marxist activities that eventually led to the Russian Revolution and his rise to the leadership of the Bolsheviks.

Internally, Lenin introduced central planning, and externally he focused on building national power and prestige in the international world. In order to achieve his goals, Lenin and his political party allocated the best land, labor, and capital to the armed forces, the space program, and the production of such capital goods as farm equipment and factories.

Committees were organized to run the new communist system. Their responsibilities were to decide the quantity, the production process, and the distribution of goods and services throughout the Soviet Union.

Agricultural Changes

Once the country came under Lenin's rule, large state-owned farms and collectives were created. Private ownership of land was no longer allowed, and on the new state-run farms the state provided farmers with all the equipment, seed, and fertilizer they would receive. Farmers worked for daily wages set by economic planners. Collectives were also state-run farms, but they were leased to peasant farmers to manage and operate on their own. Although the collectives were still required to produce what the government instructed, the farmers received either a share of what they produced or a small income from the sale of the crop.

Under Lenin's new communist rule, agricultural workers were guaranteed employment and income. In return, the government established quotas of production and oversaw how the crops would be distributed. These changes in agriculture did not improve the Soviet Union's productivity. Under this system, individuals had little incentive to produce more or better crops. While Russia had been a major exporter of wheat until 1913, the Soviet Union could not keep its own people fed.

Industrial Changes

Factories within the Soviet Union were also state-owned. The primary focus of the new regime was the defense industry, the space program, and heavy industries such as chemical, steel, and heavy machinery—the commanding heights of an economy. Most resources were used to maintain and expand these industries, with consumer goods and services being the opportunity cost. By 1940, the Soviet Union was the second-largest producer of iron and steel in Europe.

Much like the agricultural sector, in the manufacturing sector jobs were guaranteed and wages were set by the government. Once a production quota was met, there was no incentive to produce more goods. Workers had very little incentive to work harder or to innovate, since they had no control over the factors of production. It was illegal for workers to start their own businesses or exhibit entrepreneurial behavior.

Consumer Changes

With the focus of Lenin's Communist Party being heavy industry, consumer goods were in short supply and of poor quality. Quantity outweighed quality, since the quota system was in place. Consumers typically had a difficult time getting goods. Shortages resulted in hours-long waits in lines to purchase goods and services. Even though government price-setting made goods affordable, the goods were rarely available. Housing shortages were also a major issue, forcing people to live in crowded, poorly constructed apartments.

The many changes that Lenin instilled in the Soviet Union did not produce the international power and prestige he hoped for. In his final years, he introduced a New Economic Policy that included small amounts of private enterprise, mostly in the agricultural sector. This massive change in policy was intended to help motivate the workers of the nation, with international power still the focus and the goal.

Unfortunately for Lenin, his rule of the Soviet Union was short-lived. He suffered a stroke in 1922 while still leading the Soviet Union. He never fully recovered from the stroke, and he continued to decline until his death on January 21, 1924, in Gorki Leninskiye, Russia.

LIST, FRIEDRICH

Born: August 6, 1789, in Reutlingen, Germany; Died: November 30, 1846, in Kufstein, Austria; Nationality: German; Professional Interests: political economy; Major Work: *The National System of Political Economy* (1841).

Friedrich List was a German economist who promoted a national system of development to international trade. While influenced by Adam Smith, List had significant differences with Smith and other classical political economists of the time. List's theory of national economic system focused on the nation as a whole rather than on the individual. List promoted an economic system where the efficient production of resources created wealth, not the accumulation of goods. List believed a nation must first develop its domestic agricultural and manufacturing industries, before it is capable of participating in international free trade. List died in 1846.

Georg Friedrich List was born on August 6, 1789, in Reutlingen, Germany. His father was a successful tanner, but List chose public service over joining his father in business. Starting as a civil servant at age 17, List had risen to a ministry undersecretary by 1816. The following year, he was selected to teach political economy at the University of Tubingen.

In 1818, List urged the abolishment of tariffs on trade between German states. He formed an organization of Frankfurt businessmen to promote this liberal idea. The political opposition to his ideas was very intense. It led to his resignation from his teaching post in 1819. Having been elected to the Wurttemberg Assembly in 1820, he was dismissed only two years later for his criticisms of the government. His expulsion from the Assembly forced List to leave Germany to avoid prison. After visiting France and England, he returned to Germany where he was arrested, expecting to fulfill his prison sentence. However, he could avoid prison if he left Germany, so in 1825 he left Germany for the United States.

In the United States, List located in Reading, Pennsylvania, where he became a farmer and also became the editor of a German language newspaper. Influenced by Alexander Hamilton, List began to write and promote his ideas for a national economy. In 1827, he published *Outlines of American Political Economy.* In this publication, he returned to his early ideas when in Germany. He reasoned that a young national economy such as the United States needed tariffs to protect the new enterprises responsible for the early growth of the economy and stimulate new development. With the publication of *Outlines of American Political Economy*, List crossed over from businessman and journalist to political economist. Having gained a degree of financial independence with the discovery of coal on his land, List devoted more time to promoting his ideas and structure for a national economy. He also became an American citizen.

In 1832, List returned to Germany as U.S. consul to Baden and later Leipzig. In Germany, List became passionately involved in extending Germany's railroads. Following the mixed success of his efforts with the railroads, he completed his tenure as U.S. consul and in 1837 moved to France. In 1841, he wrote what would become his classic contribution to the study of the political economy: *The National System of Political Economy.*

List's work is marked by several disagreements with Adam Smith. For one, List submitted that the wealth of a nation was more dependent on the "productive forces" that would create the wealth as opposed to the wealth of goods accumulated. List argued that Smith had put too much emphasis on material wealth (accumulation of goods) and exchange of the wealth, and not enough emphasis on the productive side of an economy (accumulation of productive resources).

List considered the productive resources more important to a national economy because they were investments in future development.

A second distinction between List and Smith has to do with their interpretations of productive labor. According to List, Smith had not done an adequate job crediting and promoting "mental labor" as a measure of wealth. This included the professions of the law, religion, the arts, science, and education. List also disagreed with Smith on the value of free trade. While Smith promoted free trade without limitation, List saw trade developing nationally and through definite stages of development.

List argued that national economies must progress through four stages of development. The first stage is when agriculture is the major domestic industry and manufactured goods are imported. In the second stage, domestic manufacturing begins to increase, although the nation continues to import foreign manufactured goods. During the third stage, domestic manufacturers are sufficiently large to provide for domestic consumption. And in the fourth stage, agricultural products and large-scale productive resources are imported and there is large-scale exporting of manufactured products. Ultimately, the main idea of List's theory is that nations must first develop their agricultural and manufacturing industries to take care of their domestic needs—as a prerequisite to participating in international trade.

Though List advocated a national economic system, he argued that too much government interaction would be more costly than beneficial. He was not for regulating all aspects of an economy, and he recognized that certain aspects of the economy needed to be worked out on their own.

List's writings on the development of a national economic system have been promoted among developing nations and have been highly influential there. His emphases on the importance of advances in transportation, education, law and order, and efficient government have created a framework for successful national development.

Friedrich List's *The National System of Political Economy* (*Das Nationale System der Politischen Okonomie)* is one of the classics of economic thought. It has been translated from its original German to English, French, Russian, Swedish, and Hungarian.

Friedrich List had little good fortune in his later days. He lost his property in the United States and his health was failing.

Friedrich List died in Kufstein, Austria, on November 30, 1846, by committing suicide.

LOCKE, JOHN

Born: August 29, 1632, in Somerset, England; Died: October 28, 1704, in Essex, England; Nationality: English; Professional Interests: political philosophy; Major Works: *Two Treatises on Government* (1690), *Some Considerations of the Consequences of the Lowering of Interest, and Raising the Value of Money: In a Letter Sent to a Member of Parliament* (1696).

John Locke was a political philosopher whose most enduring contributions were the development of Empiricism (the belief that knowledge comes from experience) and the idea of popular sovereignty (the belief that a government's right to rule comes from the people). His work also affected economics more directly in his rationale for private property, his belief that human beings are motivated by self-interest, and his advice to the British government on monetary theory. Locke died in 1704.

John Locke was born on August 29, 1632, in Somerset, England. He would spend his life as a member of the intellectual middle class. He received an elite education as a result of his lawyer father's connections to a member of Parliament. Locke earned bachelor's and master's degrees in philosophy from Christ Church College at Oxford University, and later a bachelor's degree in medicine. Locke had various careers, including lecturer in Greek, lecturer in rhetoric, and personal physician to the Chancellor of the Exchequer.

In many ways, the English government saw John Locke and his ideas as a threat to the king. In 1682, Locke was forced to Holland in exile. Locke finished writing *An Essay Concerning Human Understanding* during his exile. During England's Glorious Revolution in 1688, John Locke returned to England and became a policymaker for the government of the American colonies.

It was in this role as secretary to the Council for Trade and Plantations that Locke was compelled to comment directly on economics—specifically, monetary policy. His purely economic writings do not constitute his most important contributions to economic thought. These are contained in his writings on political philosophy, which included two ideas that would become central to a modern understanding of a market economy: private property and the utility of self-interest.

Locke's approach was starkly in contrast to historical Western notions of government at the time. The classical Greeks and Romans believed that government existed primarily to promote virtue. Medieval Christians saw government as an extension of God's rule over creation. Locke and other Enlightenment thinkers based their thinking on a notion of humankind's natural rights.

He began his analysis by envisioning a "state of nature," in which civilization did not exist and human beings lived unaffected by society, culture, or government. In such a world, humans naturally possessed the rights of "life, liberty, and property." These rights were insecure, however, since people were likely to attack and enslave one another. Locke wrote that people voluntarily create governments with limited power in order to protect their natural rights. However, in doing so, they actually give up some of their rights, since the government exists to prevent people from doing whatever they please. They surrender some rights in order to protect more important rights. Lastly, and perhaps most importantly, since the government is created by the people in order to protect their rights, the government is ultimately accountable to the people for its authority—a concept known as popular sovereignty.

In this analysis, Locke assumed that private property is a person's right. This was not the general belief at the time time. Before Locke, most scholars had theorized that since the world belonged to God, people could not truly claim property as their own. To them, private ownership was regarded as a necessary evil in an imperfect world. Locke disputed this view, asserting that since people were entitled to enjoy the work of their hands, they were also entitled to possess the land that they developed by their own work; his theory could be called the "labor theory of property." For Locke, property was an indispensable measure of life and liberty.

Also implicit in his thinking was the view that people are motivated by self-interest. Locke did not emphasize duty as the classical thinkers had, or adherence to God's laws. Locke assumed that individuals make the choices that they think are most likely to improve their standard of living. The concept of individual self-interest, along with the belief in a person s right to private property, would become an important piece of the philosophical groundwork for later classical economists, most notably Adam Smith.

Lastly, in his role as a policymaker for the colonies of North and South Carolina, Locke contributed to a growing body of practical economic thought. He argued that interest rates were linked to the supply of money, so they should not be changed arbitrarily. Such laws would not work as intended, but would simply interfere with trade and act as a subsidy to borrowers. Locke also argued against a view popular in the English government that asserted that coins should be made with smaller amounts of precious metals. Locke pointed out that this would simply cause merchants to demand more coins for the same quantity of goods, since the value of money was determined in part by its scarcity. This last view makes him an early contributor to the quantity theory of money.

John Locke will be remembered among philosophers for his early contributions to the school of Empiricism and remembered among political scientists for his writings on limited government, popular sovereignty, and natural rights. His thoughts on self-interest and private property found their way into the core of late 18th-century thought, clearing the way for Adam Smith and *The Wealth of Nations*. Without Locke's work, Smith's writings might have faced a much more difficult audience.

Prior to his death, four additional editions of *An Essay Concerning Human Understanding* were published. He occupied his time responding to critiques of his work and exchanging letters with Edward Stillingfleet. The series of correspondence was later published.

John Locke died in Essex, England, on October 28, 1704.

LONG RUN VERSUS SHORT RUN

One measure of time in economics is the use of one's productive resources (land, labor, capital) and the ability to change, reuse, or alter the way in which the productive resources are utilized. This timing for the use of the productive resources is known as the long run and short run.

Long Run

Long run is a period of time that is long enough for firms to have the ability to change, reuse, or alter all the productive resources available to them. The term *long run* does not necessarily reflect a specific time frame, so it can be difficult to define in terms of days, months, or years. Generally, the term reflects a company's ability to vary all its labor, capital, and land resources. One might think of the long run as companies having a clean sheet of paper on which to create and use the available land, labor, and capital any way they choose.

In addition, firms are able to exit and enter the market in the long run. While new firms have the ability to enter a market in response to economic profits, existing firms in a market have the ability to leave as the result of economic losses.

Short Run

The *short run*, as opposed to the long run, is the period of time in which firms do not have the ability to change, reuse, or alter all the productive resources available to them. When a firm or an industry is in the short run, at least one productive resource (land, labor, capital) cannot be changed through either a contract or an agreement such as a rental lease or a labor contract. Like *long run*, the term *short run* does not necessarily reflect a specific time frame, so again it can be difficult to define in terms of days, months, or years. Generally, the short run reflects a company's lack of mobility relative to at least one productive resource. Using the "sheet of paper" analogy, one might think of the short run as a company having a sheet of paper with something written on it, so the paper has to be used in a previously prescribed way. In addition, firms in the short run find it much more difficult to enter or exit a market.

MALTHUS, THOMAS

Born: February 14, 1766, in Surrey, England; Died: December 29, 1834, in Bath, England; Nationality: English; Professional Interests: economic principles, demographics; Major Work: *Principles of Political Economy* (1820).

Thomas Malthus is considered the father of demographic economics. He was the first to study the relationship between population growth and food production. He would become a friend of David Ricardo, and they would spend much of their lives debating each other on everything from the Corn Laws to the nature of value. Malthus would be the first to use a demand schedule, in his 1820 *Principles of the Political Economy*. Malthus died in 1834.

Thomas Robert Malthus was born on February 14, 1766, in Surrey, England, the son of an English gentleman. His father was a friend of Jean-Jacques Rousseau and David Hume. After being taught by his father and a number of tutors, Malthus entered Jesus College, Cambridge, in 1784. There he was ordained as a minister in 1788 and received his master's degree in 1791. As a result of debates with his father about the ideas of William Godwin and the Marquis de Condorcet, Malthus decided to write down his own thoughts on the subject of population growth. The result was *An Essay on the Principles of Population* (1798).

In preparing this work, Malthus collected data on births, deaths, marriages, and longevity, making him one of the founders of the field of demographics. But he was working on a bigger idea. Malthus noted that population had the capacity and tendency to outstrip food production. Indeed, it is the misunderstanding of this inverse relationship between population growth and food production that most people link to his name. Critics of this relationship often point to Malthus as an example of economic predictions gone wrong, as history has shown that food production and population can both grow geometrically. But the reality is that he was writing at the dawn of the Industrial Revolution. He had no way of predicting the vast increase in productivity that would accompany the increase of capital and new technology.

But his view was larger than the simple inverse population–food production relationship. Malthus noted that despite past tendencies, humankind had not starved itself out. He attributed this to people choosing to change their behavior in the face of such economic incentives as higher food prices. The choices included choosing to marry later and to have fewer children. These choices ultimately helped to bring population back in line with food production, at which time prices would drop and create a different set of incentives. Then the new incentives would begin population growth on a track to outstrip food production again, and the cycle would repeat.

In 1804, Malthus married, which meant he had to give up his fellowship at Cambridge. In 1805, he was named professor of modern history and political economy at the East India Company College in Hailey, Hertfordshire, becoming England's first academic economist. It was also during this decade that Malthus became interested in monetary economics. Around 1810, he read a number of papers on monetary issues by an economist named David Ricardo. He began a correspondence with Ricardo, and they became friends on a number of levels. However, they would disagree on such economic issues as the Corn Laws.

In 1814, Malthus became interested and involved in the debates over the Corn Laws. Initially, he sided with the free-traders, agreeing that the cheaper prices afforded by imports would help make food more affordable. Later he would switch sides, noting that foreign countries may place an export bounty on grain in periods of drought or famine, making food supplies in England subject to foreign political maneuvering. He felt that self-sufficiency in food would be guaranteed if domestic production were encouraged—an example of the strategic industry argument for trade protection.

In 1815, Malthus was the first of four scholars to espouse a theory of rent. Unlike some of his predecessors, who saw rent as a cost of production, Malthus saw rent as a deduction from surplus, or a return on production. And while some disagreed on parts of his theory, his observation that land differed in quality and was scarce would be integrated into other theories of rent, most notably that by David Ricardo.

Malthus and Ricardo also differed in their views of value. Ricardo believed in a theory that ascribed value to a good based on the amount of labor needed to produce it—essentially, a cost-based or supply-based approach. But Malthus saw value as deriving from the amount of labor something could command, or the amount of work someone was willing to do to acquire a good or service. This view was more demand-based, and essentially it depended on the amount of utility or satisfaction consumers believed they would receive from a good.

This view manifested itself more fully when Malthus published his *Principles of Political Economy* in 1820. There, he would be the first to use the idea of a demand schedule, thus drawing a relationship between prices and the amount of goods sought—essentially, the willingness to buy at each price level. Prior to this, the relationship had been strictly one of price and the quantity sold as seen from the supply side of the transaction.

Finally, it was in his *Principles* that Malthus presented arguments against Say's Law, stating that general gluts were possible, differentiating between the equilibrium of the long run and the cyclical swings of the short run.

Malthus was elected a member of the Royal Society in 1819. He became a member of the Political Economy Club in 1821. He became a royal associate of the Royal Society of Literature in 1824. He cofounded the Statistical Society of London in 1834. And his influence, despite criticisms, was significant and long-lasting, affecting scholars and intellectuals like Charles Darwin, Karl Marx, and John Maynard Keynes.

Thomas Malthus died on December 29, 1834, in Bath, England.

MARGINAL ANALYSIS

Economic decision-making involves marginal analysis. *Marginal analysis* means looking at what a business (or an individual) must give up when making a decision, or looking at what additional cost or benefit someone obtains from a decision.

Marginal analysis is used to allocate scarce resources in a way that will maximize the benefit of the output being produced. The term *marginal* refers to the additional, or next, unit being produced. Marginal analysis is based on changing a variable such as the quantity that is purchased, the quantity of output that is produced, or the quantity of an input that is used. Changing one of these variables makes it possible to determine whether or not one more unit of a good should be produced. Then, the marginal cost and benefit of making such a change can be examined. If the marginal benefit exceeds the marginal cost, the change should be made.

Marginal analysis focuses heavily on the effect that cost-benefit analysis has on a business (or, again, on an individual). A business might choose to analyze how the additional cost of producing another unit of a good will affect profits, as well as to determine what the break-even point is for the firm. When applying marginal analysis, the business should also examine its fixed and variable costs.

Marginal cost is a key piece of marginal analysis. When making an economic decision, a business must examine the marginal or additional cost of producing another unit of a good or service. An *increasing* marginal cost implies that each additional unit of an activity costs more than the previous unit did. This can be displayed graphically on a marginal cost curve. A *constant* marginal cost implies that each additional unit does not increase marginal cost—rather, that it stays the same.

Marginal benefit must also be examined when marginal analysis is being applied. The *marginal benefit* is the benefit gained from producing one more unit of a good or service. A *decreasing* marginal benefit means that producing one more unit results in less marginal benefit.

Businesses should apply both marginal cost analysis and marginal benefit analysis when making an economic decision. Ideally, they should choose the quantity at the point where marginal cost equals marginal benefit.

Marginal analysis can be applied in other areas of economics as well. For example, when seeking to hire an additional worker, the business should examine the *marginal product of labor*, or the cost and benefit of hiring one additional worker. Marginal analysis can also be applied in the form of *marginal utility*, or the additional satisfaction gained from consuming one more unit of a good or service. *Opportunity cost* is yet another form of marginal analysis—one in which the business looks at what must be given up, or the next best alternative, when making an economic decision.

Many economic decisions are made at the margins, which makes marginal analysis an important economic concept.

MARKET CAPITALISM

Capitalism is an economic system that emphasizes the private ownership of the factors of production, competition, and markets, where the interaction of buyer and seller is free and unregulated. Capitalism can also be referred to as the free enterprise system or a market economy.

Capitalism existed long before the term was used. Ancient European trade routes were utilized for years to exchange goods. In some cases, merchants became wealthy as a result of trade and the expansion of trade networks.

Capitalism can be traced back to the European system of trade called mercantilism. From the 1400s to the 1700s, European nations sought to gain money by exporting more of a particular good than they imported. The mercantilist system was nationalist in nature, and it existed for the sole benefit of the mother country. Countries also used their overseas colonies for trading purposes, with those colonies not permitted to trade freely with other nations; the mother country would extract raw materials from its colonies and then produce final goods that would be sold to the colonies.

In *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776), Adam Smith (1723–1790) attacked mercantilism and promoted the benefits of free trade. *The Wealth of Nations* emphasizes that the government should not interfere in economic affairs of individuals and businesses. Smith spoke of *laissez-faire* trade, a system in which the government should not interfere in trade and should not impose trade restrictions, such as tariffs. This idea of free trade was a new and radical economic philosophy in the 1700s. The writings of Adam Smith would later be adopted by much of the world, as the mercantilist system was abandoned and a new economic philosophy changed the world.

Critical of capitalism, Karl Marx (1818–1883) believed it gave an advantage to business owners at the expense of workers. He stated that at some point, the system of capitalism would be overthrown by the working class, or *proletariat*. His beliefs, published in books such as *The Communist Manifesto* (1848), led to the creation of the system of government known as communism. Marx believed that ultimately capitalism would be overthrown in favor of socialism and communism.

Max Weber (1864–1920) is also linked to capitalism. In his major work *The Protestant Ethic and the Spirit of Capitalism* (1930), he discusses how the Protestant work ethic contributed to the development of capitalism.

The Industrial Revolution also contributed to the growth of capitalism. As new technology was created, so were new products. For example, Britain's textile industry boomed as the result of the spinning jenny, invented in 1764, and the water frame, invented in 1768. This revolution led to the faster production of new goods, but it also led to low wages and long hours for workers. As countries industrialized, new problems and challenges developed, such as unfair competition, child labor, and a larger gap between the rich and the poor.

As a result of the Great Depression in the 1930s, economist John Maynard Keynes (1883–1946) developed a new theory of government intervention to stabilize a capitalist economy. In his book *The General Theory of Employment, Interest and Money* (1936), Keynes promoted government's increased role in society in response to the severe economic crisis.

A distinct feature of capitalism is open markets that are naturally regulated by supply and demand and the unfettered interaction of buyers and sellers. Individual choice is the basis for a capitalist economy, where consumers choose which goods and services to consume in order to satisfy their economic wants. Producers produce goods to satisfy economic wants and to make a profit. In this system, there is little government involvement, as the factors of production are privately owned and are not regulated or owned by the government.

In market capitalism, incentives play the key role. In an economy that has an environment with the appropriate incentives for producers and consumers, both gain. Market capitalism sets the appropriate incentives for individuals as producers to be successful and earn profits. Competition helps create the proper incentives for a market economy.

Market Failure

For the consumer, competition can drive down prices and lead to high-quality goods and services. Private businesses can also be created that are free from government control. Furthermore, this type of market is characterized by specialization, as businesses produce the goods and services that they are suited for or that they can produce most efficiently or at a low opportunity cost. The circular-flow model details how interactions occur in a market economy.

After the fall of communism in the Soviet Union, more countries turned to capitalist economic systems. This transition is not an easy one, and it has resulted in economic struggles for many former communist nations. Economic powerhouses such as China have mixed economies that contain some capitalist elements. Most economies today are, in fact, mixed economies and are not truly capitalist in nature.

MARSHALL, ALFRED

Born: July 26, 1842, in London, England; Died: July 13, 1924, in Cambridge, England; Nationality: English; Professional Interests: general equilibrium theory, marginal utility; Major Works: *The Economics of Industry* (with Mary Paley Marshall) (1885), *The Postulates of English Political Economy* (with Walter Bagehot) (1885), *Principles of Economics* (1890).

Alfred Marshall had far-reaching influence on the foundations of what is now called microeconomics, which ultimately led to the development of macroeconomics. Alfred Marshall introduced the supply-and-demand curves as we know them, noting that they go together like the blades of scissors, to arrive at the price point. His insights were adopted by other members of his school, students, and professionals. These included A. C. Pigou, John Maynard Keynes, Joan Robinson, Jacob Viner, Milton Friedman, and George Stigler. Ironically, John Maynard

Keynes would ultimately challenge his teacher and would change the foundations of economics. Marshall died in 1924.

Alfred Marshall was born on July 26, 1842, in London, England. He was the son of a cashier at the Bank of England who originally chose the clergy as a career for his son. Marshall's father was very intense and refused to allow young Alfred to play chess because he believed it to be a waste of time. Alfred's father also thought mathematics was irrelevant for a budding clergyman. However, Marshall excelled in mathematics, and while attending Cambridge University he was drawn to the field of economics. In 1865, at the age of 23, Marshall was elected to a fellowship at St. John's College, Cambridge, and became a lecturer in moral sciences in 1868. Violating a tenet of the fellowship by getting married, he lost the fellowship after nine years. His first major work, *The Economics of Industry*, was co-authored with his wife in 1879. He became professor of political economy at Cambridge in 1885 and remained there until his retirement in 1908.

In 1890, Marshall wrote *Principles of Economics,* which would become the dominant economics text of the era, supplanting John Stuart Mill's work. Despite his own mathematical ability and his desire to make economics more rigorous, he strove to make his work understandable to the general reader, relegating his calculations and computations to the footnotes and appendices of his work.

Alfred Marshall introduced the supply-and-demand curves as we know them, noting that they go together, like the blades of scissors, to arrive at the price point. This insight was crucial as it gave the demander (consumer) a role in determining the price. Many prior to Marshall had seen price as a function of cost alone and as set largely by the supplier (producer).

That was not the only significant idea to be derived from the supply-and-demand curves. It was Marshall who would develop the idea of consumer surplus and describe it as the "triangle" bounded by the market price and the demand curve. This measure showed the difference between the demander's willingness to buy and the market price, and it helps illustrate the surplus value or utility that consumers receive in the market. Thus it is an important part of understanding the welfare received by market transactions.

The concept of elasticity, or the responsiveness of supply or demand to change in price, is also attributable to Marshall. Marshall showed that producers have some freedom to change prices without impacting revenue. Products that demonstrate lower price elasticity of demand tend to generate lower revenues when prices are lowered and higher revenues when prices are increased. This is because of the percentage change in demand relative to the percentage change in price. Conversely, a producer with a product that has a high level of elasticity of demand may actually generate higher revenues by slightly reducing the price of the product. On the supply side, elasticity can provide insights into the producer's ability to increase production when faced with changes in demand and, in turn, price.

One further contribution of Marshall was his recognition of time and its impact on decision-making. Marshall divided time into three categories: immediate, short-term, and long-term. He believed that this division had a significant effect on decisions, particularly as they relate to elasticity, and surplus.

Thanks to these insights, Marshall became the face of what would later be called the neoclassical school of economics. Marshall and his fellow Cambridge economists would combine the classical works of Mill and Ricardo with other ideas, such as the concept of marginalism developed by William Stanley Jevons. Additionally, it would be the neoclassical school that would help professionalize the field and develop it into a separate field of study in academia. In keeping with Marshall's views on the value of mathematics, the classical school would focus on the development of intuitive arguments. However, this would often lead to generalizations that would frustrate other economists in other schools of economics, including the Austrian School.

Alfred Marshall died on July 13, 1924, in Cambridge, England.

MARX, KARL

Born: May 5, 1818, in Trier, Prussia (Germany); Died: March 14, 1883, in London, England; Nationality: German; Professional Interests: economic philosophy; Major Works: *The Communist Manifesto* (with Friedrich Engels) (1848), *Capital: A Critique of Political Economy* (1867).

Karl Marx used the study of economics to write harsh and systematic criticisms of capitalism, and by extension, the governments and societies that foster it. He proposed a completely new world order called communism, characterized by a stateless society and an equal distribution of resources. Marx's writings covered political philosophy, history, and economics. Marx died in 1883.

Karl Heinrich Marx was born May 5, 1818, in Trier, Prussia (present-day Germany). Karl's father, a lawyer and descendant of Jewish rabbis, had disavowed Judaism and converted to Lutheranism. Karl later rejected religion of any type, coining the famous dictum "Religion is the opiate of the masses."

Marx studied law to please his father. However, he was more interested in philosophy, transferring to the University of Berlin and changing his studies to philosophy. He earned his doctorate in 1841. Upon graduation, Marx found a job in Cologne as a journalist for the Socialist newspaper *Die Rheinische Zeitung*. Prussia—indeed, most of Europe—was not tolerant of dissident ideas, and Marx soon found himself expelled from Prussia. He spent most of the next decade moving from country to country, repeatedly exiled for his radical beliefs. In 1848, in Brussels, Belgium, Marx penned his seminal *The Communist Manifesto*. It was intended as an outline of doctrine for the small international Communist movement.

The Communist Manifesto (or in the original German, *Manifest der Kommunistische Partei)* begins with a sweeping statement that history of the existing society is a history of class struggles. Marx describes human history as characterized by conflicts between the oppressed and the oppressors of social classes. To Marx, any and every idea, institution, religion, or belief serves to support the accumulation of wealth of the dominant social class.

Marx identifies capitalism as the economic system that replaced feudalism. He credits capitalism with immense powers of production, and he describes a shrinking, globalizing world that brings industrial workers—the *proletariat*—into closer association with one another as they crowd into cities to seek jobs. However, he also notes several "contradictions" within capitalism that will eventually spell doom for the system.

Marx submits that shrinking profits force the capitalist bourgeoisie either to seek new markets for their products or to exploit their workers with increasing cruelty. Even though these techniques restore profits, the frenzy of exploitation causes overproduction followed by financial panics, recessions, and reduced profits. Eventually, the cycle begins all over again. According to Marx, capitalism also results in an increasing concentration of the proletariat into factories. This competition among workers reduces wages to the bare level of subsistence. This idea is similar to David Ricardo's iron law of wages. As workers become more like one another, they are more likely to band together to fight for a bigger share of the profits, even while resources are monopolized under fewer and fewer capitalists. The final result of this unstable equilibrium will be a revolution of the proletariat. Marx then predicts that the proletariat will overthrow the bourgeoisie and usher in a new social and political order. A brief period of socialism with the proletariat acting as the ruling class will exist, in which the government reorganizes society to achieve total equality. Once this equality is realized, the government will become irrelevant and wither away, making way for a classless state called communism.

Marx was the intellectual giant of the early Communist movement. As such, he was under constant pressure by his colleagues to write a full-length work that would show the economic necessity of the ideas enshrined in *The Communist Manifesto.*

Marx lived his years in poverty, supported mainly by his friend and co-writer, Friedrich Engels. Engels encouraged Marx to expand his work. In 1867, Marx published a more thorough analysis of capitalism, titled *Capital: A Critique of Political Economy.* He used many of the tools of economic analysis that were created by classical economists such as Adam Smith and David Ricardo. The book begins by addressing the concept of value and how commodities become valuable. For Marx, items are valuable according to the amount of labor it takes to produce them. By adding capital resources to the production process, capitalists can reduce labor to that of a simple tool from which still more value, or surplus value, is obtained. Marx's economic analysis merged the political and historical theories he described in *The Communist Manifesto.*

Soon after his death, the impact of his ideas gained such influence that he has been called the most important thinker of the second millennium. His writings inspired revolutions in Russia, China, Cuba, North Korea, Vietnam, and Cambodia. By 1950, about a third of the world lived under a political system based on Marxist thought. Perhaps more importantly, Marxian methods have been introduced into every social science discipline. Marx's work taught later social researchers to use class analysis, which in turn opened the door for others to think in terms of oppressed cross sections of society. Ironically, Marxian analysis is used least in the field of economics. Marx's ideas continue to challenge a world still coming to terms with the implications of capitalism.

Karl Marx died on March 14, 1883, in London, England.

MARXISM

Marxism is the economic and political theory and practice introduced by the German political philosophers Karl Marx (1818–1883) and Friedrich Engels (1820–1895). Marxian economics holds that actions and human institutions are economically determined and that class struggle is the basic agency of historical change. This class struggle will result in capitalism ultimately being overtaken by communism.

Karl Heinrich Marx was born on May 5, 1818, and died in March 1883. Marx is best known as a revolutionary socialist. His class struggle theory has influenced much of economic thought. Marx published *The Communist Manifesto* (1848) and *Capital*, or *Das Kapital* (1867), two key publications of the Marxist movement.

Friedrich Engels was born on November 28, 1820, and died on August 5, 1895. He was a German social scientist, philosopher, and author, and he was also known as the father of Marxist theory. He was the publisher of *The Condition of the Working Class* in England (1844). This book was written based on his personal observations and his research. After Karl Marx died, Engels continued working on *Das Kapital*, publishing two of that book's three volumes.

Marx and Engels's writings had a significant impact and influence on their fight for Marxian economics. *The Communist Manifesto* has been recognized as one of the world's most influential political manuscripts. The book was held dearly and championed by the Communist League as it laid out its purposes and program. *The Communist Manifesto* presents an analytical approach to the problems with capitalism and the resulting class struggle. The book contains Marx and Engels's theories about the nature of society and politics, in their own words. The book briefly describes their ideas about how capitalist society would soon be replaced by a classless society, or socialism, then advancing to communism. It does not offer a prediction of communism's potential future forms.

In *Das Kapital*, Marx submits that the true worth and value of an economy is based on the value of its labor. Labor, therefore, is the definitive source of a company's profit. Marx further claims that the value of the labor exceeds a company's profit, leading to the surplus value of labor or exploitation of the laborer. As a result, Marx argues, capitalism's excessive surplus value of labor leads to capitalists abusing the laborer. This abuse of the laborer will lead to an uprising of the laborer over the capitalist in a revolution that he and Engels describe in *The Communist Manifesto*.

According to Marxian economic theory, social relations form the basis of society, including the forces and relations of production. The components of the production process can be understood as the employer–employee working relationship and conditions, the division of labor, and the property relations that people enter into to produce the necessities of life.

These relations make an impact on society's other relationships and ideas, which translate into a societal superstructure. The superstructure of a society includes culture, institutions, political power structures, roles, and rituals. Along with the location, also known as a state, the economic system creates the base. Forces that people apply in the process of production (materials, resources, tools, and techniques, and the human body and brain) are defined by this concept, including management and engineering functions. In addition, human knowledge can be defined as a productive force.

MENGER, CARL

Born: February 28, 1840, in Austrian Galicia, now in Poland; Died: February 26, 1921, in Vienna, Austria; Nationality: Austrian; Professional Interests: macroeconomics, microeconomics, political economy, marginal utility; Major Works: *Principles of Economics* (1871), *Investigations into the Method of the Social Sciences with Special Reference to Economics* (1883), *The Theory of Capital* (1888), *The Origin of Money* (1892).

Carl Menger is considered the father of the Austrian School of economics. While a reporter in Austria, Menger observed inconsistencies in the classical theories of price and value. Further pursuing a study of political economy, he worked out a system of thought that reconstructed the classical theory; he published his ideas in a book titled *Principles of Economics*. Menger created the foundation for what would become the Austrian School of economics. Over his lifetime, he made significant contributions to the study of economics in his explanation of the origin of money. Menger died in 1921.

Carl Menger was born on February 28, 1840, in Austrian Galicia, which is now part of Poland. He was born into an old Austrian family that had been ennobled, but he dropped the title of “von” from his name. He had two brothers: Anton was an eminent Socialist author and fellow professor in the law faculty of the University of Vienna, and Max was a lawyer and Liberal deputy in the Austrian Parliament. Menger studied economics at the University of Prague and the University of Vienna from 1859 to 1863, receiving his doctorate of law from the University of Krakow in 1867.

Menger began his career as a newspaper journalist in 1876, reporting and analyzing market events. He worked at the *Lemberger Zeitung* in Lwów, Ukraine, and then at the *Weiner Zeitung* in Vienna. During this time, Menger observed a contrast between the theory of price determination in classical economics, on the one hand, and what market participants believed was truly the determinant of pricing in real-world markets, on the other. In 1870, Menger was given a civil service appointment in the press department of the *Ministerratspraesidium* (Austrian government cabinet), followed by an appointment as a *privatdozent* (unpaid professor) on the faculty of law and political science at the University of Vienna. He was promoted to the position of professor *extraordinarius* in 1873.

Between 1876 and 1879, he served as a tutor to Crown Prince Rudolph von Hapsburg. In 1879, Menger was appointed to the chair of political economy in Vienna's law faculty, where he served as professor *ordinarius*. During his professorship, he published *Investigations into the Method of the Social Sciences with Special Reference to Economics* (1883); this book and several articles and pamphlets he had written were widely criticized by German economists. Also during this time, he served on a commission charged with reforming the Austrian monetary system. He resigned his post in 1903.

During his time as a reporter, Menger observed incongruencies in the classical theories of price and value. In response, he pursued a study of political economy and worked out a system of thought that would reconstruct classical theory. He published his theories as *Principles of Economics,* thereby creating the Austrian School of economics. Classical theorists had shown that price and production are determined by the universal law of supply and demand, determined by the interaction of all participants in an economy. However, the classical view recognizes the decisions and calculations of only those producers who are motivated by profit. This creates a price theory in which only supply is explained as a determinant of monetary calculation by profit-motivated businessmen.

What classical theory does not consider are the nonmonetary values and preferences of the consumer, whom Menger insisted is the beginning and end of all economic activity. To Menger, the classical theory views consumer demand for goods treated as a given. Therefore, prices are pushed toward equilibrium by the costs of production. Derived values of resources are also unexplained. This inconsistency creates a "paradox of value."

Classical economics could not explain why life-sustaining products are priced very low compared to non-necessity items. Menger resolved this by developing a comprehensive theory of the pricing process that places human action at the center. He used the law of marginal utility to refute the classical theory that price is determined by the cost of production, asserting instead that it is a result of satisfying consumers' wants.

Another important contribution Menger made to the study of economics is his explanation of the origin of money. From 1889 to 1893, he published seven essays on the topics of monetary theory and currency reform. In these he explained that although generally accepted mediums of exchange have been used in all ancient civilizations, the exact method and standard with which money was established is unrecorded. Menger rejected theories asserting that individuals or government leaders instituted this medium, instead suggesting that it emerged spontaneously through the self-interested actions of individuals.

Menger addressed the issue of salability in a barter economy. Different items have different levels of salability based on the availability of buyers wishing to purchase the item. With market experience, items develop a standard value or true economic price in relation to other commonly traded goods. Goods that are most saleable are traded more often, because buyers recognize these goods as something that can be exchanged more readily for what they desire. Eventually, Menger claimed, certain goods become universally accepted in exchange by sellers of all other goods, thereby becoming a medium of exchange, or money.

The work of Carl Menger influenced further development of economic theory in pricing, monetary policy, currency, and marginal utility by Eugen von Böhm-Bawerk, Friedrich von Wieser, Ludwig von Mises, and Friedrich von Hayek. Menger did not continue to publish after he resigned his professorship in 1903.

Carl Menger died in Vienna, Austria, on February 26, 1921.

MERCANTILISM

Mercantilism refers to an economic system, preferred in Europe between the 16th and 18th centuries, in which governments regulate their nations' economies through commercial trade. The practice was heavily used, especially in British colonies.

The governments in mercantilist economies sought to regulate their nations' economies by controlling trade. They believed that their economic strength was dependent on maximizing exports and minimizing imports through the heavy use of tariffs. Maximizing exports was at the heart of mercantilism because gold was believed to be the key to economic strength: If one country had more gold than another, that richer country was seen as stronger. Taking full advantage of exports guaranteed that gold would always be coming into the nation, and limiting the amount of imports through high tariffs ensured that the gold in the nation would not leave its boundaries.

Known as the bullion system, accumulating gold was necessary for a nation to be strong. Some nations, such as England, passed specific laws, such as the Navigation Acts, seeking to maximize their gold stores by restricting other nations from trading with England and its colonies. Passed in 1651, the Navigation Acts were intended to restrict trade from the Americas. In all, four Navigation Acts were passed, and these acts declared that only English ships could carry cargo between ports; that certain goods, like tobacco and furs, could not be shipped to foreign nations; that Parliament would pay bounties to Americans who produced raw goods, while at the same time raising protectionist tariffs on the same goods produced in other nations; and finally, that Americans could not compete with English manufacturers in large-scale manufacturing. The Navigation Acts ensured that any bullion available in the colonies remained with the British, and only the British.

Also, during the Napoleonic Wars, the French wore down their opponents by not allowing them to export goods and by allowing only imported goods. Forcing those countries to use up their gold by making them purchase foreign goods was seen as a far worse fate than allowing a country to starve.

Mercantilism, though, could benefit a nation for only so long. In his classic book *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776), the economist and theorist Adam Smith (1723–1790) argued that mercantilism was not the best way for nations to maintain their power and add wealth. Smith made three important arguments against mercantilism:

1. He stated that trade benefits all nations involved.
2. He argued that when nations specialize in the production of goods and services, it improves growth and efficiency.
3. He declared that although mercantilist policies benefited both the government and the commercial class, few others in the nation would see any gains from the practice. Through trade, all people in a nation could see an economic benefit.

For example, although the British used a mercantilist system, they could not adhere only to domestic production of goods and services to maintain their wealth. A black market for imported goods began, and the government could do little to stop it. Also, with the production gains from the Industrial Revolution, maintaining an export-only nation was deemed to not be profitable. Soon, Great Britain eliminated mercantilist policies and adopted a free-trade stance, with many other nations following suit.

Later, in the 20th century, British economist John Maynard Keynes (1883–1946) argued that the way to increase national wealth was for a nation to maintain a positive balance of trade, which caused increased demand. Anyone asking for protective tariffs on imports was considered a mercantilist.

After World War I, several nations passed protectionist policies to support their industries. For example, the United States saw the passage of the Tariff Act of 1930, also known as the Smoot-Hawley Tariff or Hawley-Smoot Tariff. The Tariff Act was passed to protect products in the United States by imposing massive tariffs on imported goods. At first, the policy seemed promising, as employment and production by various industries increased. However, many other nations retaliated against the Tariff Act of 1930 by placing huge tariffs on imported goods themselves. The global economy, which was in a recession by this time, began to take an even-deeper downward turn as import and export levels fell across the world, leading to lessening of each nation's gross domestic product (GDP). Many economists feel that the Tariff Act worsened the global recession, fueling the Great Depression.

After the end of World War II and the economic chaos that followed, a series of agreements were passed to stop mercantilist policies from taking effect again. The General Agreement on Tariffs and Trade (GATT) was passed in 1947 to guarantee a reduction in tariffs and trade barriers across the world. Furthermore, organizations such as the World Trade Organization (WTO) and the General Agreement on Trade in Services (GATS) were entered into in order to enforce international trade rules.

Arguably, some mercantilist policies and ideas still exist today. Some economists and politicians consider any country whose trade policies are heavily weighted toward exports with minimal imports to be the "new mercantilists" of today's modern global economy.

MILL, JOHN STUART

Born: May 20, 1806, in London, England; Died: May 8, 1873 in Avignon, France; Nationality: English; Professional Interests: economic history, utility theory; Major Works: *Principles of Political Economy with Some of Their Applications to Social Philosophy* (1848), *On Liberty* (1859), *The Subjection of Women* (1869), *Autobiography* (1873).

John Stuart Mill was an influential 19th-century British philosopher. Mill's father, James Mill, and Jeremy Bentham influenced Mill's interpretation of utilitarianism, which emphasized personal action toward the greatest possible happiness. Mill also greatly contributed to the advancement of economic thought. In 1848 he authored *Principles of Political Economy*, which became the leading economics textbook for the next 40 years. Mill died in 1873.

John Stuart Mill was born on May 20, 1806, in London, England. James Mill, his father and author of the *History of British India* (1818), had a profound influence over him. Mill spent his childhood at home under the strict guidance of his father, who served as his tutor. He learned Greek at age 3 and Latin at age 8. He read all nine books of Herodotus, Homer's *Iliad,* and Plato's six dialogues, in addition to an impressive array of others in their original language. He studied logic, math, and the basics of economic theory, including works by Adam Smith and David Ricardo. Mill accompanied his father on daily walks, where he was expected to provide a daily account of his learning. Mill's father used the Socratic method to question the younger Mill's learning and understanding of particular writings and concepts. He was also held responsible for teaching his younger brothers and sisters, which he later admitted that he disliked but that allowed him to learn more thoroughly and lastingly. In addition to his father, family friends David Ricardo and Jeremy Bentham served to influence and educate Mill. In the spring of 1820, Mill studied with Bentham's brother, Sir Samuel Bentham, for one year in France, where he became a fluent speaker of French as well as a student of French thought and history.

His father's ambition was to mold a remarkable intellect to carry on his views of utilitarianism. Mill suffered the unhappy consequences of this imbalance of a life focused on study without emotional outlets. Fortunately, Mill eventually found recovery from his depression through reading the poetry of William Wordsworth.

In 1828, at age 17, Mill joined the East India Company to become an assistant examiner. He eventually headed the British company's relations with the Indian States and ultimately became chief of the examiner's office in 1856. Mill worked for the company for 38 years. Mill also contributed to two newspapers, the *Traveler* and the *Morning Chronicle,* both edited by friends of his father. He took part in regular discussions at his family home, in a newly formed reading society in English historian George Grote's home, and in the London Debating Society. This contact and discourse with others helped Mill develop his own ideas and theories, apart from his father's sphere of influence.

Mill's philosophy—influenced by John Locke, George Berkeley, David Hume, and Jeremy Bentham—takes a positive view of the world and assumes that people contribute to the progress of knowledge, individual freedom, and well-being. Mill believed strongly in freedom of speech; he considered it a necessity for achieving development as a whole person. Mill believed that as long as individuals did not harm other individuals, they ought to be free to do what they wished. Mill denounced slavery, promoted women's rights, and valued the environment.

In 1848 Mill wrote *Principles of Political Economy*, which became the leading economics textbook for the next 40 years. In it, he defends free markets with limited government intervention on utilitarian grounds. Believing that progressive taxes were unfair to those who worked hard, he instead advocated the use of a flat tax. He continued to advance the ideas of Ricardo and Smith in his writings on economies of scale, opportunity cost, and comparative advantage. His defense of free markets was not entirely consistent, in that he also believed in trade protectionism and regulation of work hours for laborers.

Mill married Mrs. Harriet Hardy Taylor in 1851. He had been introduced to her in 1830 while she was in a previous marriage. Mill credits Taylor with having a significant influence on his own intellectual and moral growth. She helped Mill develop his expansive concept of the human good, conceived in utilitarian terms, in contrast to the more traditional ethic espoused by his father.

Mill retired from the India Company and became a member of Parliament from 1865 to 1868. He called for women's suffrage and other voting reforms, although he believed that the more-educated voters should receive more votes as they had a better understanding of the world around them. He will continue to be remembered for his lasting influence on the world of economics and philosophy.

John Stuart Mill died on May 8, 1873, in Avignon, France.

MISES, LUDWIG VON

Born: September 29, 1881, in Lemberg, Austro-Hungarian Empire; Died: October 10, 1973, in New York City; Nationality: American, naturalized U.S. citizen; Professional Interests: trade cycle theory, monetary policy, credit policy analyst, economic epistemology; Major Works: *Theorie des Geldes und der Umlaufsmittel* (1912) translated as *The Theory of Money and Credit* (1934), *Die Gemeinwirtshaft* (1922) translated as *Socialism* (1936), *Nationalokonomie* (1940), *Human Action: A Treatise on Economics* (1949), *Theory and History* (1957).

Ludwig von Mises was one of the most influential Austrian economists of the 20th century. Not only was he a driving force and influence behind many contemporary Austrian-born economists, including Friedrich August von Hayek, Gottfried Haberler, Alfred Schutz, and Fritz Machlup. He also made important contributions in the areas of epistemology, history, political philosophy, trade cycle theory, and the economic effects of monetary and fiscal policy. Mises's output and influence laid the groundwork for a significant revival in Austrian and neo-Austrian economics. Mises died in 1973.

Ludwig von Mises was born on September 29, 1881, in the city of Lemberg, a part of the Austro-Hungarian Empire, to Arthur von Mises and Adele Landau. Mises attended the *Akademische Gymnasium* in Vienna from 1892 to 1900, studying the classics, classical languages, and the liberal arts. After a one-year military obligation with an artillery regiment near Vienna, Mises returned to his studies in 1903 and the initial phase of his academic studies at the University of Vienna. It was in this year that he attended the lectures of Friedrich von Wieser and read *The Principles of Economics* by Carl Menger, the acknowledged founder of the Austrian School. He was also greatly influenced by the lectures (1905) and guidance of Finance Minister Eugen von Böhm-Bawerk, a second-generation Austrian economist who wrote *Capital and Interest,* a two-volume treatise on economics and the history of economic thought. Mises would attend Böhm-Bawerk's seminar until 1913. After obtaining a doctor of laws degree in 1906, and with the assistance of Böhm-Bawerk, Mises began work on a monetary treatise that was published in 1912 under the title *Theorie des Geldes und der Unlaufsmittel,* translated in 1934 as *The Theory of Money and Credit.*

This path-breaking work on monetary theory, which integrated the theory of money and banking into the framework of Menger's theory of value and price, brought Mises significant recognition. Money was no longer seen as a *numeraire*, or "measure of value," or as a historical accident, but rather as a natural commodity that has an integrative effect on the economic system. Unable to obtain a full professorship at an Austrian university, Mises taught as a *privatdozent*, an unsalaried position, at the University of Vienna in 1913 and was given the title of associate professor in 1918. After a short stint as a lawyer in Vienna, he obtained a full-time position in 1909 at the Austrian Chamber of Commerce as a *konzipist*, or "analyst," remaining there for the next 25 years. It was at this post that Mises conducted his famous *Privatseminar*, which met regularly in his *Kammer* office throughout the 1920s.

During World War I, Mises saw action as a first lieutenant at the Eastern Front, but he was called back to Vienna in 1917 after sustaining injuries and contracting typhoid fever. For the remainder of the war he worked in the economics division of the Department of War in Vienna. From 1918 to 1920, he was director of the *Abrechnungsamt,* an office designed to reconcile various settlement questions arising from the Treaty of St. Germain. It was in this capacity that he first met and hired his lifelong friend and colleague, the Nobel Prize–winning economist Friedrich August von Hayek, as an assistant.

His reflections on the political situation in Europe after the war prompted him to write *Nation, Staat und Wirtschaft* (1919), later translated as *Nation, State and*

Economy (1983). The book contained an in-depth analysis of the various causes of the war, personal reminiscences, and observations about the economic challenges and political pressures facing a post–World War I Austria. It was followed in 1922 by another pathbreaking work, *Die Gemeinwirtschaft*, translated in 1936 as *Socialism: An Economic and Sociological Analysis*. Mises not only laid out a cogent argument for the impossibility of Socialist economic calculation, but also he now became a leading critic of all forms of socialism.

In 1926, Mises was instrumental in establishing the *Osterreiches Konjunkturforschungsinstitut*, the Austrian Institute for Business Cycle Research, with Hayek as one of its major contributors. A successful private association from its inception, it became an important intellectual outlet for Austrian economic research on business-cycle theory, predicting with great accuracy the banking crisis in Austria in 1931. In addition, his 1927 work *Liberalismus*, translated as *The Free and Prosperous Commonwealth* in 1962, signaled to his contemporaries his adherence to and advocacy of the free-market economy. In 1934, Mises joined the faculty of the Graduate Institute of International Studies in Geneva, Switzerland, as a professor of international economic relations.

In 1940, forced to leave his post because of the Nazi threat, Mises sought refuge in the United States, settling in New York City and obtaining U.S. citizenship in 1946. Unable to find a salaried teaching position at an American university, Mises accepted and held the position of visiting professor at the Graduate School of Business Administration at New York University from 1945 to 1969. Sponsored largely by the William Volker Fund, Mises was able to reinstitute his seminars, continue his writing and research, and attract a new generation of students and scholars as he had earlier in Vienna.

Mises's most important work was *Human Action: A Treatise on Economics* (1949). This comprehensive treatise of economics grew out of his earlier work, *Nationalokonomie* (1940), and firmly established him as the primary spokesman for classical liberal thought in the United States. This work would later become a cornerstone document in the revival of the Austrian School, especially in the works of Murray N. Rothbard. During this period, Mises also published *Bureaucracy* (1944), *Omnipotent Government* (1944), *Planning for Freedom and Other Essays and Addresses* (1952), and *The Anti-capitalist Mentality* (1956). In his last two significant works, *Theory and History* (1957) and *The Ultimate Foundation of Economic Science* (1962), Mises presented the epistemological case for capitalism.

Mises was the recipient of the William Volker Fund Distinguished Service Award (1956), the Austrian Medal of Honor (1962), an honorary doctorate from New York University (1963), and an honorary doctorate in political science from the University of Freiburg (1964); he was also a distinguished fellow of the American Economic Association (1969).

Ludwig von Mises died on October 10, 1973, in New York City at the age of 92.

MONEY, HISTORY OF

Most people would refer to money as the coins and bills in their wallet or the paycheck they receive at their job.

The coins and paper that are used as money in the United States today were not always used as currency. In the past, societies used a wide range of objects as currency. Cattle, salt, furs, precious stones, gold, and silver have all served as currency at various times in various places. Even teeth, rice, shells, and olive oil have been used as currency in some nations. Although all of these items were used successfully in the past, none of them would function very well in our economies today. Each of these items lacks at least one of the six common characteristics that economies use to judge how well an item serves as currency. These six characteristics are durability, portability, divisibility, uniformity, limited supply, and acceptability.

Durability

Objects used as money must withstand the physical wear and tear that comes with being used over and over again. If money wears out or is destroyed too easily, it cannot be trusted to serve as a store of value. Unlike salt, rice, or olive oil, coins last for many years. Also, when paper bills wear out, the United States government can easily replace them with new bills.

Portability

Currency needs to be easy to transfer from one person to another. People must be able to carry it as they go about their daily business; therefore it must be lightweight and small. Paper money and coins are very portable, which is why they are used as the primary means of currency throughout the world.

Divisibility

For money to be useful, it must be easily divided into smaller denominations or units of value. When money is divisible, people have to use only as much of it as necessary for any exchange. Most currencies around the world are available in various denominations, such as 10-cent coins, 50-cent coins, $1 bills, $10 bills, and so on.

Uniformity

Any two units of money must be exactly the same in terms of what they will buy. In other words, people must be able to count and measure money accurately. A $1 bill in the United States must always buy $1 worth of goods or services in order for the currency to work accurately.

Limited Supply

Just like any other item's supply creates its value, currency must also be in limited supply in order to have value. If leaves were used as currency and your nation was filled with trees, the currency would be too abundant to have any value. Therefore, in the United States as well as in most other nations, the government controls the supply of money in circulation.

In the United States, the Federal Reserve System acts as the nation's central bank and controls the money supply. The Federal Reserve is able to monitor, distribute, and limit the amount of money available at all times. This system helps to limit the supply of money in circulation, which in turns helps to maintain the value of the currency.

Acceptability

Finally, everyone in an economy must be able to exchange the objects that serve as the money (dollars and coins) for goods and services in a society. When one person uses a certain currency, the receiver of that currency must be able to reuse it in subsequent transactions—throughout the entire society.

In the United States, people expect that other people will continue to accept the government-issued paper and coins in exchange for purchases of goods and services. The use of the money issued and accepted throughout a nation makes an economy flow more easily and with a common currency language.

The earliest forms of representative money in the United States were receipts issued by goldsmiths for gold and silver deposits. Gold and silver were not easily portable, so merchants would deposit their gold or silver with a goldsmith and in return would receive a paper receipt showing how much gold or silver they owned. Eventually, merchants began to accept the paper receipts instead of the gold itself, which allowed the paper receipts to become the earliest form of paper currency.

Two of the earliest forms of paper currency issued by the United States government were "Continentals" and gold/silver certificates. *Continentals* were issued during the American Revolution by the Second Continental Congress to finance the war against Great Britain. Few people were able to redeem them, however, because the federal government had no power to collect taxes. Therefore, the federal government had no currency to exchange for the Continentals.

The *gold/silver certificates* issued by the United States government were backed by gold or silver. The holder of a certificate could redeem the paper currency at a local bank for the actual commodity of gold or silver. The problem with this type of currency was that the federal government had to keep vast amounts of gold and silver stockpiled in order to convert the certificates into the actual commodity. By the 1930s the government had stopped converting paper money into gold and silver, and by 1971 the United States did away with the gold standard altogether.

Fiat money is the final source of value for money. This type of currency has value because the issuer of the money, typically the government of a nation, has ordered that this is an acceptable means to pay debts. Most developed nations of the world have fiat money that is issued and regulated by a central bank.

MONT PELERIN: A CRISIS IN ECONOMIC THOUGHT AND ACADEMIA, 1947

Postwar globalization was a silent crisis that led to decades of long economic decline and de-industrialization in the United States. Unlike most economic revolutions, this went unnoticed at the time except in the halls of academia; yet the effects of its ultimate devastation of American industry and jobs would be far greater in the United States than the Great Depression and America's wars. The roots of this crisis and American de-industrialization go back to April 1947 in Switzerland. The exact location was the luxurious Hotel du Parc at Mont Pelerin, overlooking Lake Geneva. There the free-market economist Friedrich von Hayek assembled a group who would lead a revolution in economics—ousting the economics of John Maynard Keynes and ushering in free-trade economics and the de-industrialization of the United States. This crisis and battle would first play out in the economic schools of America's great universities. By the 1970s, the new economic approach would be embraced by the United States and both of its political parties.

The radical economic views of the Mont Pelerin Society in 1947 promised a world free of major wars. World economists believed the Great Depression had led to two problems: (1) the shutdown of trade, which crippled countries such as Great Britain and the United States; and (2) the rise of fascism in Germany and Italy. The Mont Pelerin Society saw free trade as a basis for world peace, and they believed achieving this would require a major change in world outlook. That change would have to go beyond simple economic philosophy; it would mean that industrial growth would be redistributed from the United States to ensure world peace. Free trade would require world unity, and the United Nations would be part of that vision. World overview organizations would have to be formed to monitor trade disagreements. The General Agreement on Tariffs and Trade (GATT) and the International Monetary Fund (IMF) would evolve from the work of the Mont Pelerin economists. Today, they are known as the World Trade Organization and the World Bank, respectively

Senior economist John Maynard Keynes would be discredited somewhat by the Great Depression and the world war that followed. Keynesian economists dominated the universities in the 1940s, so even the apparent failures of Keynes's theory would not soon result in a new approach. Hayek was the rising star of anti-Keynesian economics, and with him came the idea of free trade as a tool for world peace and a defense against Marxism and socialism. The Mont Pelerin view of free trade would soon become dominant in all the various schools of economics, would come to dominate economic thought, and would be supported internationally by the United Nations and the World Trade Organization.

It would be the economist Milton Friedman, who had reluctantly attended the Mont Pelerin Conference in 1947, who would change America's philosophy. Friedman had changed his beliefs before. He had gone from a being a socialist in the 1930s to a Keynesian New Dealer by the end of the 1940s. He then believed in government intervention to control the economy. In 1950, when Friedrich von Hayek joined Freidman at the University of Chicago, the new economic philosophy espoused by Hayek started to take root. After years of study at the University of Chicago, Friedman slowly converted to the free trade and international capitalism of the Mont Pelerin Society. The University of Chicago became the center of Mont Pelerinism in the United States, followed by Harvard and other universities. Princeton's Nobel laureate economist, Alan Blinder, declared: "By about 1980, it was hard to find an American macroeconomist under the age of forty who professed to be a Keynesian" (Wapshott 2012, 268). At major universities, the only people who would sit at the lunch table with the Keynesians were visiting creationists.

These universities would become the training ground for presidential economic advisers from John F. Kennedy on, and these advisers would help shift the nation to open trade after 100 years of protecting American industry.

Labor unions had held the economic advisers of presidents in check into the 1990s. One of the great American triumphs of the Mont Pelerin Society, the North American Free Trade Agreement (NAFTA), would be the end of American industrial dominance. In 1993, NAFTA represented a final political victory of Mont Pelerin Society economics as the Democratic Party fully embraced free trade. The Republicans had embraced free trade under President Reagan. President Bush and President Clinton would both agree on NAFTA. The United States had no political party to challenge free trade. In fairness, every American president has questioned the hardships of open trade on American labor, but there is no creditable opposing economic theory for government.

MORAL MOTIVATION

Morality means "doing the right thing." It entails notions of justice that can trump our preferences or interests. Moral judgments are by their nature inescapable, and they would apply to all in the same circumstances. They are buttressed by emotional feelings and reasoned argument. Consequently, morality differs fundamentally from matters of mere convenience, preference, convention, or conformism.

Societies and economies cannot function without moral bonds and rules. Matters of economic and social policy required a deep understanding of human motivation. If all motivation is treated as stemming from individual "preferences," approaches to policy are more easily diverted into the narrower channels of material or pecuniary incentives, neglecting moral motivations and appeals to ethical values.

Much of the theoretical work by economists that attempts to explain cooperation in the real world conflates issues of morality with altruism or cooperation under the description of "social" or "other-regarding" preferences, such as in the work of Bowles, Gintis, Camerer, Fehr, and Fischbacher. The assumption of "other-regarding" preferences contrasts with the previously prominent idea that economic humans were entirely selfish. But people with "other-regarding" preferences are still maximizing *their own* utility, and they may be regarded as selfish too.

In his philosophical account of the *Evolution of Morality*, Richard Joyce (2006) argues on the basis of considerations in the philosophical literature that morality has most or all of the following characteristics:

1. Moral judgments express attitudes (such as approval or contempt) and also express beliefs.
2. The emotion of guilt is an important mechanism for regulating moral conduct.
3. Moral judgments transcend the interests or ends of those concerned.
4. Moral judgments imply notions of desert and justice.
5. Moral judgments are inescapable.
6. Moral judgments transcend human conventions.
7. Moral judgments govern interpersonal relations and counter self-regarding individualism.

These characteristics do not establish a valid morality; they instead help us to identify what is a moral judgment, whether acceptable or otherwise. Like Darwin, Joyce emphasizes the role of the emotions as well as deliberation. Point 1 in the list above establishes that a moral judgment must involve both beliefs and sentiments, and is not reducible to either alone. If an action is impelled purely by emotion and sentiment, then it cannot amount to moral motivation. Deliberations and beliefs are also vital, but they are themselves insufficient because they must be backed by sentiments or emotions: acting morally is more than calculated conformity to moral rules.

Joyce's points 3–7 reveal the limitations of typical utilitarian approaches. Moral judgments are not simply expressions of an individual's interests, preferences, sentiments, or beliefs. They are also claims to universality in their context, which would apply irrespective of the interests, preferences, sentiments or beliefs of those to whom they are supposed to apply. Humans are capable of considering moral rules, and understanding that their observance is more than a matter of personal whim or satisfaction. This dimension is missing in much of economics. Moral values are either ignored or subsumed under matters of utility or preference.

It is a commonplace observation that what may be a moral rule for one culture may not be so for another. But this does not mean that moral rules are reducible to conventions. The cultural specificity of some moral judgments does not mean that one person's morality is as good as any other.

In Charles Darwin's account (1871), morality results from a combination of emotional impulses and thoughtful deliberation. He argues that although primitive moral feelings have evolved for millions of years, humans alone have a developed sense of morality. For Darwin, morality emerged in humans upon a long-evolved foundation of instinct and impulse. Frans De Waal (2006) argues that primates express moral feelings.

Studies show a number of common features of moralities across cultures, notwithstanding important cultural variations. All cultures regard many acts of harm against others as immoral and invest many acts of reciprocity and fairness with moral virtue. All cultures have moral rules concerning required behaviors specific to particular social positions, roles, or ranks. Moral codes restraining individual selfishness are also commonplace. As well as sustaining enormous cultural diversity, genetic and cultural coevolution has ensured that some specific types of prosocial moral rule have endured.

Darwin proposed that groups with individuals that devote themselves to the interests of their group will have an advantage in the struggle for survival. Among humans, binding sentiments of sympathy and solidarity are strengthened by a moral code. On the basis of existing evidence, the genetic foundations of altruistic and moral feelings seem more likely to have evolved first through mechanisms of kin altruism and then through reciprocal altruism. Genes play a role, but also indispensable is culture, particularly through the inculcation of behavioral norms in children by parents (Palmer and Steadman 1997).

Through our genes we inherit the capacity to quickly respond to social dilemmas by developing emotions. These emotions not only dispose us to make choices; they also help us to form rapid judgments concerning what is morally right or wrong. Moral judgments help us justify our actions to others and exhort others to approve or imitate. Our genes do not tell us what is moral or immoral. We try to learn that through engagement in a social culture.

The foundations of our moral capacity have evolved over the millions of years that we have been a social species. But in the last hundred thousand years or so, the full development of human moral capacities has been highly dependent on particular cultural settings, allowing for multiple and contrasting moral systems on the basis of a shared instinctive bedrock. In sum, morality depends on language, communication of abstract concepts, discussion and reflection upon them, and the derivation of general moral principles. The implications of a moral dimension to human motivation are profound, with implications for understanding and the design of incentives and policy, taking us behind a focus on pecuniary incentives alone.

MORAL SENTIMENTS AND ADAM SMITH

Adam Smith's writings spanned a wide range of topics—from the evolution of ideas in physics (*The History of Astronomy*), to causes and effects of effective communication (*Rhetoric and Belle Lettres*), to virtue and morality (*Theory of Moral Philosophy*), to, of course, economics (*Wealth of Nations*). Smith's idea about moral sentiments was that simple feelings could indicate right from wrong. Smith's emphasis on simple feelings was part of his reaction against the practice of casuistry and the use of revelation for settling disputes. *Casuistry*, or "case-based reasoning," became the object of criticism for creating moral rules out of "whole cloth." For every conceivable set of circumstances people could find themselves in, casuistry could derive from these reasoned moral rules. As opposed to the contrivances and deliberations of the casuists, Smith favored simple feelings.

A second reason for Smith's interest in moral sentiments was his consideration of how members of a commercial "society of strangers" could develop social bonds and live a virtuous life. He saw a solution in an individual suppressing the ego and entering into the feelings of another. This was easiest in small groups in the private sector in which people use their reason, meaning a warm feeling guiding their behavior toward virtuous behavior.

Smith, who is often held up as the spokesperson for greed and rapaciousness, begins his 1759 book *The Theory of Moral Sentiments* (*TMS*) with this statement: "How selfish so ever a man may be supposed, there are evidently some principles in his nature, which interest him in the fortune of others, and render their happiness necessary to him, though he derives nothing from it, except the pleasure of seeing it . . . As we have no immediate experience of what other men feel, we can form no idea of the manner in which they are affected, but by conceiving what we ourselves should feel in the like situation" (Smith 1969, 1).

What are the attributes of the moral sentiments that allow us to put ourselves in another person's "shoes"? In *TMS* Smith speaks of two central characteristics: sympathy and the impartial spectator. *Sympathy* is the ability to place oneself in another's shoes. According to Jacob Viner (1972), sympathy consists of "subrational feelings," almost instinctive to humans and central in human psychology and choice. Sympathy with another, a correspondence of our sentiments with those of another, is a major source of pleasure (utility).

Smith calls the second attribute the impartial spectator (IS). The IS is the objective part of us, our moral sense. When you use the IS you "divide yourself" into two persons: the examiner and the examined, the judge and the one being judged. Through the IS we can gain needed insight and clarity, because if we're left to the devices of "the selfish and original passions of human nature" (Smith 1969, 233), we will always overexaggerate our pain and rejoice excessively about our joy. Doing so is the "fatal weakness of mankind, is the source of half the disorders of human life" (Smith 1969, 263). For Smith, sympathy and the IS were two parts of one phenomenon. In *TMS* Smith refers to these two facets as the "sympathetic feelings of the impartial and well informed spectator" (Smith 1969, 466).

Smith's economics treatise, *The Wealth of Nations* (WN), does not explicitly deal with moral sentiments. It is a book about the effects of self-interest and competition on the economy (and society). However, consider these two reasons for believing that *WN* and *TMS* are connected with each other: The idea of the "invisible hand" appears in both *TMS* and *WN*. In *TMS*, Smith (1969, 275) writes that "by acting according to the dictates of our moral faculties, we necessarily pursue the most effectual means for promoting the happiness of mankind, and . . . cooperate with the Deity. . . ." In *TMS* Smith also says that the "sympathetic feelings of the impartial spectator" are in our self-interest. In *TMS* Smith observes that being considered worthy of praise or honor is a stronger motivation for human action than is accumulating wealth. Further, in striving for sympathy we create enough wealth to feed even the poor. Receiving sympathy—being praiseworthy—stems from others believing you, and hence from you being persuasive. Why do individuals trade instead of taking things by force? For Smith, the desire to be considered worthy of admiration and approval—sympathy—makes force unacceptable; sympathy requires mutually beneficial (exchange) trade.

MUN, THOMAS

Born: June 17, 1571, in London, England; Died: July 21, 1641, in London, England; Nationality: English; Professional Interests: merchant, mercantilist; Major Work: *A Discourse of Trade from England unto the East Indies* (1621).

Thomas Mun, one of the first mercantilists, is known for his emphasis on the importance of the balance of trade for economic prosperity. As a proponent of the balance-of-trade theory, Mun believed that a healthy nation will sell a greater value of goods to foreigners than it consumes of foreign goods. Mun believed that gold was a stable measure of wealth, and that government should regulate trade to produce an excess of exports over imports in order to gain more gold for the country. In response to the economic depression that had began in 1620, in 1622 Mun was selected as a member of the great commission of trade to make recommendations concerning economic policy. Mun died in 1641.

Thomas Mun was born on June 17, 1571, in London, England. He was the third son of an important London family. At a young age, he lost his father and his mother remarried. His stepfather was a director of the newly formed East India Company, where Mun later began his career in business by engaging in Mediterranean trade, primarily in Italy and the Levant (the area encompassing Turkey, Syria, and Lebanon). He later settled in London, having amassed a large fortune. He is reported to have had commercial dealings with Grand Duke Ferdinand I of Tuscany. Nothing specific is known of his education.

Mun rose to public prominence in England during the economic depression of 1620. As the director of the East India Company, Mun was called on to defend the company's practice of exporting large amounts of silver while there was a silver shortage in the country. Many people in the country blamed the East India Company for the crisis, because the company financed its trade by exporting £30,000 in bullion on each voyage.

In large part, Mun penned his first work in 1621 in defense of the East India Company's practices, and it may have been made in self-interest as well. In *A Discourse of Trade from England unto the East Indies,* Mun argued that as long as England s total exports exceeded its total imports in the process of visible trade, the export of bullion was not harmful. In his argument, he pointed out that East Indian goods, when re-exported, earned more silver than had originally been exported to pay for them.

As one of the members of the commission of trade set up in 1622 to make recommendations concerning economic policy, Mun successfully opposed the advocates of two different policies, each based on a distinct theoretical analysis of the mechanism of foreign trade. Out of this opposition, Mun composed his second book, *England's Treasure by Foreign Trade,* which he completed between 1626 and 1628 but was not printed until 1664 by his son. The book was considered to be a direct repudiation of the arguments of Gérard de Malynes, who believed that excessive export was intrinsic to a healthy foreign exchange and advocated exchange rate controls with a fixed exchange rate as presented in *The Maintenance of Free Trade* (Malynes 1622).

In his second book, considered a classic of English mercantilism, Mun emphatically and formally defined the doctrine of the *balance of trade*. Mun asserted that foreign trade is governed by the demand for commodities, that the flow of goods rules the exchange rate, and that silver itself is merely another commodity. He was among the first to recognize the exportation of services as valuable trade, and he made early statements strongly in support of capitalism.

Mun asserted that trade was the only way to increase England's treasure (i.e., its national wealth). He suggested several courses of action in pursuit of this end: frugal consumption in order to increase the amount of goods available for export, increased utilization of land and other domestic natural resources to reduce import requirements, and lowering of export duties on goods produced domestically from foreign materials.

His recognition of the principle of elasticity of demand may be his most notable contribution to economic theory. Understanding that goods with inelastic demand command higher prices in the marketplace, Mun advocated exporting goods with inelastic demand to generate greater profits from international trade.

As a mercantilist, Mun believed that government should regulate trade to produce an excess of exports over imports in order to gain more gold. His position depended on the idea that the nation's holding of gold was the main measure of its wealth. Mun's view was later challenged by economists such as Adam Smith, who showed that trade is self-regulating and that governments that seek to hoard gold or other hard currencies will make their countries worse off.

Mun's works on the theory of the balance of trade deeply influenced subsequent economic thought and were published in several editions. Laissez-faire economists such as John R. McCulloch, who saw Mun as a tentative exponent of freedom of trade, commended his practical liberalism.

Mun died on July 21, 1641, in London, England, at the age of 70.

NATIONAL ASSOCIATION OF SECURITIES DEALERS AUTOMATED QUOTATION

The National Association of Securities Dealers Automated Quotation (NASDAQ) is an American stock exchange. It is the second largest securities exchange in the world—just behind the New York Stock Exchange (NYSE). However, it is the largest *electronic* market for stocks, and it handles more trades than any another other market in America.

The NYSE, as the largest and oldest stock exchange in the United States, handles the largest and most financially sound stock transactions, known as blue chips, for elite U.S. and international companies. The NASDAQ differs from the NYSE in the type of stock invested and how trade takes place.

The NASDAQ building is located in New York City at 43rd Street and Broadway in Times Square. A corner of the building enshrines a tower displaying financial news and advertisements, called the NASDAQ MarketSite. The NASDAQ was founded on February 4, 1971, and trading began on February 8, 1971. NASDAQ uses the U.S. dollar as its type of currency. The trading session of the NASDAQ is based on Eastern Standard Time, with early, regular, and after-market trading hours. Early trading begins at 4 a.m. and ends at 9:30 a.m.; regular trading hours begin at 9:30 a.m. and end at 4 p.m.; after-market trading begins at 4 p.m. and ends at 8 p.m.

Many major stock exchanges like the NYSE are auction markets that are conducted on the trading floor. The NASDAQ does not have a traditional trading floor. The inception and advancements of computer technology have made electronic trading available. NASDAQ was created to provide a more efficient way to trade stock. Unlike the NYSE, the NASDAQ uses telecommunications networks to relate up-to-date information for any trade and transaction; it was the first stock exchange to incorporate computer technology. Stocks are directly traded in an over-the-counter (OTC) market. That is, investors buy directly from a broker or dealer via telephone or the Internet.

The NYSE is considered the most prestigious stock exchange, and it attracts the more-well-established corporations globally. However, the mystique of the NASDAQ has been its use of technology. As a result, technology-based companies and other growing companies are drawn to sell their stocks on the NASDAQ. Such prominent companies include Google, Apple, Microsoft, Amazon, and Cisco. The NASDAQ has enlisted over 2,900 companies, has a current market capitalization of $8.5 trillion, and is growing. It should be noted that investing in the NASDAQ is considered to be riskier and more volatile than investing in the NYSE.

Because monitoring every single security trade would be too challenging, indices have been created to measure the performance of stock; these indices are based on a selective group of corporate stocks that represent the common stock market. The NASDAQ is measured using three indices: NASDAQ-100, NASDAQ Composite, and NASDAQ Biotechnology. The NASDAQ-100 (abbreviated NDX) is an index made up of the 107 nonfinancial securities issued by the top 100 nonfinancial corporations. The NASDAQ Composite (abbreviated IXIC) is another stock market index. While the NASDAQ-100 and Composite are often thought to be one and the same, there is a difference between them: The Composite lists and tracks *all* the available companies, whereas the NASDAQ-100 lists and tracks the 100 *leading* companies. In summary, the NASDAQ-100 is a subset of the NASDAQ Composite. Finally, the third index, the NASDAQ Biotechnology (abbreviated NBI), includes biotechnology and pharmaceuticals companies.

Most indices are based on market capitalization, a tool to measure a company's size. Investors use market cap to determine the potential risk and return of a stock. The NASDAQ market capitalization is divided into three categories, or tiers: small, mid, and large. Each category is determined by distinct and strict requirements and degrees of market capitalization. The smallest market cap and least restrictive tier is the NASDAQ Capital Market (often referred as "small cap"). The NASDAQ Global Market (or "mid cap") consists of stocks with greater restrictive requirements and larger market capitalization than the NASDAQ Capital Market. The most selective market capitalization category is the NASDAQ Global Select Market. To qualify for this "large cap" category, a company must meet the strictest financial requirements. Each year, a company's stock is reviewed within each tier. If a company's stocks meets or exceeds its current market cap requirements, then it may be promoted to a larger market capitalization tier. If a company's stock does not perform up to the market cap requirements, then it can be demoted to a smaller market capitalization tier.

NATURAL RESOURCES ECONOMICS

Economics is the continual conflict between our desire for unlimited goods and services and our efficient use of the limited resources available to us to produce those goods and services. Natural resources are one of those limited resources.

A *natural resource* is an element or commodity that exists naturally, undisturbed by humans. Clearly, humans have always used natural resources to subsist (one markedly inventive use of natural resources has been hydropower, which is first evident in ancient Greek poetry that mentions waterwheels). Beyond the basic uses of lumber for shelter and transportation, European quests for gold and the extraction of rubber and dyes from sites in Latin America had residual effects beyond the economic enrichment of the exploiting and exploited nations.

The Spanish and Portuguese colonization of much of the Southern Hemisphere was the result of these incentives and discoveries. But as industrialization is understood to be a turning point in the economic history of the world, one reason the Industrial Revolution of the 18th century began in England was widespread use and innovation involving coal. As land is one of the factors of production, coal's abundance allowed the other two factors, capital and labor, to help make England the vanguard of industrial growth 300 years ago. In the emerging American colonies during the same era, natural resources moved from providing subsistence to being economic assets, as timber and iron were the second and third leading exports from the unformed United States in the mid-1700s (PennState 2014).

The discovery of oil in Titusville, Pennsylvania, in 1846 changed the economic and political mechanization of nations forever, as did the European jostling for resources on the African continent in the same century. The extraction of precious metals from South Africa and Zimbabwe created diamond consortiums in northern Europe and the Rhodes Scholar program at Oxford University, but it is the energy demands of the developed world that have played the biggest role in human interaction with natural resources since the widespread proliferation of the internal combustion engine and the population booms that followed two world wars in the 20th century. The transition of the People's Republic of China to a controlled state-capitalism economy since the 1980s is inextricably linked to that nation's use of natural resources on a scale previously not seen.

According to the OICA, an international trade organization of automobile manufacturers, between 2005 and 2013 the number of new automobiles registered on the world's roads increased by 20 million. This demand for new automobiles extended to a higher derived demand for tires, outstripping the natural rubber supply. Synthetic rubber became the primary building block of these tires, but also made from petroleum. As the world's population eclipses nine billion by 2050, the economic impact of the derived demand for petroleum for the production of tires will continue, even though synthetic rubber is being used instead of natural rubber.

As evidence of this, in 2012 the American energy company Exxon Mobil, the world's largest oil producer, entered into an agreement with Russia to invest $500 billion in oil and gas exploration in the Kara Sea. Cambridge University scientist Stephen Emmott notes this development in his 2013 book *Ten Billion*, adding that it was made possible by climate change as the Kara Sea is no longer ice-locked (Emmott 2013, 87).

Coal is another natural resource being tapped as never before to meet the world's increasing energy demands. As growth in China has made it the world's second largest economy, the nation has fueled this growth with coal. Fatalities in coal mines annually number in the thousands, but in spite of this China's demand for the resource continues to increase. Emmott notes that in one year alone (2011 to 2012) U.S. coal exports to China doubled (Emmott 2013, 90).

Widely perceived as a cleaner and potentially more plentiful resource, natural gas is increasingly playing a larger role annually in meeting the world's demand for energy.

The most essential natural resource in terms of human survival is water. Globally, the peoples most in need of it are the least economically capable of accessing it. According to the United Nation's 2012 report on Millennium Development Goals,

> The eleven per cent of the global population—783 million people—remains without access to an improved source of drinking water and, at the current pace, 605 million people will still lack coverage in 2015. (United Nations 2012)

For those enterprises that are able to meet the market's demand for water, which predominantly are willing and able consumers in developed nations, economics mirror those of the energy sector.

Governments and industry are learning to address demand for this resource, as evidenced by construction of the largest desalination plant in the Western Hemisphere in California. By early 2014, the Carlsbad Desalination Project was one-quarter completed; when finished, it is expected to bring 50,000,000 gallons of fresh water daily from the Pacific Ocean to 3.1 million area residents (Roach 2014).

Although a decade-long drought in the western United States was the catalyst for this undertaking, the essential nature of water suggests that this project will be pursued elsewhere in the future. As access to seawater and technology are prerequisites to such projects, the economic benefits of converting this resource to a more usable form can be expected to fall to those whose geographic locations and state-of-the-art technologies make using the oceans this way possible.

Globalization and the continually evolving world of technology have continued to create new markets for the world's natural resources. Phosphorus, tin, and rubber are now employed in ways that entrepreneurs could not have imagined a century earlier. The nation of Chile continues to benefit from being the world's largest copper exporter, attracting $30 billion in foreign investment into 2012 and boasting an economic growth rate in excess of 5 percent (Craze and Quiroga 2013).

NEW CLASSICAL ECONOMIC THOUGHT

The new classical economic thought originated in the early 1970s. During the 1980s, mainstream economic theory rejected Keynesianism and returned to its classical market roots, with its emphasis on market freedom and a limited role for the state. Despite differences of emphasis, neoclassical theory tended to agree that development is best left to the markets. In particular, new classical economists believe that in order to develop, countries must liberate their markets, encourage entrepreneurship (risk-taking), privatize state-owned industries, and reform labor markets.

Opponents of this theory—such as Paul Krugman (b. 1953), another Nobel prize–winning economist—agree that the neoclassical attacks on Keynesian economics, specifically their inconsistency with rational behavior, gained traction as a result of the stagflation of the 1970s. In the words of Paul Krugman, "New classical macro was and still is many things—an ideological bludgeon against liberals, a showcase for fancy math, a haven for people who want some kind of intellectual purity in a messy world" (Krugman 2014). Two fundamental tenets of new classical macroeconomics have emerged: (1) Individuals are viewed as optimizers who choose the best options available. Firms maximize profits, and people maximize their utility. (2) As prices adjust, the incentives for individuals change; thereby, their choices change as well, leading to a new alignment of quantities supplied and demanded. Both the International Monetary Fund (IMF) and the World Bank were quick to adopt this new classical perspective.

One of the leaders of the new classical theory was Robert Lucas (b. 1937), who received the Nobel Prize in Economics in 1995. Lucas points out that in standard microeconomics, economists assume that people are rational. He extends that assumption to macroeconomics: assuming that people would come to know the model of the economy that policymakers use. Most economic decisions are forward-looking. To know whether today is a day for work or for leisure, we need to decide whether tomorrow will be more or less productive than today; in other words, we must have an expectation of what will happen in the future. Lucas specified one reason why econometric models were poor predictors, and his argument became known as the "Lucas critique" of econometric models. He argued that individuals' actions depend upon expected policies; therefore, the structure of the model will change as a policy is used. But if the underlying structure of the model changes, the appropriate policy will change, and the model will no longer be appropriate

The new classicals adopted John Muth's (1930–2005) "rational-expectations hypothesis." Muth argued that an economic model in which people's expectations differ from the outcomes predicted by the model itself is poorly formulated. If the predictions of the model were correct—and therefore people's expectations were wrong—then people could use the model to correct their own expectations. The new classicals appeal to Abraham Lincoln's well-known adage: "You can fool some of the people all of the time, and all of the people some of the time, but you cannot fool all of the people all of the time." New classicals send policymakers this warning: Policies that depend on the assumption that the public systematically misunderstands its own interest are likely to fail.

Three new classical approaches have emerged: (1) the free-market approach, where market forces alone are sufficient to generate maximum welfare; (2) the public-choice approach, where the extreme new classical model emphasizes government is "bad" and leads to corruption and the gradual confiscation of private property; and (3) the market-friendly approach, which suggests that while markets work, they sometimes fail to generate maximum welfare—in which case, government needs to play an important role in compensating for three main market failures: missing markets, imperfect knowledge, and the correcting the effects of negative or positive externalities.

NEW DEAL

In 1932, the U.S. economy was mired in the depths of the Great Depression. The unemployment rate had leapt to about 25 percent, and production had collapsed. In the presidential election of 1932, voters turned to the charismatic candidate Franklin D. Roosevelt, who promised "a new deal for the American people."

The "New Deal" was the name given to a broad array of government programs intended to combat the Great Depression. The New Deal represented a move away from a philosophy of a small government with a limited role in the economy, and a shift toward confidence in direct action by a large, powerful federal government in keeping with the new economic philosophy of John Maynard Keynes. New Deal programs created the framework for the contemporary American welfare state, and they provided a rallying point for those who saw a larger federal government as a force for the protection of liberty and prosperity.

The New Deal began immediately upon the inauguration of Roosevelt as president in March 1933, and with the seating of many new congressional representatives who were sympathetic to the president's ideas. This first phase of the New Deal lasted until 1935. Most of the programs can be put into one of three categories: relief, recovery, or reform. Relief programs attempted to provide jobs so that people could meet immediate needs; recovery programs were intended to help damaged sectors of the economy get moving in the right direction again; and reform programs were an attempt to prevent future crises. Significantly, the New Deal abolished the gold standard, meaning that people could no longer demand payment of contracts in gold rather than paper money. This was one of the New Deal's many efforts to shore up the banking system, which had been devastated by panics.

The new laws, loans, and public spending poured money into the economy and caused substantial budget deficits. But production increased, and the unemployment rate dropped—although it remained above 20 percent. Importantly, the New Deal legislation was broadly popular. But it was not popular with everyone.

Conservatives were troubled by the unprecedented and unrelenting expansion of government power. Others, of the opposite political persuasion, thought that the New Deal had not gone far enough to redistribute wealth, and they offered Roosevelt a bruising political challenge from the left. Roosevelt dealt with these threats by giving up on winning conservative support and moving to adopt policies that increased government intervention still further—therefore winning more liberal backing, and short-circuiting some truly radical strains of thought from the left.

This shift marked what has been called the Second New Deal, which lasted from 1935 to 1938. Roosevelt launched a verbal assault on the "entrenched greed" of the "money classes," and he followed this rhetoric with ambitious and populist government programs, like increased taxes on the wealthy. The Second New Deal included the Works Progress Administration (WPA), in which the federal government directly hired several million unemployed Americans for tasks ranging from raking leaves to building airports, and the Social Security Act, which provided welfare payments to vulnerable people and guaranteed pensions for retirees. Roosevelt won the 1936 election by a landslide.

Nevertheless, Roosevelt's policies continued to encounter difficulties, in both the political and the economic realms. Starting in 1935, the Supreme Court had declared several aspects of New Deal legislation unconstitutional. Congress had proceeded by amending and moderating these laws in order to pass the scrutiny of the Court. But the New Deal reforms were always in danger of being struck down by wary justices. Roosevelt decided to alter this situation by simply changing the makeup of the Supreme Court, adding more justices of his own choosing in order to gain favorable rulings. In this, he made a political miscalculation—Congress did not support him, and he alienated much of the Democrat voting base, therefore slowing the pace and scope of the Second New Deal. To make matters worse, late 1937 brought a sudden and sharp recession-within-a-depression, and the unemployment rate, which had sunk to 14 percent, shot back up to 20 percent. Dismayed voters elected a more conservative Congress in 1938.

By 1939, Roosevelt had to be content to simply maintain the New Deal programs that he and the Congress had already implemented. By this time, a new crisis was looming: World War II. But New Deal programs stayed in place even as the nation whirred to life in preparation for global war.

The economic impact of the New Deal is not entirely obvious. Though the economy certainly turned around and began to recover with the onset of the New Deal, after six years the unemployment rate still stood at 17 percent. Some economists claim that the New Deal did not spend enough money to boost the economy. Others claim that it spent too much, and that the money was wasted. It is likely that some programs were harmful to the economy and others were helpful. The Agricultural Adjustment Act of 1936, which paid farmers to produce fewer crops, probably falls into the former category. But most economists agree that the abolition of the gold standard aided recovery by expanding the money supply and halting bank runs, therefore allowing the economy to begin its long, slow recovery.

The political legacy of the New Deal is clearer. Its popularity created a new political coalition that solidified the identity of the Democratic Party. It laid the foundation of the U.S. welfare state and instituted programs and government agencies that still exist—most notably, Social Security. The New Deal greatly increased the size and scope of the federal government in American life, reflecting a growing belief that a powerful national government could, in fact, be an agent in securing people's economic well-being.

NEW INSTITUTIONAL ECONOMIC THOUGHT

New institutional economics (NIE) combines economics, law, organization theory, political science, sociology, and anthropology, attempting to understand the institutions of social, political, and commercial life. Its goal is to explain what institutions are, how they arise, what purposes they serve, how they change, and in which ways (if any) they should be reformed. The new institutional economic thought has elements of neoclassical economic theory; but it differs by keeping and building on the central notion of scarcity and competition as the basis of choice underlying microeconomics but removing the assumption of rationality of choice. The phrase "the new institutional economics" was coined by Oliver Williamson (b. 1932) and differentiated the "old institutional economics," which was antitheoretical (without a theory to bind together their collection of facts, it was very difficult to pass on). NIE is explained in terms of the goals, plans, and actions of individuals. It accounts for social phenomena like corporate culture and organizational memory.

The need for institutions exists because of the network externalities. The neoclassical efficient market is obtained only if it is least costly to transact. Overcoming these externalities requires the creation of institutions, with structure and rules of enforcement altering the payoffs and inducing cooperative solutions. Institutional plans or policies provide securities to deal with the externalities, including environmental as well as social issues that accompany the economic model. It is accepted that free-market members will react to a given model established by an institution once it is known, and the individuals and organizations with bargaining power as a result of the institutional framework have a crucial stake in perpetuating the system and the current model. Successful institutional policy requires an understanding of the dynamics of economic change in order that policies have the desired outcomes.

Karl Marx long ago pointed out that the tension between the organizational needs of technology and the existing property rights was a fundamental source of conflict and change. Marx's error was that he thought it was capitalism that was incompatible with the new technology, when in fact the flexibility of the political and economic institutions of market economies has enabled them to adjust in order to realize the productivity achieved in the second economic revolution. Ironically, it has been the inflexibility and rigidities of centrally planned economies that have led to their demise (North n.d.).

While it is difficult to prescribe the correct medicine to improve the performance of different economies, Douglass North (1920–2015), a co-recipient of the Nobel Prize in 1993, has identified three characteristics of institutions that provide guidance:

1. Institutions should consist of a set of formal rules, informal norms, and the enforcement measures that apply to specific economies characteristics.
2. Policies will shape economic performance, since they define and enforce the economic rules of the game. Therefore, the heart of development policy must be the creation of polities that will create and enforce efficient property rights.
3. The key to continuing good economic performance is a flexible institutional matrix that will adjust in the context of evolving technological and demographic changes as well as shocks to the system. As such, the guide to policy should be adaptive rather than allocative, an allocative policy being a static concept with a given set of institutions.

NEW KEYNESIAN ECONOMIC THOUGHT

New Keynesian economics is a school of thought focused on macroeconomic theory, although its supporters do not necessarily share a single view about economic policy. At the widest level, new Keynesian economics suggests that recessions are withdrawals from the normal efficient functioning of markets. The elements of new Keynesian economics—such as coordination failures, staggered prices, and efficiency wages—represent significant deviations from the traditions of classical economics. This provides the intellectual basis for economists' usual justification of *laissez-faire*. New Keynesian economics theories hold that recessions are caused by some economy-wide market failure, and thus new Keynesian economics provides a rationale for government intervention in the economy, such as monetary or fiscal policy that moves in the opposite direction of the overall economic cycle.

New Keynesian economic thought found its beginnings in the late 1970s in the writings of economists who dissented from the new classical revolution. Robert Lucas is often regarded as the central figure in new classical economics. He became famous for incorporating the theory of rational expectations into macroeconomic models. The primary disagreement between new classical and new Keynesian economists is over how quickly wages and prices adjust. The label "new Keynesian" describes those economists who in the 1980s responded to the new classical critique with adjustments to the original Keynesian tenets.

The key separation between new classical and new Keynesian economists was that precept wages and prices are flexible. New classical thought believes prices "clear" markets by adjusting quickly to supply and demand forces. Conversely, new Keynesian economists advocate models with "sticky" wages and prices. New Keynesian explanations of sticky prices often emphasize that not everyone in the economy sets prices at the same time. Instead, the adjustment of prices is staggered throughout the economy. Staggering complicates the setting of prices, because firms care about their prices relative to those charged by other firms, including their competitors. Staggering can make the overall level of prices adjust slowly, even when individual prices change frequently.

Additionally, some new Keynesian economists suggest that recessions result from a failure of coordination. Market coordination occurs in both the labor market and the product market. When contracts are negotiated, the labor union negotiators worry about what other union leaders will do during their negotiations. In the product market, businesses are always attentive to the prices that other businesses set for the same, similar, complementary, or supplementary products.

New Keynesians also created new ways looking at unemployment. According to standard economic theory, unemployment is a self-correcting problem. Classical economic theory suggests that a labor surplus leads to a decrease in prevailing wages. As wages decline, unemployment declines—as employers are willing to hire additional workers at the lower wage rates. New Keynesians do not agree that lower wages lead to lower unemployment. New Keynesians theorize that higher wages, what they call "efficiency wages," lead to increased productivity. New Keynesians go further to suggest that higher wages are a reason why a business does not decrease wages when there is a labor surplus. New Keynesians claim that the lower wages that businesses could pay in response to the labor surplus do not occur because the businesses fear a resulting decrease in worker productive with a consequent decrease in profits. This is one reason Keynes referred to wages as "sticky wages."

NEW YORK STOCK EXCHANGE

The New York Stock Exchange (NYSE) is the largest stock exchange in the Unites States, based on the size of the companies listed on the exchange. The NYSE is used for setting policy, listing securities, supervising the members' activities and the transfer of member seats, and finding and evaluating new applicants. The NYSE has a unique history, plays a major role in the U.S. economy, and has many pros and some cons.

The NYSE originated with the signing of the Buttonwood Agreement. Just a few years later, the first stock was introduced when Alexander Hamilton founded the first Bank of the United States. Originally, only five securities were traded in New York City. The Bank of New York was the first security listed. Later, more banks and insurance company stocks were added to the list of securities.

In March of 1792, 24 merchants and stockbrokers from New York met secretly at Corre's Hotel to find ways to organize the securities business. On May 17, 1792, the 24 men signed the Buttonwood Agreement. The document was given this name because the group's traditional meeting place was under a buttonwood tree at 68 Wall Street in New York City. The men agreed that they would trade only with each other; further, they would set commissions for themselves and not participate in auctions. As time went on, the number of people gathering under the tree grew too large, so they moved the meeting to the Tontine Coffee House. This was to be the nation's securities marketplace, the New York Stock Exchange.

The purpose of the NYSE can be related to many different operations. It is used by and for the economy, business, government, individual investors, and as an economic indicator. The economy needs the NYSE, because the NYSE has a great focus on economic efficiency, and thus it promotes transferring money from low-yield investments into potentially high-yield investments. What encourages this transfer and continuous flow of money is the chance to enlarge the returns coming from the values invested in securities in the NYSE. As a result, the money from investors gives the companies in the NYSE the opportunities and resources to help build their growth, which helps build economic activity.

The NYSE helps business by promoting a corporate level of governance and by raising money. For example, when a company sells a stock, it is released to the public, making that company partly owned by the stockholder. The shareholders are held personally responsible for the leadership of the public company, because they decide what actions the company needs to undertake and how it works. This promotes the improvement of management, because shareholders want to keep the money they have invested. In exchange for the purchase of a stock, the company receives money that it can use toward expanding.

Government's ties to the NYSE are similar to those of business. All types of government—local, state, and federal—need money for the upkeep of services and projects. Government bonds are sold to investors, so that taxes do not have to be raised. The money from bonds is given back to the government agency to use for the services and projects, similar to company stocks. The NYSE handles the buying and selling of government bonds so that governments can meet their expectations and requirements.

Investors—whether they are companies, individuals, hedge funds, or wealthy citizens—clearly are vital to funding. Individual investors are able to participate in the NYSE because of the continuous demand for money to fund services and projects. The brokers, and others who are highly educated in the workings of the NYSE, do the actual trading, but all investors have a place in the NYSE market.

Because the NYSE is the largest stock exchange in the world, the companies it lists do business both globally and internationally. The New York Stock Exchange Composite index is home to all activity of the U.S. and global stocks that are a part of the NYSE. The NYSE Composite gives an estimate of economy fulfillment, investor expectations, and market state depending on the activity of the NYSE.

The stock market has many positive and negative attributes. Achieving success with a stock requires investors to understand the possibility of a decline in value; when investors know a business and the factors that change an economy, they can better determine the best time to sell or buy a stock. A negative aspect of the stock market would be the roller-coaster ups and downs in value or prices, called *volatility*. This changeability can alarm some investors, making them invest in safer alternatives. The time-consumption of investing is also a negative. Investors must complete diligent research before determining which funds to buy. However, online trading accounts give investors a great amount of research for the funds. Time is also needed to check and change the stock that investors have invested in. The positives aspects are the abundance of choices, liquidity, and much more. Companies and stock investments can create portfolios to meet specific standards.

The large amount of funds allows investors to have a range of different options. Any time investors want to sell a stock, they can simply trade it. This is known as *liquidity*, and it gives comfort to those who want their money back from a stock.

The NYSE is a globally known market. It has a unique history, and it plays an important role in the U.S. economy. Regardless of the pros and cons of investing in stock, the NYSE provides with many opportunities that people should use to their advantage.

NIMBY AND LULU

The Not in My Backyard (NIMBY) syndrome arises when a facility exhibits a locally undesirable land use (LULU) that lowers property values and diminishes residents' well-being around the land use facility. The NIMBY syndrome occurs when individuals agree that a facility is a good idea for society as long as it is not in their backyard. Examples of local negative externalities that create the NIMBY syndrome include airports that exhibit noise externalities to the local community, landfills that exhibit both smell and safety externalities to the local community, prisons and halfway houses that exhibit safety externalities to the local community. and wind farms that exhibit viewshed externalities to local residents. Sometimes, the negative externality manifests primarily in increased risk to health. such as from a nuclear power plant or a hazardous waste disposal facility. One of the major NIMBY issues in the United States is where to locate high-level nuclear power plants and their waste.

Many times, it is efficient for the LULU to be built because the aggregate gains to society as a whole are greater than the cost borne by the local community. The nature of the political process, however, finds that LULUs are often difficult to site because the vocal nature of the small groups affected by the local negative externality. Often in the political process, a loud vocal minority—one that is more likely to be politically active due to the high individual costs—finds that their preferences influence political decisions more than a majority that receives only small benefits individually and that is less politically active. The efficiency problem occurs when politicians act on the minority preferences even when the benefits are larger than the costs in the aggregate.

To address the problem of inefficiency and to encourage the placement of a LULU, those that receive the benefits could compensate the neighborhood around the site for bearing the external cost. When choosing a location for a NIMBY, politicians' concern for remaining in office makes the status quo the default, due to a reluctance to infringe upon the perceived property rights. When individuals perceive that the status quo defines the property rights, then the willingness to accept becomes the appropriate measure of compensation. If an appropriate compensation can be measured, LULUs can be located and a Pareto improvement in well-being can occur. Many political mechanisms have been suggested to site LULUs—from potential locations bidding on receiving offers of tax breaks for accepting LULUs, to citizens voting in referendums to accept the facilities in their communities. Others, however, suggest that the strategic importance of compensation to solve the NIMBY syndrome is difficult if the local community perceives the compensation as a bribe. When compensation is perceived as a bribe, local residents may become less trustful of governments and policymakers, which suggests that the solution to the NIMBY syndrome includes both compensation and moral considerations. Public input into the locating decision therefore plays a major role in addition to compensation.

Another problem surrounding LULUs and the NIMBY syndrome is environmental justice concerns. Many times, LULUs are located in poor and minority communities, not for efficiency reasons but because these populations have few economic alternatives. In addition, environmental justice concerns suggest that poor communities are targeted for LULUs because residents may not be fully aware of the risks involved—due to these communities likely not having access to experts who could provide accurate information about benefits and costs. Environmental justice further suggests that a combination of this lack of awareness coupled with low-income residents' lack of political and economic power makes poor communities a frequent target for environmentally hazardous activities. Environmental justice concerns suggest that when poor communities are chosen as a site for a LULU for efficiency reasons the process should be transparent, the company and government must be fully accountable to the community for the potential hazards of the LULU, and the process should have full community participation. Environmental justice suggests that the equity concerns are as important, if not more so, when deciding upon a location for a LULU. In this case, compensation for accepting a facility in a neighborhood could not only address the efficiency criterion but also address equity concerns for accepting LULUs in one's backyard.

NOBEL PRIZE IN ECONOMICS

The Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel was first awarded in 1969. During 46 ceremonies between 1969 and 2014, 75 people received the Nobel Prize in Economics. This prize got its name in 1968, not only from Alfred Nobel but also from the central bank of Sweden during the bank's 300th anniversary. The award is granted by the Royal Swedish Academy of Sciences and follows the same principles that all of the Nobel Prizes have followed since 1901. The Nobel Prize in Economics has been awarded 23 times to a single winner, 17 times to two recipients simultaneously, and 6 times to three awardees at once.

While the most commonly awarded field is macroeconomics, these prizes have been given to laureates in more than 30 different areas. Examples include development economics, economic growth, financial economics, game theory, international economics, public finance, and theory of market institution.

The monetary prize given to laureates is the product of Alfred Nobel's estate, which was converted to a fund and invested in "safe securities." The earnings from this portfolio are distributed annually. In 2014, recipients were awarded a prize amount of 8 million Swedish kroner (SEK), or approximately 1 million U.S. dollars.

The Economic Sciences Prize Committee sends confidential forms to persons who are qualified and knowledgeable enough in the field to produce a valid nomination. Nominators are considered qualified if they meet such criteria as being Swedish and foreign members of the Royal Swedish Academy of Sciences, previous winners of the Nobel Prize, permanent professors in relevant subjects, and other invitees.

The Royal Swedish Academy of Sciences is responsible for selecting laureates who have been recommended by the Economic Sciences Prize Committee. Candidates cannot nominate themselves; they are eligible as long as a qualified person nominates them and they receive an invitation from the committee. Nomination forms are sent out in September, and February is the deadline for submission. From March until May, there is consultation with experts, from June to August the judges write their report, and in September the committee submits its recommendations. In October the Economics laureates are chosen, and the ceremony follows in December. Nomination to the prize is by invitation only, and the names of nominees and other information is not revealed until 50 years after the award is given for a particular year.

The average age of all Economic Sciences Nobel Prize recipients between 1969 and 2014 is 67 years of age. The youngest winner, Kenneth J. Arrow, was 51 years old when he was awarded the prize; Leonid Hurwicz was 90 years old when he received his Nobel Prize, and he remains the eldest of all prize winners across the board. So far, only one female, Elinor Ostrom, has been awarded the Nobel Prize in Economic Sciences; she received the prize in 2009.

The University of Chicago has the largest number of Nobel Prizes in Economic Sciences awarded to individuals who were associated with the university at some point in their career—as students, faculty, or researchers. Perhaps the most notable individuals associated with this institution are Paul A. Samuelson, Friedrich August von Hayek, Milton Friedman, Ronald H. Coase, Gary S. Becker, and Robert E. Lucas Jr.

The Nobel Prize awards encourage innovation, exceptional research and discovery, as well as superior acts of humanitarianism. The Nobel Prize in Economic Sciences is not technically a Nobel Prize, but one that was adopted by Sweden's Central Bank. It has been awarded by the Royal Swedish Academy of Sciences following the same principles that the Nobel Prize has adhered to since 1901.

A record of all recipients of the Nobel Prize in Economic Sciences and their corresponding area of research and accomplishments is presented in "Nobel Laureates in Economics" in this book's Appendix.

The Nobel Prize has been awarded to a number of recipients in various disciplines since 1901. The Nobel Prize is awarded in memory of Alfred Nobel, who established the foundations of the award in his will and left adequate funding for prizes. Between 1901 and 2014, the Nobel Prize has awarded laureates for their achievements in physics, chemistry, medicine and literature, and for work in peace.

NON-GOVERNMENTAL ORGANIZATION

A *non-governmental organization* (NGO) is a special interest group that conducts research, disseminates information, and advocates for change at the national and international levels. In recent years, NGOs have also been services providers, sometimes in partnership with multilateral organizations such as the World Bank and the United Nations. Most NGOs maintain branches in, and solicit membership from, more than one country. An international non-governmental organization (INGO) is a NGO with cross-border affiliations. INGOs often promote activist agendas in areas that transcend nationality, such as human rights, global poverty, and the environment. NGOs represent an important element within civil society. *Civil society* is a catchall term used to describe the volunteerism of individuals who work for the common good. Civil society organizations (CSOs) are groups, including NGOs, that promote positive economic, social, and political change. NGOs are organized along democratic lines to express the collective will of members. The London-based Center for Civil Society and Center for the Study of Global Governance estimate that nearly 50,000 NGOs operated in the local and global arenas during the early 2000s (Anheier, Kaldor, and Glasius 2004).

At the national and international levels, NGOs give a voice to marginalized, distressed, and powerless groups of people in the global economy. In recent years, NGO voices have become more powerful for a variety of reasons. First, NGOs benefited from new information and communications technologies (ICTs), such as the Internet, email, and the World Wide Web (WWW). ICTs have boosted cross-border communications and facilitated organization-building by NGOs. Second, NGOs benefited from democratization. The rise of democratic political systems in Eastern and Central Europe and elsewhere expanded freedom of expression, including the freedom to dissent. Third, NGOs benefited from policies of inclusion by multilateral organizations, including the World Bank, the International Monetary Fund (IMF), the World Trade Organization (WTO), and the specialized agencies and programs of the United Nations system. Inclusion increased the visibility of NGOs and legitimized their role as change agents. Kofi Annan, secretary-general of the United Nations, called NGOs "indispensable partners" in global decision-making. Fourth, NGOs benefited from more generous flows of financial resources since the 1970s. Individuals, foundations, transnational corporations (TNCs), and multilateral organizations supplied billions of dollars to NGOs during the early 2000s. Fourth, NGOs showed a record of accomplishment. NGOs linked people with essential services, many of them financed by governments, multilateral organizations, and other agencies. NGOs also advocated for change through mass protests. NGO demonstrations at the WTO's ministerial meeting in Seattle, Washington, in 1999, and at other global forums in subsequent years, were expressions of this newfound power.

Typically, NGOs are organized around a common cause, which is outlined in the group's mission statement. Today, many NGOs are devoted to protecting human rights, preserving peace, reducing poverty and hunger, preventing environmental degradation, promoting good governance, and furthering a host of other causes related to economic and human development. Among the world's largest NGOs are Amnesty International and Human Rights Watch, which advocate for human rights; CIVICUS and Transparency International, which promote good governance; Friends of the Earth and the Nature Conservancy, which support environmentalism; Oxfam International and Save the Children, which promote poverty reduction and food aid; and Eurodad and ActionAid, which deal with issues related to sustainable economic development. Increasingly, governments, multilateral organizations, and TNCs solicit NGO advice to form policies.

NUCLEAR ENERGY, SAFETY, AND WASTE

Nuclear energy is the use of fission to create heat. *Fission* is the process of splitting a heavy nucleus into a number of light nuclei with the liberation of a large amount of energy. The heat produced from fission is used to boil water, which is then used to create steam. The steam goes into a turbine to generate electricity. Chain reactions are controlled by neutron absorbers, which are called control rods. Less waste is produced in fission than in other ways of creating energy, because fission doesn't create greenhouse gases like coal or natural gas do.

Nuclear energy is used in 31 countries worldwide, making up 12 percent of the energy produced globally. The United States has 99 active nuclear power plants, which generate close to 20 percent of the power used here. In contrast, France's nuclear energy accounts for about 75 percent of its total electricity.

Nuclear energy creates low-carbon electricity, which means it does not generate carbon dioxide. It is also one of the most affordable forms of energy in the United States. Further, nuclear energy is fuel-efficient: One pellet of nuclear energy is equal to 1 ton of coal, 194 gallons of oil, or 17,000 cubic feet of natural gas. This type of energy is clean and carbon-free. It also has economic benefits and creates jobs. People working in the field of nuclear energy are likely to be paid better than other workers. Lastly, many Americans favor the use of nuclear energy.

Nuclear energy is used on ships and submarines, primarily to generate electricity for people to use. Nuclear propulsion is also used to drive the ships; the system is powered by water, heat, and steam to produce energy to power the ship's propellers.

The federal government controls the safety regulations for nuclear power. Both the Department of Energy (DOE) and the Nuclear Regulatory Commission (NRC) mandate safety standards. In addition to governmental regulations, the industry self-regulates through the Institute of Nuclear Power Operatives (INPO) and the Electric Power Research Institute (EPRI). Both government and private industry are dedicated to the safe nuclear generation of electricity for the United States. In addition to government and industrial organizations, local utilities make public their operational experiences (OE) in order to share successes and concerns regarding the maintenance of the operating plants that generate electricity.

The generation of power through fission results in a waste product of a concentrated ash of radioactive material that requires regulated, controlled handling. The waste from fission is significantly smaller than the greenhouse gases generated by the burning of fossil fuels. The waste from fission is more controlled, through the historical records of the medical, industrial, and governmental experience in sequestering the waste. Despite nuclear power generation being a proven technology that is affordable and stable, with no greenhouse gas emissions, the waste is still an obstacle to the technology being widely accepted in the United States.

Nuclear power generates hundreds of thousands of highly skilled jobs in engineering, operations, and maintenance throughout the globe. As an example, the economic impact of nuclear power in Illinois is estimated at $8.9 billion annually, supporting 28,000 jobs along with $290,000 million in Illinois taxes and nearly $1.1 billion in federal tax revenue each year (NEI Nuclear Notes 2014).

Both the opponents and the proponents of nuclear energy will continue their missions to enlighten the general public to their views. Opponents highlight the hazardous wastes and the potential for more events like the Fukushima nuclear disaster in Japan in 2011. Proponents continue to claim nuclear power's benefits and potential for a cleaner environment. What is certain is that the economic benefits and costs of nuclear power will continue to be discussed in policy debates regarding the electric power generation for a cleaner future environment.

OPPORTUNITY COST

Opportunity cost is the next best alternative of any decision and is at the core of economics. *Economics* is the study of how a society satisfies its needs and wants by making choices with limited or scarce resources. The next best choice is the opportunity cost of any decision. For any economic decision, it is always best or most efficient to select the option or choice with the lowest opportunity cost. Critical thinking such as this will also yield the decision with the largest benefit of all the choices. While there are always multiple alternatives or trade-offs to any decision, it is only the next best option that is the opportunity cost. Additionally, opportunity cost can vary from person to person depending on how each person values each alternative. The most effective way to understand the concept of opportunity cost is by example.

One of the classic examples is the cost of going to college. When asked about the costs of college, most students will reply that the costs of college are tuition and books. While these are some of the costs of college, they are only the explicit costs or the costs the student pays directly. The implicit costs or opportunity costs of going to college are the wages that were never earned because of attending classes or the activities the students would be enjoying during their free time. The true costs of attending college are the explicit and implicit costs. If faced with the decision of going to college or joining the labor force immediately after high school, every student needs to fully examine the explicit and opportunity (implicit) cost of each decision. Many highly skilled collegiate athletes are often faced with the decision of staying in college to finish their degrees or becoming professional athletes. If the wages earned as a professional athlete are more than the satisfaction of completing the college degree and more than the potential future earnings of that college degree, the student should drop out of college immediately and become a professional athlete. On the other hand, if the wages earned as a professional athlete are less than the satisfaction of completing the college degree and less than the potential future earnings of that degree, the student should stay in college.

In rural societies and less developed countries, many people are self-sufficient—performing many essential tasks for themselves, such as growing food for subsistence, constructing their own homes, preparing their own meals, and even repairing basic household items. The primary reason why people who live in these types societies are often self-sufficient is because the opportunity cost of performing these essential tasks are very small. They have few alternatives that produce a better outcome than performing these essential tasks themselves.

The concept of opportunity cost is embedded in the production possibilities frontier model and the theory of comparative advantage. In the production possibilities frontier model, the opportunity cost of producing an additional unit of "x" is the loss of some "y" production. In a global economy, the *theory of comparative advantage* states that a country will produce the goods and services for which it has the lowest opportunity cost of production compared with another country, and it will trade for the goods and services that it has a relatively high opportunity cost in producing.

Individuals behave in the same manner in the pursuit of their own self-interest. The economic concept of comparative advantage is a clear example of measuring one's opportunity costs in today's modern specialized society. Very few people grow their own food, construct their own homes, repair household items, or even prepare their own meals, due to the increased opportunity costs of performing these tasks. People have alternatives that produce greater outcomes than can be obtained by people performing these essential tasks themselves. This explains why some highly skilled people often hire other people to perform many of these essential tasks for them. For example, a highly skilled brain surgeon would need to be paid a much greater amount to mow lawns compared to a highly skilled high school graduate, due to the opportunity costs of their time.

PATERNALISM

Paternalism refers to the benevolent intervention of a social planner to improve the welfare of people against their will and consent, thus curtailing the beneficiaries' liberties. At the heart of a paternalistic intervention thus lies a trade-off between welfare and liberty (and/or autonomy).

In economics, there is widespread opposition to paternalism and strong support for the opposite—namely, antipaternalism (or synonymously, consumer sovereignty). Individuals are typically held to know best about their preferences and interests (or at least to know better than any benevolent social planner), and hence individual preferences are to be respected and not interfered with. The only legitimate interferences in this paradigm concern cases of market failure—and paternalism is permissible only in fringe cases, such as for minors or mentally incompetent persons.

Some behavioral economists challenge this idea of individuals being the best judge of their interests—which Buchanan (1991) also calls *epistemic privilege*—by providing evidence on the fallibility of human decision-making. Many individuals are prone to make errors, are subject to a number of systematic biases, and rely on decision heuristics that may or may not work in certain decision environments. It is thus no longer *a priori* clear that individuals are always the best judges of their own interests, thus weakening the case for antipaternalism. Some behavioral economists, such as Thaler and Sunstein, even argue that antipaternalism becomes "incoherent" and paternalism becomes "inevitable" because policies and rules are bound to frame individuals' decisions so that influencing people's choices cannot be avoided. But the assumption here is that experts aren't prone to the same biases and errors that typical individuals are.

Behavioral economics has thus led to the development of a new species of so-called "soft" or "light" paternalism, which tries to avoid restricting individuals' liberties. The best-known example of soft paternalism is libertarian paternalism, where, for example, Thaler and Sunstein argue, the "emphasis . . . is not on blocking choices, but on strategies that move people in welfare-promoting directions while also allowing freedom of choice." Individuals are "nudged" toward welfare-improving behaviors through subtle cues such as default rules (but not hard coercion). The twist of libertarian paternalism is that freedom of choice is left intact and fallible individuals are prodded into better behavior, but the individuals can reverse these "nudges" if they wish to with no or small costs.

Libertarian paternalism is controversially debated (Rebonato 2012; Binder 2014). It is uncontroversial that the insights of behavioral economics prompt a revision of the idea of epistemic privilege, and social planners need to be aware of the fact that in some choice environments, it is impossible to implement a policy without influencing individuals through the framing of options. However, claims of the inevitability of paternalism are exaggerated, and behavioral economists should be careful not to throw out the baby of consumer sovereignty with the bathwater of rational choice. Even with bounded rationality, not all choices are welfare-reducing. Nonrational choice can very well be adaptive and welfare-enhancing, as the literature on ecological rationality demonstrates (see, e.g., Berg et al. 2011). Moreover, many imperfections in human behavior are still not well understood, and hence they provide only shaky foundations for public policy. It is also not clear whether social planners do not suffer from similar cognitive limitations when implementing paternalistic policies, so that "dumb" behavior would then be replaced by "dumb" interventions (Rizzo and Whitman 2009).

Finally, libertarian paternalism may still violate individuals' liberties. For example, while nominal freedom of choice is left intact, default rules can be set in ways that individuals with limited cognitive capacities won't even be aware of, hence voiding their freedom of opting out. Despite nominal freedom of choice, in these situations individuals thus enjoy no real freedom of choice. Moreover, equating liberty with freedom of choice is quite controversial. Other definitions of *liberty* and *autonomy* are conceivable, and interventions that the individual is not aware of are prone to violate individuals' autonomy. This prompts concerns of soft paternalistic policies being manipulative. In this respect, soft paternalism might be more insidious than overt hard paternalism, where individuals at least are perfectly aware of being curtailed in their liberties (Binder 2014).

PATH DEPENDENCY

A key finding of path dependence is a property of "lock-in" by historical events. Small chance events then have durable consequences in the long run. Arthur (1989) and David (1985) address increasing returns in technology by using a model of path dependence. In a world of increasing returns to scale, initial and trivial circumstances can have important and irreversible influences on the ultimate market allocation of resources. An inefficient outcome can persist. The form of path dependence conflicts with conventional economics, where efficient outcomes are attained. Liebowitz and Margolis (1994) claim that where there is a feasible improvement to be gained from moving onto a better path, economic agents are willing to pay to bring that improvement about.

Social interactions often lead to patterns of what are called "positive feedbacks." Generalized increasing returns due to institutional complementarities appear to be a source of multiple equilibria (Bowles 2004). According to Leibenstein (1966), individuals supply different amounts of effort, where effort is a multidimensional variable, under different circumstances. The difference between maximal effectiveness of utilization and actual utilization is considered as the *degree of X-inefficiency*. Altman (2000) introduces effort discretion into the path-dependency modeling. Given effort discretion, incentives need not exist in order for agents to adopt superior economic regimes. The introduction of effort variability allows for the existence of suboptimal equilibrium in the long run. The existence of high- and low-productivity regimes might be a product of history. Furthermore, in Teraji (2007), effort depends on the prevailing norm within an organization. The process by which norms evolve through socialization exhibits generalized increasing returns. In a world where effort levels depend on norms, the path-dependent low-effort equilibrium can exist.

As Denzau and North (1994) point out, individuals with common cultural backgrounds will share reasonably convergent mental models. Agents who belong to the same cultural group are exposed to the same external representation of knowledge, which produces shared mental models. Culturally shared mental models expedite the process by which people learn directly from experiences; these models also facilitate communication between people. In a way, human actions are imprinted by their history. Path dependence includes features such as sustained persistency and lock-in. North (1990) applies increasing-returns arguments to institutions more broadly. Generally speaking, *institutions* are understood to be systems of established and prevalent social rules that structure social interactions. Established institutions generate powerful inducements that reinforce their own stability. Path dependence in the evolution of belief systems results from a "common cultural heritage," which "provides a means of reducing the divergent mental models that people in a society possess and constitutes the means for the intergenerational transfer of unifying perceptions" (North 2005 27). Cognition may have more subjective aspects, while culture enables individuals to develop mental models that they share intersubjectively. Because culture reflects habituation, which one acquires in one's group, culture is slow to change. Some individuals are resistant to altering their belief systems, and hence the resulting behavior. *Belief systems* are the ideas and thoughts common to individuals that govern social interaction and can contribute to path-dependent outcomes and equilibrium.

PAYMENTS FOR ENVIRONMENTAL SERVICES

Payments for Environmental Services (PES) is a mechanism by which landowners are compensated for the environmental benefits generated by their land management practices. There are five key criteria to describe the principle of PES: (1) a voluntary transaction in which (2) a well-defined environmental service (or a land use likely to secure that service) (3) is bought by a (minimum of one) buyer (4) from a (minimum of one) provider (5) if and only if the provider continuously secures the provision of the service (conditionality).

These criteria cover a wide variety of programs. Examples of environmental services include watershed protection, carbon sequestration, and biodiversity conservation. The buyer of the services may be a national government, using PES as an environmental policy instrument. Alternatively, the buyer may be a private company or a domestic or foreign conservation organization, aiming to provide incentives for others to provide certain environmental services.

Given this wide variety of potential programs, Engel et al. (2008) provide three necessary conditions for the design of a genuine PES scheme: (1) the relationship between the type of land use being promoted and the provision of the ecosystem service must be clear; (2) stakeholders must have the possibility to terminate the contractual relationship (it is a voluntary transaction); and (3) a monitoring system must accompany the intervention, in order to ensure that the provision of services is taking place (additionality and conditionality of payments).

PES is one of a set of policy options for obtaining environmental services. PES programs are increasingly being used in preference to regulatory measures such as protected areas, particularly in developing countries, because of their win–win potential; that is, they can provide benefits of both environmental protection and poverty alleviation.

PES is close in spirit to the Coase theorem, in which it is argued that socially suboptimal situations (e.g., too little provision of environmental services) can be resolved through voluntary market-like transactions, provided that transaction costs are low and property rights are clearly defined and enforced. In other words, it is possible that individuals, communities, and even supranational entities may be able to negotiate toward efficient provision of environmental goods and services. The creation of markets for trading environmental services thus becomes a potential solution for market failures that lead to the undersupply of these types of services.

Conservation approaches such as PES can be much more effective than indirect approaches with respect to achieving environmental objectives. Some researchers assert that, in contrast to decades of what have been referred to as policies for conservation by distraction (e.g., community development programs, or integrated conservation and development projects) that have only indirect effects on conservation, direct payments such as PES schemes are likely (1) to be institutionally simpler; (2) to be more cost-effective in delivering benefits to buyers; (3) to be more effective in generating economic growth among suppliers by improving cash flow, diversifying income sources, and reducing income variance; and (4) to provide new sources of finance for conservation.

One of the earliest PES programs was the Conservation Reserve Program (CRP), introduced in 1985 by the U.S. federal government. Under the CRP, eligible agricultural producers receive payments for land retirement and approved conservation practices. Landowners apply for enrollment by bidding to undertake certain activities in return for a specified payment. Offers for contracts are ranked using the Environmental Benefits Index (EBI), which is based on expected benefits to water quality, soil erosion, air quality, and wildlife habitat, as well as the cost of the contract. The highest-ranking contracts are then selected to participate.

Research on the impacts of the CRP suggests that it has reduced soil erosion, a key environmental indicator, and that benefit–cost targeting using the EBI is a cost-effective way to achieve the desired environmental outcomes. There are some concerns that the 10- to 15-year contracts for land retirement are not sufficient for the full benefits to be observed. However, many farmers re-enroll their land at the end of their contract, and the majority of those who do not enroll are still not expected to bring land back into production.

A newer program, on a scale similar to the CRP, is the Sloping Land Conversion Program. This was introduced in China in 1999, with the dual objectives of soil conservation and poverty reduction. Farm households receive payment in the form of cash, grain, and seedlings, in return for converting cropland to forest or grassland. The intention is to convert around 15 million hectares of land. Contracts last between two and eight years, depending on the type of vegetation planted, and all households within each of two broad geographical regions receive the same subsidy level.

Although the program is voluntary in principle, studies have shown that participation is not always voluntary in practice. However, for those who do participate, evidence suggests that the program tends to raise incomes, as the subsidy payment exceeds the opportunity cost of the retired land on average. It is still early to identify the impacts on soil protection, but while the majority of land entered into the program is steeply sloping, there is some mis-enrollment of low-slope land. This suggests that targeting could be improved.

The Costa Rican Pagos por Servicios Ambientales (PSA) was established as a PES program in 1996. This program grew out of an existing institutional structure of payments for reforestation and forest management, but it contains several notable features: (1) most payments are for conservation of existing mature tropical forest with no harvesting allowed, (2) payments are justified and targeted to produce ecosystem services rather than to support the timber industry per se, and (3) funds come from both earmarked taxes and international donations.

Studies of participation in the PSA program have consistently found that participants differ from nonparticipants in important farm-level characteristics that directly affect land use; that the PSA program significantly increased participating farm forest cover in a microlevel analysis; and that the payments had a positive and significant impact on forest gain at the national level, with reductions in net deforestation. However, research does not conclude that PES contracting has reduced gross deforestation.

PEACE CORPS OF THE UNITED STATES

The Peace Corps of the United States is an independent agency within the executive branch of the U.S. government. President John F. Kennedy established the Peace Corps by signing Executive Order 10924 on March 1, 1961. Initially, the Peace Corps was a pilot program. On September 22, 1961, Congress gave its stamp of approval by passing the Peace Corps Act, solidifying the Peace Corps' status as an agency of the federal government. The Peace Corps' mission was to advance the cause of peace and to improve the quality of life for people in the developing world. The Peace Corps was also designed as a cultural bridge between American volunteers and the international community.

Since the Peace Corp began in 1961, over 220,000 Peace Corps volunteers are serving or have served the world promoting peace. Peace Corp volunteers have lived and worked in more than 140 countries. In 2016 alone, more than 7,000 Peace Corps volunteers are working in 63 countries. Volunteers serve in these general regions: Africa (45 percent of all volunteers), Latin America (22 percent), Eastern Europe/Central Asia (10 percent), Asia (12 percent), the Caribbean (4 percent), and North Africa/Middle East and Pacific Islands (4 percent each). The Peace Corps sends volunteers only to countries that request assistance.

The operation of the Peace Corps is the responsibility of a director and deputy director, each of whom is appointed by the president of the United States and confirmed by the U.S. Senate. The Senate Foreign Relations Committee and the House Committee on International Relations also monitor Peace Corps activities and programs.

The Peace Corps has maintained a commitment to peace, human progress, and international understanding, yet its priorities have evolved over time. In recent years, the Peace Corps has increased the flow of resources to rural development, mainly to improve agricultural practices in some of the world's poorest regions. The Peace Corps also extends emergency assistance to people in distress; for example, the Peace Corps created a Crisis Corps to aid relief efforts in Thailand after the massive tsunami of December 2004 ravaged that country's coastal regions. The

Crisis Corps was composed of former Peace Corps volunteers, many of whom served in Thailand in the past.

The Peace Corps responds to new challenges as well. For example, HIV/AIDS education and prevention is a top priority on the Peace Corps agenda. The Peace Corps identified the HIV/AIDS crisis as the most serious humanitarian challenge of the modern age. Today, all Peace Corps volunteers working in Africa are trained in HIV/AIDS prevention, education, and care. The Peace Corps supports human capital development. For example, the Peace Corps provides information technology (IT) education programs throughout the developing world to bridge the digital divide. Volunteers teach such computer literacy skills as word processing, Internet use, and Web page design. Instruction also highlights applications of IT technologies, such as distance learning in education and e-commerce in business. In 2015, the Peace Corps volunteers' primary work areas included education (37 percent of all volunteers), health and HIV/ AIDS (24 percent), environment (10 percent), agriculture (6 percent), youth (10 percent), and community economic development (9 percent). The Peace Corps' poverty-reduction efforts complement the work of multilateral development organizations, and they are consistent with the United Nations' Millennium Development Goals (MDGs).

PEACE ECONOMICS

A distinctive area of economics, peace economics focuses on the economic effects of peace. That is to say, peace economics does not necessarily require an absence of conflict; rather, it develops economic systems from peaceful activity as a mitigating force. Peace economics serves to reduce the negative effects of violence and conflict. It also measures conflict in order to understand conflict's economic implications, and it develops systems to overcome these constructs. A large part of peace economics is uncovering the cost and consequences of war on macro and micro economic levels. In doing so, peace economics identifies how firms, organizations, corporations, local governments, and individuals are affected.

One of the most poignant examples of peace economics comes from the Paris Peace Conference in the wake of World War I. In his 1919 book *The Economic Consequences of the Peace*, John Maynard Keynes explained the danger of marginalizing the Axis powers after their defeat. He explained that specific postwar reparations policies served to disillusion Central Europe (specifically Germany), and therefore could provide fertile ground for another global war. In this case, the warning was not heeded, and the impossible impoverished conditions of Germany and other nations greatly influenced World War II. Therefore, the Paris Peace Conference and the world of Keynes is a representation of a different method of economic thought, one that takes into account the ramifications of conflict before, during and after.

The methodology and application of peace economics is a multifaceted representation of multiple economic theories—specifically, rational choice theory, normative economics, and positive economics. *Rational choice theory* assumes that individuals act rationally and that these individual behaviors make up an aggregate social behavior norm. By extension, peace economics develops the needs and behaviors of individuals to mitigate conflict based on the reasoning that societies are disadvantaged by the presence of conflict. *Normative economics* is more ethics-driven, focusing on how society should be. In contrast, *positive economics* is concerned with the reality of outcomes, or the way things are. Peace economics synthesizes all of these approaches to develop a systems-thinking method of understanding social, political, and economic issues surrounding conflict.

Given the frequently changing global environment, peace economics proves consistently relevant. Walter Isard, founder of the Peace Research Society (now known as the Peace Science Society International), asserts that the need for continued interdisciplinary research and development in the field (also called Peace Science) is evidenced by the continued existence of international conflicts.

Further studies of the field of peace economics include such topics as space or land economics. Within peace economics, this branch of theory is specifically concerned with the political and social implications of controlling space or territory. Therefore, the subsequent economic and social results can be vital in determining causes of conflict. In modern times, peace economics is highly influential within the topic of defense, with varying opinions on appropriate methods of application. Peace economics is complex and diverse, with a myriad of methods and uses, but the underlying principle is to understand conflict in order to promote peace and an absence of violence.

POPULATION

Population refers to the number of people living within a region, such as a city, a country, or the world. In 2015, for example, the population of the United States was 320 million people, while the population of the world stood at 7.2 billion people. Economists, demographers, and others study population to better understand how population affects economic and human development.

Two important global population trends are readily observable. First, the world's total population will continue to grow well into the 21st century. Historically, it wasn't until 1850 that the world's population hit its first billion people. In 2000, 6 billion people inhabited the planet. By 2050 the world's population will jump to nearly 9 billion people. The rapid population growth over the past 150 years was due mainly to progressively lower mortality rates and a higher life expectancy for people in many world regions. Access to modern medicine and health care facilities, improved nutrition, knowledge about hygiene and sanitation, and better communications and transportation networks contributed to lower mortality rates and a longer life span for people in most countries. While death rates fell, fertility rates among women remained relatively high, however, especially in the developing world. The world's population will climb by nearly 3 billion people between 2000 and 2050.

The second global population trend illustrates the divergent paths of more-developed and less-developed countries. The population outlook for the more-developed countries over the next 50 years is one of stability. In 1950, 32 percent of the global population lived in the more-developed countries in Europe and North America, and in Japan, Australia, and New Zealand. The remaining 68 percent of the world's people lived in the less-developed regions of Africa, Asia, and the Pacific, and Latin America and the Caribbean. The population gap between richer and poorer countries widened by 2000, when the percentage of people living in more-developed countries shrank to 20 percent, compared with 80 percent in the less-developed countries.

By 2050, just 14 percent of the world's people will reside in the more-developed countries, and 86 percent will live in less-developed countries. According to the United Nations, 99 percent of the world's population growth will occur in the less-developed regions. In addition, population growth in the 50 least-developed countries (LDCs) will roughly triple from 2000 to 2050, rising to 1.7 billion people. In contrast, the populations of many developed countries will decline by the mid-21st century. The population of the United States will continue to climb, however, topping 400 million by 2050. In the United States, a relatively high fertility rate, and immigration, will account for most of the country's population boom. A comparison of the world's largest countries from 1950 to 2050 illustrates the population shift toward the less-developed countries.

Rapid population growth is a major challenge to sustainable economic development, especially in the world's poorest regions. Population pressures perpetuate the vicious cycle of poverty, which plagues billions of people in the developing world. Rising populations in low-income developing countries strain fragile ecosystems as larger numbers of people compete for dwindling supplies of fresh water, arable land, and energy resources. In addition, resources devoted to people's rudimentary survival needs, such as food, clothing, and shelter, weaken national savings and investment in new capital goods, research and development, and technology. Prospects for breaking the cycle of poverty are further dimmed by an underdeveloped and overburdened social infrastructure, which cannot support a quality educational system, health care, and other social services.

In 1994, the United Nations convened the International Conference on Population and Development (ICPD) to address population issues. The ICPD, which was held in Cairo, recognized the link between population growth and the vicious cycle of poverty in the developing world. The ICPD adopted a 20-year Program of Action, which created a global blueprint for reducing the population growth rate and advancing social and human development. The UN General Assembly strengthened the blueprint five years later (ICPD + 5). First, the blueprint called for educational reform to equalize opportunities between male and female children. Second, the blueprint proposed legal reforms to protect women's rights in employment, property ownership, and inheritance. Expanded protections against gender-based violence were also included. Third, the blueprint stressed women's reproductive rights, including the right to choose the number and spacing of children. Fourth, the blueprint proposed expanded family planning services to reduce unwanted or mistimed pregnancies. Family planning services require skilled medical personnel, adequate health care facilities, family counselors, and access to contraceptives.

Ten years after the ICPD Program of Action was approved, the United Nations Population Fund (UNFPA) issued a progress report on the state of human population in the world. The UNFPA identified promising developments in integrating population policies with countries' development plans, expanding reproductive health programs and women's rights initiatives, strengthening HIV/AIDS education programs, and improving access to family planning services. Significant challenges remained, however. Topping the list were relatively high fertility rates and maternal mortality rates in many of the world's LDCs; the spread of the HIV/AIDS epidemic in Africa, the Caribbean, and other world regions; and gaps in program coverage for traditionally marginalized peoples such as the rural poor, urban slum-dwellers, and refugees. The United Nations Department of Economic and Social Affairs predicted the global population will plateau at roughly 9 billion people by the mid-21st century.

PORTFOLIO MANAGEMENT

Portfolio management has these essential basics: defining or identifying investment objectives, identifying resources and limitations, constructing an investment portfolio, and monitoring and revising the portfolio.

The first step in investing is perhaps the most important. Most people think of investment as only part of retirement planning. In fact, purchasing a house, saving for children's college, making bequests, and saving for emergencies are all part of the investment goals. The sooner these objectives are identified, the easier it will be to achieve them.

The earning power of individuals usually follows a pattern known in economics as the *income life cycle*. In general, in the early stages of life, we tend to earn less and at the same time accumulate debts. As we gain education and experience over time, our earning power improves as well. This is generally the period when we start to pay off the debts we accumulated in the first phase of our life. In the third phase of the income life cycle, as we get closer to retirement, the increases in earning power eventually diminish and either stabilize or decline. The accumulation of excess income that is available for investments usually occurs during phases two and three. While earning power and the ability to set aside excess income are easiest in the latter part of phase two and most of phrase three, the best time to start investment planning is at the latter part of phase one. Due to the effect of compounding, a small amount invested early in phase one will have a significantly higher return than a large amount invested in phase two or phase three. Failure to set investment goals early in life can have significant costs.

Thus, when we're setting investment objectives, the impact of the time value of money must be taken into consideration. It might be worthwhile to delay some major purchases/spending. Sometimes, it is even worthwhile to take out a loan and not reduce the amount being put into investment; one example of this is to purchase a house by taking out a mortgage. The idea that all debt is bad is naïve. Debt that is for consumption purposes is bad. But debt that could improve future income or decrease cost is good; college tuition loans (up to a certain point) and mortgages are examples of good debt.

It is also important to set investment objectives that are realistic and practical. One cannot expect a rate of return higher than market average without being willing to take on additional risks. An investment advisor or portfolio manager should be able to help identify a class of assets that meets a person's desirable level of risk and return. Think of it like this: A member of a board of trustees for an endowment fund or trust will need to have an investment policy that guides the portfolio manager on how to invest the fund. The portfolio manager can serve in an advisory role in setting the investment policy, but the main responsibility on this task lies with the board.

Common investment objectives include growth of income, stability of principal, income, and capital appreciation. Some of these objectives are mutually exclusive. For example, stability of principal and appreciation of capital are mutually exclusive. The role of cash and liquid assets in an individual's spending needs throughout the economic life cycle is also an important factor to consider in setting objectives.

Portfolio Construction and Management

Once the investment objectives and resources are identified, the next step is to construct a portfolio that will achieve those objectives. It is not enough to realize that it is important to invest early. It is also important to identify the asset class that will give the best return for a given level of risk. The historic average return for stocks is about 11 percent to 15 percent, depending on the market capitalization of the stocks. The average return for corporate bonds is about 7 percent, and the average for U.S. Treasuries is about 5 percent. Other asset classes typically have returns of 5 percent or lower on average. Given these figures, to achieve more than 10 percent return, stocks will be the only option. So, if the investment process is delayed, achieving investment goals may not be possible if contributions are not greatly increased. Investments in the leveraged asset class (options and futures, for examples) are typically more speculative and carry more risk. They are not ideal for most investors.

There are a few special investment strategies that result in a higher level of return. Value investing and contrarian investing strategies both outperform the broad market index by about 2 percent return annually. But if more investors are participating in these strategies, the return will decline accordingly.

Most individuals will likely never use the services of an investment professional. Most people have their retirement savings account through their work, and most assume that their employer will arrange to have this work done. This is one of the biggest investment mistakes people make, and often they never find out until it is too late. Most companies use a mutual fund company or the wealth management division of a major bank to manage their employees' 401(k) plan. These management companies have no fiduciary duty to the plan holders. Typically, it is the company's Human Resources department that decides, with advice from a management company, what the default investment options are. The initial options can range from ultrasafe assets such as U.S. Treasuries, or even money market funds, to equity index funds. The most common default today is either a balanced fund or a life cycle fund. A life cycle fund will reset the asset mix automatically throughout an individual's life cycle. As an individual gets closer to retirement, the fund's mix will move more toward bonds and less toward equities.

This passive investment strategy will meet the needs of most individuals who have no time for or little knowledge about the various investment options. But the management company has no responsibility to put an individual's investment fund into the company's best-performing funds within a certain asset class. So, the typical life cycle fund often performs below the market average of a portfolio with a similar asset mix. Therefore, it is very important that individuals pay attention to the asset allocation policies for any life cycle fund; perhaps people can pick their own sets of funds, ones that will match similar risk characteristics and achieve better returns.

For individual investors who have more time and/or knowledge, actively engaging in adjustment in asset allocation may yield a better return in the long run. However, anticipatory changes to asset allocation (known as tactical strategy) can work only if the timing is right most of the time. It is very difficult for even for the most seasoned portfolio manager. Thus, passive strategies with limited changes in anticipation of direction of the market might be preferable to active strategies. It has been shown that over the long run, dollar cost averaging (consistent monthly, quarterly, or annual contributions) yields a better outcome than market timing strategies.

While a passive strategy is preferable to active strategies for portfolio management, the strategy must be reviewed when major events occur in an individual's life cycle. Major changes in financial condition (getting a higher-paying job, being laid off, etc.) or in beneficiaries (through marriage, divorce, having kids, etc.) should trigger a revision in one's investment portfolio.

POVERTY

Poverty is a human condition in which people lack the material goods necessary for a minimal standard of living. Essential material goods include food, clothing, and shelter. The most common measurement of poverty is level of income or consumption. In 2015, the World Bank introduced the income standard of $1.90 per person per day to distinguish the poor from the nonpoor in the developing world. The $1.90 per person per day poverty line is measured in purchasing power parity (PPP) prices to reflect different costs of living in different countries. Over time, the $1.90 per person per day standard has become the world's most universally accepted poverty line, or poverty threshold. According to the World Bank, in 2012, 896 million people in the global economy lived on less than $2 per day.

Extreme poverty refers to people who fall beneath the World Bank's $1.90 per day poverty line. The poverty rate, also called poverty incidence, is the percentage of a country's total population that lives in extreme poverty. Since the poorest nations set poverty lines, there will also be people in the world who live in extreme poverty regardless of the poverty line set. In some of the world's poorest countries, more than half the entire population lives in extreme poverty. According to the World Bank, extreme poverty was projected to drop by about one-half, or 600 million people, between 1990 and 2015, and the number of people living in extreme poverty was expected decline in all regions except sub-Saharan Africa.

Many countries in the developing and developed world have established their own measurements of poverty. In developing countries, the national poverty line typically falls between $1 and $2 per person per day. The World Bank's poverty threshold is $1.90 per day. In the United States the U.S. Census Bureau uses a household's money income, size, and composition to distinguish the poor from the nonpoor. In 2014, a household consisting of two people was poor if its money income dipped below $15,934; a household of four was poor if its income fell below $24,230; and a household of nine or more persons was poor if its income fell below $49,021.

As was the case with developing countries, the income or consumption level that separates the poor from the nonpoor is called the poverty line, or poverty threshold. In the United States the government calculates the poverty line by multiplying a typical household's annual food budget times three. Thus, the poverty line inches upward each year, as price levels rise. In 2014, about 47 million people were considered poor, and the poverty rate, which measures the percentage of Americans living in poverty, was 14.8 percent.

Glaring disparities in income and consumption exist between nations and within nations. In 2011, 43 percent of the population in sub-Saharan Africa lived under the $1.90 per day threshold. In contrast, the number in Europe and Central Asia is only 2.1 percent. Disparities in income and consumption also exist within countries. The level of inequality is based on the amount of income or consumption by the richest and poorest 20 percent of the population in each country.

Income inequality and consumption inequality are less severe in the advanced economies than in many developing countries. In the United States, for example, the richest 20 percent of the population has about eight times the income of the poorest 20 percent. The income inequality in Norway, Sweden, Japan, and Finland is less than half that of the United States. There are many reasons for the income disparity between the different economic classes in the U.S. economy. Income distribution is influenced by the compensation that workers receive in labor markets, as well as income derived from interest payments, dividends, capital gains, rents, entrepreneurial profits, and a variety of public transfer payments. The U.S. Census Bureau reported a widening income gap between America's richest and poorest citizens over the past quarter century. Stricter regulations on public assistance for the poor, stagnant or declining real wages for many middle-class wage earners, and higher incomes for the highly educated and well-connected professional classes helped account for the growing income gap.

Income and consumption are the most widely used measures of poverty. Some economists view monetary measures as narrow and inadequate, however. These economists favor the inclusion of a broader spectrum of factors related to the human condition. Broader measures of poverty not only include people's income, but also daily calorie intake, level of educational attainment, personal health and security, and degree of inclusion in the economic and political mainstream. Some experts suggest that a broader, multidimensional approach to defining poverty enables the government to identify and address specific problems of the poor.

The Millennium Development Goals (MDGs), which were approved by the United Nations in 2000, solidified the world's commitment to poverty reduction. The MDGs' first goal, to "eradicate extreme poverty and hunger," is the centerpiece of global efforts to establish a more just and secure global economy. The World Bank, the International Monetary Fund, regional development banks, specialized agencies and programs of the United Nations system, and other major institutions in the global economy have hopped onto the poverty-reduction bandwagon.

PRE-CLASSICAL ECONOMIC THOUGHT

The study of economics did not begin with Adam Smith and *The Wealth of Nations*. It is not clear when the study of economics originated, but it certainly dates back to St. Augustine, Thomas Aquinas, Aristotle, and other ancient philosophers and great thinkers. The early thoughts and ideas about economics did not come from economists. Even Adam Smith was not an economist, but a teacher of moral philosophy at the University of Glasgow. Economics was not recognized as its own discipline until the 19th century.

Modern economics focuses on the efficient and effective allocation of resources. This was not true of pre-Classical thought. As moral philosophers, religious leaders, and secular thinkers and writers, these men were more focused on what we would consider noneconomic outcomes, like integrity, honesty, and quality of life.

The earliest thoughts of economics go back to the second and third centuries BCE. The works of Plato and his pupil Aristotle (fourth and third centuries BCE) contain ideas about property rights and wealth creation. There are writings of Aristotle that include such topics as personal finance, markets, and voluntary exchange—and ideas on what motivated human economic behavior.

As the Greek era ended and the Roman era began, new avenues of economic thinking emerged. Economic topics are a constant in both the Old Testament and the New Testament of the Bible. Early Jewish law claimed that property rights were fundamental and to be protected. Two of the Ten Commandments relate directly to property rights. Jewish thought condoned wealth creation, seeing it as virtue. Roman law is responsible for the development of the contract. The Muslim historiographer Ibn Khaldun first wrote about the division of labor in the 14th century, several hundred years before Adam Smith.

The writings of the Scholastics (13th and 14th centuries) focused on four themes: property, usury, money, and honesty in an economic exchange. The writings of Thomas Aquinas made economic references, including honesty, noting that price-gouging and raising prices are theft and immoral. He wrote that businesses had a moral obligation to avoid raising prices, even if demand warranted the increase. Most writings on topics that today would be considered economics generally involved money, usury, agriculture, or taxes.

From the 16th century to the early 19th century, an economic system and economic thought enveloped Europe. Mercantilism as an economic philosophy on national wealth and power superseded individual wealth. National wealth was obtained by countries exporting as much as they could in exchange for gold or other precious metals. One part of a nation's game plan was to institute high tariffs. High tariffs accomplished two goals: First, they provided the national treasury with additional income, and second, they discouraged imports. This kept nations from having to use their gold to pay for imports. The Age of Mercantilism is also known for the myriad of explorers and adventurers who travelled to new lands searching for gold and other precious metals for the national treasury and the kings and queens of their homeland. Mercantilism was the backdrop that led Adam Smith to write *An Inquiry into the Nature and Causes of the Wealth of Nations*, in 1776.

The Mercantilist movement and philosophy began to end with the growth of an antimercantilist economic movement coming from France. The Physiocrats countered the mercantilists by their philosophy that the source of wealth was agriculture, not piles of gold and other precious metals. The Physiocrats borrowed from medicine and the discovery of a blood circulation system in the human body. They fashioned their analogy of the economy on the human circulatory system. In the early 18th century, the Physiocrats produced the first circular flow of economic activity, known as the Tableau Economique (1759).

With the publication of *An Inquiry into the Nature and Causes of a Wealth of Nations* in 1776, the era of pre-classical economic thought began to end. By the close of the 18th century, a new era, the modern era, of economic thought had begun.

PRISONER'S DILEMMA

The two-person game Prisoner's Dilemma (PD) and its *n*-player analogue Social Dilemma (also called the Tragedy of the Commons) are the basis for using game theory (the formal analysis of conflict and cooperation) to study coordination failures. Prisoner's Dilemma and Social Dilemma are *noncooperative* games (games in which there is no external authority, such as a legal system, to enforce agreements among players) in which the unique equilibrium yields an outcome that is not *Pareto-efficient* (that is, some other combination of strategies would produce an outcome in which some player, and perhaps every player, was strictly better off, and no player was worse off). The payoff matrix for Prisoner's Dilemma was formulated, and the first PD experiment (100-round repeated) conducted, by RAND Corporation researchers Merrill Flood and Melvin Dresher in January 1950, with the name Prisoner's Dilemma and the accompanying story provided shortly afterwards by Princeton mathematician and RAND consultant Albert Tucker in a May 1950 lecture on game theory to Stanford's Psychology Department (Flood 1958 used the name "Hangman's Paradox," quoted from a letter from John Nash). The game was not published until 1958, in a condensed version of Flood's 1952 RAND Research Memorandum.

According to a letter from Tucker to Dresher (Poundstone 1992, 117–18), in Tucker's lecture two prisoners are interrogated separately about a crime they are accused of having committed together. Using more convenient payoffs in place of Tucker's, each prisoner is told that if he confesses and the other does not, the one who confesses (turns state's evidence) will be set free and the other one will be sentenced to three years in prison. If neither confesses, they will both be sentenced to one year in prison on a lesser charge. But if both confess to the more serious charge, each will be sentenced to two years to prison. So the payoffs to (Player A, Player B) are as follows:

Table 1. Prisoner's Dilemma

	Player B	
	Confess	**Deny**
Confess	2, 2	0, 3
	Player A	
Deny	3, 0	1, 1

The strategic combination (Confess, Confess), which leads to each prisoner being sentenced to two years in prison, is not only the unique Nash equilibrium: No player can improve his or her payoff by being the only player to change his or her strategy, so each wishes to confess given that the other one confesses. It is also a dominant strategy equilibrium: Each player will choose to confess, regardless of what the other player does, provided they chose independently, even though (Confess, Confess) makes each of them strictly worse off than (Deny, Deny) would do. If player B chooses to Deny, player A prefers to Confess, because 0 (zero) years in prison is better than 1 year. If B chooses to Confess, A prefers to Confess, because 2 years in prison is better than 3. B faces the same incentives, so both Confess and each is sentenced to 2 years in prison, even though adhering to an unenforceable prior agreement to (Deny, Deny) would have limited their prison time to one year each.

The RAND Corporation, a consulting firm whose only client at the time was the U.S. Air Force, was not interested in puzzles of criminology. Prisoner's Dilemma could be read as describing the Cold War, with the United States and the Soviet Union each deciding whether to launch a nuclear strike on the other. The implication that each had a dominant strategy to launch a first strike, regardless of whether the other was going to or not, was most disturbing both to military strategists and to such peace researchers as Anatol Rapoport. John Nash predicted that the outcome would be the same in a finitely repeated PD, however many the repetitions, because the last round would be a one-shot game in which the unique dominant strategy equilibrium would be (Confess, Confess), regardless of what happened in prior rounds. If the outcome of the last round of play was determined, then the next-to-last round would also be a one-shot PD with unique dominant strategies (Confess, Confess), and by backward induction so would all the other rounds. Flood and Dresher tested Nash's prediction with a 100-round PD game played by the UCLA economist and the RAND mathematician John Williams. Instead of Nash's prediction of (Confess, Confess) 100 times, Williams chose cooperate (Deny) 78 times and Alchian chose it 68 times, with mutual cooperation (what would be Deny, Deny in Tucker's subsequent story) being achieved 60 times and the Nash prediction of mutual defection occurring only 14 times. Alchian began by defecting (Confess), as Nash predicted, but gradually responded to Williams's strategy of rewarding cooperation and punishing defection. Nash denounced the two players as irrational, but over the whole game they achieved higher payoffs than Nash's prediction would have yielded. Later experiments, such as those surveyed by Rapoport and Chammah with Orwant and many later experiments, consistently found more cooperation in one-shot or finitely repeated PD games than predicted by Nash's theory of independent maximization of individual payoffs.

One way of explaining such cooperation is altruism, whereby each player derives some utility from the other player's payoff. This amounts to redefining the payoffs in utility terms, so that defecting is no longer a dominant strategy and the payoff matrix is no longer that of Prisoner's Dilemma. Alternatively, the players may engage in some form of precommitment, forcing them to keep their promises to cooperate, in which case the game is no longer a noncooperative game. Robert Axelrod conducted a repeated PD tournament in which, instead of the number of rounds of play being fixed and known in advance, there was a small probability (about one-third of 1 percent) of any round being randomly chosen as the last round, so that at any point the tournament was expected to continue for another 200 rounds. Backward induction was then impossible, since there was no known last round from which to solve back to the beginning of the tournament. "Tit for Tat," the strategy submitted by Anatol Rapoport of cooperating until the other player defected and then doing whatever the other player had done on the previous round, achieved the highest payoffs when each submitted strategy was played against each of the other strategies. Although an Axelrod tournament will end in finite time with probability one, the fact that the ending is probabilistic makes it equivalent to an infinitely repeated PD. For the case of infinite repetition, where retaliation or reward on future rounds is always possible, the "folk theorem"—that almost any sequence of outcomes can be supported by a subgame perfect Nash equilibrium—provided that there is neither too high a probability of the game ending on any given round or too high a discounting of future payoffs. (The folk theorem was so named by Robert Aumann because game theorists and economists felt that they had always known it, even though no one could remember its origin.) Kreps argued that cooperation can be rational even in finitely repeated PD games of known length, provided that there is incomplete information, which allows for investment in developing a reputation for rewarding cooperation and punishing defection.

Prisoner's Dilemma and its *n*- player version (Social Dilemma or Tragedy of the Commons) are invoked to explain a wide range of coordination failures, including global climate change, tariffs, investment in research and development, spending on advertising campaigns, and crime deterrence. Some game-theoretic New Keynesian economists use this analysis to understand the macroeconomic coordination failure of equilibrium at low employment, where if firms jointly hired more workers, the newly employed workers would spend their wages in such a way as to justify the firms having hired them. PD has proved widely applicable in understanding coordination failures, while experimental and empirical evidence consistently indicates that, while cooperation is far from complete or universal, there is more cooperation than the Nash prediction of no cooperation at all in Prisoner's Dilemma games.

PRIVATE PROPERTY

The origins of private property may lie deeply, perhaps genetically, ingrained in human nature. The first hominids that found a useful rock or stick, or crafted a tool, or settled in a place, almost certainly asserted ownership, and then had to defend it. As societies formed, rules were adopted to protect citizens' rights and possessions. As people(s) began to trade, possession inherently acknowledged ownership.

In 350 BCE, Plato and Aristotle argued over whether property should be owned privately or collectively (by the state). More than 2,000 years later, the debate continued, as capitalism, fundamentally dependent on private property rights, waged ideological war with socialism and communism, which espoused collective ownership of the means of production, for the economic future of the world. It is also worth noting that, in the fairly recent past, the world was torn over whether property could even include human beings!

While public property is owned by the state (government), economists recognize *private property* as that which assumes ownership or the exclusive right over a productive resource by entities other than the government, including not only material things but also the product of one's labor, such as original ideas, symbols, methods, and writings. These rights can generally be traded or transferred through legal contracts.

Free-market (capitalist) advocates such as Milton Friedman (1912–2006) and Friedrich von Hayek (1899–1992) believed that private property, and the exclusive right to profit from it, is absolutely essential for the efficient allocation of resources to achieve the greatest economic benefits to society. When individuals are allowed to directly own productive resources and to employ the resources to create things of value for others, the potential to earn profits will serve as a very powerful incentive to protect, maintain, and even improve upon those assets. Those resources will then be employed in innovative and productive ways to generate profit for the owners by serving others, producing useful new goods or services, and solving problems in an economy. Conversely, when property is owned collectively, or when individuals cannot earn personal profit from employing the resources productively, there is no direct or enduring incentive for them to do so. Then, resources tend to be underutilized, poorly maintained, or even abused.

In every society, there is common property such as streets, parks, and waterways; natural resources; and intangible things like (clean) air and even peace and quiet. What if one person's right over property or use of it infringes on the rights, or diminishes the well-being, of others—perhaps the whole of society? Think of a factory polluting the surrounding air or water. Those outside the direct market who must bear costs associated with others' consumption or production of a good are said to suffer negative externalities. Likewise, those who receive benefits enjoy positive externalities. When the public good is served, government may actually seize private property (after fairly compensating the owners) for such purposes as constructing dams, bridges, parks, and so on, through the process of eminent domain. Even nations with developed legal systems and effective enforcement mechanisms struggle with issues and conflicts where property rights are not clearly defined.

When there are no clearly established private property rights, productive assets tend to be overutilized, depleted, or even destroyed by users who gain direct personal benefit from using the common resource before others do, but who do not share in the cost of maintaining it. The "tragedy of the commons" is exemplified by the plight of the Atlantic cod-fishing industry in the 1980s, as fishermen competed vigorously to catch clearly depleting stocks of cod before other fishermen took them. This rule of capture, asserting clear private ownership only upon capture of the common good, led to more and more overfishing as the price of cod rose, reflecting its dramatically escalating scarcity. Despite recognition that continued fishing would diminish the fish population below levels necessary to effectively reproduce and sustain a stable population, thus destroying the entire industry and thus their own livelihood, individual fishermen were perversely incentivized (through higher prices and the rule of capture) to actually increase fishing until the fish stocks went commercially extinct.

Market failure occurs whenever resources are not efficiently allocated toward their most productive uses. This is not to say that alternative solutions are apparent. But establishing and enforcing clear property rights, especially for common resources, continues to pose significant challenges to all economic systems to this day.

PRIVATIZATION

Privatization is the process of converting state-owned assets, production facilities, or service-delivery systems to the private sector. Since the 1980s, many countries in the global economy have privatized government assets and enterprises. Privatization accompanied the global shift toward market-oriented economies over the past quarter century. The transfer of goods-producing and services-producing enterprises from the public to the private sector was designed to increase production efficiency, improve product quality, create domestic and foreign investment opportunities, and stimulate entrepreneurial activity. Privatization also addressed structural reforms in national economies. Privatization helped reduce bloated government bureaucracies, dismantle ineffective state planning agencies, and end expensive subsidy programs. Further, privatization generates a one-time revenue windfall for governments.

Governments privatize companies and other assets in a variety of ways. The most common privatization approach is the issuance of shares of stock in the enterprise. The issue of new stocks is called an initial public offering (IPO). Shares of stock are sold to individuals, workers, financial institutions, local businesses, transnational corporations (TNCs), and other investors. Often, the government holds some of the shares in the privatized enterprise. Another approach to privatization is the issuance of "vouchers." Vouchers dominated the early years of Russia's privatization from 1992 to 1994. Under the voucher system the government issued vouchers to the Russian people. Vouchers gave citizens the right to buy small enterprises or buy shares of newly privatized corporations at public auction. Russia's privatization has gone through additional phases since the mid-1990s. Some privatization occurs through simple asset sales. The purchase of government assets by TNCs illustrates this type of asset transfer. Privatization, broadly interpreted, also occurs when the government retains ownership in an enterprise but hires a private firm to manage the facility. Management contracts are common in larger facilities such as airports and convention centers.

Privatization swept through the global economy during the 1980s, 1990s, and early 2000s. Governments in Latin America and the Caribbean launched extensive privatization initiatives earlier than most world regions. From the mid-1980s to the early 2000s, governments privatized key services such as banking and telecommunications, and features of the economic infrastructure such as water and transportation systems. In Europe, the United Kingdom was in the vanguard of privatization. From 1979 to 1990, Conservative British Prime Minister Margaret Thatcher aggressively privatized key industries, including telecommunications, coal, and some railway operations. France, under the leadership of Prime Minister Jacques Chirac, carried the privatization torch to the European mainland. Between 1990 and 2001, the 15 European Union (EU) countries privatized more than half a trillion dollars worth of government assets.

Since the early 1990s, privatization has been a centerpiece in the epic shift from communism to capitalism for 27 transition economies in Eastern and Central Europe and Central Asia. The pace of privatization has varied significantly, however. Most transition economies successfully privatized small- and medium-sized enterprises (SMEs). SMEs include retail stores, construction firms, and personal and professional services. The privatization of large state-owned enterprises (SOEs), such as mines and heavy industries, was less successful. The European Bank for Reconstruction and Development (EBRD) provides development loans and privatization assistance to transition economies. EBRD reported significant progress in most countries' privatization. EBRD gave most transition economies high marks for their privatization efforts. In terms of small-scale privatization, 19 transition countries, including Russia, earned a "market economy" designation. Just 9 transition countries earned market economy status for the more difficult privatization of large SOEs. Reforms in 8 transition countries were insufficient to meet the market economy standard in either privatization category.

Privatization has sparked controversy around the world. In Latin America, for example, price hikes resulting from the privatization of key services, such as water supplies and transportation, created a storm of protest. The 2000 privatization of the water supply in Cochabamba, Bolivia, was reversed after mass demonstrations and strikes destabilized the country's third largest city. People throughout Latin American also blamed privatization for rising unemployment and the widening income gap between the rich and poor. People resented the highly favorable terms extended to foreign TNCs by national governments. Discontent with privatization also stems from the process of transferring ownership or control to private interests. Russia's voucher system, for example, was criticized for giving unfair advantages to the traditional power elite. In some countries, privatized firms have been reacquired by the government to ensure a reliable supply of a product at a reasonable price.

PRODUCTION POSSIBILITIES CURVE

The production possibilities curve (PPC) or production possibilities frontier (PPF) is a simple theoretical economic model demonstrating the efficiency, growth, opportunity cost, and societal trade-offs of production choices for a two-goods economy.

The model is constructed with a single quadrant graph and just two goods, with the vertical axis labeled as one good and the horizontal axis with the other good. The model is based on a few basic assumptions: (1) fixed point in time, (2) resources are finite, and (3) technology is fixed.

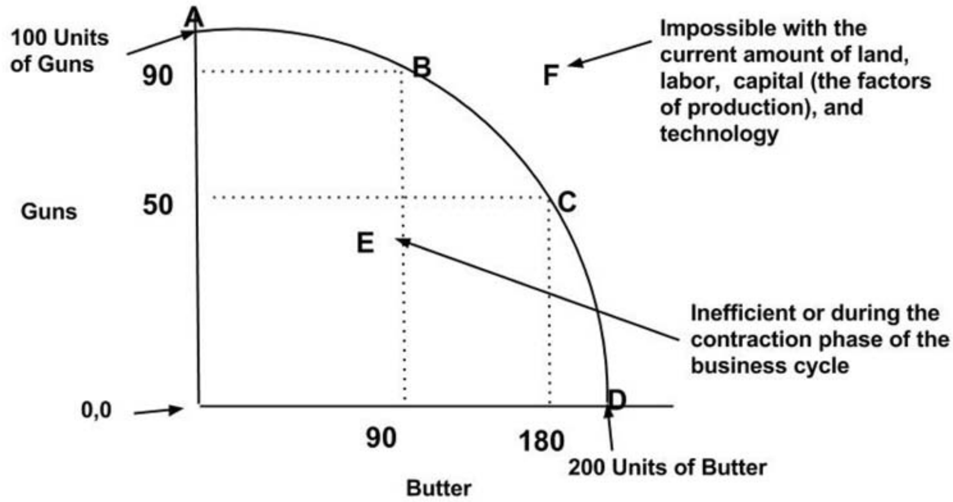

Figure 1. Three conditions of an economy: Inefficient, Efficient, Impossible

The classic example of a production possibilities curve is the "guns and butter" economy. In this two-goods economy, "guns" is a metaphor for government/public sector spending and "butter" is a metaphor for household/business/private sector spending. A society facing this type of production possibilities must make decisions on the level of government spending versus private spending by households and businesses.

Any point that is on the production possibilities curve represents total efficiency or a maximum use of the factors of production and technology. It is up to society to determine at which point to produce; all the production possibilities curve does is demonstrate efficiency. Any point that is below the production possibilities frontier is inefficient and represents the contraction phase of the business cycle of unemployment that is larger than the natural rate of unemployment. In the "Production Possibilities Curve" illustration, point E is inefficient. Any point that is beyond the production possibilities frontier is impossible with the current amount of resources and technology. In the illustration above, point F is impossible. The only way that point F can be obtained is with an increase in the factors of production or technology. However, the production possibilities curve does not have to shift equally for both military goods and consumer goods. Economic growth is demonstrated with an outward or rightward shift of the production possibilities curve.

Opportunity cost can also be demonstrated with the production possibilities model. In the illustration, when this economic system is producing at point A, it is producing 100 units of military goods and no consumer goods. When it moves production to point B, it is producing 90 units of military goods and 90 units of consumer goods. The opportunity cost of producing the first 90 units of consumer goods is only 10 units of military goods (simply subtract the number of military goods produced at point B from point A). When it moves production from point B to point C, it is producing 50 units of military goods and 180 units of consumer goods. The opportunity cost of producing the next 90 units of consumer goods is 40 units of military goods. This large increase in opportunity cost in producing the second 90 units of consumer goods is termed the "law of increasing cost," and it is why the production possibilities curve has a bowed-out or convex shape. In the illustration above, the production possibilities curve is bowed out because not all of this economic system's resources are best used to make military goods; for example, there may be fertile land that could be used to grow wheat. As this economic system moves from point A to point B, it gives up only the resources that are best used at making consumer goods—such as the fertile land, which yields a large increase in consumer goods at a very minimal opportunity cost of military goods production. As this economic system moves from point B to point C, it begins to give up resources that are best at making military goods to make the additional consumer goods, which is why the opportunity costs has increased.

The production possibilities frontier is represented in two other important economic models. The long-run aggregate supply curve in the aggregate supply and demand model represents the production possibilities frontier. Any point to the left of the aggregate supply curve is a point beneath the production possibilities frontier, and when the aggregate supply curve shifts to the right or increases, the production possibilities frontier shifts to the right or increases.

The production possibilities curve for the United States and the world has greatly increased over the last 200 years. A few of the inventions and events that have increased the production possibilities are electricity, immigration, automobiles, trains, phones, computers, the assembly line, new manufacturing processes, and, most importantly, education. Any decrease in physical or human capital could result in a decrease in the production possibilities frontier. Natural disasters, war, and territorial disputes between countries often result in the stagnation or loss of physical and human capital.

As the United States and the world community continue to increase their physical and human capital, the production possibilities of a global economy will continue to increase.

PROGRESSIVE ERA

The 30 years in between 1890 and 1920 were copious with business expansion, breakthroughs in technology and science, economic productivity, and increases in the standard of living throughout the United States. During this time, writers and journalists, known as muckrakers, aimed to bring to light the problems that society faced. These problems included the need to end government corruption, improve working conditions and environments, and make society more secure. This period of history became known as the Progressive Era.

A period full of ingenuity, new methods, and innovation was exactly what transpired. Progressive political reformers fought to provide the public with direct control over the American government. One of the reforms they sought involved a direct primary preliminary election, allowing every member of each party to be a part of the nomination. This was deliberately aimed at limiting the influence of "political machines." Also, the idea of a *referendum*, enabling people to pass legislation that a state legislature is either unwilling or unable to pass, and a *recall*, the action of granting voters the power to remove elected officials through petitioning and voting, helped to transform America's politics. Not only that, but legislators became concerned with the welfare of their citizens. This brought up the idea of *workers' compensation*, a form of insurance payments to a worker or a worker's family due to the worker's job-related disability or death.

Along with political reforms came moral reforms. One reform that changed America was the event in which the Supreme Court ruled that "separate but equal" facilities were legal under the Fourteenth Amendment. Segregation of African Americans had been a moral issue for many Americans, and this event was a moral revolution for the country. Women's suffrage was another moral reform that occurred during the Progressive Era. Elizabeth Cady Stanton ascended to national prominence and leadership when she organized the first women's rights convention. Women were seeking access to a higher level of education and occupations, the right to divorce, and, above all, the right to vote. The Nineteenth Amendment to the U.S. Constitution was approved in 1920, granting women the right to vote.

However, moral and political reforms weren't the only revolutions occurring. Business and social reforms were also shaping America. Industries such as the automobile industry began to boom. The invention of the automobile created many jobs and sent labor industries into high demand. Business began to boom, and industrialization caused the population to increase; at the same time, working conditions became hazardous during this era of labor and prosperity.

Whether it was the election of Theodore Roosevelt or the idea of Prohibition, the Progressive Era was a period in which America boomed with new ideas and revolution. This era helped to shape the United States into the country it is today.

PROHIBITION

Prohibition—the banning of the manufacture, sale, and transportation of alcoholic beverages—became national policy in the United States with the ratification of the Eighteenth Amendment in 1919. The act, however, did not outlaw the consumption of alcohol. Congress passed the Volstead Act, also known as the National Prohibition Act, in 1920 in order to further define the parameters of the amendment, as well as to give the national and state governments the tools necessary to carry out the law. The act also created a special agency inside the U.S. Treasury Department, known as the Prohibition Bureau, to enforce it. Many wealthy Americans and private businesses were able to purchase and store large supplies of alcoholic beverages before the law went into effect.

The movement actually originated at local levels before the American Revolution, but it began to receive more national attention during the 1800s. The average American in the early 1800s consumed almost seven gallons of pure alcohol a year (Burns and Novick 2011), more than three times what Americans drink today. Alcohol abuse challenged the stability of many families during this time, especially when the limited legal rights and financial dependence of women are considered. Reaching for the same tools as were used by abolitionists and Protestant Church reformers, supporters of prohibition first urged moderation and then later full prohibition via legislation. Temperance activist Neal Dow led Maine to become the first of many states to pass Prohibition laws during the mid-1800s. This created momentum for the creation of a national Prohibition law. Groups such as the American Temperance Society and the Woman's Christian Temperance Union (WCTU), the latter led by Francis Willard, argued that alcoholic beverages were the cause of many of the social ills of the time. Alcohol was blamed for contributing to such immoral behavior as gambling, domestic violence, and prostitution. Business interests also supported the movement, because they felt it would improve productivity and reduce absenteeism. The Anti-Saloon League, founded in 1893, worked to create political support for Prohibition under the leadership of Wayne B. Wheeler. The Anti-Saloon League quickly became an incredibly successful lobbying group, drawing diverse groups of Americans from all walks of life, including Republicans, Democrats, suffragists, and Populists, to create a constitutional amendment supporting Prohibition.

The movement gained further momentum during the Progressive Era, when many middle-class reformers saw the prohibition of alcoholic beverages as a means to improve the moral behavior and economic condition of the urban poor and working classes. World War I became the final impetus for the passage of a constitutional amendment banning the production, sale, and transportation of alcohol. Anti-German sentiments gave force to the Progressive arguments that poor, urban areas inhabited by immigrants were hotbeds of immorality and disloyalty. The powerful Anti-Saloon League helped to promote the idea that beer and brewers were viewed as a German plot to sap America's will to fight the war.

In 1913, the federal government ratified the Sixteenth Amendment, making income tax a major form of revenue for the federal government. Consequently, the government was no longer dependent on liquor taxes as a major revenue source. This left a clear road for the Eighteenth Amendment to pass through both houses of Congress and achieve state ratification in just 13 months.

Prohibition was an unpopular law from the start, creating black markets and a significant underground economy. Many Americans made liquor at home, and others visited underground bars known as "speakeasies," which were numerous in most large cities across the United States. Loopholes in the law allowed people to obtain alcohol through unconventional, black market, and nonmarket economic means. Farmers, physicians, pharmacists, and even religious leaders could all use exceptions to the law to obtain and distribute alcohol to the greater public. "Bootlegging" was a term used to describe the illegal production, sale, and distribution of alcohol during Prohibition. Bootleggers also smuggled alcohol into the United States from Canada, the Caribbean, and Europe.

Bootlegging, black market, and underground economic activity led to a rise in organized crime and corruption in the United States. Organized crime had existed throughout U.S. history, but it grew to unprecedented levels during Prohibition, as the illegal distribution and sale of alcohol became quite lucrative. Gangsters such as Al Capone built criminal empires with the money they made from black market operations, bootlegging alcohol, and speakeasies. Al Capone was able to monopolize Chicago's illegal activity by murdering his competition and anyone else who stood in his way. At the height of his operations, Capone had built a multimillion-dollar empire from his black market operations. Capone was never convicted of murder, but he was found guilty of tax evasion and sentenced to 11 years in the famous Alcatraz Federal Penitentiary.

Problems enforcing the amendment were apparent from the start. Federal, state, and local governments were in charge of policing an action that many, if not most, Americans felt was a natural part of society. Complicating matters was the issue of resources allotted to the Prohibition Bureau. Only 1,500 federal agents were assigned to the bureau, which made it impossible to patrol the nation's thousands of miles of coastline and international borders, much less find and shut down illegal stills and underground bars. Al Capone alone employed 1,000 men to protect his liquor trade.

Supporters believed that prohibition it would stimulate local economies. They believed people would purchase household goods and luxury items like soft drinks, movies, or real estate as they looked for other forms of recreation. The reality was the closing of many entertainment industries and restaurants due to slow sales without alcohol. Many people also lost jobs within and related to the brewing, distilling, and saloon industry.

The movement to end prohibition began shortly after the act became national policy. It quickly became apparent that the costs of enforcing the Eighteenth Amendment far exceeded the benefits.

The Great Depression furthered the cause of ending prohibition. Those who wanted to repeal the Eighteenth Amendment argued that many jobs could be created by allowing the sale and manufacture of alcohol, which would also increase government revenues through excise taxes. Opponents successfully used these arguments and others to fight for the passage and ratification of the Twenty-First Amendment in 1933, which repealed the Eighteenth Amendment. Several states went on to pass their own statewide prohibition laws, which were not fully repealed until 1966.

QUESNAY, FRANÇOIS

Born: June 4, 1694, in the village of Méré, France; Died: December 16, 1774, in Versailles, France; Nationality: French; Professional Interests: Physiocrat; Major Work: *The Tableau Oeconomical: An Attempt towards Ascertaining and Exhibiting the Source, Progress, and Employment of Riches* (1758).

François Quesnay is considered the founder of the economic philosophy called the Physiocratic system, and the leader of economic thinkers during the Enlightenment called Physiocrats. The Physiocrats assumed that society was subject to natural laws. They believed that an economy's force came from the economy's agriculture. The Physiocrats put forth the propositions that led to the basic elements of capitalism. They promoted deregulation and reduced taxes. Quesnay and the Physiocrats are also credited with deriving the term *laissez-faire*. Quesnay was elected to the Academy of Sciences and earned the nickname "modern Socrates." Quesnay died in 1774.

François Quesnay was born on June 4, 1694, in Méré, France. Méré is located outside Versailles. Quesnay grew up in a lower-middle-class home. He father was a country lawyer and did not earn much money. It appears that Quesnay was a slow learner growing up, not learning to read until he was 12 years old. Even though he was orphaned at 13, his desire to read and learn led him to study and become self-educated in medicine. When he was 24 he began a medical practice in the village of Mantes, France.

Quesnay's skills quickly developed a solid reputation, and eventually he was providing medical services to local aristocrats. Quesnay wrote many articles on surgery, which increased his medical reputation. Through his writings, he elevated surgery into a medical science. In 1749, Quesnay became the personal physician of King Louis XV's mistress, Madame de Pompadour, and eventually he became a resident of Versailles.

In 1756, at the age of 60, Quesnay developed an interest in economics. Based on his rural background, he wrote several articles on farming for the *Encyclopedia* of Diderot. Quesnay based his writings on the works of Richard Cantillon, Marchal de Vauban, and Pierre de Boisguilbert.

In 1766, Quesnay wrote what became his most famous work, *Tableau Économique*, which depicted the income flows between the different economic sectors. This work and the income flows concept became the founding document of the Physiocratic thinkers.

In *Tableau Économique,* attempting to understand and explain the causes of economic growth, Quesnay detailed a circular-flow diagram of the economy. The diagram illustrated what was produced by producers and how consumers spent money. In the *Tableau*, he defined "sterile classes" as both the producers and also the consumers of everything they produced. According to Quesnay, production and consumption were equal, so there was no surplus production to carry over to the next economic period.

Quesnay emphasized the role of the agricultural sector. The wealth of a nation, Quesnay argued, lies in the size of its net product. According to Quesnay, only the agricultural sector could produce a surplus that could then be used for economic growth the following year. He concluded that both industry and manufacturing were "sterile." Quesnay used the term *sterile* to mean that these economic sectors were unproductive relative to future economic growth.

Quesnay constructed the "Table" to fit his belief of the economy, not the reverse. As a result, the Table contains inconsistencies so that it would illustrate the story that best suited his thinking, which was that industry and manufacturing were zero-surplus economic sectors.

Quesnay's thesis that manufacturing was a "sterile" economic sector for economic growth has not held up over time. However, he was proved correct in his criticism of mercantilism. Quesnay was very critical of the mercantilist doctrines of Louis XV's finance minister, Jean-Baptiste Colbert. Quesnay asserted that the French government used mercantilist policies to protect French manufacturers from foreign competition, increasing the prices of manufactured goods. Quesnay believed that the French court supported manufacturing and industry more than it did agriculture.

As a product of the Enlightenment, Quesnay promoted eliminating many of the medieval rules that governed the production of agricultural products. This, according to Quesnay, would permit the economy to find what he called its own "natural state." Quesnay defined the *natural state of the economy* as the balance in the circular flow between income of the economic sectors and the net product. Drawing on his medical background, Quesnay compared the circular flow to the circulation of human blood and the human body's ability to maintain a stable, continuous condition.

Quesnay and the Physiocrats advocated freer trade for French companies with major tax reform and deregulation leading to a freer French economy. Quesnay's attacks on the mercantilist French economic system and his advocating for his tax and regulation reforms were ultimately found to be more acceptable than his economic theories on economic "sterility" of the manufacturing industry.

Quesnay and the Physiocrats promoted private property, property rights, and the merits of free choice for the individual, finding them to be at the heart of any economic system. In addition, however, a central authority (i.e., government) must assert itself to protect those rights. Quesnay credits John Locke for many of his views on private property and liberty.

Quesnay's works were the foundation on which Adam Smith wrote *An Inquiry into the Nature and Causes of the Wealth of Nations,* culminating the fight against the mercantilist economic systems.

François Quesnay died on December 16, 1774, in Versailles at the age of 80.

RATIONAL EXPECTATIONS

The economic philosophy of rational expectations was first introduced in the 1960s. The theory is credited to Indiana University economist John Muth. But the idea behind rational expectations and predicting the expectations of decisions goes back to the writings of John Maynard Keynes as well as others. The idea behind rational expectations is that people have certain expectations regarding the outcomes of their decisions. Both producers and consumers make decisions based what they expect will happen when they make a certain decision. Keynes used this idea as he described it as a basis of economic activity.

To define *rational expectations* is to claim that the outcomes of decisions do not vary from a person's expectation of the decision's outcome. Economists of rational expectations believe in the inherent economic assumption that people make decisions rationally to maximize the returns of the decision. In short, people are rational decision-makers. The rational expectations philosophy is based on thinking about and making predictions about the future in order to determine decisions in the present.

In recent history, the rational expectations philosophy has been used in financial markets to determine equity prices and efficient markets. It is the foundation of the efficient markets theory, used to determine prices in equity markets. Rational expectations have also been a basis for studying hyperinflation, different theories of consumption, and certain macroeconomic stabilization policies. An early application of rational expectations was to determine asset prices. Economists who implement the rational expectation philosophy to present decision-making have the incentive of predicting the future to expect a particular future result.

As mentioned, rational expectations was used early on by John Maynard Keynes. Keynes theorized a positive relationship between personal consumption and personal income. Another famous economist of his era, Nobel laureate Milton Friedman, confronted Keynes's theory successfully with his own "permanent income theory" of consumption. Friedman used as his background the earlier work of another Nobel laureate, Irving Fisher, on the relationship between personal consumption and personal income, both current and future. Friedman's submission was that people consume from their permanent income without using their wealth, which included a prediction of future income.

Economists have used rational expectations theory to think differently about such macroeconomic stabilization policies as fiscal policy and the use of taxes. Keynes first suggested tax cuts as a way to stimulate an economy by boosting consumption. This idea has been challenged, however, by Friedman's permanent income model. The permanent income model suggests that the increased consumption caused by tax cuts is less than was previously predicted by Keynes.

Rational expectations theory has been implemented in determining ideal monetary policy. Again following up on the earlier work of Milton Friedman, the theory of rational expectations has been used to clarify both monetary and fiscal policies. Rational expectations challenges the idea that lawmakers are able to successfully influence an economy with inaccurate future predictions. Nobel laureate Robert Lucas demonstrated that if rational expectations are not likely, then errors exist, and government cannot accurately change or correct those errors.

RATIONALITY: PROCESS AND NEOCLASSICAL

A key assumption in the analysis of decision-making in social sciences is rationality. In general, individuals are said to behave rationally if they are able to assess their possible choices and the consequences of those choices, and act accordingly. However, the assumption of rationality is treated in different ways in different social sciences. In economics, it has traditionally been assumed that rational individuals make decisions with an accurate perception of the environment and with unlimited computational capability. Thus, they always reach the best possible decision given their goals and the constraints that they face in that environment. In other social sciences, such as psychology, sociology, or philosophy, the knowledge of and computational abilities of rational individuals are considered to have limitations, which affect the way those individuals make decisions. Thus, interest focuses on theories that take into account not only the decisions made but also the strategies that are used in the process of reasoning and the (subjective) perception that individuals have of the decision problem. This difference has led to the appearance of new fields of economics, such as behavioral economics, which seek to explain individuals' behavior with more realistic assumptions, including ingredients from the other social sciences.

Rationality—or *substantive rationality*, to use the term coined by Herbert Simon—is the basic assumption of neoclassical economics. This school of thought began in the mid-19th century, mainly following the theories developed by such authors as W. S. Jevons, C. Menger, and L. Walras, and it still has significant influence in current economic theory. According to neoclassical economics, economic agents are rational if in taking their decisions they know the alternatives and the consequences of choosing each alternative, they can rank those consequences according to their preferences, and they choose the alternative that provides them with the best consequence. For instance, rational consumers choose the bundle of consumption that maximizes their utility (level of satisfaction), taking into account their budget constraint. Substantive rationality has been also assumed in more complex decision-making problems. For instance, L. J. Savage (1954), considering this notion of rationality, introduced the subjective expected utility theory to explain decisions made by agents under conditions of uncertainty. J. Von Neumann and O. Morgenstern (1944) also adopted it as an assumption in game theory in order to model decision-making problems by rational agents when they interact with other rational agents. In all these models, the assumption of rationality enables a solution to be found by using optimization theory.

A primary criticism leveled against substantive rationality is that it only focuses on what decisions are made (solutions of the optimization problem) and not on how they are made (decision-making process). Some economic theorists, such as the late Nobel laureate Milton Friedman (1953), defend this assumption by arguing that the sole objective of economic theory is to predict the behavior of individuals: Even if economic agents do not choose by solving a maximization or minimization problem, substantive rationality is a valuable assumption since agents behave "as if" they solve an optimization problem.

However, criticism of substantive rationality has continued, and the criticism has been reinforced by advances made in computation theory from the middle of the 20th century onward, which have shown that optimal solutions may not be obtained, even using powerful computers. Moreover, prediction is not the same thing as determining causation or cause and effect relationships. It is important to know not only what choice is made by individuals, with their cognitive limitations, but also what decision processes led to that choice: cause and effect becomes critically important here. As a result, the concept of procedural reality, imported from cognitive psychology and introduced by Herbert Simon (1976), has emerged as an alternative.

Individuals are considered to be rational when they behave according to an adequate process of reasoning, taking into account the knowledge available and their means of computation. Under this assumption there are (computationally efficient) procedures that can find "good" solutions to decision problems when the best solution cannot be computed. Closely related to procedural rationality is the assumption of bounded rationality, where purposeful individuals do the best they can, given all the constraints they face.

REAGAN, RONALD

Born: February 6, 1911, in Tampico, Illinois; Died: June 5, 2004, in Los Angeles, California; Nationality: American; Professional Interests: 40th President of the United States (1981–1989); Major Works: *Where's the Rest of Me?* (1965), *The Creative Society* (1968), *Abortion and the Conscience of the Nation* (1984), *Speaking My Mind* (1989), *An American Life* (1990).

Ronald Wilson Reagan was born in Tampico, Illinois, on February 6, 1911, to John Edward Reagan and Nellie Wilson Reagan. The family lived in a series of small towns, finally settling in Dixon, Illinois, in 1920 when Reagan's father John opened a shoe store. Reagan attended Dixon High School, where he was an avid athlete, student body president, and actor in a number of school plays. In 1928, he graduated from Dixon High School and enrolled in Eureka College in Illinois on an athletic scholarship. He played football, ran track, and was captain of the swim team. He also served as student council president and acted in several school productions. Reagan graduated from Eureka College in 1932 with majors in economics and sociology. His first job was as a radio sports announcer at radio station WOC in Davenport, Iowa. In 1937, Reagan signed a seven-year contract with Warner Brothers Studios. Over the next three decades, he appeared in over 50 films, including *Knute Rockne, All American* (1940) and *Kings Row* (1942). During World War II, after being disqualified from army combat because of his poor eyesight, Reagan spent his time in the military making training films, leaving the army as a captain.

From 1947 to 1952, Reagan served as president of the Screen Actors Guild. In 1954, he became host of the weekly television drama series *The General Electric Theater*. Part of his job as host was to tour the United States as a public relations representative for General Electric. During this time, his political views shifted from liberal to conservative. He began to lead pro-business discussions, and he spoke out against excessive government regulation; these would become the central themes of his future political career.

Reagan stepped into the political spotlight in 1964, when he gave a televised speech for Republican presidential candidate Barry Goldwater. In 1966, Ronald Reagan was elected governor of California, defeating Democratic incumbent Edmund Brown Sr. by almost 1 million votes. He was elected for a second term in 1970. In 1968 and 1976, Reagan made unsuccessful bids for the Republican nomination for U.S. president; in 1980, he finally succeeded. He defeated Democratic incumbent President Jimmy Carter, becoming at 69 the oldest person to be elected president of the United States.

On March 30, 1981, Reagan was leaving the Washington Hilton Hotel with several of his advisers when they heard shots. Quick-thinking Secret Service agents pushed Reagan into his limousine, before discovering that Reagan had been shot. The bullet pierced Reagan's lung and narrowly missed his heart. Within several weeks of the shooting, President Reagan was back at work.

Reagan's domestic agenda included advanced policies that reduced social programs and restrictions on businesses. As presidential nominee, Reagan was a proponent of a fairly new economic theory: supply-side economics. Tax cuts were the key tool of supply-side economics, as popularized by economist Arthur Laffer (b. 1940). Reagan used supply-side tax cuts to stimulate the U.S. economy. He increased military spending, instigated reductions in certain social programs, and implemented measures to deregulate business. Even though the nation's economy was starting to recover from a severe recession by 1983, Reagan's critics complained that he had increased the deficit and hurt the middle class. In 1981, Reagan also made history by appointing Sandra Day O'Connor as the first woman justice on the U.S. Supreme Court.

President Reagan was reelected in November 1984, soundly defeating Democratic challenger Walter Mondale. Reagan carried 49 of the 50 states and received 525 of 538 electoral votes, the largest number ever won by an American presidential candidate. Reagan's second term was tarnished by the Iran–Contra affair, a complex "arms-for hostages" deal with Iran. Reagan authorized the sale of arms to Iran in exchange for the release of U.S. hostages being held in Lebanon. The money gained from the sale was then illegally diverted to anticommunist insurgencies in Central America. The Reagan administration initially denied it, but later announced that it had been a mistake.

Though Reagan faced many foreign affairs conflicts, his most pressing was the Cold War. Reagan started massively building up U.S. weapons and troops. He also implemented the "Reagan Doctrine," which provided aid to anticommunist movements in Africa, Asia, and Latin America. In 1983, Reagan planned the Strategic Defense Initiative, aimed at developing space-based weapons to protect the United States from attacks by Soviet nuclear missiles. In the Middle East, Reagan sent 800 U.S. marines to Lebanon as part of an international peacekeeping force in June 1982. One year later, in October 1983, suicide bombers attacked U.S. barracks in Beirut, killing 241 Americans. That same month, Reagan ordered U.S. forces to invade the Caribbean island of Grenada after Marxist rebels overthrew its government. In addition to problems in Lebanon and Grenada, Reagan's administration had to deal with the ongoing combative relationship between the United States and Libyan leader Muammar al-Gaddafi. In 1987, the United States and the Soviet Union signed a historic agreement to eliminate intermediate-range nuclear missiles. Also in 1987, Reagan spoke at Germany's Berlin Wall (which was a symbol of communism) and famously challenged Soviet leader Mikhail Gorbachev to tear it down. The people of Germany ended up tearing the wall down in 1989, ending Soviet domination of East Germany and leading to the creation of a reunified Germany.

After leaving the White House in January 1989, Reagan returned to his home in Los Angeles, California. In 1991, the Ronald Reagan Presidential Library and Museum opened in Simi Valley, California. In 1994, Reagan revealed that he had Alzheimer's disease.

Ronald Reagan died on June 5, 2004, in Los Angeles, California. He was later buried on the grounds of his presidential library in California.

REASONS

As a result of conscious deliberation, reasons justify beliefs and motivate action. Conscious deliberation enables individuals to recognize, assess, and evaluate propositions about the world, including personal preferences; conscious deliberation is what distinguishes reasons from behavior that results from instinct or nonreflection. Reasons can be desire-based or non-desire-based, the latter of which further distinguishes reasons from traditional economic theory.

Consider two different reasons a person might use for giving to charity: (1) to maximize one's own welfare and (2) because it is the right thing to do. The first reason, which is desire-based, is largely consistent with standard economic theory, except perhaps that standard economic theory provides little scope to assess and evaluate the worthiness of personal preferences. In case 1, people examine their preferences and alternatives and they decide that the donation leads to their highest personal welfare. Thus, they have justified their personal welfare as the highest objective. Since that objective can be achieved by a state of affairs in which people contribute, they are motivated to do so and the beneficiaries are the lucky targets of their preferences.

Suppose people employ the second, non-desire-based, reason. Now they may justify giving because to do so comports with a moral principle that is true, or that they judge to be true. For instance, they may believe in the truth of a proposition like "Any feasible human survival need dominates any other person's desires after some high level of fulfillment." If people did contribute based on such a reason, it was the truth of the proposition that motivated action, not their own welfare. While this kind of individual reasoning is foreign to most economists, it has a long history—from Aristotle's use of practical reason, to psychologist Lawrence Kohlberg's pioneering studies of moral judgment. Reasons of this sort can explain behaviors that have puzzled economists, including some kinds of giving and self-sacrifice, adherence to agreements, and truth-telling instead of expected "cheap talk."

Of course, human motivation is complex. Even if an individual did employ non-desire-based reasoning, when it came time to act such reasons could still be defeated because of other overriding reasons or because of a weak will. Nevertheless, both kinds of reasons could be added to the rich tapestry of motivations—along with habit, norms, emotion and neurological processes—in order to better explain real human behavior.

RECYCLING

Recycling is the transformation of materials that would otherwise be waste into useful and valuable resources. It represents one part of a waste management plan with the objectives to reduce materials that are discarded, reuse discarded products with little reprocessing, and recover energy from discarded products through incineration. The environmental appeal of recycling is that it has the potential to reduce the quantity of virgin materials required for production, as well as reducing the amount of environmental contaminants. The economic appeal is that recycling can lead to lower production costs when inputs made from recyclable materials cost less than virgin inputs.

Recycling gained momentum in the United States in the 1960s and 1970s through federal legislation designed to manage waste disposal practices nationally. This legislation culminated in the 1976 Resource Conservation and Recovery Act (RCRA). One of the goals of the act was to conserve natural resources and energy through recycling. In 1988, the Environmental Protection Agency (EPA) raised the national goal for waste reduction and recycling from 10 percent to 25 percent. In 2002 the goal was further increased to 35 percent. In 2009, the EPA transitioned from a recycling goal to a program called Sustainable Materials Management, designed to minimize products' environmental impacts over their entire life cycle.

Awareness of recycling increased in the public conscious in 1987 when the Mobro 4000 barge searched up and down the East Coast looking for a place to dump its contents of waste. The barge had failed to secure a permit for waste disposal before setting sail from New York, and therefore it was not allowed to unload its contents. This incident raised public awareness of landfill capacity and efforts to reduce capacity constraints, possibly through recycling. In response to RCRA, many low-quality city dumps closed. Larger and more technologically advanced landfills took their place. As of 2009, there were 1,908 landfills in the United States, down from 7,924 in 1988. During that same period, the number of curbside recycling programs increased dramatically, from 1,000 in 1988 to 9,000 in 2009, and the recycling rate increased from 10 percent in 1981 to 34 percent in 2009. As of 2012, the EPA estimates that landfill capacity is not constrained at a national level, though there are locations with regional constraints.

Curbside recycling is one of many programs that supply recyclable materials to markets. Others include deposit–refund systems, in which consumers pay a deposit fee when they purchase a product and receive a refund when they return the product for recycling. Several states have laws that require this type of deposit–refund system for beverage containers and certain automotive parts, like car batteries. Another program that provides a supply of recyclable materials is a disposal ban on specific materials. Used motor oil, for example, cannot be disposed of with traditional waste in most states. Drop-off recycling centers, in which recyclers take their materials to a central location for processing, also contribute to the supply of recyclable materials.

The derived demand for recyclable materials comes from several sources. Firms demand recyclable materials when the cost of using recyclable materials as inputs is lower than using virgin material. Firms may also demand recyclable materials if their customers demand products with recycled content. Governments also can impact the demand for recyclable materials, through policies mandating the percent of recycled content in products and through policies that require government agencies to buy products with recycled content. The interaction of the supply and demand of recyclable materials determines their price in the marketplace. For some recyclable materials, such as aluminum, the price is relatively high, a reflection of the high energy savings of producing new aluminum cans from recycled material rather than from virgin material. For other recyclable materials, such as glass, the relative price is low, partly due to small energy savings from the use of recyclable glass compared to virgin materials for new glass products.

Beyond its contribution to the supply of recyclable materials, curbside recycling presents an opportunity to investigate the economics of recycling. An economist would say that recycling is beneficial to society as a whole if the marginal benefits of recycling are greater than or equal to the marginal costs of recycling. The socially optimal level of recycling is the level at which the marginal benefits exactly equal the marginal costs. The socially optimal level is said to make society as well off as possible with respect to recycling. Making such a determination requires the measurement of both benefits and costs for recycling programs. In the case of curbside recycling, the benefits could include a reduction in the amount paid for trash collection, a reduction in the use of landfills, the preservation of natural resources, and a feeling of satisfaction for those who participate in recycling efforts. The costs of curbside recycling include individuals' effort to store and deliver recyclable materials, and the expenditures to run and maintain a program for recycling collection and processing.

Studies attempting to measure the benefits and costs find that the cost of curbside recycling programs varies from city to city. Costs have been estimated to be as high as $5.79 (2012 dollars) per household per month to as low as $1.84. The cost variation arises because of such differences in program characteristics as the collection frequency and the amount of materials collected. The benefits to recycling also vary from location to location, ranging from $1.59 to $5.81 per household per month.

In some places, the benefits exceed the costs and it is socially optimal to curbside recycle. In other places, the costs exceed the benefits and it is not socially optimal to recycle. If society is interested in using its scarce resources to maximize society's well-being, then it is important to consider the implementation of recycling on a location-by-location basis and employ it only where marginal benefits are greater than marginal costs. Additionally, it is important to note that if some groups in society desire a recycling rate that is higher than the socially optimum rate, then the increased recycling would come at the expense of other members in society.

The economics of recycling are intriguing. The promise of recycling is to save resources; however, the very act of recycling uses scarce resources. If society increases recycling rates with current technology, the marginal costs of recycling will increase while the marginal benefits will decrease. The future of recycling, then, depends on society's ability to lower costs faster for recycling than for production using virgin materials.

REGULATION AND OVERSIGHT OF FINANCIAL INSTITUTIONS

The regulation and oversight of financial institutions is handled by multiple government oversight organizations. Since the entire financial system can be extremely complicated, each of these organizations regulates a specific part of the financial system and is responsible for overseeing the financial institutions that are affected. The regulating organizations are responsible for following the laws and rules to protect investors and maintain order in the financial market. Financial institutions include commercial banks, credit unions, trust companies, mortgage loan companies, insurance companies, pension funds, investment banks, underwriters, and brokerage firms. These financial institutions have numerous organizations that regulate them—for example, the Federal Reserve Board, the Federal Deposit Insurance Corporation (FDIC), the Office of the Comptroller of the Currency (OCC), the National Credit Union Administration (NCUA), and the U.S. Securities and Exchange Commission (SEC).

The Federal Reserve Board is the central bank of the United States and was created by Congress to provide a more stable monetary system. The Federal Reserve's primary function is to conduct the nation's monetary policy by attempting to influence money and credit conditions in the economy to achieve the goals of maximum employment, stable prices, and moderate long-term interest rates. The Federal Reserve is also responsible for regulating banks that report to the Federal Reserve. The Federal Reserve sets capital requirements for banks and serves as a lender of last resort for banks that are having difficulty meeting their capital requirements.

The Federal Deposit Insurance Corporation (FDIC) is the government authority that is responsible for preserving and promoting public confidence in the U.S. financial system by insuring deposits, identifying risks, monitoring risks, and addressing risks when necessary. The FDIC insures deposits for up to $250,000 for each customer, per insured bank. The FDIC insures only deposits at the banks; it does not insure securities, mutual funds, or other market investments that a bank may offer. The FDIC is responsible for supervising banks for operational safety and soundness. The FDIC examines banks to ensure that they are in compliance with regulatory laws and rules. The FDIC is also responsible for responding when a financial institution becomes insolvent and is failing. The FDIC will immediately assume control of the institution to prevent panic in the marketplace and to protect depositors at a failing institution.

The Office of the Comptroller of the Currency (OCC) is an independent bureau of the U.S. Department of the Treasury; it is responsible for chartering, regulating, and supervising all national banks. The OCC ensures that banks operate safely and soundly and are complying with applicable laws and regulations. Examiners will analyze loan and investment portfolios, funds management, capital, earnings, liquidity, and sensitivity to market risk in order to determine the financial stability of a financial institution. Examiners will also review internal controls within a bank to ensure that the bank is complying with laws and regulations. The OCC is the regulatory agency that approves or denies new charters, branches, and other corporate changes that would alter the structure of the financial institution. If the financial institution is found to not be following the rules and regulations that were set forth, the OCC is allowed to take supervisory actions against the bank—including cease and desist orders, fines, and even removal of bank officers.

The National Credit Union Administration (NCUA) is the independent federal agency that regulates and supervises federal credit unions. *Credit unions* are member-owned, not-for-profit, cooperative financial institutions. The NCUA operates the National Credit Union Share Insurance Fund (NCUSIF), which insures the deposits of credit union, much as the FDIC does. The NCUSIF insures member's accounts up to $250,000 per member. The NCUSIF also protects Individual Retirement Accounts (IRAs) and KEOGH retirement accounts up to $250,000 dollars per member. The NCUA is responsible for monitoring the credit unions in the five regions of the United States for compliance with laws and regulations to ensure that each credit union is financially sound and is fair to its members.

The U.S. Securities and Exchange Commission (SEC) is the regulatory authority that seeks to protect investors, maintain fair and efficient markets, and facilitate capital formation. The SEC requires public companies that are selling securities to investors to disclose information to the public that will allow potential investors to have a clear financial picture of the company. This information is regulated and is required for every public company, so that investors may compare two companies and be able to make an informed decision. The SEC also oversees financial institutions, such as investment banks, underwriters, and brokerage firms, that operate heavily in the securities markets. The SEC requires that the individuals and companies operating in these types of financial institutions follow laws and regulations that are particular to the securities market. For companies and financial institutions that do not follow the laws and regulations, the SEC can take actions such as sanctions, fines, or even criminal proceedings if it is deemed necessary.

RELATIVE THINKING

Relative thinking is a "bias" in decision-making according to which people consider not only absolute price differences but also relative price differences—even in situations where, according to conventional economics, relative price differences should be irrelevant. That is, when comparing two prices for the same good in two stores, or between prices of different goods, if people are affected by the percentage price difference (although from a conventional economic perspective it is unimportant), we say that they are exhibiting relative thinking.

Most recently, Azar (2011a) discusses the concept of "relative thinking." Thaler, in his classic 1980 study, mentions that people exert more effort to save $5 on a $25 radio than on a $500 TV. Also, Tversky and Kahneman (1981) find that when a calculator's price is $15 and a jacket's price was $125, 68 percent of the subjects would drive 20 minutes to save $5 on the calculator. However, when the prices were reversed—the calculator was $125 and the jacket was $15—only 29 percent were willing to drive 20 minutes to save $5. This means that people were heavily influenced by the percentage that could be saved, which was either 33.3 percent ($5/$15) or 4 percent ($5/$125). From a classical economic perspective, however, the decisions in the two cases should be identical, because what should matter is only the comparison between 20 minutes and $5 savings. But, obviously, relative savings matters as well.

Later studies replicated the results of Tversky and Kahneman with some modifications, usually showing the robustness of this behavior, but sometimes finding special cases when relative thinking behavior does not exist. Mowen and Mowen (1986), for example, find that the effect holds whether the subjects are students or business managers. Darke and Freedman (1993) found in one experiment that percentage savings did not affect the effort to save money, but in a second experiment with a higher range of percentages that could be saved, the percentage discount did have an impact on consumer choice. Frisch (1993) showed that the effect of the relative discount holds also when only a single calculator is being purchased rather than a bundle of two goods. Ranyard and Abdel-Nabi (1993) varied the price of the jacket and obtained results consistent with those of Tversky and Kahneman. Azar conducted an experiment with five goods and nine prices, finding the exact price where the subject is indifferent between the more expensive store on one hand and the less expensive store on the other hand—although the less expensive store requires 20 minutes travel time. His results suggest that the discount people require for the effort of going to the remote store is roughly proportional to the square root of the good's price. Azar (2011b) also found that people exhibit relative thinking when they consider differentiated goods or services that differ in price and quality. Sometimes subjects are affected only by relative price differences ('full relative thinking') and sometimes also by absolute price differences ('partial relative thinking'). This result was obtained in four different consumption categories and the comparison between them allows one to analyze what factors seem to strengthen the relative thinking behavior.

RELIGION AND DECISION-MAKING

The impact of religion on decision-making and economic behavior generally has been an important concern of behavioral as well as conventional economics. While not explicitly analyzing how religion affects decision-making and other behavior, Hume (1983, 6) implies such effects by historically observing "religious fanaticism" and "madness with religious ecstasies" in England during the Reformation. Such economic and related behavioral effects of religion are implied in his observation that the "wretched" and "wild" fanaticism of Puritanism was "destructive of taste and science" and by implication of technological and economic progress, as of "all law and order," with "human learning despised; freedom of inquiry detested; cant and hypocrisy alone encouraged" (Hume 1983, 101). Also, Smith (1976, 647) describes past religion as a "mixture of absurdity, imposture, or fanaticism" and implies that it has corresponding effects on economic and other behavior, specifically observing that the "sect called Independents [was] a sect no doubt of very wild enthusiasts" acting in the context of the "two principal parties of sects among the followers of the Reformation [i.e.] the Lutheran and Calvinistic sects." Like Hume and despite his Puritan background and Presbyterian sympathy, Smith (1977, 181) expresses his preference for a "gentleman, and not a puritan" as a type or instance of decision-maker and socioeconomic agent, because of the Puritans' "severity of manners [plus] cant, cunning, hypocrisy, and low manners" and the corresponding effects of such "unsocial passions" and "moral sentiments" on economic and all human behavior.

J. S. Mill explicitly suggests that religion—especially its "ascetic" type, like Calvinism—adversely impacts autonomous decision-making and economic activity in general. He registers that Calvinism denies and eliminates freedom of choice in decision-making and economic life in that it stipulates that "the one great offence of man is Self-will. All the good of which humanity is capable, is comprised in Obedience. You have no choice; thus you must do, and no otherwise" (Mill 1991, 58). He also notes that Calvinism negates and suppresses the human ability, faculty, and will for decision-making and economic activity in observing that "to one holding this theory of life, crushing out any of the human faculties, capacities, and susceptibilities, is no evil: man needs no capacity, but that of surrendering himself to the will of God: and if he uses any of his faculties for any other purpose but to do that supposed will more effectually, he is better without them," resulting in an "abnegated" decision-maker and "human nature" (Mill 1991, 58). Evoking Hume, Pareto (2000, 35) uses the image and metaphor of the "cage for the insane" to depict religion or theology and by implication its equivalent influence on decision-making and other economic behavior. In particular, Pareto (1932, 1433) observes that, contrary to the conventional wisdom, the Protestant Reformation was effectively a religious revolution directed against economic and social progress, innovation, and change, just as it "halted" the artistic, liberal, and humanistic Renaissance in Northern Europe. Generally, in Pareto's framework the type of decision-maker and economic agent guided by "religious sentiments" and thus irrational forces ("residues") is what Schumpeter (1991, 336) calls *homo religiousus* versus *homo economicus* as the perfectly rational opposite.

In contrast to Mill, Weber (1976) argues that religion such as Calvinism and other "ascetic Protestantism" enhances rational decision-making, specifically wealth accumulation and saving and investment against consumption, and continuous economic activity in that it has historically promoted the emergence and development of (the spirit of) modern capitalism in the Western world. This argument has become known as the Weber Thesis of the "Protestant Ethic" and capitalism in historical and behavioral economics as well as economic sociology and history (and theology). For instance, Akerlof (2007, 15) notes "Weber's analysis of the relation between religion and savings" and comments that "Weber describes Calvinists as aspiring to be 'worldly ascetics'." He concludes, "Economic acquisition is no longer subordinated to man as the means for satisfaction of his material needs." Here the purpose of saving is to live up to an ideal. The Calvinists are thrifty because they think they should *not* be consuming.

Within contemporary behavioral as well as historical economics, most analyses of the impact of religion on economic decision-making and behavior use or mention Weber's analysis of the effect of Calvinism on capitalism as the point of departure and reference. One stream of such analyses explicitly or implicitly adopts and supports Weber's analysis. Another strand of analyses of religion and economic behavior disconfirms or modifies Weber's analysis. In sum, the status of Weber's analysis is unsettled, and so the problem of the exact effect of religion—in particular, Protestantism—on decision-making and economic behavior remains largely unresolved in behavioral and historical economics.

RESOURCES

Resources are described as any factor required in the production of goods or services. These inputs generate value and collect returns. The most basic resources are seen as land, labor, and capital. Entrepreneurship is also categorized as an economic resource. These are the factors of production. The category of resources can be spread even further to include information, management, energy, and time. Each of these performs a specific function for production in every economic system.

Land is a natural resource that is abundant in the economies around the world. This is not only the physical land itself, but also any resources obtained from the land. This can include lumber, oil, coal, and gas. Some may say that land is an infinite resource to be used for production. Others argue that it is finite and can and will eventually run out as populations and economies continue to grow. The production of agriculture is the major use for land. Agriculture uses 51 percent of the land in the United States, worth $2.38 trillion.

Labor is a human input known as the effort put in to make a good or service. Employees are a consolidated form of labor. Employees are able-bodied people who are able to work in an economy—this includes the workers at a factory assembling cars, the employee who cooks and serves meals at a restaurant, and the janitor who cleans a high school.

There are two definitions of *capital* in terms of resources. The first definition sees capital as the monetary value of money used as a purchasing power. This money can be used to pay for the toher two resources: land and labor. Capital flows through an economy in this way as individuals or businesses purchase goods and resources. Capital is also the physical equipment a company owns. This can include tools, buildings, vehicles, and other comparable components. To stay in business, companies must have a constant flow of capital. To attain more capital, companies can apply for bank loans or search for investors.

Some economists consider *entrepreneurship* to be the fourth factor of production. Like capital, entrepreneurship also can be defined in different ways in terms of an economy. Some economists say that entrepreneurship is responsible for increasing the productivity of businesses. Others recognize that an entrepreneur brings together the other three factors of production to create a good or service. The entrepreneur also accepts the risks involved in production and is responsible for organizing and allocating the land, labor, and capital.

From product to product or from service to service, the way these four resources are allocated and needed is very different. For example, a farm would need much more labor and land than a small-pet groomer. The goal in an economy is to use these resources in the most efficient way possible. Improper use could lead to devastation—for a single firm or the economy as a whole. As economies continue to advance, the need for these resources will continue to grow.

RICARDO, DAVID

Born: April 18, 1772, in London; Died: September 11, 1823, in Gloucestershire, England; Nationality: English; Professional Interests: classical school, monetary economics, economic rent, theory of value, comparative advantage; Major Works: *An Essay on the Influence of a Low Price of Corn on the Profits of Stock Showing the Inexpediency of Restrictions on Importation; with Remarks on Mr. Malthus's Two Last Publications* (1815), *On the Principles of Political Economy and Taxation* (1817).

David Ricardo was a British economist, considered one of the classical economists. After reading Adam Smith, Ricardo began writing on the benefits of converting currency to gold. Ricardo was an early proponent of the idea that an economy's money supply and price level (inflation) are positive-related. While he was an early writer on the concept of economic rent, David Ricardo is probably most famous for his expansion of Adam Smith's idea of absolute advantage, with his introduction of comparative advantage and expanding on Smith's benefits of trade. Ricardo died in 1823.

David Ricardo was born in April 18, 1772, in London. His father was a Jewish stockbroker who had originally come from Holland. After attending school in London and Amsterdam, Ricardo joined his father's brokerage firm. Ricardo then formed his own stock firm and became very successful. In 1814, at age 41, he retired from business, worth more than $40 million in today's dollars. At his death in 1823, his estate was worth what today would be more than $100 million.

Ricardo became interested in economics in his early 20s after reading the works of Adam Smith. He would often discuss his ideas with his friend James Mill, who encouraged him to write. Ricardo began by writing articles and tracts about currency issues. In this area, Ricardo was a bullionist, arguing for the convertibility of currency to gold. He held that notes were not convertible, because they had been over-issued and inflation had resulted. In that respect, he was an early proponent of the *quantity theory of money*, which proposes a positive relationship between an economy's money supply and the price level (inflation).

Ricardo also dismissed the idea that surplus is simply what is left over after a country consumes what it produces of goods and services. He entered into a long correspondence and friendship with Thomas Malthus, debating the idea. A proponent of Say's Law, Ricardo believed that production automatically creates a market for consumption; hence, a general glut is impossible.

Ricardo drew extensively on Malthus's work in his writings about rent. Ricardo saw rent not just as a return for the use of natural resources but as an unearned surplus. By this he meant that rent was a residual, arising from the difference between the gross outputs of the land minus all of the production costs. This residual had no impact on the future supply of land; and differences in rent simply arose from differences in land–fertility, access to water, and climate. Thus, because the output of varying types of land would be the same (i.e., a bushel of corn grown on inferior land fetches the same price as a bushel grown on very fertile land), producers would bid up the price of better land, benefiting the landowner rather than the producer.

In 1815, Ricardo wrote "An Essay on the Influence of a Low Price of Corn on the Profits of Stock." In this work, he describes one of his most enduring ideas in economics: the concept of comparative advantage.

Prior to the dissemination of this essay, the general belief was that gains from trade arose from *absolute advantage*—in other words, that nations prospered because they had an advantage in the production of a good or service that other nations could not match, and that trading the good allowed the nation to increase its wealth. But Ricardo demonstrated that a nation did not have to have an absolute advantage in anything in order to trade profitably and grow. The nation needed a *comparative advantage*. This meant that as long as a nation had a lower opportunity cost in the production of a good than another nation, the first nation could trade profitably even if the other nation had an absolute advantage.

It was the recognition and application of a lower opportunity cost that provided the comparative advantage and allowed the nation to trade on terms that resulted in growth. If all nations specialized in those products for which they had comparative advantage, then unhindered trade would result in all nations trading and becoming better off.

Ricardo used this idea to argue against the Corn Laws, which set up barriers to imported grain to the benefit of English growers. He argued that reducing the trade barriers not only would make grain more affordable to the poor but also would shift England's resource use to areas where it had a comparative advantage—and so would result in greater wealth, although perhaps at the expense of English landowners.

Ricardo also contributed to the debate about value. Through most of his work, he remained a proponent of the labor theory of value, which held that the relative natural prices of goods reflected the amount of labor necessary to produce them. However, he realized early on that capital usage also was a factor in profitability and, in turn, the level of wages. This led him to develop two explanations: one based on an assumption that firms employ capital in approximately the same proportion to labor, and the other based on the existence of a single commodity that represented the average capital per worker, which would allow an explanation of price and wage variation based on variances from the average amount of capital per worker.

Ricardo's masterpiece was his *On the Principles of Political Economy and Taxation* (1817). It is not particularly easy to read, but it is significant for its breadth and understanding.

What is particularly amazing about Ricardo's work is that it was written without the benefit of the mathematics that is such an integral part of today's economics.

David Ricardo died on September 11, 1823, in Gloucester, England.

ROCKEFELLER, JOHN D.

Born: July 8, 1839, in Richford, NY; Died: May 23, 1937, in Ormond, FL; Nationality: United States; Professional Interests: U.S. industrialist and philanthropist, co-founder of Standard Oil Company.

John D. Rockefeller shaped how we live in the United States of America today in many ways. He was one of America's leading businessmen, with a net worth estimated at $336 billion when adjusted for inflation. This also makes him the richest American in recorded history. John D. Rockefeller influenced the American economy through his oil company, the laws created because of him and his company, and his charities.

John Davison Rockefeller was born in Richford, New York, on July 8, 1839. He was raised in a Baptist household, and he always valued giving to others. This attitude played a major part in his later life.

He made a business decision to open up an oil refinery in Cleveland, Ohio, and it was not long before the oil business became his main focus. He named his new oil company Standard Oil. Rockefeller quickly bought out all of his competition, making Standard Oil one of the country's first monopolies.

Due to the incredible success of Rockefeller's oil company, the government decided to intervene, trying various methods for regulating how big the company could be. Eventually, Congress passed the Sherman Anti-Trust Act, making monopolies illegal. America would be a different place for businesses without this act. With this act, the Standard Oil Company or any other company could not solely control the market. The act was intended to promote economic growth and allow for diversity and for small businesses to have success. This would serve as an example of how businesses would have to be run in the future.

Rockefeller's charities have had a lasting effect on America's economy, and he is credited with being a major figure in modern philanthropy. He believed that the best way to help people was to attack a problem at its root. All together he gave away $530 million, some of which went into founding the University of Chicago and Rockefeller University and into supporting groundbreaking medical research.

John D. Rockefeller's success in the U.S. economy brought about a better understanding of monopolies, as well as a set of laws to prevent monopolies. He also underscored the value of philanthropy through his donations to enrich the public.

John D. Rockefeller died May 23, 1937, in Ormond, Florida.

ROOSEVELT, FRANKLIN D.

Born: January 30, 1882, in Hyde Park, New York; Died: April 2, 1945, in Warm Springs, Georgia; Nationality: American; Professional Interests: 32nd president of the United States, 1932–1944; only U.S. president to be elected for four consecutive terms.

Franklin Delano Roosevelt was born January 30, 1882, in Hyde Park, New York, an only child raised in an environment of privilege. Private tutors educated him until he was 14 years old; then, in 1896, he began attending Groton School for Boys in Massachusetts. After graduating from Groton in 1900, Roosevelt went on to Harvard and graduated in three years. During his last year at Harvard, Roosevelt met and became engaged to Eleanor Roosevelt (1884–1962) (his fifth cousin and the niece of his idol, Theodore Roosevelt). Eleanor and Franklin Roosevelt were married on March 17, 1905. Roosevelt then went on to study law at Columbia. He passed the bar exam in 1907, though he did not get his degree. For the next three years, Roosevelt practiced corporate law in New York.

In 1910, at the age of 28, Roosevelt was invited to run for the New York State Senate. He ran, and he was elected as a Democrat in a heavily Republican district. As a state senator, Roosevelt opposed elements of the Democratic political machine in New York. While he angered Democratic Party leaders, he gained national attention. It was during this time that Roosevelt formed an alliance with political consultant Louis Howe (1871–1936). Louis Howe ended up shaping Roosevelt's political career for the next 20 years. Roosevelt was reelected in 1912, and he served as chair of the Agricultural Committee. During the 1912 National Democratic Convention, Roosevelt supported presidential candidate Woodrow Wilson. After Wilson won, Roosevelt was rewarded with an appointment as Assistant Secretary of the Navy. Roosevelt specialized in business operations and Navy policies during World War I.

In 1914, Roosevelt lost a race for a U.S. Senate seat in New York. He was soundly defeated, but he learned that national stature could not defeat a well-organized political organization. In 1920, Roosevelt accepted a nomination for vice-president on the ticket with James M. Cox. They were defeated, but Roosevelt once again gained experience and national exposure.

In 1921, while he was vacationing in Campobello Island, New Brunswick, Canada, Roosevelt was stricken with polio. Despite efforts, he never regained the use of his legs. Later, he established the March of Dimes Foundation. The March of

Dimes was the program that eventually found an effective polio vaccine. Roosevelt thought having polio spelled the end of his political career, but Eleanor Roosevelt and Louis Howe encouraged him to keep moving forward. He spent the next few years improving his physical and political appearance. He taught himself to walk short distances in braces, and he was never, in his entire political career, seen or photographed in public with his wheelchair. Al Smith urged Roosevelt to run for governor of New York in 1928, so he began to repair his relationship with the Democratic political machine. He was narrowly elected. While Roosevelt was governor, he established many new progressive programs.

By 1930, the Great Depression had begun, and when Republicans began to be blamed for it, Roosevelt saw his chance to win the presidency. Roosevelt had adopted the new economic policies of British economist John Maynard Keynes (1883–1946), who promoted the direct involvement of government to stimulate a failing economy. Roosevelt began to campaign on the platform that the government should help reform and recover the economy. Roosevelt defeated Herbert Hoover in the November 1932 presidential election. When Roosevelt took office in 1933, the Great Depression was at its height. The number of unemployed Americans was 13 million, and hundreds of banks were closed due to the turbulent economic times.

During the first 100 days of his presidency, Roosevelt made sweeping changes in an attempt to better the nation's economic state. First, Roosevelt temporarily closed all the banks. He formed a "Brain Trust" of economic advisers, who designed the "alphabet agencies," such as the Agricultural Adjustments Act (AAA), to support farm prices; the Civilian Conservation Corps (CCC), to employ young men; and the National Recovery Administration. Other agencies insured bank deposits, regulated the stock market, and provided relief for the unemployed. By 1936, the economy showed some signs of improvement; most notably, unemployment had dropped from 25 percent to 14 percent.

As the first U.S. president to embrace the ideas of Keynesian economics, Roosevelt faced criticism for increased government intervention in the economy he promoted. Many of his critics thought he was moving the nation toward socialism. The Supreme Court declared several of Roosevelt's New Deal programs unconstitutional. Roosevelt responded by proposing to pack the courts with justices more favorable to his reforms. Congress rejected this idea. By 1938, the negative press, the continued sluggishness of the economy, and unexpected Republican victories in midterm elections halted Roosevelt's ability to pass more reforms.

Since World War I, America had adopted an isolationist policy in foreign affairs. As conflicts raged in Europe and Asia, Roosevelt sought ways to assist China in its war with Japan. Roosevelt also declared that France and Great Britain were America's "first line of defense" against Nazi Germany.

With World War II looming, Roosevelt won an unprecedented third presidential term in 1940. In March 1941, Roosevelt signed the Lend-Lease Bill to aid nations that were at war with Germany and Italy. On December 7, Japan bombed Pearl Harbor, and Roosevelt delivered his "day of infamy" speech. That same day, he asked Congress for a formal declaration of war against Germany. In 1942, Roosevelt created a "grand alliance" of Allied powers through "the Declaration of the United Nations." In 1944, Roosevelt was reelected as president for his fourth and final term.

In February 1945, Roosevelt attended the Yalta Conference with British Prime Minister Winston Churchill and Soviet General Secretary Joseph Stalin to discuss postwar recovery. Coming into Yalta, the Allied leaders knew that victory in Europe was certain, but they were less sure of an end to the war in the Pacific. As a result, the United States and Great Britain saw it as a major strategic approach to have the Soviet Union enter the Pacific war under specific conditions discussed and agreed upon by Stalin: In exchange for Soviet participation in the Pacific war, the Soviets would have a sphere of influence in Manchuria after Japan's surrender. The future of Eastern Europe was also discussed at the Yalta conference. Specifically, France was to be included in the postwar governing of Germany, Germany would handle its own reparations, and the Soviets would pledge free elections in all territories liberated from Germany. The initial reactions to Yalta were celebratory. However, after Roosevelt's death in April 1945, Truman's new administration clashed with the Soviets over influence in Eastern Europe. Americans, alarmed by the Soviets' perceived lack of cooperation, began to criticize Roosevelt's diplomacy at the Yalta negotiations.

Franklin Delano Roosevelt died on April 2, 1945, in Warm Springs, Georgia, and was buried in Hyde Park, New York. However, his legacy lives to this day: His responses to the challenges he faced (among them, the Great Depression and the rise of Germany and Japan) made him a defining figure in American history. Under FDR, the federal government assumed new and more powerful roles in the United States' economy. For example, the New Deal plan instigated to deal with the Great Depression that was crippling the nation enhanced the capacity of the presidency to meet new responsibilities. Also, after World War II, FDR hoped for a more secure world, so the United States would become a major participant in the postwar United Nations. Roosevelt reshaped the presidency by building a bond between himself and citizens and establishing one of the roles of the president as being a caretaker of the people.

SARBANES-OXLEY ACT

The Sarbanes-Oxley Act (SOX) was passed by the U.S. Congress in 2002 and signed into law by President George W. Bush. At the time of its enactment, the United States was the largest economy in the world (as measured by gross domestic product) and entangled in a crisis surrounding the fraudulent reporting of corporate financial data by a number of publicly traded companies. Shortly following a recession (March 2001 to November 2001) that was triggered by the collapse of technology companies losing billions of dollars in stock market value (the dot-com bubble), the illegal accounting methods that precipitated SOX resulted in additional billions of dollars lost and forever changed the practices of investors, the government, and corporate executive management.

This entry will encompass the legislation as it pertains to finance and modern money management; although there continues to be debate around implementation and effectiveness, the act itself was substantial in how it changed the practices of publicly traded companies across the entire United States.

The years 2000–2009 produced several significant financial market corrections, causing trillions of dollars of paper losses to investors. Very early in the decade, stock prices soared as technology companies and others benefited from an existing exuberance. Of the two emotions—fear and greed—that dominate security selection, greed was rampant. Market participants pushed prices higher and higher as they clamored for every available share of booming technology, and other corporations continuously showed giant profits and increasing potential on their income statement, balance sheet, and other financial documents. Unknown to almost everyone, including regulators at the Securities and Exchange Commission (SEC), several significant companies were purposely reporting fraudulent financial data.

In 2001, the energy corporation Enron—one of the largest companies in the United States—began to come under scrutiny for its accounting practices. Investor questions grew more and more common, and the complex use of shell companies beneath Enron's seemingly shiny exterior increasingly confused and concerned almost everyone, from stockholders to Wall Street analysts. As the lies unfolded and the game of hiding debt was discovered, Enron stock fell from over $90 per share to under $1 per share. At the time, this was unprecedented. Employees lost their jobs and their retirement savings while equity owners saw any invested capital disappear, taking markets and overall investor confidence with it. The calamity was ubiquitous as greed quickly turned to intense fear.

In the following year, two other corporations embedded in the fabric of American investment markets were also discovered to have fraudulently altered their accounting and financial statements to make large losses magically disappear, giving the appearance of very profitably run organizations. WorldCom, one of the world's largest telecommunications firms, and Tyco, a sizeable manufacturing company, were discovered to have lied to investors in many ways, including misrepresentation of expenses, smuggling of money, and sale of unauthorized company stock. All of these occurrences, due to the structure of laws and reporting at the time, were done undercover, without shareholder knowledge. As the layers of fraud and deception were peeled away, share prices lost almost all value, investors lost billions of dollars, and many thousands of people were left without jobs as their former employers crumbled under the lens of justice. Markets, and the entire country, were now fully rattled; trust in the financial system, particularly that of corporate bookkeeping, was completely lost.

On July 30, 2002, the U.S. government responded to the accounting scandals and ensuing crisis of confidence by signing into law the Sarbanes-Oxley Act (named for its congressional sponsors Senator Paul Sarbanes and Representative Michael Oxley). The act passed with overwhelming support, obtaining 98 percent of the vote in the House of Representatives and 99 percent of the vote in the Senate.

The Sarbanes-Oxley Act contains 11 sections that include the establishment of a public company accountability board, requirements for auditor independence, details concerning corporate responsibility, enhanced conflict of interest provisions, and new criminal penalties for corporate fraud. The act boosted the reliability of corporate disclosures and changed the way securities analysts interact with corporate management. In the wake of such tremendous financial losses due directly to fraud, this sweeping legislation even required top management to personally certify corporate financial information.

Opponents of SOX contend that the legislation, particularly its requirement that public companies achieve an independent audit of internal controls, is costly for corporations to implement; it was initially feared that relatively small companies would face crippling expenses when trying to facilitate an independent audit. However, supporters of SOX cite sharp bolstering of shareholder confidence that, in turn, results in increased share prices in markets; if investors are more confident, they will be more willing to deploy their capital.

Years after its passing, SOX remains largely intact. Proponents of free markets continue to argue its existence as an impediment toward the long-term health of the financial system. But, as an attack on large-scale corporate fraud, SOX stands as one of the most major pieces of financial legislation in modern times. Throughout the history of the relationship between government and capitalism as an economic system, there has always been a fine line between policing free markets without tinkering in them. In 2002, there was overwhelming support for SOX as the metaphorical flame of fear had been lit. Time will tell if SOX did too much or too little to mitigate the opportunities for fraudulent corporate activities, while the debate concerning how involved governments should be in free markets—which includes regulatory oversight—continues in earnest.

SAY, JEAN-BAPTISTE

Born: January 5, 1767, in Lyon, France; Died: November 15, 1832, in Paris, France; Nationality: French; Professional Interests: general equilibrium, classical, political economy; Major Works: *Traité d'Économie Politique* (Treatise on Political Economy) (1803), *Catechism of Political Economy* (1817).

Jean-Baptiste Say is most famous for Say's Law, which simply states that supply creates its own demand. While those were not his exact words, they do convey the essence of his response to the 19th-century Glut Controversy, a trade dispute England was having with Brazil. Say died in 1832.

Jean-Baptiste Say was born on January 5, 1767, in Lyon, France. His parents had fled to Switzerland to escape religious persecution, and they had recently returned to their French homeland when Jean-Baptiste was born. Say's father was a silk merchant, and he made sure that his son had an education that would prepare him for the business world. Say therefore received a modern education in Lyon and then in London. In 1787, he returned to France where he later worked in the offices of a Paris life insurance company. His employer gave him a copy of Adam Smith's *Wealth of Nations,* which led him to become an economic disciple of Smith.

In 1789, the French Revolution broke out. The young Say took advantage of the general mood of progress to write articles and edit a journal in favor of a free press, republican ideals, and various mildly revolutionary topics. A common thread throughout his writings was the need for the population to be educated in the study of political economy (what is now economics).

In the midst of the Reign of Terror during the French Revolution, Say translated Benjamin Franklin's *Poor Richard's Almanac* into French. He wrote a laudatory biography of Franklin, who was something of a folk hero in revolutionary France. He also corresponded with Thomas Jefferson and considered emigrating to the United States.

When Napoleon Bonaparte became dictator of France, Say was made a member of the Tribunate (part of Napoleon's legislature), where he was given the task of reporting on the government's budget. His report stressed the need for clear accounting standards and for tax revenues to be collected before they were actually spent. These ideas drew Napoleon's disapproval. Say's economic writings lamented war, voiced suspicion of government bureaucrats, deplored slavery, and called for relaxing the restrictions on trade, all of which were features of the Napoleonic government. In 1802, perhaps because of these differences of opinion, Say was removed from his post, whereupon he left Paris and opened a cotton mill. His business was successful, and when he was not managing it, he spent his time writing.

Say did not write only about economics. In 1800, he published a short book called *Olbie,* which gave a picture of a utopian society. In it, he espoused the belief (not uncommon at the time) that if a revolutionary society could overthrow monarchy and aristocracy, emphasize education, remain untempted by greed, and build a republic where morality was enforced by meddling neighbors, then a near-perfect society could exist. Wishing to popularize the economic theories of Adam Smith and expand the subject of political economy, he published his *Treatise on Political Economy* in 1804 and continued to release updated editions throughout his life. In 1821, Say was offered a position as professor at the Conservatoire National des Arts et Metiers. It was the first professorship in political economy ever created in France.

Say is most famous for Say's Law, which in its simplest iteration is that supply creates its own demand. (There are several, sometimes conflicting, versions of Say's Law.) Say did not actually write this, but it appropriately captures his contribution to a two-decade-long dispute known as the Glut Controversy. The question at hand was this: Why do markets collapse into recession? Certain philosophers had blamed overproduction—that producers had foolishly made more than people could consume. Say disagreed, pointing out that "each of us can only purchase the productions of others with his own productions . . . the more men produce, the more they will purchase." Therefore, there could be no "general glut," or total supply greater than total demand. Instead, wrote Say, recessions happen when there is a temporary imbalance of certain goods and services relative to other goods and services. People should produce *more* of the goods that are lacking in order to pay for the ones in relative abundance, rather than seeking through public policy to cut production. Markets would eventually correct themselves.

In response to Say, Simonde Sismondi and Thomas Malthus advanced theories claiming that there could indeed be a general oversupply. For instance, increased demand for money would mean that supply could exceed demand. Demand would be satisfied by the holding of real money balances rather than by products. Another of the critics' ideas was that production might exceed an equilibrium level at which producers could profitably operate their businesses. There might be demand for goods, but producers would go out of business trying to meet that demand. Other economists, mostly notably David Ricardo, agreed with Say.

The Glut Controversy was the central economic dispute of the early 19th century, eventually involving every major economist of the time. The dispute was not always edifying. Both sides tended to misrepresent, or simply misunderstand, each other's arguments. Eventually, a consensus emerged and remained for the rest of the 19th and early 20th centuries. The consensus confirmed that Say was right.

Supply did indeed create its own demand. This theory remained almost completely unchallenged until John Maynard Keynes chose a version of Say's Law as the foil for his own theory of recessions.

Say was not available to defend his ideas. He died in 1832, almost 100 years earlier. Though out of favor with many policy makers and economists, Say's Law remains a cogent, if not quite sufficient, explanation for the tendency of markets to regulate themselves.

Jean-Baptiste Say died on November 15, 1832, in Paris, France.

SCHUMPETER, JOSEPH

Born: February 8, 1883, in Triesch, Moravia, Austria-Hungary; Died: January 8, 1950, in Taconic, Connecticut; Nationality: Austrian; Professional Interests: business cycles, economic development, entrepreneurship, evolutionary economics; Major Works: "The Common Sense of Economics" (1933), *Theory of Economic Development* (1934), *Business Cycles* (2 vols., 1939), *Capitalism, Socialism and Democracy* (1942), *History of Economic Analysis* (1964).

Joseph Schumpeter was an Austrian economist who developed a comprehensive theory about economic growth and business cycles that saw the entrepreneur as a major reason for economic growth and evolution. He was responsible for the term *creative destruction* as a way of describing economic growth. He was also a strong proponent of the use of mathematics in economics. Schumpeter died in 1950.

Joseph A. Schumpeter was born on February 8, 1883, in Triesch, Moravia (now the Czech Republic), in what was then Austria-Hungary. His father, who owned a factory, died while Schumpeter was still very young. Schumpeter would remain very close to his mother for the rest of her life. When she remarried, Schumpeter's stepfather was able to send him to a prestigious school, which prepared him well for attending the University of Vienna.

While there, Schumpeter studied law and economics. He also spent some time at Cambridge, Oxford, and the London School of Economics. In the area of economics, Schumpeter was a student of two of the leading members of the Austrian School: Friedrich von Weiser and Eugen von Böhm-Bawerk. Despite this, Schumpeter's beliefs did not develop along the lines of that school; instead, he chose to follow a more classical line of inquiry in his work.

Upon leaving the University of Vienna, Schumpeter took a teaching post at the University of Czernowitz, where he remained from 1909 until being offered a position at the University of Graz in 1911 at the age of 28. Schumpeter was the youngest professor in the entire Austro-Hungarian Empire.

In 1912, Schumpeter completed his first major work. His *Theory of Economic Development* was received to critical acclaim. But it did not receive wide recognition until it was translated into English in 1934. It was in the *Theory of Economic Development* that he first addressed one of the areas that would make him a major figure in 20th-century economics: the role of the entrepreneur. While entrepreneurs had been a subject of study throughout classical economics, Schumpeter made a clear distinction between the role of the entrepreneur and the role of the manager.

After World War I, the Austro-Hungarian Empire was dismantled. Austria, like its ally Germany, was in dire financial straits. Additionally, the winds of socialism were blowing across much of central Europe. In this climate, Schumpeter was appointed minister of finance for the new Austrian Republic in 1919. Unfortunately, his ideas were not popular, and he left the post the next year. He followed this with a stint in banking, which was also not successful. In 1925, Schumpeter found himself at a low point. He enthusiastically accepted a position at the University of Bonn, in Germany. While he was at Bonn, his "Explanation of the Business Cycle" was published in the journal *Economica*. This was a precursor to his two-volume work, *Business Cycles*. He left Bonn in 1932, concerned about the rise of Hitler and the Nazi Party in Germany.

Schumpeter landed in the United States at Harvard. He stayed there until his retirement in 1949. It was at Harvard that the rest of his major works took shape. *Business Cycles* was published in 1939. Schumpeter's theory begins with a static analysis, assuming a period of stability. However, the stability is punctuated by periods of upheaval. These booms represent eras of innovation that result in fundamental changes in production. Over time, the resulting changes lead to periods of dynamic growth that are occasionally punctuated by downturns as the resources of the economy are reallocated. The innovation that causes this instability is generated, to a certain extent, by the entrepreneur working in an environment that allows innovation to take place.

Schumpeter followed that work with *Capitalism, Socialism and Democracy* (1942). It was through this work that two of his most famous ideas became part of the public discussion. The first was his belief that, despite its superiority, capitalism would eventually be replaced by socialism. The success of capitalism would, in his view, lead to the rise of a large class of intellectuals. These same intellectuals would make their living from attacking the system that made their existence possible. But this work also built on some of his earlier work. The success of capitalism was due, in his view, in large part to the entrepreneur. It was here that the second of his famous ideas from this book came into play.

According to Schumpeter, it is the entrepreneur who unleashes what Schumpeter labeled creative destruction. Creative destruction disrupts the static situation that is represented by the circular-flow diagram. This disruption causes the creation of new enterprises and the destruction of the old, with resources being reallocated in the process. This is the cause of the underlying dynamism that was described in *Business Cycles*. Furthermore, creative destruction was the connection between the microeconomics we see in studying the firm and the macroeconomics we see in studying policy. It is the enterprise that creates change, which results in new policies, which change incentives, which lead to new enterprises.

Schumpeter held a number of roles of professional leadership during his career. He was a founding member of the Econometric Society in 1933, president of the American Economic Association in 1948, and chair of the International Economic Association in 1949. During his tenure at Harvard, Schumpeter counted Paul Samuelson, Wassily Leontief, and James Tobin among those he worked with or influenced.

His last major work, *History of Economic Analysis,* was published by his wife in 1964, 14 years after his death.

Joseph Schumpeter died at his home in Taconic, Connecticut, on January 8, 1950.

SECOND INDUSTRIAL REVOLUTION

Historians have labeled the years from 1870 to 1914 as the period of the second Industrial Revolution. The first Industrial Revolution was regional and primarily affected manufacturers and urban dwellers. The second Industrial Revolution introduced mass-produced goods into an increasingly technologically dependent and international market. It was during the second Industrial Revolution that Henry Ford mastered the moving assembly line and ushered in the age of mass production. The second Industrial Revolution brought a period of rapid growth that increased the standard of living for many Americans and created for the first time a distinct middle class. The United States became a world leader in applied technology. From 1860 to 1890, patents were issued for 500,000 new inventions, over ten times the number issued in the previous 70 years.

Manufacturing in the United States climbed steadily during the second Industrial Revolution, while the percentage of Americans working in agriculture continued to decline from 84 percent in 1800 to less than 40 percent by the beginning of the 20th century. It was also during this time that the rise of advanced capitalist economies split the globe into "advanced" and "backward" regions, creating a distinct group of industrial nations. Economic theory reveals that if one economy is a technological innovator while another economy is a technology adopter, the innovator will maintain a lead in income per capita relative to the adopter. The income gap between the two economies persists over time, even though the technology adopter ends up incorporating all of the technological advances made by the innovator.

The second Industrial Revolution has shown that to be a sustainable leader in economic growth, it is vital to be an innovator of technology. Notably, once new technology has been introduced, several decades will pass before productivity growth actually increases. Historians hypothesize that this delay occurs for a number of reasons. One possibility is that manufacturers are reluctant to abandon the expertise they've accumulated with the old technologies that are currently in use; further, in many cases their plants were designed around these old technologies. The development of electricity did not have an immediate payoff in terms of higher productivity. First of all, U.S. manufacturers were slow to accept the new innovations based on electricity, since a substantial investment of new equipment and capital would be needed. Once the plants began using this new technology, it took time to learn how best to take advantage of it. In the old economy, the pace of technological change and the introduction of new technologies were relatively slow, and thus manufacturers spent a relatively long time building up knowledge and expertise with a given technology.

In time, existing technology will eventually be replaced by new technology—in a process Joseph Schumpeter famously termed *creative destruction*. New advances are not painless to those using and producing older technologies. The phases of technological change have a slow start, because the technology is not fully understood or established. These are the early years where research and development costs are high and little if any savings is achieved. The second phase is characterized by a rapid learning process, where new discoveries are often followed by other new discoveries. In the third phase, costs begin to come down and substantial savings can be realized. In the final phase of the technology growth cycle, advances begin to slow. This is characteristic of all learning processes as they approach their theoretical limit and the law of diminishing returns begins to restrict benefits.

SELF-CONTROL

Self-control refers to the exertion of conscious, effortful control over actions, thoughts, and even emotions. The term is used interchangeably with self-regulation, self-discipline, ego strength, delay of gratification, and willpower, and it can mean a variety of different things. It may be something as simple as controlling an immediate, reflexive reaction to a positive or negative stimulus occurring in the environment or originating within the body or mind. Alternatively, it may refer to directing attention and maintaining focus to stick with a consciously deliberated plan in the presence of distracting stimuli. In all cases, the core idea is one of exercising control over behavior.

In the brain, the control over action and thoughts is believed to reside in the prefrontal cortex region, which is the anterior portion of the frontal lobes. It is often described as higher-order executive control over lower brain processes that are involved with the planning and execution of actions. Several neuroscience studies have shown that damage to the prefrontal cortex impairs ability to exercise self-control. This part of the brain develops during childhood and adolescence, and it is not fully developed till late adolescence—which might explain why, relative to adults, youth are more impulsive and more prone to risk-taking.

Some psychologists argue that over short periods of time, self-regulation is like a finite resource; when more self-regulation is used in one task, less of it is available for a subsequent task. In a series of experiments, Baumeister and colleagues (Muraven et al. 1998) have shown that individuals who were given a more effortful task performed worse on a subsequent task than other individuals who were given a less effortful first task. Other characterizations of self-control highlight the operation of dual psychological processes, one being the "fast" or "hot" system, which responds quickly to stimuli, and another, which is "slow" or "cold" and takes a more deliberated approach to formulating a response. Self-control then is the ability to override the fast and hot system with the more considered slow and cold system (Kahneman 2011).

The ability to exercise self-control is often treated as a personality trait, and a noncognitive skill. Research from longitudinal studies has shown quite consistently that differences in self-control in early childhood are good predictors of several later-life outcomes, including educational attainment, income, savings, substance use, and even criminal behavior. Even though traits exhibit a substantial degree of heritability, they also develop via training and socialization, thus offering considerable potential for development in school and home environments.

Because self-control is necessarily about the trade-off between lower-valued short-term outcomes and higher-valued, but discounted, longer-term outcomes, its standard treatment is framed in terms of intertemporal choice. But various experimental findings cast doubt on the assumptions of these models, in particular on the inconsistency of preferences. Alternative models in behavioral economics have taken a more realistic approach to human behavior. In these models, the role of self-control is conceptualized in terms of a conflict between myopic, short-term interests, and patient, longer-term interests.

One way of modelling this is by examining how individuals who have essentially long-term interests get a short-term, more realistic, counterpart of themselves to execute a plan (Thaler and Shefrin 1981). The long-term planner is treated as the principal (individual) and the short-term counterpart is the long-term planner's agent. Another, essentially similar, approach is to model the decision-maker as made up of one patient long-term self and a sequence of myopic short-term selves, make assumptions about the preferences of these various selves and interactions between them, and then examine the implications of self-control (Fudenberg and Levine 2006). What differentiates these models from the more standard intertemporal choice models is that they have more realistic depictions of human behavior, and as a result their conclusions and predictions are more reasonable.

SEMINOLE TRIBE OF FLORIDA V. FLORIDA

Seminole Tribe of Florida v. Florida, 517 U.S. 44 (1996) was a Supreme Court case that determined the extent of an Indian nation's economic autonomy. The case's economic impact on the Native American economy lay in the transition from a traditional economic system to a market-based system. The Supreme Court addressed a confrontation between tribal sovereignty, states' rights, and federal supremacy powers. It determined the economic future and direction of Native Americans throughout the United States.

The Seminole tribes struggled through economic challenges as their way of living changed from their traditional economy to a market-based economy. The Indian gaming industry was an evolution of ideas starting with bingo and graduating to class III high-stakes gambling (high-stakes gambling venues such as casinos and racetracks). The revenue from these businesses and other associated enterprises allowed the Seminole Indian tribes to support health care facilities, schools, roads, and other such infrastructure and to distribute dividends from the profits among the entire group of remaining tribe members. With this case, the Supreme Court determined the extent of an Indian nation's economic autonomy.

Case Summary

The Seminole are a blend of various Southeastern Indians who relocated to what is now the state of Florida. After the Civil War, the U.S. Congress passed several acts that relocated the Indians to reservations. The Seminole tribe of Florida's reservations included Hollywood, Big Cypress, and Brighton, all located in southern Florida near Lake Okeechobee and the Everglades.

Much of the background of this case centers on the tribe's economic evolution and the federal Indian policy of the early 20th century. In the 1930s, Congress recognized hundreds of Indian tribes on lands held in trust by the federal government. As wards of the state, these tribes were provided with economic support by the federal government and were granted tribal sovereignty. After World War II, Congress reversed its Indian policy. In 1953, Public Law 280 was passed, which gave the states control over criminal and limited civil issues within Indian territories. In addition, in an effort to encourage Native Americans to assimilate into mainstream American society, Congress terminated the legal status of over 100 tribes throughout the United States, which eliminated a great deal of their revenue. Most reservations during this time were geographically isolated from the economic resources necessary to grow prosperous communities.

The 1976 Supreme Court decision in *Bryan v. Itasca County* paved the way for alternative economic initiatives within Indian reservations. Members of the Minnesota Chippewa tribe, the Bryans, sued Itasca County, Minnesota, claiming that states did not have the right to assess a tax on Native American property located on Indian reservations. The state of Minnesota claimed that Public Law 280 gave the states an inherent power to tax Indian property on reservations. The Supreme Court ruled in favor of the Bryans. The Court held that Congress had that power through the Indian Commerce Clause, and the states could share in that only if Congress specifically granted that authority to them.

In the 1970s, the Seminole tribe built a bingo hall. The state of Florida allowed bingo two days a week for charitable organizations, with maximum jackpots of $100. In 1979, the tribe opened the bingo hall six days a week, with increased jackpots. The state of Florida shut it down because it violated Florida laws. An important political precedent was whether the Seminole tribe had the right to sue the state or whether the Eleventh Amendment to the U.S. Constitution (which gives the states sovereign immunity, whereby they cannot be sued in federal court without their consent) provided Florida with immunity.

In *Seminole Tribe of Florida v. Butterworth* (1981), a federal court ruled in favor of the Seminole tribe, affirming Indian sovereignty, federal supremacy, and the states' obligation to negotiate in good faith with the Indian tribes regarding gaming. In 1987, in *California v. Cabazon Band of Mission Indians*, the Supreme Court again confirmed that Indian gaming was to be regulated exclusively by Congress and not by state governments. In 1988, President Reagan signed the Indian Gaming Regulatory Act (IGRA), which established a federal commission to oversee the regulation of Indian gambling. Central to the IGRA was the duty of state officials to negotiate with the Indian tribes and enter into compacts that balanced states' rights, Indian sovereignty, and federal power. By 1991, 121 Indian tribes in 23 states had entered into 137 compacts pursuant to the IRGA.

In 1991, the Seminole Indians sued the state of Florida and its governor, alleging that they had failed to negotiate in good faith toward a tribe–state compact. The state of Florida moved to dismiss the suit on the grounds that the Eleventh Amendment to the Constitution prohibited states from being sued without their consent. The district court denied this motion, and Florida appealed to the Eleventh Circuit Court. That court reversed the district court's decision regarding the state of Florida's Eleventh Amendment rights and remanded the case (sent it back to the lower court) with instructions to dismiss the petitioner's suit.

The Seminole tribe was granted certiorari (a request by a higher court to a lower court for the files of a case to be sent up for the higher court to review) by the Supreme Court in 1995. The question was whether or not the Seminole tribe could sue the state of Florida. Florida repeated its Eleventh Amendment argument. The plaintiff supported its argument by pointing to *Ex parte Young*, a 1908 Supreme Court case that affirmed that officials representing a state could be sued when the litigation involved possible abridgment of constitutional rights. In oral arguments, the attorney for the Seminoles made it clear that the state needed to adhere to the duty required in the IRGA or there was no need for the state to be a part of this regulatory function. For the tribe, working with a single regulator, the federal government, was preferable to dealing with two regulators, state and federal. Florida's response questioned the obligation to negotiate if the only remedy was to agree with the federal government. Florida argued that negotiation choice is actually no choice, using the example that tribal gambling was illegal in Florida, but even so was happening on Indian reservations. Therefore, they would rather yield to the federal government than have Florida write regulations that could be overruled by the federal government nonetheless.

Chief Justice Rehnquist delivered the Court's opinion, in which he stated that Congress does not have the authority under the Commerce Clause to subject states to suit in federal court; nor does *Ex parte Young* allow a suit against state officials, except in a particular circumstance that was not at issue in this case. In a 5–4 vote, the Supreme Court affirmed the Eleventh Circuit Court's dismissal of the petitioner's suit. Furthermore, Chief Justice Rehnquist wrote that even if Congress intended to abrogate the states' sovereign immunity, the Indian Commerce Clause does not grant Congress that power. Therefore, the courts cannot grant jurisdiction over a state that does not consent to be sued. In the dissenting opinion, both Souter and Stevens penned different perspectives yet agreed that Congress could not abrogate state sovereign immunity. However, they did not agree that a state official and a state were the same thing. The federal government can sue a state in order to require the state to follow federal mandates, this being a political safeguard of federalism.

SEPTEMBER 11 TERRORIST ATTACKS AND RECESSION, 2001

The September 11 terrorist attacks' economic impact on the United States had short-term and long-term costs as well as direct and indirect costs. The total cost to the country was estimated at more than $3.3 trillion. The insurance loss of more than $40 billion was the largest in U.S. history, surpassing the previous largest disaster, Hurricane Andrew, by one and one-half times. In addition, it would become the world's largest insurance loss. The shutdown of air traffic for a week took many airlines to the edge of bankruptcy with long-term losses exceeding $10 billion. Loss of jobs, work, and tourism probably cost New York City near $50 billion in the long run.

The federal government poured more than $20 billion into various forms of assistance. Long-term security costs were in the billions for the transportation industries and city governments. Although the stock market drop of 600 points was temporary, the attack moved the United States into a full-blown recession. The indirect war costs in Iraq and Afghanistan surpassed $1.6 trillion. Right after the attack, the Federal Reserve added $100 billion per day in liquidity to the U.S. banking system to prevent a wider financial crisis.

The September 11 attacks took their greatest toll in 2,996 human lives. The Dow Jones Index suffered its worst one-day drop and biggest one-week drop after the attacks. They created a short-term panic on the stock market, but it was the long-term costs that hurt more. The total monetary costs are staggering. The breakdown of the $3.3 trillion total cost of the event put physical costs at $55 billion, economic impact at $123 billion, homeland security at $589 billion, war costs at $1,649 billion, and projected veteran costs at $867 billion.

The physical building replacement costs included $3.5 billion for the Twin Towers and $1 billion for the Pentagon. Related infrastructure costs were $13 billion. Cleanup costs were more than $1.3 billion. The cost of the four airplanes hijacked by the terrorists was $385 million. The physical total of $55 billion surpassed the previous Hurricane Andrew record in 1992 of $25 billion. Insurance companies and their stocks took a heavy hit. Berkshire Hathaway paid claims exceeding $2 billion, and European insurers had a major portion of the claims. Insurance companies did have significant reserves to make the payouts, but they have since had to put limits on payouts for these types of disasters.

The economic impact costs are more difficult to estimate. The estimated loss in air traffic was more than $10 billion, with another $2 billion attributed to other forms of transportation. The travel and airline industries suffered long-term negative effects as well. Fear of flying increased dramatically. Total costs to overall business disruption were estimated near $12 billion. New York City recorded a job loss of 83,000 in the year after the attack. At least 10,000 small companies were destroyed. Tourism in New York dropped around $4 billion. On the stock market, insurance, airline, airplane manufacturer, bank, financial, and travel stocks declined the most.

Security costs for all types of public events and businesses increased. Security costs added to the problems of the already-struggling airlines. Airport security created long lines and lost time, as customers had to arrive at airports hours ahead of time. Many estimate that lost work time for line waiting has also run in the billions each year. Airports that had been developing business models for increasing consumer shopping were restricted as family and friends waiting for passengers could no longer gain access to airport stores. Major sporting events took on major security costs. Nuclear plants, water-processing plants, major tourist attractions, sporting events, and large malls took on huge increased security. Americans also gave up some privacy rights in exchange for greater security with the passage of the USA PATRIOT Act.

The largest indirect costs were the two wars that followed the September 11 attacks. Known in total as the "war on terror," these government actions would include two of America's longest wars. The wars and the rebuilding funds for Iraq and Afghanistan would be part of this decade of unprecedented spending. The spending continued into 2016. Clearly, the September 11 attacks have dominated the economic history of the United States so far this century. The effects of the September 11 attacks on the recession are less clear, because the United States was already on the path to recession before the attacks. The dot-com crisis and September 11 both contributed to an economy in decline. Before these events, the Federal Reserve had already been raising interest rates in an effort to slow speculation and the economy. Unfortunately, these events hit the economy hard and took the Federal Reserve off its plan. Inflation of house prices and commodities continued. The brief 2002 recession was, to a large degree, a typical contraction of the expansion of the 1990s. The lagging indicator of unemployment showed the impact of the overall recession. The year 2001 recorded a loss of 1.8 million jobs. The unemployment rate started that year at 4.3 percent and ended at 5.7 percent. The unemployment rate peaked at 6.3 percent in June 2003. The stock market did not fully recover until 2003. Based on traditional measures, the 2002 recession was one of America's shortest. The economy continued its expansion, fueled by the growing housing bubble and inflation.

SLAVERY AND SLAVE TRADE

Slavery has existed almost everywhere in the world. The definition of *slavery* is the state of being owned by another person. Slavery was very destructive toward the physical and emotional aspects of each slave. Slaves are treated poorly, are frequently bought and sold, and are forced to carry out difficult duties and submit to many restrictions. Around the world, slavery has affected the way people respect and view other people. Today, most societies that had slavery as a part of their culture have enacted laws and restrictions to end slavery.

Slavery began in North America in roughly 1619 when a Portuguese ship brought 50 African slaves to Jamestown, Virginia, where ships could trade with colonists. The ship's crew was starving, so they traded 20 of these slaves for food and other necessities. The letters that recorded this transaction are the most reliable evidence of the earliest slavery; however, slavery could have existed in the colonies prior to 1619.

As the new country developed, Virginia became more populous and needed more laborers. One result of this can be seen in Bacon's Rebellion, which took place when Nathaniel Bacon led black and white men to revolt against the leaders of Virginia. This unity of black and white scared Virginia's ruling class, so they abolished the prevalent indentured servitude and replaced it with racial slavery. (An *indentured servant* is a person who signs and is bound by indentures to work for another for a specified time, especially in return for payment of travel expenses and maintenance.) Many slaves initially were taken prisoner by black slave traders within Africa; the slave traders sold them to Europeans, who brought them to America to sell. Slavery increased as the 1600s went forward, with the maximum number of slaves being brought from Western Africa to America in the 1800s, by which time over 80,000 Africans were sent to America annually to be slaves. Upon reaching America, two-thirds of slaves were put into the labor force, which is twice the number of free people in the labor force.

Owners regularly mistreated their slaves, although the mistreatment varied depending on many situations. Most slaves either worked in the tobacco or cotton fields or in the sugar industry. By 1850, more than 50 percent of the slaves in the United States were cotton workers; another 12 percent worked with tobacco, 5 percent with sugar, and 4 percent with rice. Working in the fields meant working from sunrise to sunset, six days a week, and being given very little food for such intense labor. The shacks that slaves were housed in had dirt floors and little or no furniture.

Although African slavery, and slavery in general, has been reduced, different types of slavery are still being practiced. It is said that 21 million to 36 million people are enslaved worldwide. Approximately 75 percent of these slaves are in forced-labor slavery, such as farming or ranching, where they're needed for manual labor. Forced-prostitution sex slavery accounts for another 22 percent. Children make up 26 percent of slaves. Slavery today is a very quiet, hidden process, making it difficult for society to identify and help the people who are affected. There are many variables influencing today's slavery, such as the increase in population size; the vulnerability of the migrants being trafficked; governments that still allow slavery to go unpunished; and discrimination across different cultures, gender, and race.

SMITH, ADAM

Baptized: June 5, 1723 (exact birth date unknown), in Kirkcaldy, Scotland; Died: July 17, 1790, in Edinburgh, Scotland; Nationality: Scottish; Professional Interests: moral philosophy, political economy (economic theory); Major Works: *The Theory of Moral Sentiments* (1759), *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776).

Adam Smith is considered the father of modern economics. The theories contained in his seminal book, *The Wealth of Nations,* include division of labor, the importance of competition, the idea of the "invisible hand," and arguments for free trade. These concepts form much of the foundation of modern economic thought. Though Adam Smith is considered the founder of free-market economics, other ideas that he held, such as the labor theory of value, were used by later writers to form the foundation for socialism. For his part, Smith was a quintessential Enlightenment thinker. He believed in natural rights, natural law, and limited government. Theology had little place in his writings. He viewed the world, human society, and hence the economy as being governed by natural law that if left on its own would work smoothly, like a grand machine. Smith died in 1790.

Adam Smith was born in Kirkcaldy, Scotland, in 1723. His father, a lawyer and customs official, died shortly before his birth. He was raised by his mother, Margaret Douglas, with whom he had a close, lifelong relationship. At the age of seven, he was enrolled at the reputable Burgh School of Kirkcaldy, where he studied classics and mathematics. He studied moral philosophy at Glasgow University and Oxford University. Upon graduating, he sought an academic career, eventually becoming the professor of moral philosophy at Glasgow. He held this position for 13 years, during which time he assembled his lecture notes into a book titled *The Theory of Moral Sentiments*, published in 1759. In *The Theory of Moral Sentiments,* Adam Smith argues that human morality originates through a natural desire to identify with the emotions of others.

Smith quit his position at Glasgow when he was offered a lucrative job as tutor to a Scottish duke. Though this job lasted only about two years, it provided Smith with a pension on which he could live for the next decade without having to worry about other employment.

The Wealth of Nations begins with the observation that "division of labor," or specialization, is essential for increasing the production of wealth. Division of labor occurs because human beings have a tendency to "truck, barter, and exchange one thing for another," that is, to trade. This causes people to become dependent on one another. Smith's fundamental insight is his explanation of how this complex interdependence is organized: Trade and division of labor occur because of individual self-interest, not from kindness or the designs of politicians. When individuals act as they see best, within the constraints of the law and in a competitive business environment, the economy organizes itself naturally, as if guided by an "invisible hand."

Trade was a controversial issue in the British Empire in Smith's time, and *The Wealth of Nations* was a powerful weapon for those who favored free trade. The book explains that division of labor is limited by the extent of the resources available to a market and that a greater division of labor, and therefore greater wealth, could be obtained by expanding the market through global trade. It also sharply criticizes the ideas of mercantilism, which hold that a country should attempt to accumulate gold by encouraging exports and discouraging imports. By showing the importance of trade, Smith gained great popularity among merchants, whose work had previously been considered distasteful.

While Smith's work legitimizes the work of traders and capitalists, it asserts that an item receives its value from the work of the laborers who made it; this is called the labor theory of value. The labor theory assumes that a given commodity has a natural price that is made up of the amount of work that went into producing it. However, this natural price is difficult to know, since the circumstances of the world can cause the price for which the item is actually sold to change. Smith explains that the sale price will gravitate to the natural labor price, even if the two prices are not always exactly the same. In this analysis of value, Smith recognizes the importance of supply and demand (which had been described by earlier economic thinkers) but defers to the labor theory of value.

The labor theory has been rejected by economists, who now see value as something subjective and price as being determined by supply and demand. It gained adherents, however, in David Ricardo and Karl Marx. Marx built his entire economic philosophy on the labor theory, and he drew other parts of socialist thought from elements of Smith's macroeconomic observations. Later economists used Smith's work in a different way, applying his concepts of supply and demand, competition, spontaneous order, market price, and voluntary trade to all areas of economic thought, eclipsing the indefensible-labor theory and turning economics into the versatile social science that it is today.

Adam Smith died on July 17, 1790, in Edinburgh, Scotland. His gravesite in Edinburgh has become a shrine and symbol of free markets, capitalism, and the strength and power of individual freedom.

SOCIAL CAPITAL AND BEHAVIORAL ECONOMICS

What is *social capital*? As several social scientists have emphasized, it is a concept that can bridge various estranged social sciences—political science, economics, psychology, sociology, and anthropology. Social capital is assumed to consist of a set of norms, networks, and organizations through which people can gain access to power and resources, and through which decision-making and policy formation take place. Because it has been defined in a number of social sciences, economist Joseph Stiglitz (2000, 59) has found social capital to be "a concept with a short and already confused history."

For sociologist James Coleman (1988, 598), *social capital* can be defined as "a variety of different entities, with two elements in common: they all consist of some aspects of social structure, and they facilitate certain actions of actors—whether personal or corporate actors—within the structure." A narrower definition, or perhaps a better one, has been provided by political scientist Robert Putnam (1993, 322): *Social capital* has "features of social organization such as trust, norms, and networks that can improve the efficiency of society by facilitating coordinated actions."

On the basis of such definitions, we can argue that social capital is the glue that holds society—thus, the economy—together. This function can take in two different forms: (1) structural, through rules, procedures and networks; and (2) cognitive; consisting of norms, values, and attitudes like trust that influence the actions of economic agents.

As some economists have argued, social capital can be useful in both the micro level and the macro level of the economy, enhancing the way markets function and, by improving the performance of various institutions, enhancing society's legal framework and government's impact on the economy.

However, not all economists have been enthusiastic about the use of social capital in economic analysis. For example, Robert Solow (2000) found it misleading to include capital in the term *social capital*, because capital is usually identified with tangible, durable, and alienable objects such as buildings and machines whose accumulation can be estimated and whose worth can be assessed. Barron and Hannon (1994) criticized the "social capital" metaphor, arguing that to qualify as capital an entity must possess an opportunity cost, something that social capital lacks. Kenneth Arrow (2000) urges the abandonment of the "capital" metaphor, and thus the term *social capital*, emphasizing that capital implies a deliberate sacrifice in the present for future benefits, which he claims does not apply to elements of social capital. Interestingly, even some institutional economists find the use of the term *social capital* problematic. According to Schmid (2002, 747), "Institutional economists have long argued that social relationships involved in habit, custom, norms and law make a difference in the realization of the potential in physical goods and human skills. But a new name extending the capital metaphor is not needed to describe the institutions of collective action"

Social capital has relevance to behavioral economics. With indirect roots in the works of Adam Smith, social capital is a paradigm that is capable of bridging various social sciences (Hosseini, 2004). This makes it very appropriate for behavioral economics. After all, behavioral economists have tried to make economics consistent with carious social sciences—in particular, psychology. This connection explains why, for example, Jeffrey Dayton-Johnson (2003) incorporates the concept of social capital into a behavioral economics model, where social capital has an impact on the choices made by individuals. Also, social capital can help, for example, explain economic underdevelopment in terms of affecting the choices of decision-making at a multiplicity of levels (Hosseini 2004).

SOCIAL CAPITAL AND PERSONAL CAPITAL

Social capital is a type of resource that a person can cultivate through social networking and interpersonal activities to increase productivity and achieve certain personal goals. The process of social capital accumulation depends primarily not on the person's own effort, but on the person's interaction with relevant past and present peers and social networks. *Personal capital* refers to a person's own activities and experiences that affect the well-being of the person. Hence, the main difference between social capital and personal capital lies in the emphasis on interpersonal activities in the former and personal experiences in the latter. According to Becker's original description, both social and personal capital contribute to a person's human *capital stock*, which is defined as knowledge and skills a person acquires to increase that person's productivity (Becker 1996, 5). Recent literature, however, focuses more on the distinction between *social capital* and *human capital*, where the latter term is used in the context similar to Becker's definition of *personal capital*.

In economics, capital is considered a factor of production that can be used to produce goods and services of economic value. Investment in physical capital such as machinery, for example, increases the production of present and future goods and services. Similarly, people can invest in their own productivity through the accumulation of personal, social, and human capital. However, people's external social environment often constrains the types and amounts of capital they can accumulate.

The social institutions in a person's external social environment—such as school, religious organization, family, and network of peers—determine the types of capital that are feasible within a person's choice set. The choices that are available to people are shaped, but at the same time limited, by their cultural and personal backgrounds, which play an important role in the formation of a person's capital stock. For instance, children born to nonreligious families have less exposure to religion at a young age, and so are less likely to build their capital stocks through religious institutions.

Certain experiences and social networks may contribute to capital accumulation that decreases the well-being of a person or of society as a whole. For example, *criminal capital* refers to knowledge and skills a person would develop in order to become more productive in criminal activities that are negatively valued by conventional society. A person may not prefer to invest in such types of capital, but may have no other feasible choices due to limitations in the external social environment (such as growing up in a poor neighborhood with limited access to conventional social networks and institutions).

Becker suggested two factors that can affect capital accumulation: peer pressure and habitual behavior. A person's choices are often subject to peer pressure that can shape the type of capital accumulated over time. Regarding habitual behavior, an individual's past choices continue to affect current and future choices. As a person starts to build capital stock, it becomes easier for the individual to continue with activities that reinforce the type of capital stock already accumulated—there would be a higher marginal product. Hence, in a person's capital accumulation process over different time periods, there are close links that explain habitual and addictive behavior, some of which are the results of peer pressure.

The rational choice framework suggests that people attempt to maximize their own well-being in a constrained environment, with financial constraints being the most common type accounted for by economists. In the context of social interactions, a person faces social constraints that are partly defined by exposure to various types of social institutions that, in turn, affect the person's accumulation of capital stock and eventually the final choice about how to maximize one's own well-being. This interplay between constraints and incentives brings the study of economics and sociology together under the rational choice framework. Applying the concepts of human capital and social capital to research has become increasingly popular since the late 1990s—especially in fields that are interdisciplinary by nature, such as criminology and social work. In the study of criminology, for example, accumulation of human, social, and criminal capital, through different types of social institutions, has been used to explain a rational individual's decision to engage in criminal activities. In short, the concepts of social, personal, and human capital capture how personal experiences and social interactions influence individual decisions in all aspects of life.

SOCIAL LENDING OR PEER-TO-PEER LENDING

Peer-to-peer (P2P) or social lending is a relatively new lending and investing platform in the United States. Started by Prosper in 2005, the concept is quite simple: Individuals both borrow and lend money without using the traditional financial system. Lending Club and Prosper are the dominant players in the social lending platform. Both are registered with the Securities and Exchange Commission (SEC) and have filed the required documents.

In the past, financing was available primarily through mortgage brokers, banks, and quick high-interest-rate payday lenders. Borrowers could also obtain high-interest and fee-heavy loans through their credit cards. Through an online peer-to-peer marketplace, borrower members may borrow directly from lenders without going through a traditional lender.

Borrowing and Lending with Peer-to-Peer

Borrowers apply for loans to consolidate credit cards, fund a business, pay for a home remodel, or engage in any number of financial endeavors. Their credit score impacts the interest rate. Borrowers are categorized according to creditworthiness from A to G for Lending Club. Prosper grades loans from AA for those with higher credit scores down to E for borrowers with the weakest credit histories. Applicants with poorer credit receive higher-interest-rate loans. The practice of matching higher interest rates with higher-risk borrowers is common with both traditional and nontraditional lenders.

The term of loans in the peer-to-peer system ranges from three to five years. Borrowers can obtain from $1,000 up to $25,000 at Prosper and up to $35,000 at Lending Club.

To illustrate: Karen is a typical borrower with a job and credit card debt. She sought a loan from a traditional bank to consolidate her credit card payments. Although Karen had a high credit score, she could not secure a bank loan. She went online and applied for a peer-to-peer loan and got funded in one week at a rate of 5 percent. Her interest rate was favorable because she had a job and a good credit history. This rate was substantially lower than the one she was paying on her outstanding credit card debt.

Lenders (or investors) in social lending platforms obtain higher returns on their investments than are obtained in other types of fixed income securities. Lenders can choose whom they wish to lend to and in what amount. To minimize the *default risk* (the possibility that the borrower won't pay off the loan), lenders typically invest small amounts in many loans. It's customary for an investor with $1,000 in peer-to-peer loans to contribute $25 apiece to 40 different borrowers. This diversification protects the lender from excessive losses if borrowers default on their loans.

Lenders can hand-pick the loans and choose preferred use and loan grades to fund. A conservative lender might choose to invest only in A through C grade loans. For example, Henrik invested only in high grade loans, and he never funded borrowers looking for money for a vacation or a wedding. He preferred to fund smaller and shorter-term loans.

Disadvantages of Social Lending Platforms

Lenders tie up their money for three to five years, and they may face loss of principal (that means they won't get all of their money back) if they need to sell a loan before it matures. This type of investing is less liquid than investing in the traditional financial markets. There are high default rates, and thus lenders need to diversify their investments among many individual loans.

Since this type of lending platform is so new, it hasn't been thoroughly tested during poor recessionary economic times. When the economy performs poorly, loan default rates are likely to rise. In fact, Prosper loans issued during the recession of 2007 lost money.

Lending Club states, on page 1 of its SEC prospectus, "This offering is highly speculative and the Notes involve a high degree of risk. Investing in the Notes should be considered only by persons who can afford the loss of their entire investment." Since the loans are not secured by collateral like a home mortgage or car loan would be, they are considered riskier. In other words, when the borrower does not make payments, their loan does not have any property attached that the lender can take in exchange for the missed payments.

Lending Club acknowledges that the borrower members may supply inaccurate information in order to obtain the loan. In fact, Lending Club states that the borrower-supplied information should not be relied upon.

Risks described in the Lending Club's SEC documents explain that Lending Club does not verify a borrower's time on the job, home ownership status, or intended use of the loan. Nor does Lending Club verify paystubs, IRS forms, tax returns, bank and savings account balances, retirement account balances, home or car ownership records, or any records related to past legal proceedings. Thus, borrowers may be submitting false information in order to receive the loan. In fact, during the last nine months of 2012, when borrower members' income and employment were verified, only about 60 percent of those individuals provided satisfactory responses to requests for income or employment verification.

Additionally, not all states allow these companies to operate, and some states require that lenders demonstrate minimum income levels in order to participate.

This information underscores the riskiness of the social lending platform for the investor.

Advantages of Peer-to-Peer Lending

In contrast with traditional lending, social lending streamlines the borrowing process. The middleman is the online platform. The lending platforms take approximately a 1 percent fee, and the rest of the principal and interest repayments pass from the borrower to the lender. This affords lenders much higher returns on the amount of money loaned.

Borrowers who are unable to obtain a traditional loan may qualify through this platform at lower interest rates and lower credit card rates. This gives borrowers more financing possibilities.

The social lending platform gives investors greater investment opportunities and access to a market previously unavailable. Investors in these loans obtain higher returns than are otherwise available in the financial markets.

For example, Maria wants to fund a new business venture and cannot obtain a traditional loan. She borrows $5,000 from Prosper. Due to her credit score, financial history, and work background, her interest rate is 11 percent. Duane invests $25 in Maria's loan as part of his loan portfolio. After the 1 percent fee to Prosper, Duane receives a prorated portion of all of Maria's loan repayments. If Maria defaults on her loan and after 6 months stops making payments on the loan, Duane does not receive any additional interest or principal payments on this particular loan. The advantage to Duane is that he has many other loans to offset the loss on this one. Further, most loans are repaid, and he earns a higher interest rate than can be found in the financial marketplace.

In the peer-to-peer lending platform, borrowers get fixed-rate personal loans that may have lower interest rates than credit card debt, which may take many years to pay off. Peer-to-peer lending transforms the borrowing and lending activities from traditional financial institutions to individuals borrowing from and lending to other individuals.

SOCIAL PREFERENCES WITHIN A POPULATION

Social preferences refer to the predisposition of humans to care about others. In particular, people might be concerned about other people's gains, their actions, their opinions, or what kind of people they are. Because of social preferences, people can feel elevated or feel envious because of other people's success, or they can feel bad because others are treated unfairly. Economists are interested in these preferences, as they can influence people's decisions and thus can have economic consequences. For example, donations to charity or the consumption of fair-trade products can be expressions of social preferences.

Economists distinguish three general classes of social preferences:

1. Models with *outcome-based* preferences presume that people's utility or well-being depends not only on how much is allocated to the people themselves, but also on how much other people get. Prominent examples are models of *altruism*, *envy*,

concerns for efficiency, and *inequity aversion*. Altruistic persons give from their own wealth because they feel better when another person's outcome can be increased, even when this comes at their own cost. Envious persons, on the other hand, can engage in costly action to decrease another person's outcome.

2. A second class of social preference theories, so-called *belief-based* models, presumes that people's utility is affected not only by the final allocation but also by additional psychological factors that can be derived from the beliefs that people hold. In such models, the *intentions* that people attribute to other people's actions affect their joint outcome. Joint outcome is also affected by *guilt*, which arises if one's own actions do not meet the beliefs that another person is perceived to have about these actions. Intentions affect outcomes of social interaction if a person wants to increase or decrease the outcome of another person—even at a cost to the first person. Depending on whether the action of the other person was perceived as kind or unkind, such behavior is also referred to as *positive* or *negative reciprocity*. Or, people might take an action that is less favorable to themselves in order to meet the expectation of people, and thus to avoid feeling *guilt*.
3. Finally, models of *interdependent* preferences presume that people have preferences over the type of the other people they interact with. This third type of model can explain, for example, why the same person can act in a nice way towards an altruistic person while being mean to an egoistic person.

All of these models describe the strength of social preferences by a "preference-parameter." For example, in the altruism model, a preference-parameter allows us to say something about the *level of altruism* of a person that determines how much an altruist is willing to give to other persons. Individual preference-parameters represent a person's social preferences. Contrary to other personal characteristics, such as age or gender, social preferences are not directly observable. In order to elicit social preferences as personal traits, economists use experiments of social interactions that involve two or more persons—for example, dictator, ultimatum, trust, or public-goods games. Repeated observation of subjects' behavior in these games allows researchers to measure individual preference-parameters.

From studies that employ such experiments with a large-scale subject pool comprising members of the general population, we can learn how individual preference-parameters are distributed across people. Currently, such studies exist only for the Dutch population covering model classes (1) and (2). Their results suggest that different subgroups of a population seem to be similarly averse to receiving less than others, with retired persons being more averse. Subgroups differ, however, in their aversion to having more than others: young, more-educated persons and persons with higher income are less averse to having more. Men and women are equally averse to having less or more than others. Persons who dislike having less than others are also more averse to having more. People react to perceived intentions and are similar in their negative reciprocity. They vary, however, in their positive reciprocity: young persons and persons with a higher income level have higher levels of positive reciprocity. Also, guilt aversion has been found not to vary across subgroups.

SOCIAL SECURITY

Social Security, created in 1935, is a federal program of social insurance and benefits. This program is the foundation of financial security for retirees, disabled persons, and families of retired, disabled, or deceased workers. The program is funded though Social Security tax (Federal Insurance Contributions Act, or FICA) paid by American workers and their employers. It is a pay-as-you-go program, which means that today's workers pay Social Security taxes, and their payments form the Social Security benefits of current retirees.

Social Security differs from the traditional company pension, which is "prefunded." Prefunded program funds are paid in advance, saved, and subsequently disbursed at a later date. Funding in advance programs protects employees from the possibility that a company goes bankrupt, goes out of business, or is unable to pay its pension obligations.

History of Social Security

The Social Security Administration (SSA), initially called the Social Security Board (SSB), was created in 1935 with the passage of the Social Security Act under President Franklin Delano Roosevelt. The stock market crash and ensuing Great Depression prompted President Roosevelt to develop a social insurance system to protect against such major personal economic hazards as unemployment and old age. The three-member board, created to administer the Social Security Act, targeted old age insurance, unemployment compensation, and public assistance.

The SSA began as an independent agency where the Chairman of the Board reported to the president. In 1939, the board became a subcabinet member of the Federal Security Agency.

In 1995, the SSA returned to independent status. Throughout its history, the SSA has undergone much reorganization and may experience further changes in response to implementation of the Affordable Care Act of 2010.

Social Security Retirement Benefits

The earliest a worker can receive Social Security retirement benefits is 62 years of age. Workers who elect to receive Social Security retirement benefits before they reach full retirement age will receive only a percentage of their full retirement benefit. The *full retirement age* is the age when a person may receive full or unreduced retirement benefits. If the retiree chooses to receive benefits after full retirement age, the monthly benefit may increase.

The full retirement age is based upon birth year. For those born in 1937 or earlier, full retirement age is 65. The full retirement age increases monthly until a birth year of 1943, when full retirement age becomes 66. Full retirement age remains at 66 for those born between 1943 and 1954. For the years 1955 through 1959, the full retirement age increases in monthly increments from age 66 to age 67. For birth years of 1960 and later, the full retirement age is 67.

In general, once a retiree begins taking Social Security, the benefit amount remains constant.

Who Receives Social Security Benefits?

Although most people assume that senior citizens are the only recipients of Social Security, a disabled 50-year-old factory worker might also receive Social Security benefits. The Social Security program helps the widows and orphans of both military and nonmilitary citizens as well. For example, children of an army private killed in Iraq receive survivor Social Security payments.

Approximately 57 million people, or one in six U.S. residents, receive Social Security. One in four households has someone receiving Social Security. Retired workers receive approximately 65 percent of the total Social Security benefits paid, or $36.9 million. Adults disabled since childhood are the smallest group of Social Security recipients, receiving just $1 million, or 1.76 percent of the total. Other disabled Americans receive 15.49 percent of the total, or $8.8 million. Widows and widowers, spouses, and children make up the rest of the Social Security beneficiaries (Reno and Walker 2013).

How Much Do Social Security Recipients Receive?

According to the National Academy of Social Insurance, in January 2013 the average monthly Social Security benefits were $1,264 for retired workers, $1,217 for widows or widowers over the age of 60, and $1,130 for disabled workers. For a worker retiring at full retirement age 66, the maximum monthly benefit is $2,533 per month. Benefits are indexed annually to keep pace with inflation.

Although higher-paid workers receive greater amounts of Social Security benefits in retirement, a smaller percent of their preretirement income is replaced. For example, workers who were paid $110,100 per year receive $29,020 in annual Social Security benefits, or 26 percent of their preretirement income, whereas the lowest-paid workers, who earned $19,670 preretirement, receive 56 percent of their preretirement income, or $11,070.

What Is Social Security Disability Insurance?

Initiated in 1957, Social Security Disability Insurance (SSDI) provides monthly payments to disabled workers who cannot work due to a major disability that is expected to last at least a year or to result in death within a year. Workers who paid Social Security taxes in their prior employment are covered. Benefits are determined by past earnings, and they are paid to eligible workers and their dependent family members. Two years after starting to receive SSDI, these individuals are eligible for Medicare.

Additional Social Security Facts

Through FICA Social Security payroll tax reduction, workers pay 6.2 percent of their earnings for Social Security and 1.45 percent of their earnings for Hospital Insurance (HI) earmarked for Medicare (Part A). Employers pay an equivalent amount into the Social Security system. If an employee earns more than $113,700 (in 2013), no additional Social Security FICA tax is owed.

Social Security payments are held in the Social Security trust funds. In 2012, income in the trust funds included $840.2 billion from contributions and $785.8 billion in benefit payments (one percent of the outgoing funds include administrative costs). This resulted in a $54.4 billion surplus (Reno and Walker 2013).By law, the surplus is required to be invested in U.S. Treasury securities, whose interest payments are returned to the trust funds.

Retirees need to provide for additional income during their nonworking years, as Social Security does not contribute enough to cover all of a retiree's living expenses. In spite of the fact that Social Security is not designed to be the sole source of a worker's retirement income, 36 percent of Social Security recipients receive almost all of their income from Social Security according to the National Academy of Social Insurance (Reno and Walker 2013).

Security, Demographic Trends, and the Future

In order to accommodate the growing number of future retirees and lifespan increases, the full benefit retirement age was increased. Additionally, out-of-pocket Medicare premiums and the share of benefits subject to income taxes also will rise. The effect of these changes is that earners' average income replacement percentage will decline from approximately 39 percent in 2002 to 31 percent in 2030.

In less than 10 years, Social Security revenues will not cover benefits owed. The SSA projects that by 2021, revenues and interest income to the Social Security trust funds will not cover expenditures. At this point, reserves will be tapped to fund benefits. By 2033, trust fund reserves are expected to be spent. The SSA predicts that by 2033, income will cover only 77 percent of benefits due (Reno and Walker 2013). Assuming there is no change in taxes, benefits, or assumptions, Social Security revenue would cover 72 percent of benefits due at that point.

This is not the definitive Social Security projection scenario. A positive view predicts trust fund reserves lasting until 2068. A more dire analysis posits trust fund reserves will be exhausted by 2027.

Many options are being considered to increase Social Security funding and benefits for the underserved. For Social Security to continue in a semblance of its present form, changes to the Social Security program are necessary.

SOCIALISM

Socialism is one major form of government where the government—rather than individual people and companies—controls industries. This level of control enables the government to focus on equality rather than profits. Corporations are seen as beneficial only to the top 1 percent, and wealth would be evenly distributed.

This form of government is a lesser form of communism, but it is formed upon the same principles. Unlike communism, in socialism the government gives some freedom of choice to the people rather than exerting total control. Also, unlike in capitalism there is no "market," because corporations are nonexistent and the government controls market activity. Socialism can be beneficial when poverty and inequality are major problems in an economy. Redistribution of wealth and regulation of government enable people to live financially secure lives.

Socialism first appeared in the Industrial Revolution during the 18th century, although references of socialism appear in the Old Testament of the Bible. Political and religious turmoil was often was the reason given for implementing socialism. Socialism emerged from the success of capitalism, with people striving to improve conditions for workers by moving control from the companies to the state, although the free-market aspect of capitalism was overlooked in the development of socialism.

Early Utopian Socialist reformers were impressed by the success of industrial capitalism, and they wanted to find a way to keep this success while distributing profits more fairly. They noticed that the efforts of lower-class workers were being unfairly exploited. These early leaders knew that they needed to keep business, yet eliminate wealthy business and replace it with the state.

Socialists pictured capitalism as a way to train workers to make large profits for the capitalists who owned the businesses and the means of production. Through capitalism, the wealthy capitalists become out of touch with the lower workers who run the businesses. By eliminating wealthy executives through government control and income redistribution, the wealth can be easily redistributed instead of staying with the wealthy capitalists.

Opponents of socialism view income redistribution as unfair to those who work hard to advance in their careers or build their business. Opponents claim socialism takes a much larger proportion of money earned from those who earn high incomes and either expands government control of the economy or redistributes a larger proportion to the undeserving in order to make incomes more equal.

Socialism exists in three forms:

- Democratic socialism views socialism as an economic principle. Its proponents believe that production should be in the hands of ordinary people.
- Revolutionary socialism looks at socialism with a need for social change rather than gradual reform.
- Utopian socialism was the early economists' model for socialism. It was based on an ideal world where everyone contributed equally to the community. In this model, socialism takes money from the wealthy and distributes it evenly in order to create an economy equal for all while leaving some rights with the people.

SOCIETY FOR THE ADVANCEMENT OF BEHAVIORAL ECONOMICS

The Society for the Advancement of Behavioral Economics (SABE) was founded by a group of scholars, mostly economists, who were in a variety of ways dissatisfied with mainstream economics. What these scholars wanted was an interdisciplinary economics distinguished by scientific practices different from those of the economic orthodoxy. SABE members sought to combine economics with psychology, sociology, anthropology, history, political science, philosophy, and other disciplines. They also aspired to create an economics that is less narrow, rigid, intolerant, mechanical, and individualistic than mainstream economics.

SABE's founding meeting was organized by Shlomo Maital; took place on December 29, 1982, in New York City; and was attended by 14 people. The first SABE conference was held at Princeton University on May 22–29, 1984, and was attended by a veritable who's who of prominent scholars, including Harvey Leibenstein, Amos Tversky, Daniel Kahneman, Thomas Schelling, and Richard Thaler. Subsequent conferences were held at Middlebury College; at a kibbutz near Haifa, Israel; and at San Diego State University.

Around 1989, at the impetus of the prominent sociologist Amitai Etzioni, SABE was transformed into the Society for the Advancement of Socio-Economics (SASE), a multidisciplinary organization that was oriented more to non-economic social science scholars—especially sociologists, not economists. During 1990–1991, some SASE economists who were unhappy with the position of behavioral economics in SASE came to the conclusion that SABE needed to be restore. On January 4, 1992, in New Orleans, SABE was officially reestablished independent of SASE, and John Tomer was elected president. Tomer organized the next SABE conference, which took place August 13–15, 1993, in Rensselaerville, New York (outside of Albany). In the years that followed, SABE members began to find common ground with members of the International Association for Research in Economic Psychology (IAREP). This communication led to a pattern of association where every other year SABE would jointly sponsor a conference with IAREP, usually in Europe.

During the late 1980s, SABE became affiliated with the *Journal of Behavioral Economics*, whose editor was Richard Hattwick of Western Illinois University. During the time that SABE was becoming SASE, the journal's name was changed to the *Journal of Socio-Economics* (JSE). After SABE's split with SASE, the journal (now JSE) again became affiliated with SABE. In early 2001, Morris Altman became the JSE's Editor, and he has done much to make the JSE into the widely respected and cited behavioral economic journal that it is today.

It is important to note that in SABE's early years its members' conception of behavioral economics was in some respects considerably narrower than it is today. In the early years, research in the traditions of economist Harvey Leibenstein and psychologist/economist Herbert Simon were prominent. Today, SABE members' research includes all strands of behavioral economics, including notably psychological economics in the tradition of Kahneman and Tversky, experimental economics in the tradition of Vernon Smith, and macrobehavioral economics in the tradition of George Akerlof. SABE's growth and change has to a considerable extent paralleled the emergence of behavioral economics as a much more important and prominent field in the economics profession.

STALIN, JOSEPH

Born: December 18, 1879, in Gori, Russia; Died: March 5, 1953, in Kuntsevo, Russia; Nationality: Russian; Professional interests: ruled the Soviet Union from 1929 to 1953.

Iosif Vissarionovich Dzhugashvili (he later changed his name to Stalin) was born on December 18, 1879, in the village of Gori, Georgia (a country that was part of the Russian empire). A bout of childhood smallpox left his face scarred and his left arm slightly deformed. The village children treated him cruelly and made him feel inferior as they made fun of his deformed face and arm. Stalin grew to have a need for greatness and respect, and he had a cruel streak toward those who crossed him. In 1888, Stalin's mother enrolled him in church school in Gori so he could become a priest. In 1894, he graduated at the top of his class and went on to Tiflis Theological Seminary in the village of Tbilisi on a scholarship. A year later, he came into contact with a secret organization, the Georgian Social Democratic organization, which supported Georgian independence from Russia. It was this organization that introduced Stalin to the writings of Marx and Lenin, and Stalin officially joined it in 1898. Stalin then left the seminary in 1899 and stayed in Tbilisi to focus on the revolutionary movement. He was arrested not long after, in 1902, for joining the Social Democratic Labor Party, and he was exiled to Siberia. After only a month in exile, he escaped and returned to Gori. It was around this time that he adopted the name Stalin, meaning "steel" in Russian.

In the years after 1905, the radicals retreated underground, and Stalin finally met Lenin at a party conference after writing an anti-Menshevik creed that attracted Lenin's attention. Stalin also helped the revolutionaries in banditry, for the revolutionaries were forced to turn to crime as a way to get money. Stalin was arrested in the city of Baku in Azerbaijan in March 1908. He was sent to Siberia for two more years, but he escaped within a year. He was re-arrested and sent to Siberia yet again, but this time he had to stay and serve his full sentence. Stalin was never politically inactive; he corresponded with Lenin throughout the duration of his stay.

In February 1917, the Russian Revolution began, and the tsar abdicated the throne. Stalin immersed himself in Marxism. Although he was never a strong speaker like Lenin, Stalin was extremely proficient at doing the mundane tasks of the revolution, like handing out pamphlets. In 1922, Stalin was appointed the general secretary of the Communist Party. This appointment gave him control over all other party member appointments. He abused this power, however, and he made shrewd appointments that only strengthened his power as secretary.

After Lenin's death in 1924, Stalin set out to take Lenin's place. His success was partly due to his political genius, and partly due to the way Stalin always found it easy to bend and twist things to his advantage. His rivals were gifted idealists and Marxists to the core. Stalin, however, never truly understood the core principles of Marxism and was always willing to change them so they favored him. When Stalin took control of Russia, paranoia set in. His reign of terror began. Stalin had people arrested during the night and, with public trials, executed them in the morning; he wanted to teach a lesson to all "opposition." Also, Stalin had potential rivals killed, saying they were aligning with capitalist nations.

In the late 1920s and the 1930s, Stalin began industrializing Russia rapidly. This was hugely successful in the beginning, but it soon turned destructive. The heavy machinery and industry caused the death toll to skyrocket and had a heavily impact on the environment and the national budget; an idea that was originally fruitful turned sour in Stalin's hands. In 1939, Stalin signed a nonaggression pact with Hitler, never thinking that the German forces would double-cross him. This naiveté caused the Russian forces to be unprepared when the Nazis struck in June 1941. The "purges" that Stalin had ordered in the 1920s and 1930s did nothing to help the Soviet Army against the Nazis, and the Soviets suffered massive losses.

Stalin had been suspicious of the West ever since the Soviet Union threw off the tsar. In 1945, this suspicion deepened when the Allies refused to open a second front against Germany in World War II. Even after the war was over, Stalin was obsessed with the fear that the United States would invade Russia. Stalin made a "buffer zone" between Western Europe and Russia so that no one could pass into Russia unnoticed. Stalin also ordered an economic blockade of the now-Soviet-controlled German city of Berlin. He went so far as to build a wall around the city. In 1989, the Allies forced the Soviets to back down and tear down the wall, ending the blockade. East Germany and West Germany reunified into a single state in 1990.

Stalin's health began to deteriorate in the early 1950s, and he died of a stroke on March 5, 1953, at the age of 74. His successor, Nikita Khrushchev (1956), rekindled the popularity that Stalin had lost with Russia's younger generation. Although Stalin left a legacy of death and terror, he had managed to turn Russia into a world superpower to be revered and feared.

STANDARD & POOR'S 500

The Standard & Poor's 500, often referred to as the S&P 500, is a stock market equity index that serves as a representation of the stock market at large. A *stock market index* compiles the performance of various stock groups classified in a variety of ways and gives an index indicator of the performance of that group of stocks. The Standard and Poor's 500 is unique in that it attempts to gather and analyze the performance of 500 publically traded domestic companies. The S&P 500 was launched on March 4, 1967. Investors and economists alike agree it is the best single indicator of the health of the American stock market.

The history of Standard and Poor's involves its beginnings, the merger, development and expansion, and the S&P's role in the global markets. Standard and Poor's was begun in 1860 by Henry Varnum Poor as a source for investment information. The need for Poor's services was initiated largely by the rise of capital markets in the United States—driven by the introduction, construction, financing, and implementation of the railroad as it began to greatly impact the lives of Americans and businesses alike. This created the need for record-keeping, transparency, and analysis.

Poor operated a company called Poor's Publishing, where he and his son wrote and published material about U.S. railroads and their impact on economic affairs. In 1906, Luther Lee Blake recognized the need for a standardized, central, credible area where investors could turn for financial information. Out of these efforts, Standard Statistics was born. Information about a variety of industries was published on 5 x 7-inch cards that were continuously revised and eventually published in an annual edition. These informational cards were published by Babson Stock and Bond Card System, which Blake purchased. In 1919, Babson was merged with Moody's Manual Company and Poor's Railroad Company, becoming Poor's Publishing Company. Poor's Publishing and Standard Statistics would soon begin rating bonds and securities. The first stock index was developed in 1923, in order to most accurately mirror market trends. The initial index compiled financial data on 223 companies and was compiled weekly. This was the first published capitalization-weighted index.

In 1941, Standard Statistics merged with Poor's Publishing. During this year the companies would also publish the *Bond Guide*, a bond-rating guide that focused on statistics and the quality of 7,000 municipal bond ratings. Standard and Poor's revenue, employees, and capabilities continued to grow substantially through the 1940s and 1950s. In 1962, Standard & Poor's began trading on the New York Stock Exchange (SPX).

In 1966, McGraw-Hill Companies acquired Standard and Poor's. When the Committee for Uniform Security Information Procedures (CUSIP) was created, Wall Street was able to manage the level and volume of trading taking place on a daily basis. If not for Standard and Poor's publishing the data from the CUSIP, the buying and selling of stocks on Wall Street would not exist as it is known today.

S&P would begin charging issuers for ratings their first mortgage-backed securities, signifying a level of sophistication in the market that had not previously existed. In 1976, the SEC named Standard and Poor's a Nationally Recognized Statistical Rating Organization (NRSRO), as a result of the high level of credibility, reliability, and clarity that investors received from Standard and Poor's Ratings. During the 1980s, Standard and Poor's expanded globally. They initially entered the European markets by establishing a presence in London and over the next 20 years they opened offices in 20 countries worldwide.

Throughout the 1990s and 2000s Standard and Poor's continued to expand both their presence and the variety of their services. They began rating derivatives, and they introduced other index services such as the SmallCap 600 and the Standard and Poor's 1500. They also began to provide a Stock Guide Database, grouping 8,700 securities, dividing them into 11 economic sectors and 122 industry groups. In 2002, Standard and Poor's began the Hedge Fund Index, and in 2003 they acquired Smith Barney's global business, which encompassed the rating of 7,500 companies in 52 markets globally.

Companies included in the S&P 500 must meet specific eligibility requirements. These criteria include market capitalization, liquidity, domicile, public float, financial viability, treatment of IPOs, and eligibility securities. The stocks must have an unadjusted company market capitalization of U.S. $5.3 billion or more. The companies need to demonstrate adequate liquidity, and at a reasonable price. They must be U.S. companies—according to their annual reports, recognition by the SEC, their fixed assets and revenues, the exchange market where they are primarily listed, and their corporate governance structure. They must maintain a public float of at least 50 percent of the propositioned stock and must contribute to sector balance and maintenance relevant to market capitalization ranges. The sum of their last four consecutive quarters along with their most recent quarter should display positive earnings. After their initial public offering, they must be tried and tests for 6 to 12 months before ever being considered for addition to any index.

As of January 30, 2015, the top 10 companies by index weight were Apple Inc., Exxon Mobil Corp., Microsoft Corp., Johnson & Johnson, Berkshire Hathaway, Wells Fargo & Co., General Electric Co., Procter & Gamble, JP Morgan Chase & Co., and Pfizer Inc. The 500 stocks ranged from sectors including Information Technology, Financials, Health Care, Consumer Discretionary, Industrials, Consumer Staples, Energy, Utilities, Materials, and Telecommunication Services. The Standard

& Poor's 500 encompasses approximately 80 percent of the total market capitalization. It is considered the best indicator of the U.S. large cap stocks market.

SUICIDE

Suicide can be considered to be a rational decision over the life cycle under both certainty and uncertainty. Lester and Yang (1997) have analyzed suicide under certainty with a static framework in a demand and supply model and in a cost-benefit analysis. From the perspective of a cost-benefit analysis, an individual will choose suicide when the benefits of suicide outweigh the costs, bearing in mind that the individual uses a highly subjective evaluation of the mental relief and pain involved. When this is framed in a demand and supply model, the equilibrium is an unstable one. Lester and Yang note that these models support the restriction of access to lethal methods for suicide (such as gun control) as a method of suicide prevention.

Under certainty, the analysis can be expanded over the life cycle. Hamermesh and Soss (1974) argue that an individual's permanent income is negatively associated with the risk of suicide, and so suicide is expected to increase with age. If a spouse's income is incorporated into the model, then divorce and widowhood increase the likelihood of suicide. However, Becker and Posner (2004) note that Hamermesh and Sosh's model fails to take into account what decisions might be made at a later point in life. In this case, suicide should decline with age because the people who survive to an older age are those who are the happiest.

Game theory has also been used for economic models of suicide. For example, Robert Rosenthal viewed suicide attempts as a credible signal intended to manipulate the behavior of the receiver (a spouse) in a way favorable to the sender. Another application concerns crisis intervention, where seeking help is an alternative to committing suicide. In a game-theoretical approach, Yaniv (2001) notes that the mental health practitioner has the choice of offering crisis intervention or hospitalization, and under certain behavioral assumptions crisis intervention minimizes society's expected loss from suicide and the cost of prevention.

If physician-assisted suicide were available, then terminal patients could evaluate the benefits and costs associated with euthanasia in order to arrive at an informed decision about easing their pain and suffering. Leo Chan and Donald Lien conclude that the policy implication resulting from their analysis of this was that more medical research in pain management would help reduce the demand for euthanasia.

Under uncertainty, since suicides ignore the uncertainty of the future and the option value of life, some economists deem suicide to be an irrational choice. Two other types of behavior are defined by Gary Becker as irrational: (1) random, erratic, and whimsical choices and (2) repetitive choices. This definition of *irrationality* parallels the major typology of suicidal behavior in which suicidal behavior is treated as a time-limited impulsive crisis or as a chronic maladaptive pattern.

At the aggregate level, Yang (1992) has analyzed how suicide is tied to the business cycle. She notes that Emile Durkheim argued that both business expansions and contractions result in rapid changes in social integration and social regulation and, therefore, both increase the suicide rate. On the other hand, Ralph Ginsberg proposes that individuals commit suicide because of the discrepancy between rewards and aspirations, resulting in a cyclical relationship between the economy and suicide, while Andrew Henry and James Short theorize that suicide is driven by changes in the hierarchical ranking of people of different social classes as a result of the business cycle, resulting in a countercyclical relationship.

Yang and Lester (2006) have noted that these three distinctive theories of suicide and the business cycle imply the existence of a "natural rate" of suicide for societies (based on steady-state unemployment). In their 2006 study, they estimated the natural rate of suicide in the United States to be about 8 per 100,000 per year; for other, selected countries the rate ranged from 5 in Poland to 17 in France.

SUPREME COURT

The Supreme Court of the United States was established under Article III, Section 1, of the U.S. Constitution when the Constitution was ratified in 1789. The Supreme Court is a part of the judicial branch of the government. The role of the Supreme Court is to interpret the laws created by the legislative branch of the government. The rulings by the Supreme Court are considered final. These rulings set a precedent for all other rulings similar to them.

When Congress first met on March 4, 1789, one of the first items of business was how to organize and establish the court system. Article III, Section 1, of the Constitution establishes the need for a court system and asks for a Supreme Court, stating, "The judicial Power of the United States, shall be vested in one supreme Court, and in such inferior Courts as the Congress may from time to time ordain and establish." The Constitution allowed Congress to decide how the court system should be organized. To do this, Congress passed the Judiciary Act of 1789. This act created 13 district courts in major cities, three circuit courts, and a Supreme Court comprising a chief justice and five associate justices. It also set up a lower federal court system.

The Supreme Court is the highest court in the United States and is considered the court of last resort. The Supreme Court has a great deal of power due to judicial review. In 1803, the case of *Marbury v. Madison* established the principle of judicial review, allowing the Supreme Court to declare any laws that went against the Constitution as invalid. This gave the Supreme Court much more influence, as the Court now could oversee the executive and legislative branches to ensure that what they were doing was constitutional. Since the Supreme Court uses the Constitution as its guiding document, the decisions made by the Court are said to stand the test of changing.

Over time, the number of justices who serve on the Supreme Court has increased from six to nine, with one serving as chief justice. Supreme Court justices are chosen by the president and confirmed by the Senate. According to the Constitution, the justices "shall serve their offices during good behavior." This has been interpreted as justices serving for life terms, until they decide to retire or resign or are impeached from their position. Congress cannot change the salaries of justices during their term in office. This is done so as not to influence the justices in their decisions by increasing or decreasing their pay.

Under Article III, Section 2, of the Constitution, the Supreme Court has original jurisdiction in cases that involve more than one state and cases involving ambassadors, ministers, and consuls. It also has jurisdiction in cases that involve treaties and events that happen on the open sea. The Supreme Court has appellate jurisdiction over cases that deal with constitutional or federal law. The Court receives over 10,000 petitions for a writ of certiorari on a yearly basis. A *petition for writ of certiorari* is a document that a losing party files with the Supreme Court asking the Supreme Court to review the decision of a lower court. It includes a list of the parties, a statement of the facts of the case, the legal questions presented for review, and arguments as to why the Court should grant the writ. Of these 10,000 petitions, the Court agrees to hear oral arguments on 75 to 80 cases yearly. The

Supreme Court hears these cases during yearly terms while it is in session—from the first Monday in October until the first Monday in October the following year.

For a case to be heard by the Supreme Court, there must be a quorum of six justices present. The justices review the decisions of the lower courts and the history of the case prior to listening to oral arguments from the petitioner and the respondent. Justices can also participate in cases by listening to audio recordings of the arguments and reading transcripts from the cases. Justices make a decision by voting on how they feel the case should be decided, either upholding the decision of the lower courts or reversing the decision. A decision is reached when five of the nine justices have voted for or against the decision of the lower court.

The Supreme Court justices have responsibilities in addition to hearing cases and making decisions based on precedent and the Constitution. Whenever they make a decision, they may also decide to write their opinions on the cases. These opinions may concur with the majority opinion or dissent from it. Also, the Supreme Court justices are responsible for overseeing one or more of the 13 federal circuit courts and handling emergency applications from these courts.

The Supreme Court plays a vital role in how the U.S. government functions. With the power to oversee the actions of both the executive and legislative branches, the Court sets appropriate limits on the government and ensures that all Americans can enjoy the freedoms promised to them through the Constitution and proper due process of law.

SUSTAINABILITY

The concept of sustainability plays an important, if contested, role in the related fields of environmental and ecological economics. Historically, environmental economists focused on the use of benefit–cost analysis to identify the efficient allocation of nonmarket goods and services. This had major implications for the conservation of environmental resources, which typically involve complex streams of costs and benefits accruing to diverse sets of stakeholders. In informal terms, benefit-cost analysis involves assigning monetary values to unpriced costs and benefits. When these externalities are internalized, the result is often a conservative approach that involves the sustained provisioning of high-value ecosystem services.

That said, the limitations of benefit–cost analysis were apparent quite early on, as emphasized for example in Ciriacy-Wantrup's (1952) work on safe minimum standards. The conservation of natural resources, ecosystems, and biodiversity typically involves significant short-run opportunity costs that are well-defined and that often accrue to politically influential stakeholders. If decision-makers employ high discount rates based on impatience and/or a reliance on short-run planning horizons, the costs of conservation can dominate the perceived benefits both in formal benefit-cost analysis and in practical decision-making. On the other hand, the long-run benefits of conservation are often difficult to gauge because of scientific uncertainty and uncertainty about the preferences and needs of future generations. Ciriacy-Wantrup was concerned that at least some environmental resources might be truly essential to posterity, anticipating the more recent discourse surrounding ecosystem services and their role in supporting human flourishing. As such, he embraced an approach to decision-making in which unique and potentially irreplaceable resources should be conserved unless the costs were judged to be unbearably large. In effect, this approach placed bounds on the application of the benefit-cost approach as a way of managing catastrophic environmental risks under conditions of strong uncertainty.

Ciriacy-Wantrup's framework is similar to the concept of strong sustainability that has emerged in the ecological economics literature. Broadly, ecological economics studies the economy and an embedded subsystem of social and ecological systems, adopting a transdisciplinary approach to environmental policy and governance. More specifically, ecological economists emphasize a tripartite approach to managing the links between the economy and the environment, with equal importance attached to the goals of (1) enhanced human flourishing, (2) distributive and procedural fairness, and (3) ecological sustainability. Advocates of strong sustainability see environmental resources as the joint or common property of present and future generations. While the present generation has a right to utilize resources for short-run economic gains, it also holds a duty to conserve the resource base for the enjoyment of future generations. In this framing, the degradation or despoliation of ecological systems would impose a wrongful harm on future generations in the absence of restorative measures, such as the rendering of appropriate compensation. As a rule of thumb, ecological economists are skeptical about the ability of monetary payments to compensate for the loss of ecosystem services over multigenerational time scales. Operationally, then, this approach is in line with Ciriacy-Wantrup's criterion. The depletion of natural resources (say, high-quality petroleum resources) carries with it a duty to develop and provide substitutes (e.g., renewable energy technologies) that could generate equivalent services on a sustainable basis. Good policies would then achieve this goal cost-effectively with due attention to equity concerns.

In environmental economics, the concept of weak sustainability has received comparatively more emphasis. At a fundamental level, this approach is based on the moral supposition that the utility or well-being of a typical member of society should be maintained or enhanced from each generation to the next. This framework envisions environmental resources as a form of capital that contributes importantly to production and consumption and to the provisioning of nonmarket goods and services. As such, it calls for modeling and accounting techniques that explicitly gauge the value of natural capital stocks and the role they play in supporting the material economy. Weak sustainability, however, views natural capital, manufactured capital, and new technologies (i.e., blueprints used for combining inputs to produce outputs) as appropriate substitutes. Accordingly, it does not call for the conservation of environmental resources as a core policy objective. Rather, the focus is on maintaining the overall productive capacity of the economy and its ability to sustain human well-being in the long run.

Operationally, advocates of weak sustainability often argue that an economy is sustainable if the rate of investment in manufactured capital is at least as high as the monetary value of natural resource depletion. National governments and international agencies have therefore developed accounting frameworks for tracking changes in the monetary value of natural capital stocks. This approach, grounded in the early and important contributions of John Hartwick (1977), is strictly valid only under idealized conditions it holds for economies in which population, technology, and terms of trade are all constant through time, and where resources are allocated in a fully efficient manner through the correction of all market failures. In the face of population growth, a higher rate of capital investment is needed to achieve weak sustainability, while technological change allows society to derive higher well-being from a given set of capital assets. In theory, then, it is not possible to gauge the sustainability of an economy in the weak sense based on accounting metrics alone. Instead, forward-looking models are required that simulate the coupled dynamics of complex ecological–economic systems.

One interesting theme of the sustainability literature is its emphasis on the endogeneity of preferences and the complex relationship between economic growth and human welfare. Daly and Cobb's (1989) Index of Sustainable Economic Welfare (ISEW), for example, corrects a standard measure of per capita consumption for a wide array of social and environmental costs. This indicator suggests that the robust economic growth that occurred in the 1970s through the 2000s led to relatively little improvement in social welfare. This disparity can be explained by two factors: rising inequality and the social costs imposed by greenhouse gas emissions. While controversial in terms of its details, the ISEW indicator is interesting both for the clarity of its rationale and its attempt to provide a comprehensive welfare metric that accounts for a wide array of market and nonmarket goods. Similar results stem from survey research on life satisfaction or happiness, which suggests that relatively little improvement in experienced well-being has occurred in recent decades in the world's advanced industrial societies. This may be in part because economic growth has led to upward pressure on the social norms that define what people understand as the good life. Also, it may be that the gains of increased private consumption have been offset by declines in the quality of social interaction and other factors known to strongly affect happiness. While these results do not undercut the importance and legitimacy of the weak sustainability concept, they do suggest that it is inappropriate to gauge well-being using uncorrected measures of income and consumption.

The concepts of weak and strong sustainability point to a broad and pluralistic approach to understanding and managing the relationship between ecological and economic systems. On the one hand, it is surely salient to construct deep and meaningful measures of well-being plus models that project the welfare implications of environmental degradation over intergenerational time scales. On the other hand, Ciriacy-Wantrup's core arguments remain well taken in the face of uncertainty; conserving environmental resources is often essential in securing the life opportunities of future generations. This is an area of research and praxis and involves a deep engagement among multiple disciplines and among academic researchers, practitioners, and stakeholders.

TABLEAU ECONOMIQUE

The *Tableau Economique* is considered the forerunner to the circular flow of economic activity. The individual most associated with the Tableau is François Quesnay. The economic philosophy responsible for the creation of the Tableau Economique is the French Physiocrats, of which Quesnay was a member. The Physiocrats were an 18th-century French group who believed that wealth in an economy was based on agriculture surpluses through wages and rents, while consumption created economic wealth. They were also government minimalists. This was in contrast to the reigning philosophy of the day, mercantilism. Mercantilists believed that wealth was based on the accumulation of gold, silver, and other precious metals and that national wealth was the pinnacle of economic standards.

François Quesnay first introduced the Tableau Economique in 1759. Using the Tableau as their flow chart, Physiocrats labeled three classes of individuals in the economy. The first class, which the Physiocrats called the productive class, consisted of farmers, landowners, and other laborers in agriculture; they had no surplus, as they consumed all they produced. The second class, the sterile class, included artisans, merchants, and laborers in manufacturing and industry; they, too, consumed all they produced so there was no surplus to carry forward. The third class, the proprietor class, was much like proprietors in today's economy; they were people who generated agricultural products and rents and created the surplus for the future. An economy would be in a natural state of balance when all three sectors' income flows were equal. This natural state, once achieved, would replicate itself in perpetuity.

Quesnay pictured these three sectors of the economy in a zigzag pattern. In his zigzag diagram of a circular flow, he illustrated who and what each sector produced with who and what each sector spent and on what. Using the Tableau Economique, Quesnay was explaining how an economy grew.

As we now know, Quesnay was incorrect in his calculation about the sterility of the manufacturing sector. What the Tableau Economique did show was that the poverty in Quesnay's homeland of France was the direct result of the mercantilist philosophy that the French government was pursuing at the time. The work of Quesnay and his Tableau Economique laid the groundwork for Adam Smith's *An Inquiry into the Nature and Causes of the Wealth of Nations* and a whole new world of economic thinking.

THATCHER, MARGARET

Born: October 13, 1925, in Grantham, England; Died: April 8, 2013, in London, England; Nationality: English; Professional Interests: Prime Minister of the United Kingdom, 1979–1990; Awarded the Presidential Medal of Freedom in 1991; Major Works: *The Downing Street Years* (1993), *The Path to Power* (1995).

Margaret Thatcher made her mark in British politics and economics. The first woman to lead a major Western democracy, she was the British prime minister for more than 11 years. Thatcher reshaped almost every part of British politics and helped create a school of conservative, conviction-led politics. She left office in 1990 after winning three consecutive general elections, and she died on April 8, 2013, in London, England.

Margaret Roberts was born in Grantham, England, on October 13, 1925. Her parents, Alfred and Beatrice Roberts, were Methodists, and her childhood was based on an ethos of self-help, charitable work, and truthfulness. It was this upbringing that helped her to become the powerful politician and speaker that she was known to be. Her father was a local councilor in Grantham, and he often came home and talked to Margaret about the issues that had arisen in his work. Margaret went on to study chemistry at Oxford under the future Nobel Prize winner Dorothy Hodge, an experience that greatly influenced her outlook in politics. While at Oxford, she became president of the Oxford University Conservative Association, clearly demonstrating her interest in politics.

In 1951, Margaret married Denis Thatcher and took his surname. She also left her chemistry studies behind and ran as the conservative candidate for the safe Labour seat of Dartmouth. Margaret Thatcher twice failed to win the seat, but nevertheless gained national publicity. Her experience standing for election in Dartmouth also helped shape her political style; she was known to speak with poise and confidence on issues that mattered to voters.

In 1951 Thatcher studied to become a lawyer, and in 1959, she was elected to serve in England's Parliament as MP for Finchley. During the late 1960s, she established her place among senior figures of the Conservative Party as a shadow minister. In 1970, Thatcher achieved a cabinet position in Ted Heath's government as Education Secretary, which was not an easy position to gain or hold. Facing a bleak economy, she imposed a series of harsh budget cuts, the most notorious being the removal of a program left over from the days of the Great Depression that guaranteed a daily pint of milk to schoolchildren between the ages of 7 and 11. The abolition of this program gave Thatcher the nickname "Milk Snatcher," which haunted her for the rest of her career. The early 1970s also saw student radicalism at its peak, and Thatcher's speeches were often disrupted by protesters. In 1975, Thatcher was elected as the Conservative Party leader, becoming the first woman to lead a British political party. In 1976, she earned her iconic nickname, "Iron Lady," given to her by the Soviets for her uncompromising speeches against them. However, while she did not soften her criticisms of the Soviet system, when Mikhail Gorbachev became the new leader of the Soviet Union Thatcher declared him to be someone she could "do business with."

In the 1974 general election, no party had a majority. The Conservative Party won the popular vote, but the Labour Party took the most seats. Heath tried to negotiate a coalition with the Liberal Party but failed, and he subsequently resigned. The Labour Party, led by Harold Wilson, had established itself as the minority government. By the end of 1975, there had been some economic growth, but inflation was still high. In 1976, Wilson resigned and was replaced by Callaghan. During the winter of 1978–1979, public opinion was against the Labour government. "The Winter of Discontent," as it was dubbed, was characterized by widespread strikes by trade unions in response to the ongoing pay caps that Callaghan's Labour Party had imposed in an effort to control inflation. The government's inability to control the strikes helped the Conservatives (led by Thatcher) win a Parliamentary majority in the 1979 general election. The very next day, Thatcher took office, becoming the first female prime minister of the United Kingdom.

During Thatcher's first term as prime minister, from 1979 to 1983, her government pledged to check and reverse Britain's economic decline. Although the key economic goal during the first Thatcher government was controlling inflation, Thatcher took steps toward privatization through less government intervention in the economy, less government spending, and lower taxes. Thatcher's privatization was associated with marked improvements in performance (especially in labor productivity). Regulation was also expanded to compensate for loss of direct government control. At first, however, the measures she took were painful and produced no noticeable change in the economy. She did cut the abhorred direct taxes; however, she increased indirect taxes to make up for this loss of income. By the end of Thatcher's first term, more than 3 million British citizens were unemployed. Thatcher's reelection was made certain only by the British victory in the Falklands War. The British response to the Argentine invasion of the Falkland Islands in 1982 displayed the firm and careful touch for which Thatcher was known. When diplomacy failed, Great Britain's military action was quick and successful. The Falklands were back under British control in 1982. By fighting for the islands in a calm and efficient manner, Thatcher not only ensured her reelection but also increased public confidence in her.

In 1984, during Thatcher's second term (1983–1987), the government found itself dealing with a yearlong miners' strike. In 1986, the Irish Republican Army tried to assassinate Thatcher by bombing her hotel in Brighton during the Conservative

Party Conference. She survived unharmed, but some of her closest colleagues were injured or killed. Thatcher proceeded to negotiate the Anglo-Irish Agreement of 1985 to improve security and cooperation between Britain and Ireland. In 1985, Thatcher's reforms aimed at curbing the influence of the trade unions defeated the miners' union, proving that the reforms would endure. Thatcher, however, faced heavy criticism from within her own party for her decision to allow U.S. warplanes to fly from Britain's bases to attack Libya in 1986. But the economy continued to improve during the period from 1983 to 1987. With the strong economy, in June 1987, the Conservative government was reelected and Thatcher returned as prime minister for a third term.

Thatcher's third and final term was her most ambitious one. In 1988, she took measures to reform the education system by introducing a national curriculum. She also introduced a new tax system for local government, commonly known as the poll tax, which replaced the property tax. All of these measures, however, were controversial and stirred up heavy criticism. It did not help that the previously booming economy started to decline, and the public was made aware of a division within the government over different styles of management. Thatcher found herself at odds with her foreign secretary on everything involving European integration.

In 1990, many of her cabinet ministers had already begun to desert her by the time Michael Heseltine launched a challenge to her party leadership. Although Thatcher won the first ballot, she did not win by a wide enough margin to secure an outright victory. She resigned on November 28, 1990, and was succeeded by her chancellor, John Major.

After 1990, Thatcher remained an internationally recognized political figure, though the Conservative Party distanced itself from her. She wrote two memoirs, *The Downing Street Years* (1993) and *The Path to Power* (1995). She began touring and lectured around the world. In 1991, Thatcher received the Presidential Medal of Freedom from U.S. president George H. W. Bush.

Thatcher remains an intensely controversial figure in Britain. Critics claim that she was harsh and uncaring, pointing to her treatment of the coal miners in the 1980s, the withdrawal of free milk for children, and the controversial poll tax, while defenders point to how much Britain's economy grew and changed under her administration. Both critics and supporters recognize her time in government as a period of significant change in British political history.

Margaret Thatcher died of a stroke on April 8, 2013, in London, England, at the age of 87.

THEORY OF PUBLIC CHOICE

The *theory of public choice* (or public choice theory) is rooted in the application of economic principles used by economists to understand and predict people's actions in the marketplace. It also deals with understanding government or political behavior in collective decision-making situations. The theory states that no matter which roles people play in the collective decision-making process—voter, elected official, or interest group—they are largely motivated by self-interest.

Public choice theory dates to the 1950s, and it evolved throughout the early 1970s. The founders of the theory of public choice include Anthony Downs, James Buchanan, Duncan Black, Kenneth Arrow, Gordon Tullock, Mancur Olson, and William Niskanen.

Modern public choice theory begins with Anthony Downs, who is known for the idea that voters are not always aware of current political issues. He believes that the vote of one person generally does not decide an election. Therefore, most informed voters reason that their votes will be canceled out by those of uninformed voters, making their time investment in becoming informed a waste. The informed voter then rationalizes a zero–sum game in being knowledgeable about the issues. As a result, since most voters are easily influenced, politicians do what they can to get votes and win an election. Downs also believes that some people vote simply to preserve the democratic practice and that people vote based on their pocketbooks or how well-off they are—or are promised to be (Pressman 2004).

James Buchanan is considered to be a founder of public choice theory, and he earned a Nobel Prize in Economic Sciences in 1986. He is famous for referring to the theory as "politics without romance" (Buchanan 2003), meaning that there are many self-interested factors that influence the decision-making of politicians and bureaucrats.

In 1962, James Buchanan and Gordon Tullock wrote *The Calculus of Consent: Logical Foundations of Constitutional Democracy*, which describes how economists view the organization of the political society. The authors examine how government officials, politicians, and bureaucrats use their self-interest when making decisions on behalf of the public. Both men also look to the U.S. Constitution as a basis for how the government works and how it can be regulated. In this work, they also emphasize voting and how majority rule is necessary when approaching public issues. In the end, if everyone is aware of the rules in democratic society, even self-interested politicians are not dangerous to society as a whole because the Constitution itself places limitations on things such as the powers of the government. These ideas have evolved into a theory called constitutional economics.

Mancur Olson, the author of *The Logic of Collective Action: Public Goods and the Theory of Groups* (1965), is known for the idea that public choice is heavily influenced by interest groups who seek to redistribute wealth. Despite this, these groups often struggle to gain support from those who would benefit the most from their work. Interest groups, or lobbyists, fight for specific causes or reforms for citizens and are rewarded by getting politicians to listen to their concerns. For example, an interest group that's pushing for a higher minimum wage might ask a particular congressperson or senator to help introduce a bill on the issue.

The theory of public choice applies economic principles to understanding and predicting the decision-making actions of legislators. Legislators, elected to carry out the best interests of their constituents, make decisions on behalf of many others, not just themselves. Legislators may also engage in pork-barrel politics or logrolling, trading votes on one issue in order to gain something in another area. *Pork-barrel politics* involves politicians promising something to constituents to gain their support. In an effort to gain votes, the politician might promise to spend more on local public schools, be tough on crime, or build a new public park. *Logrolling* involves politicians supporting the bills of other politicians in an effort to gain support for a bill that is important to them. Politicians are often criticized for these practices, but politicians use them to gain things for the districts they represent. In this case, the constituents would be pleased with their legislators because they are bringing benefits to their local city or town.

Another element emphasized in the theory of public choice is government failure and the idea that sometimes government intervention in the marketplace can do more harm than good. For example, a government of a country decides to take over its health care system in an effort to streamline it and make it more affordable for citizens, but instead makes the health care system worse off. When a government intervenes in the economy, its goal is to put something in place that the people will view favorably. Perhaps this new health care reform policy is what people favor, but at the same time it puts more power in the hands of the government—and too much government involvement can cause the government to fail.

Today, the theory of public choice still focuses on collective decision-making and its impact on the political world. Political parties are increasingly working toward appealing to the median voter, and voters seek to weigh the costs and benefits of policies when voting for a particular political party.

TRADE-OFFS

The title line from the popular song "You Can't Always Get What You Want" by the Rolling Stones (a British rock band that got its start in the 1960s) announces the basic dictum of economics. Anyone exposed to this song was, perhaps unknowingly, being introduced to the prime economic concept of trade-offs. While the resources available to produce economic goods and services are limited, the desire to obtain the goods and services is limitless. Economic wants are unlimited, yet the ability to produce goods and services is limited. Therefore, it is up to an economic system to make choices and decide the trade-offs of an economy. When decisions are made to allocate resources to a set of goods and services, the same decision is also claiming that society is not going to allocate those resources to other goods and services. There is a trade-off between what to produce and what not to produce.

A trade-off describes what you sacrifice to get something else. Scarcity forces people and societies to make choices—and choices always involve a trade-off. Trade-offs are part of everyone's daily life. Whether it is how we spend our income or what we do with our time, our resources are never enough. Every time we make a decision, we are giving up the possibility of choosing something else or doing something else with that resource. Every trade-off has both a cost and a benefit that must be considered.

Every choice has a cost, called the "opportunity cost." *Opportunity cost* refers to the cost of not choosing what was given up. For example, one might choose to read this entry instead of making a sandwich. The trade-off is giving up time needed to make the sandwich for the chance to read. Opportunity cost refers to what was given up. In this example, the opportunity to eat was relinquished. Most decisions are not a matter of "all or nothing." They are made incrementally, or at the margin. This is known as "marginal analysis."

Our world is one of trade-offs and opportunity costs at all levels of life. Since all decisions involve a trade-off and an opportunity cost, trade-offs are made by individuals, families, companies, and governmental agencies at all levels—and, more and more often, globally. All these entities have limited resources and therefore must give up something with each decision. Not all decisions are made in the same way. Companies make decisions via their leadership or stockholders. Government decisions are made by voters or those who are voted into office. Consumers make decisions in the marketplace. Not all trade-offs are identical. One consumer may choose a hamburger over french fries, while another consumer may choose a hamburger over a soda.

Another type of trade-off made by economic systems is between the social goals of an economy. One society may decide that economic security is more important than economic freedom. Yet another economic system may choose economic freedom over economic security. While both may be worthwhile, an economic system and a society must decide which is more important. Societal and economic system decisions, and their trade-offs, are made by political leaders, by voters when they vote, or by consumers when they vote with their money in the marketplace.

Individuals face similar dilemmas. All of the choices that individuals make in the marketplace involve a trade-off of another good or service. In a market economy, the decisions and trade-offs of consumers determine which goods and services will be produced and which will not. As a result, the market economy decisions of consumers determine which businesses will be successful and which will fail. Any situation that involves losing one quality or aspect of something in return for gaining another quality or aspect can be considered a trade-off. Everyone, everywhere, has been forced to make decisions with trade-offs. The decision to read this entry has taken away the time to spend doing something else. The term *trade-off* may refer to a decision made with full comprehension of both the up side and the down side of a particular choice; it can also be used in an evolutionary context, in which case the selection process acts as the "decision-maker."

This concept does not apply only to decisions involving money. Every time you are asked, "Would you like fries with that?" or your Amazon checkout reminds you that there is free shipping on orders over $25, you are being asked to practice marginalism and make trade-offs that will afford you the greatest satisfaction for your buying power. Producers, in an attempt to maximize profits, will seasonally adjust the size of the workforce and the items produced. If you want to lifeguard in the winter or eat a mince pie in July, you are likely to be disappointed. At times like that, it is a good idea to remember the wisdom of the Rolling Stones.

TVERSKY, AMOS

Born: March 16, 1937, Haifa, British Palestine (Israel); Died: June 6, 1996, Stanford, California; Nationality: Israeli; Major Works: *Prospect Theory* (1974), *Choices, Values and Frames* (2000).

Amos Tversky, born in Israel to immigrant parents in 1937, served courageously in the Israeli military, and then completed his undergraduate education at Hebrew University of Jerusalem. In 1964, he received his PhD in psychology from the University of Michigan, and continued his academic career through teaching positions at Michigan, Harvard, and Hebrew University. In 1970 he joined the Center for Advance Studies in the Behavioral Sciences at Stanford as a fellow, and in 1978 he joined the Stanford faculty of psychology. Afterward, he received prestigious awards and fellowships, as well as four honorary doctorates in psychology and other fields. He passed away at age 59 and is survived by his two sons and one daughter. His wife, Barbara, whom he met in Michigan, is a professor emerita of psychology at Stanford University.

Tversky is known for extending psychological findings to other fields, especially economics, law, and medical decision-making. *Rational decision theory* assumes that people seek information in logical ways and use information to calculate probabilities or chances for possible outcomes, and then combine their findings to choose the option with the highest payoff. Tversky turned his observations of advertisers and salesmen into mathematical relations and used the resulting models to test the assumptions of economic rationality. For example, rational people experience the same level of utility from receiving $1 as they feel loss from losing $1 (this time in the negative domain). But, in reality people weight losses more than gains in terms of utility. *Loss aversion* refers to the reality that the loss of $1 causes more bad feelings than the good feelings brought by the gain of $1. As a result, people deal differently with losses and gains. In 1974, Tversky and Kahneman developed this idea in the book *Prospect Theory*. Together, these scholars also generated a list of “cognitive illusions,” which are the basis for predictable mistakes and have generated a sizable literature. Together with Paul Slovic, they outlined an approach to human decision-making based on heuristics and errors and biases.

Heuristics are rules of thumb that people regularly use to make choices in risky situations. These rules do not completely agree with the rules of logic or statistics.

The *heuristics and biases* view holds that people are predisposed to make certain errors because of their mental biases. *Anchoring* is an example of biases that are hard for the human mind to overcome: When starting with a larger number, people make larger estimates because they are anchored on the first value received. In general, people react to information based on the form of presentation or the *framing* of information not based on logic. For instance, patients are more willing to accept a treatment if the doctor says, "There is a 99% chance of cure," and they're less willing when told, "There is a 1% chance of death."

Tversky's legacy is bringing vigor to cognitive psychology by providing a mathematical or more logic-based framework that allows testing the assumptions of rational decision theory with respect to observed behavior. The results from such studies forced theorists to pay attention to actual human behaviors as they exert an impact on decision-making and the decision-making process, which in turn contributed to the emergence of fields such as behavioral economics.

U

UNITED NATIONS SYSTEM

The United Nations System consists of the six branches of the United Nations (UN), and 25 autonomous specialized agencies, programs, and funds. The United Nations System promotes world peace, sustainable economic development, and human rights. In 2000, the UN adopted the Millennium Development Goals (MDGs) to focus the energy of the United Nations System and other international organizations on poverty reduction, sustainable economic development, and related objectives.

The UN was born in 1945 when 51 countries formally adopted the UN Charter at the San Francisco Conference. Membership climbed during the post–World War II era, as newly independent countries from the developing world joined the UN. The largest membership increase occurred during the 1960s, when 44 nations, mainly from Africa, joined the UN. In 2016, the UN comprised 193 countries. The secretary-general is the UN's leading official.

The six principal branches, or organs, of the UN protect the personal and economic security of the world's peoples. UN branches include the General Assembly, Security Council, Economic and Security Council, Trusteeship Council, International Court of Justice, and Secretariat. Five UN branches are located in New York City. The sixth, the International Court of Justice, or World Court, is located in The Hague, Netherlands.

The United Nations System also consists of 15 specialized agencies, and 10 special programs and funds. These institutions of the UN family are autonomous, self-financing bodies. Yet, the specialized agencies, programs, and funds are linked to the UN through formal agreements and a shared mission to improve the human condition. Many institutions of the UN family are directly involved in promoting sustainable economic development. Key specialized agencies within the UN family include the following:

- **World Bank Group:** The World Bank Group works to reduce world poverty and promote sustainable economic development. Through its five complementary institutions, the World Bank Group makes development loans, provides technical assistance, and supports foreign investment in developing countries.
- **International Monetary Fund (IMF):** The IMF promotes financial and monetary stability and economic growth in developing countries. Its main policy tools are financial assistance, technical assistance, and financial and monetary surveillance.
- **World Health Organization (WHO):** The WHO sets global health standards and supplies technical and financial assistance to strengthen nations' health programs. WHO assistance is vital to human capital development in the world's poorer regions.

- **International Labor Organization (ILO)**: The ILO establishes and monitors core labor standards to safeguard workers' rights and improve working conditions and wages. The ILO's labor standards set a benchmark for acceptable labor practices in the global economy.
- **United Nations Educational, Scientific and Cultural Organization (UNESCO)**: UNESCO promotes educational opportunity, scientific collaboration, and cultural preservation and development. Its mission directly supports human advancement in the developing world.
- **Food and Agriculture Organization (FAO):** The FAO strives to improve people's standard of living and quality of live by boosting agricultural productivity, mainly in the developing world. Agriculture is the backbone of many of the world's least-developed countries (LDCs).
- **World Intellectual Property Organization (WIPO):** WIPO protects copyrights, trademarks, patents, and other forms of intellectual property in the global economy. The protection of intellectual property encourages invention, innovation, and entrepreneurship.

A number of autonomous UN programs and funds also support global poverty reduction and sustainable economic development. Key programs and funds include the following:

- **United Nations Development Program (UNDP):** The UNDP sponsors development projects, especially those directly related to the overriding goal of poverty reduction. Projects reverse desertification; provide advanced education and training for women; and promote agricultural development, technology sharing, and infrastructure construction.
- **United Nations Environment Program (UNEP):** The UNEP promotes environmentally sound programs and sustainable economic development in the developing world. UNEP projects expand access to clean water, reverse local environmental degradation, and introduce appropriate technologies. Globally, the UNEP works to reduce global warming, ozone depletion, desertification, deforestation, acid rain, and threats to the world's biodiversity.
- **United Nations Children's Fund (UNICEF):** UNICEF provides a number of basic services to the developing world to improve people's quality of life. UNICEF programs improve nutrition and health care, sanitation systems, education, and other social services for women and children. UNICEF also responds to people's needs after natural disasters and other crises.
- **World Food Program (WFP):** The WFP provides food aid, mainly to alleviate human suffering in crisis situations. WFP food aid reaches refugees and others dislocated by civil strife, warfare, or other human calamity. The WFP is the world's largest food aid organization.
- **United Nations Population Fund (UNFPA):** The UNFPA supports programs to improve reproductive health, a precondition for sustainable economic development. Specific initiatives help young people plan their families, avoid sexually transmitted diseases, and stop violence against women.

The United Nations has also sponsored major international conferences, approved global resolutions, and used its prestige to promote positive change in the global economy. For example, in 1992 the United Nations Conference on

Environment and Development, more commonly called the Rio Earth Summit, produced *Agenda 21*—the world's most comprehensive statement on sustainable production, worker and human rights, and protections for the natural environment and indigenous peoples. In 1999, the UN's Global Compact garnered international support for corporate social responsibility in the realms of human rights, worker rights, and environmental protection. In 2000, the UN's MDGs gave focus to global development efforts. Today, the work of such multilateral institutions as the World Bank Group and the IMF is guided by measurable objectives listed in the MDGs.

UNITED STATES CENSUS BUREAU

The United States Census Bureau collects data on the quality of life of U.S. citizens and the state of the U.S. economy. There are two types of U.S. Census Bureau programs: economic and demographic. Most widely known for its data collection on the U.S. population and housing every 10 years, the U.S. Census Bureau also collects data every five years on the economy and government. The economic, agriculture, and government censuses taken every five years comprise more than 98 percent of U.S. economic activity. The Census Bureau also collects data on U.S. foreign trade.

The data collected are used in many ways, including allocation and planning. One of the most important areas is population and housing data, collected each decade and used to determine the number and location of congressional seats in the House of Representatives. At the federal level, census data are also used to determine distribution of federal funds to local governments. Many state and local governments use the data to identify their legislative districts. The census data are also used by local governments to identify and plan where roads may be built, to determine school district boundaries, or to determine the distribution and location of public health care facilities. A second area of service provided by the U.S. Census Bureau is age-related data drawn from its population census. The federal government uses Census Bureau data to plan and budget for Social Security and other age-related government benefits and federal programs.

The first census of the U.S. population (censuses had been conducted in the 13 American colonies as well) was taken in 1790, as ordered in the U.S. Constitution. The census was carried out by Secretary of State Thomas Jefferson. It was used only as a head count, and it only classified the population by age (over 16 or under 16 for white males), race, and sex. The first censuses were taken by local census-takers, who asked only a few basic questions, then tabulated and reported the results locally. This simple process became more complex and the questions more detailed as the country grew and as political and business leaders came to understand the value of the data. Today, the Census Bureau conducts over 200 surveys.

In the early days of the census, U.S. marshals were responsible for collecting information. They had no training on what information to gather, no forms on which to record the information they obtained, and no schedules for when to conduct the census. In 1879, part-time trained census-takers were hired to replace the marshals and conduct the 1880 and subsequent door-to-door censuses. The U.S. Census Bureau began using mail questionnaires beginning with the 1960 census. Today, census-takers are used only for remote areas, special circumstances such as shelters and soup kitchens, and nonresponse follow-ups. The 2010 census was the first census in which the census-takers used hand-held GPS devices.

The census expanded its information-gathering in 1810 to include economic data, such as manufacturing and products being produced. In 1840, it expanded again to gather data on the additional economic sectors of agriculture, fisheries, and mining. The 1850 census data expanded even further, covering for the first time demographic data on taxes, church attendance, and crime. With each subsequent census, the amount of data collected increased. Through an act of Congress in 1902, the U.S. Census Bureau became a permanent agency of the federal government, located in the U.S. Department of Commerce.

Once it became a permanent government agency, the U.S. Census Bureau greatly expanded its data-gathering abilities. During the 20th century, the Census Bureau significantly expanded its ability to accumulate economic information. It created three new surveys that continue to be used today: the American Housing Survey, the Current Population Survey, and the Survey of Income and Program Participation. These new programs go far beyond the historical decade population survey.

Not only has the Census Bureau expanded its date-gathering capabilities; it has led the world in technology innovation. The U.S. Census Bureau was the first nonmilitary government agency to enter the computer age. The 1950 census was tabulated by a UNIVAC I computer, one of the fastest and most modern computers of its time. The global positioning systems (GPSs) we now enjoy in our cars and on our cell phones are directly attributed to the cartographic innovations of the U.S. Census Bureau during the 1970s and 1980s. Census data-gathering has grown from neighborhood walks and local surveys to computer tape and CD-ROMs, and now to the Internet.

The U.S. Census Bureau is headquartered in Suitland, Maryland. The bureau also has 12 regional offices, in Atlanta; Boston; Charlotte, North Carolina; Chicago; Dallas; Denver; Detroit; Kansas City, Kansas; Los Angeles; New York; Philadelphia; and Seattle. The Census Bureau director is appointed by the president and confirmed by the Senate.

UNITED STATES MINT

The United States Mint is part of the Department of the Treasury and is responsible for producing, manufacturing, and distributing coins as well as providing security for the nation's $100 billion in gold and silver assets.

Article 1, Section 8, of the United States Constitution states, "The Congress shall have power . . . [t]o coin money, regulate the value thereof, and of foreign coin, and fix the standard of weights and measures." With this statement, the Constitution places the power of creating a monetary system on Congress. The task of developing this system fell to the first Secretary of the Treasury, Alexander Hamilton. As soon as he began his term in 1789, Hamilton was quick to organize the nation's finances and come up with ideas about how to make the United States an industrial powerhouse. His ideas included establishing a national bank, funding the national debt, taking on the war debts of individual states, and encouraging manufacturing. With Hamilton's assistance, Congress passed the Coinage Act on April 2, 1792. The Coinage Act created the U.S. Mint and authorized construction of a building to house it. At that time, the nation's capital was in Philadelphia. When construction began, the U.S. Mint was the first federal building erected under the Constitution.

The primary mission of the U.S. Mint is to serve the American people by manufacturing and distributing precious metals and collectible coins and national medals, and providing security for the assets entrusted to the Mint. One of its most important jobs is to manufacture and distribute coins. The production of these coins takes place primarily at the Philadelphia and Denver Mints.

The U.S. Mint operates six facilities across the United States, with each facility performing unique functions. These facilities include the Mint headquarters in Washington, D.C., and production facilities in Philadelphia, Pennsylvania; West Point, New York; Denver, Colorado; and San Francisco, California. In addition, there is the United States Bullion Depository at Fort Knox, Kentucky, which does not produce anything but serves as a storage facility for the nation's $100 billion in gold and silver bullion.

The facility in Washington, D.C., is responsible for policy formulation, administrative guidance, program management, research and development, marketing operations, customer services, and order processing. The Philadelphia Mint is responsible for all engraving, manufacturing of coin and medal dies, and production of circulating coins. The Denver Mint is also responsible primarily for circulating coins. Both the Philadelphia and Denver Mints are open to the public for tours. The San Francisco Mint is responsible for producing proof coins for numismatic collectibles as well as some commemorative coins. The West Point Mint is responsible for manufacturing gold, silver, and platinum bullion and proof and uncirculated coins, and it also strikes some commemorative coins.

UNITED STATES SOCIETY FOR ECOLOGICAL ECONOMICS

The United States Society for Ecological Economics (USSEE) is one of several regional professional organizations within the broader scope of the International Society for Ecological Economics (ISEE). USSEE and the other regional ecological economics organizations provide a venue for intellectual exchange and collaboration on issues related to the theory, policy, and implementation of sustainability and sustainable development. USSEE consists of interdisciplinary scholars and practitioners who seek to develop integrated solutions to our most pressing economic, social, and environmental problems, and who care about the well-being of the earth. Other regional ecological economics societies represent ecological economists in Africa, Australia–New Zealand, Brazil, Canada, Europe, India, Latin America, and Russia. All ecological economics societies hold professional meetings that serve as a forum for exchanging information, presenting cutting-edge research results, and advancing practical solutions toward an ecologically sustainable and economically viable future.

Ecological economics is the science of sustainability, which is predicated on the notion that environmental problems are complex and nonlinear, and that transdisciplinary approaches are required to solve them. This integration of economic, social, and ecological systems brings together scholars and practitioners from a variety of natural and social science disciplines. The common goal of ecological economists is to enhance theoretical understanding and practical solutions for achieving long-term economic and social well-being, without undermining the absorptive, regenerative, and resource capacity of the natural environment. The focus of the USSEE is on developing new approaches to understanding our economy and its dependence on the biophysical systems that govern life on earth. USSEE is intentional about advancing dialogue across different disciplines, backgrounds, and professional contexts to address pressing social and ecological problems. The society is particularly interested in identifying concrete solutions and actions to bring about a more just and sustainable future.

The USSEE is a membership organization, and USSEE members are also members of the ISEE. A portion of annual dues paid to the ISEE are contributed to USSEE initiatives and activities.

The USSEE was founded in 2000. Its past presidents have been Robert O'Neill (2000–2001), John Gowdy (2002–2003), Barry Solomon (2004–2005), Karin Limburg (2006–2007), Sabine O'Hara (2008–2009), Jon Erickson (2010–2011), and Valerie Luzadis (2012–2014).

The board of directors of the USSEE establishes policy for the society and is responsible for the fulfillment of the stated purposes of the society. Officers of the society include the president, president-elect, immediate past president, and secretary-treasurer. The USSEE board of directors comprises eight individuals—drawn from the president, president-elect, immediate past president, secretary-treasurer, four at-large members—and one student member. The positions of president-elect and immediate past president are vacant every other year for periods of one year so that the two never simultaneously serve on the board. The at-large members, student member, secretary-treasurer, and president-elect are elected by a direct vote of the USSEE membership.

The USSEE's biennial conferences provide a national and international forum to focus on the latest issues in ecological economics and to share information about new developments and activities. Biennial conferences provide opportunities for students of ecological economics to present their research and to engage with scholars in the field. Students are represented on the USSEE board, and the society provides financial aid and volunteer opportunities to students to enable them to participate in meetings in order to present work and share ideas for the future. USSEE biennial conferences are held in odd-numbered years, and ISEE conferences are held in even-numbered years. The inaugural conference for the USSEE was held in Duluth, Minnesota (2001), and subsequent conferences have been held in Saratoga Springs, New York (2003); Tacoma, Washington (2005); New York (2007); Washington, D.C. (2009); East Lansing, Michigan (2011); and Burlington, Vermont (2013).

In between conferences, USSEE board and members work to advance knowledge in ecological economics through publications, higher education, workshops, blogs, and other formal and informal communications. *Ecological Economics*, the long-standing transdisciplinary journal of the ISEE, is concerned with extending and integrating the study and management of nature's household (ecology) and humankind's household (economics). This integration is necessary because conceptual, academic, and professional isolation has led to economic and environmental policies that are mutually destructive rather than reinforcing in the long term. USSEE previously sponsored the publication of *Ecological Economics Reviews* as a special issue of the *Annals of the New York Academy of Sciences*. The USSEE also supports regular webinars related to ecological economics, edited collections of papers from biennial conferences, and regular posts to an online blog that highlights education opportunities, publications, general discussion topics, and related job postings.

The USSEE honors scholars and practitioners in ecological economics through the Herman Daly Award, which is given in honor of Herman Daly, one of the visionaries who founded the field of ecological economics. The award is designed to recognize individuals who have connected ecological economic thinking to practical applications and implementation of solutions that are sustainable in scale, equitable in distribution, and efficient in allocation. The award is given in conjunction with the USSEE biennial conference. Past recipients of the Herman Daly Award include David Batker (2003), Mathis Wackernagel (2005), Gretchen Daily (2007), John Gowdy (2009), Juliet Schor (2011), and Annie Leonard (2013).

The USSEE also provides leadership in curriculum development at the undergraduate, graduate, and continuing-education levels in such academic fields as environmental science, environmental studies, ecological economics, policy, management, law, and ethics. UNIVERSITY ECONOMICS DEPARTMENTS

Many economic programs offer doctoral degrees with a specialty in environmental and resource economics and/or agricultural economics. University of California at Riverside, University of New Mexico, and University of Wyoming were among the first schools (1969, 1974, and 1975, respectively) to begin offering the environmental and resource economics field as part of their doctoral degree in economics. However, students seeking a doctorate in economics with a field in environmental and resource economics have a host of universities to choose from, including both traditional economics departments and agricultural economics departments.

Agricultural economics departments are listed on the Agricultural and Applied Economics Association website (www.aaea.org) and on individual department websites. Graduate programs in economics are listed on the American Economic Association website (www.aeaweb.org) and on individual department websites, and are also obtained through email correspondence. Some departments provide students flexibility to choose a field without limiting the choices offered by the program.

The following agricultural economics departments offer a PhD in the field of environmental and resource economics (in alphabetical order): Arizona State University, Auburn University, Colorado State University, Cornell University, Iowa State University, Kansas State University, Michigan State University, North Carolina State University, Ohio State University, Oklahoma State University, Oregon State University, Pennsylvania State University, Purdue University, Texas A&M University, Texas Tech University, University of Arizona, University of California at Berkeley, University of California at Davis, University of Connecticut, University of Georgia, University of Florida, University of Illinois, University of Maryland, University of Minnesota, University of Missouri, University of Nebraska, University of Rhode Island, University of Tennessee, University of Wisconsin, Utah State University, Virginia Tech University, Washington State University, and West Virginia University.

The following economics departments offer a PhD in the field of environmental and resource economics (in alphabetical order): Arizona State University, Auburn University, Clemson University, Colorado School of Mines, Colorado State University, Cornell University, George Washington University, Georgia State University, Harvard University, Iowa State University, Michigan State University, North Carolina State University, Oregon State University, Rensselaer Polytechnic Institute, Stanford University, SUNY Binghamton, Texas Tech University, Tulane University, University of Arizona, University of California at Riverside, University of California at San Diego, University of California at Santa Barbara, University of Colorado, University of Connecticut, University of Delaware, University of Hawaii, University of Kentucky, University of Maryland, University of Miami, University of Michigan, University of New Mexico, University of Notre Dame, University of Oregon, University of Rhode Island, University of Tennessee, University of Texas, University of Utah, University of Washington, University of Wyoming, Vanderbilt University, Virginia Tech University, Washington State University, West Virginia University, and Yale University.

Many schools appear in both the agricultural economics and economics lists. In these cases, a PhD in environmental and resource economics is offered through both programs, either as a separate program or a joint program.

Economists and prospective students are interested in how academic departments fare relative to others in research productivity. Such rankings serve as an aid in benchmarking research productivity, aligning perspective graduate students with PhD programs, or matching job candidates with potential academic employers. In the field of environmental and resource economics, studies provide rankings for economics departments based on faculty research productivity in *Journal of Economic Literature* (JEL) category Q, which is Agricultural and Natural Resource Economics; Environmental and Ecological Economics. Rankings are typically based on quality-weighted publication measures such as citation impact scores. Other methods of department rankings include surveys of faculty, graduate student placements, and journal article page counts in select journals.

Using faculty publications between 1985 and 2010 provided in the Econlit database and quality indicators provided by the Social Science Citation Index (SSCI) and Research Papers in Economics (RePEc) in JEL category Q, the top agricultural economics programs (in ranked order) are the University of California at Davis, Iowa State University, University of Maryland, University of California at Berkeley, Cornell University, North Carolina State University, Purdue University, University of Illinois, University of Minnesota, Michigan State University, University of Wisconsin, Ohio State University, Texas A&M University, Oregon State University, Washington State University, and Utah State University.

The top economics departments (in ranked order) are Iowa State University, University of Wyoming, North Carolina State University, Yale University, Harvard

University, University of California at Santa Barbara, SUNY Binghamton, University of Rhode Island, Massachusetts Institute of Technology, Stanford University, University of Colorado, University of Connecticut, Georgetown University, and Rensselaer Polytechnic Institute.

There are differences in the top departments in the subdisciplines of JEL category Q. In JEL category Q1—Agriculture—agricultural economics departments dominate the top 10 based on total productivity in this field. The top 10 departments (in ranked order) are the University of California at Davis, Iowa State University, Purdue University, Cornell University, North Carolina State University, University of California at Berkeley, University of Illinois, University of Maryland, Michigan State University, and University of Minnesota.

In the other JEL subdisciplines—Q2,·renewable resources and conservation; Q3,·nonrenewable resources and conservation; Q4,·energy; and Q5,·environmental economics—there is a mix of agricultural economics and economics departments in the top 10. The top departments in the field of renewable resources and conservation (in ranked order) are the University of Wyoming, University of Maryland, University of California at Davis, University of California at Berkeley, Iowa State University, North Carolina State University, University of Illinois, Cornell University, University of Minnesota, and Ohio State University.

The top departments in the field of nonrenewable resources and conservation (in ranked order) are the University of California at Berkeley, University of Maryland, University of California at Santa Barbara, University of Wyoming, University of California at Davis, University of Minnesota, University of Wisconsin, Cornell University, Purdue University, and University of Colorado.

The top departments in the field of energy (in ranked order) are the University of Wyoming, Cornell University, Iowa State University, University of California at Davis, Harvard University, University of Minnesota, University of California at Berkeley, Purdue University, University of California at Santa Barbara, and Texas A&M University.

The top departments in the field of environmental economics (in ranked order) are the University of Wyoming, University of Maryland, University of California at Santa Barbara, Michigan State University, University of California at Berkeley, University of Illinois, Iowa State University, University of California at Davis, Oregon State University, and Cornell University.

While schools may be ranked differently according to their productivity, statistical analysis indicates that there may be minimal difference between groups of schools.

URBANIZATION

Urbanization is the process by which cities develop from smaller villages and towns. Cities form and expand when people from many different, often rural, areas move to the same central locations, forming large communities. Urbanization is a historical process that has occurred for millennia, with larger and larger populations concentrating in small geographic areas over the centuries.

The formation of cities is primarily accomplished through economic forces, with most migrants to cities seeking employment or other benefits such as natural resources. For this reason, cities have generally emerged in areas with favorable climates, with high natural resource concentrations, and with emerging industries seeking to expand. While the process of urbanization as led to many economic advances, it has also caused concerns. Both historically and in modern times, prevalent issues for large cities include sanitation, pollution, and overcrowding.

Early urbanization traces to the formation of cities in Mesopotamia in the fertile valley between the Tigris and Euphrates Rivers. This land was especially suitable for agriculture due to its proximity to the rivers. The rivers provided resources and facilitated transportation by water. This being the case, people from different groups migrated to this area of abundance, concentrating in the small portion that afforded them the greatest economic opportunities. Famous cities—including Uruk, Babylon, and Nineveh—emerged in Mesopotamia, generally concentrated on the banks of the rivers.

In the centuries and millennia after these cities arose, urbanization continued to predominate in areas with abundant natural resources, in particular along waterways. Prominent cities the world over—including London, Tokyo, and New York—have emerged along the coasts of rivers, lakes, and oceans. The original factors that drove the settlement of coastal areas (fertility of land and transportation) still invite urbanization in these regions.

During the Industrial Revolution of the 18th and 19th centuries, power emerged as a new necessity. By locating along water, factories could capture energy from the movement of water to operate machines mechanically. Eventually, the need for electricity led to the development of hydroelectric methods for obtaining energy from water's motion. The availability of energy led factories to locate along the water and in turn brought workers to these cities, spurring a new age of urban growth and increasing population density.

This entrance of job-seekers into cities demonstrates the relevance of this group even in the modern era of job specialization. While most people no longer need direct access to the natural resources surrounding their cities, settling these concentrated areas still offers many benefits. In addition to increased job opportunities, cities offer many more cultural attractions than are available in most rural areas. They also facilitate the easy transfer of ideas and resources, allowing for increased trade and innovation while encouraging an improved standard of living and creating more opportunities for human growth and development.

Urbanization has generally led to improved conditions for the concentration of populations, but it also has had many consequences. Waste management and lack of adequate sanitation have always been challenges in cities, resulting in health hazards. Having many people in close proximity has facilitated the spread of disease, with many deadly outbreaks arising in cities due to increased opportunities for exposure and transmission. Tensions between different ethnic, socioeconomic, and racial groups increase when the groups are so near each other. This closeness has resulted in the rise of crime—in particular, organized crime—in the cities.

WAR OF 1812

The War of 1812 between the United States and Britain was about economics and trade. The problem started with *impressment* (the act of seizing for public use or public service) of sailors. Conditions on British ships were particularly poor; a harsh system of discipline was used, and British sailors were often forced into service. In contrast, American sailors made about $30 a month compared with $7 a month for British sailors. As a result, British sailors often signed on with American ships. To combat this practice, British ships began to stop American ships and search for British deserters.

In a British seizure, rule of law was lacking, as the British authorities impressed sailors for being deserters—on suspicion alone. In just one year, 250 American flagged ships were seized and searched. Between 1808 and 1811, more than 6,000 sailors were impressed from American ships. Another underlying factor in the dispute was the rise of American shipping and the decline of British shipping. Further economic tension between the United States and Great Britain occurred on the western frontier. Britain wanted to hold on to the fur trade. Americans had also become expansionists, looking west for land. Even Southerners were looking west for land as tobacco depleted the soils of Maryland and Virginia. In the long view, the United States and Britain had never ended the mutual economic warfare that had started in 1776.

The political and military conflicts in Europe complicated the situation. The British and French were at war with each other and were consequently interfering with American trade, and the American public was split on which nation to support in the Napoleonic wars. In New England, many sailors and their families believed the United States should declare war to stop impressments. Yet New England was suffering from the loss of trade before the war, and for economic reasons, therefore, many opposed America's entering the war. The western states of Ohio, Tennessee, and Kentucky wanted war because the British were interfering with the fur trade and western expansion. In 1811, Congress changed hands and was led by Speaker Henry Clay, a Kentuckian and a war hawk. President James Madison was under pressure to declare war after being sworn into office in 1812.

On June 18, 1812, the United States declared war against Britain, and initially found success as Great Britain was bottled up in a war with Napoleon. Britain hoped to win by a naval blockade because of the United States' dependence on trade with Britain and her colonies. The interruption of trade not only hurt citizens but also caused a major decrease in tariffs, which were the main source of government revenues. The U.S. government moved from having a surplus to having to make loans to cover its debt. Government expenses soared, too, as the army and the navy needed to expand. By 1814, the United States was again moving into deep debt.

The British blockade of America was devastating, and prices soared. The blockade prevented use of the sea route from the Midwest down the Mississippi to New Orleans and then by ship to New York and Philadelphia. Kentucky and Tennessee whiskey prices tripled in New York. Wagon trains over the Appalachian Mountains were needed to meet demand. Sugar from the West Indies could still get to New Orleans, but not direct by sea to New York. Sugar that sold for $9 a pound in New Orleans cost $40 a pound in New York. South Carolina rice, which normally went by sea to New York, was blockaded as well. This drove rice prices from $3 per 100 pounds to $12 per 100 pounds.

As the national debt rose, Congress was forced to implement a series of taxes to finance the war. States were charged a direct tax. Taxes on goods focused on luxury items. The whiskey tax was doubled. Taxes were put temporarily on manufactured goods such as tobacco, iron, candles, saddles, boots, gold products, silver, jewelry, and furniture over $100. In 1815, the nation raised $13 million, which covered some of the war expenses. In addition, fees, such as the price of postage stamps, increased. To cover most of the expenses, the government had to issue Treasury bills paying 6 percent interest. Taxes, fees, borrowing, and trade shortages created an inflationary spiral that would reduce support for the war among average American citizens.

The total cost of the war and its economic suffering left Americans with little interest in new wars. Total costs, including those from lost economic opportunities, were estimated at $157 million. Naval expenditures were more than $16 million. The government was forced to borrow $80 million. Total debt reached $147 million by 1815. The government also gave away much in land contracts to cover soldiers' pay. Washington, D.C., was burned by the British, resulting in millions of additional war-related expenses.

Little was gained from the war, though the impressments of sailors on U.S. ships were halted. Soon, Britain would begin a new type of economic warfare against the United States: mountains of manufactured goods were awaiting shipment to America. One positive outcome was that the American iron, textile, and glass industries had expanded to meet shortages from the British naval blockade. After the war, America experienced a short economic boom. The South prospered as tobacco went from 3 cents a pound in 1812 to 16 cents a pound in 1817. Cotton went from 2 cents a pound to 10 cents a pound. Exports boomed from $30 million to $68 million by 1817.

WEALTH VERSUS INCOME

In today's society, the terms *wealth* and *income* are often used interchangeably for the same purpose. However, they are quite different, and the difference can be significant when considered in regard to an individual's personal economic health. First, wealth is a *stock value*, which means it is a measure at a given point in time—for example, December 31. Income is a *flow value*, which means its value measured is over a given period of time—for example, per week or per month or per year.

People can be quite wealthy while having only a moderate income or even a low income. Vice versa, people can have a high to very high income and have no wealth at all or have even negative wealth. We do not often hear or read about the former, but quite often we hear news of someone with very high income filing for bankruptcy.

Wealth is the total accumulated value of a person's assets at any given point in time. An *asset* is anything that has monetary value. Real estate, including equity in a home, is an asset. Other examples are cars, savings, stocks owned, the value of paintings owned, and life insurance cash values. Wealth does not necessarily include items of sentimental value, such as a family keepsake ring or a stack of old record albums saved since childhood. The age of an item does not determine its value. An item's value is determined by the value someone else places on the item. Items may also lose value over time; while an automobile may have some value, most automobiles—other than classic cars in pristine condition—are depreciating assets, with their value decreasing over time. Some assets, such as stocks and bonds, may fluctuate in value over time.

Net wealth is the accumulated value of all of a person's assets minus the person's liabilities. *Liabilities* are the debts an individual still owes others. For example, a home may have a market value of $500,000, but if the home's owner still owes $200,000 the net asset value of the home is only $300,000. The homeowner still has a liability of $200,000 to the mortgage holder. Other liabilities can include credit card debt, car loan debt, and student loan debt. A person's net wealth is determined by subtracting the value of the liabilities from the value of the assets at a point in time.

Notice that income was not a variable in determining wealth. Wealth is accumulated, while income is current. *Income* is the money a person receives in return for performing a work function. Income represents the value of one's human capital to an economy. Income can be described as current wealth versus accumulated wealth (net worth).

Income is a variable in a person's personal economic ledger that changes over time. Income is a variable that depends on several other variables, such as business cycle, experience, level of expertise, or demand for a skill. As a person accumulates more experience and expertise in a particular career, income may increase to reflect those changes. Conversely, if one's expertise is no longer needed because of technological changes or a downturn in the economy, there may be a decrease in income.

Income is also dependent on one's life cycle of work. While a person is young and still in school, part-time and odd jobs determine income level. Once that person has graduated from school and entered into a career, income levels will rise above the part-time levels the worker earned as a student. Income levels likely will continue to rise—through further education, experience, and potential promotions and job changes—during the peak years to retirement. At retirement, income levels decline to a level based on one's savings and retirement planning during the working years.

Spending all—or even more than all—of one's income in the present is a primary reason why high-income earners often file for bankruptcy and we read about them in the news. They have confused income with wealth.

WELFARE ECONOMICS

Welfare economics is the study of social well-being. If one's utility, or happiness, rises, then one enjoys a welfare improvement (and vice versa). Social welfare is a function of all individual welfare levels. In environmental and resource economics, with its focus on market failures, welfare economics is often used to consider whether society is better or worse off in response to government policy. The early welfare economists, such as Arthur Pigou, thought that utility could be measured by assigning numbers to units of happiness so that welfare could be compared directly from one person to another. Economists realized that such cardinal utility measurement was not feasible, and they came to favor ordinal utility. *Ordinal utility* means that individuals can rank bundles of goods and services from the most preferred to the least preferred.

Using the notion of ordinal utility, one way to judge if a reallocation of resources improves social welfare is to determine if it improves the well-being of at least one member of society without making any other members of society worse off. If it does, then the policy is called a Pareto improvement (named after the Italian economist Vilfredo Pareto). The Pareto criterion has come to be viewed as very strict.

Very few, if any, policies make no one worse off. Under the strict Pareto criterion, a policy that takes one dollar from the richest person in society and gives it to the poorest person in society would not be an improvement: the richest person is worse off by one dollar. Alternatively, a potential Pareto improvement is a policy that passes the compensation test if it has benefits greater than costs such that the winners could compensate the losers so that the losers are no worse off than before the policy. The compensation need not actually occur in order to pass the potential Pareto test.

Benefit-cost analysis, a method used to calculate and compare monetary gains and losses, is the practical application of welfare economics. The concept of economic surplus is the basis for the theory of economic benefit and cost measurement. Considering a market good—for example, a car—the consumer's economic surplus is the difference between the amount the consumer is willing and able to pay and the market price of the car. The consumer may be willing and able to pay the manufacturer's suggested retail price of $35,000. However, if the negotiated price is $31,000, then the consumer surplus is $4,000: the difference between the consumer's maximum willingness to pay and the market price. The consumer surplus is a monetary measure of the net benefit that the consumer gained from the transaction.

Goods that are not sold in markets, such as water quality, also provide consumer surplus. Consider an angler who is willing and able to pay $5 for each additional fish caught per trip. If an environmental regulation leads to a water quality improvement, and the improvement enables the angler to catch two additional fish beyond the usual catch, then the consumer surplus per trip increases by $10.

Producer surplus is the difference between the amount a business firm is willing to accept in exchange for a product and the additional cost of producing that unit of the product. It is measured as the difference between the revenue earned by business firms and the variable costs of production (i.e., the sum of marginal costs). Producer surplus is equivalent to profit if the fixed costs of production are zero. With environmental regulations that negatively affect business firms, the loss of producer surplus is a measure of the cost of the policy.

Consumer surplus is usually a good approximation of what is known as an exact welfare measure. Consumer surplus is not exact, because of income effects. Consider a price reduction that leads to an increase in consumption of a market good. As the price falls, the amount of money available to spend on all goods, including the one for which the price has fallen, increases. This is a form of the income effect on demand. As income increases, the demand for a product increases for normal goods and decreases for inferior goods. In the same way, a price decrease will lead to a positive change in income available for spending, which might further increase the amount consumed of the good for which the price has changed (if it is a normal good). On the other hand, a price increase will lead to a negative change in income available for spending, which might further decrease the amount consumed of the good for which the price has changed.

Consumer demand has both income effects and substitution effects. A demand function with income effects is known as a Marshallian (named after the economist

Alfred Marshall) demand function. Exact, income-compensated, or Hicksian (named after the economist John Hicks) demand functions are preferred for welfare analysis because they focus on the substitution effect. The *substitution effect* is the change in quantity demanded that arises solely due to the willingness to pay for more or less of a good, not due to a change in the ability to pay (i.e., the income effect).

Exact welfare measures include compensating and equivalent variations and surpluses. The *compensating variation* is the amount of money an individual would need in order to obtain the initial utility level after a price change. When a policy leads to a price decrease, the compensating variation is the willingness to pay to obtain the price decrease. When a policy leads to a price increase, the compensating variation is the willingness to accept compensation for the price increase. In both cases, the utility level with the price change and after income is adjusted by the compensating variation is equal to the utility level before the price change.

The *equivalent variation* is the amount of money an individual would need in order to obtain the subsequent utility level after a price change. When a policy leads to a price decrease, the equivalent variation is the willingness to accept compensation to forgo the price decrease. When a policy leads to a price increase, the equivalent variation is the willingness to pay to avoid the price increase. In both cases, the utility level with income adjusted by the equivalent variation and the price change is equal to the utility level that would result after the price change.

In environmental and resource economics, it is often the case that a policy will change a nonmarket good instead of a market price. In this case, there are compensating and equivalent surpluses. The *compensating surplus* is the amount of money an individual would need in order to obtain the initial utility level after a change in environmental quality or resource quantity. When a policy leads to a quality or quantity increase, the compensating surplus is the willingness to pay to obtain the increase. When a policy leads to a quality or quantity decrease, the compensating surplus is the willingness to accept compensation to avoid the decrease. In both cases, the utility level with income adjusted by compensating surplus and the quality or quantity change is equal to the utility level before the quality or quantity change.

The *equivalent surplus* is the amount of money an individual would need in order to obtain the subsequent utility level after a quality or quantity change. When a policy leads to a quality or quantity increase, the equivalent surplus is the willingness to accept to forgo the increase. When a policy leads to a quality or quantity increase, the equivalent surplus is the willingness to pay to avoid the decrease. In both cases, the utility level with income adjusted by equivalent surplus and the quality or quantity change is equal to the utility level after the quality or quantity change.

The differences in exact welfare measures are subtle but important. The correct measure is a function of the implicit property rights to the environment. If those who are affected by the policy feel that they have a property right to the *original* level of price, quality, or quantity, then the compensating measures are appropriate. If those who are affected by the policy feel that they have a property right to the *subsequent* level of price, quality, or quantity, then the equivalent measures are appropriate.

Total economic value is the decomposition of willingness to pay and willingness to accept into use value and passive use value. *Use value* is the willingness to pay for a change in the resource allocation that results from on-site or direct use of the environment or natural resource. Use value can derive from consumptive or nonconsumptive use. *Consumptive use value* is when the resource is extracted from the natural environment; examples include hunting and fishing (catch and keep) and mining. *Nonconsumptive use value* is when the resource is enjoyed but not extracted from the natural environment; examples include hiking and wildlife-watching. *Passive use value* is the willingness to pay for (or accept) the resource reallocation that does not lead to changes in behavior.

WICKSTEED, PHILIP

Born: October 25, 1844, in Leeds, West Yorkshire, England; Died: March 18, 1927, in Childrey, Berkshire, England; Nationality: English; Professional Interests: Unitarian minister and lecturer, Austrian economics; Major Works: *An Essay on the Co-ordination of the Laws of Distribution* (1894), *The Common Sense of Political Economy* (1910).

Philip Wicksteed was a Unitarian minister who spent the latter part of his life as a lecturer of economics. He is best known in economics for *An Essay on the Coordination of the Laws of Distribution* (1894) and *The Common Sense of Political Economy* (1910). He is usually associated with Austrian economics, though he had no formal connection. His research focused on marginalism, microeconomics, and the actions of the economic individual in the marketplace. Wicksteed died in 1927.

Philip Henry Wicksteed was born on October 25, 1844, in Leeds, England. His father was a Unitarian minister, and his mother came from a family with a long business history. He received his master's degree (with a gold medal for classics) in 1867 after studying at University College (1861–1864) and Manchester New College (1864–1867). In 1868, he became a Unitarian minister himself, serving in various locations around London and Manchester. While he was a minister, he developed a great interest in the ethics of the commercial society, and his study of economics led him to begin lecturing on economics in 1884. In 1897, he began lecturing full-time.

Wicksteed's involvement with economics began around the early 1880s as he began to study Henry George's *Progress and Poverty* (1879) and the works of William Stanley Jevons. Wicksteed was exposed to *Progress and Poverty* through his membership with the socialist Fabian Society in the 1880s, and the books seemed to open his eyes to distribution and labor problems that lead to poverty. He expressed in a letter to George his agreement about the benefits of the expanded use of technology in agriculture and the problem of labor not being helped by increased capital. Wicksteed would also take ideas about the labor supply from Jevons and expand on them.

Despite the socialist nature of the Fabian Society, Wicksteed was a major opponent of the views of Karl Marx. One of Wicksteed's first forays into economic writing came in 1884 in a critique of Marx's *Das Kapital,* where Wicksteed pointed out fallacies in Marx's ideas of "abstract labor" and the cost of production in the labor force. In 1888, Wicksteed published his *Alphabet of Economic Science,* which focused on utility, marginal utility, and the theory of demand. During this time, Wicksteed began what would be a more than 30-year involvement with the London Society for the Extension of University Teaching (LSEUT), during which time he would teach over 300 courses in a variety of subjects, especially economics.

In 1888, Wicksteed republished a series of articles in *Getting and Spending: Papers on the Meaning and Uses of Money.* This work focused on what people's spending reveals about what they value. In 1894, he published *An Essay on the Coordination of the Laws of Distribution,* which dealt with expansions of ideas by Jevons and George on marginal products. In this work, he proves how the distribution of marginal factors, if paid relative to marginal product, would exhaust the total product. This relationship between marginal factors and marginal product with total product was first made by Leonhard Euler and became known as Euler's theorem.

Wicksteed's next major work, published in 1910, was the two-volume *Common Sense of Political Economy.* It attempts to examine human action in a comprehensive way, including morality in its analysis of economic action. This subjective approach to economics also worked against the concept of the economic man by taking economic actions as "non-tuistic." Wicksteed coined the word *non-tuistic* to describe an economic transaction where the consequences to someone involved in the economic decision are not considered. He also used economics to analyze seemingly noneconomic behaviors, like spending time leisurely. Aristotle's ethical works and Jevons's marginalism were both very influential to Wicksteed's publication.

Among other insights, the *Common Sense* is known for the idea that prices will come to an equilibrium or a balance point, now known as the Wicksteedian state of rest (WSR). To illustrate the movement of prices, Wicksteed used the example of a fruit market, where prices are determined and changed in real time as fruit-sellers observe customer behavior and factor in customer preferences. In this process, an equilibrium price can be achieved through the actions in the market place. According to WSR, forecast errors in plain state of rest (PSR) values will lead to the ideal values of the WSR.

Wicksteed was also accomplished as a medievalist through his study of Dante Alighieri and Thomas Aquinas. His work with the LSEUT included lectures on sociology, Dante, Aristotle, and other topics. He wrote *Six Sermons on Dante* (1879), *The Religion of Time and Eternity* (1899), *Dante and Aquinas* (1913), *The Reactions between Dogma and Philosophy, Illustrated from the Works of St. Thomas Aquinas* (1920), and other books and articles, as well as a translation of Dante's *Divine Comedy.* He was also a student of Old Testament criticism and Dutch liberal theology.

Philip Wicksteed died on March 18, 1927, in Childrey, England.

WILLS AND TRUSTS

A *will* is a legal document that states who should receive a person's possessions after the person dies. A *trust* is a fiduciary relationship (where one trusted individual is directed to act on behalf of another) in which one person, known as a trustor, gives another person, the trustee, the right to hold title to property or assets for the benefit of another who is known as the beneficiary. A trust can be in effect during the trustor's lifetime or created upon the trustor's death. Both wills and trusts are governed by state law.

History of Wills and Trust

During the Middle Ages, the Catholic Church exercised authority over domestic matters, such as probate. *Probate* is the legal process by which a court validates a will.

Under religious beliefs at this time, it was thought not to have a will was sinful, and it was expected that some portion of the deceased's estate would go to the Church for the saying of masses. Therefore, the ecclesiastical (religious) courts would oversee the distribution of all personal property, and if an individual died without having made a will, the Church would then assume jurisdiction of the dead person's goods. In 1857, the English Parliament passed legislation that transferred probate from the ecclesiastical courts to the Courts of Probate. Early American colonists brought English traditions with them, and they established the first probate court in the United States in Massachusetts.

The idea of a trust being created upon the death of a trustor can be traced back to Roman times, but it is not until the Middle Ages that living trusts were introduced. During the Crusades, when a knight went to fight in a foreign land, he conveyed ownership of his lands, and the income generated from that land, to another person (a trustee) with the understanding that upon the knight's return, the lands would be returned to him. The trustee was holding the land and income for the knight's benefit. When many of these knights returned, however, the trustees refused to re-convey the lands and rents. The knights then had to petition the king, who set up the Courts of Chancery to hear such cases. It quickly was established that the knights did not "give away" their land, but in fact established a trust relationship stating that the land was held for the benefit of the knights while they were away fighting for the king. It is from this circumstance that the concept of the modern-day inter vivos trust, or living trust, developed (Beyer 2012).

Wills

The idea behind a last will and testament is that individuals have the ability to own property during their lifetime and should have a say in the dispensation of that property upon their death. Wills give people the ability to make their wishes known regarding how their personal belongings should be distributed, who should care for any minor children they leave behind, and how any final expenses should be paid. Many people, however, die without making their wishes known. It is estimated that up to 70 percent of Americans currently do not have a will. To die without a will is known as dying intestate.

When a person dies intestate, the probate court does not have a document to follow, so it must look to the state's law of intestacy to determine who will inherit the decedent's estate. Though this varies from state to state, typically the property goes first to a surviving spouse, then to children and their descendants. If there is no spouse and there are no children, the law of intestacy looks to the decedent's parents, then siblings, the siblings' descendants, the grandparents, and so forth until a surviving relative can be found. If no surviving relative can be found, then the decedent's estate is turned over to the state government.

Today, many commercial legal publishers have created do-it-yourself will kits that allow individuals with no legal training to create basic last will and testament documents inexpensively.

Trusts

Trusts take two forms: those created upon an individual's death for the benefit of another, known as testamentary trusts; and those created while an individual is still alive, known as either inter vivos trusts or living trusts.

A testamentary trust is created by the terms of a will, and it goes into effect only after the person's death. The person who creates this type of trust is known as the trustor or settlor. The trustor may name an individual to act as the trustee, and that person oversees how the assets are managed in the trust and makes payouts to the beneficiary, who will receive funds from the trust. Often these types of trusts are used for the benefit of an individual, such as a minor child or an incapacitated individual. Testamentary trusts are irrevocable, because they fund only after an individuals has died.

A living trust is created during the trustor's lifetime through a declaration-of-trust document and by placing property into the trust. This type of trust has a duration that is determined at its creation, and it can include distributions of assets to the beneficiary during or after the trustor's lifetime. Often this type of trust is used in estate planning to avoid the lengthy probate court process, which can be costly and can expose a wealthy family's private financial matters to the public. A living trust can be either revocable or irrevocable.

A *revocable trust* allows the trustor to retain control of all the assets in the trust, and the trustor can revoke or change the terms of the trust at any time. An *irrevocable trust* does not allow the trustor to revoke or make changes to the trust once it has been created.

Specialty Trusts

In certain situations, families need trusts to assist them in managing more complex financial or medical circumstances. The following is a brief synopsis of some of these specialty trusts.

Credit Shelter Trust

A *credit shelter trust* allows a spouse to include in the will an amount up to but not exceeding the estate-tax exemption. This is a dollar amount that the heir may inherit federally tax-exempt. The remaining assets fund a testamentary trust for the benefit of the trustor's heirs and avoid estate taxes. The amount equal to the estate-tax exemption passes tax-free to the surviving spouse.

Generation-Skipping Trust

A *generation-skipping trust* is used to transfer a substantial amount of money tax-free to beneficiaries who are at least two generations the junior, typically grandchildren, of the trustor.

Health and Education Exclusion Trust

A *health and education exclusion trust* is created to pay for the education and medical care of grandchildren and more remote descendants, without the trustor being subject to the generation-skipping tax.

Pet Trusts

A *pet trust* is used for the care and maintenance of a trustor's pets in the event of the pet-owner's disability or death. In some states, the trust may continue for the rest of the animal's life or for 21 years, whichever comes first.

Special Needs Trust

A *special needs trust* is created to for the care of beneficiaries who are disabled or mentally ill. These types of trust also may shelter beneficiaries from losing access to essential government benefits.

Qualified Terminable Interest Property Trust

Qualified terminable interest property trusts are often used by families in which there have been divorces, remarriages, and stepchildren. This type of trust allows surviving spouses to either receive income from the trust or remain in a home during their lifetime, and the beneficiaries (e.g., children from a first marriage) will get the principal or home upon the surviving spouse's death.

Wills and trusts are part of the overall estate-planning process. They are tools that individuals can use to manage the effective disposal of their assets in accordance with their wishes. Wills and trusts are, in effect, the last personal financial activity in which a person will engage.

WORLD WAR II RATIONING AND SHORTAGES, 1940s

The United States of America has known rationing in all of its wars. World War I, for instance, created shortages in rubber, gasoline, auto tires, chemical dyes, starchy foods, sugar, and coffee. World War II, because of its long duration and the volume of its requirements, imposed severe effects on the public. Rubber, nylon, tires, gasoline, steel, alloy metals, cotton, wool, and a variety of foods were, at times, in critical shortages. World War II and its shortages would be aggressively addressed through rationing, substitute materials, recycling, new foods, conservation in industry, home victory gardens, and aggressive research programs. By 1945, for example, more than 20 million victory gardens produced 40 percent of America's fresh vegetables.

Initially, rationing was the only route possible to secure war materials. The first wave of rationing included tires, cars, gasoline, fuel oil, rubber, nylon stockings, typewriters, sugar, and coffee. The next wave included meat, cheese, shoes, and stoves. More than 8,000 rationing boards were established, and prices were frozen on all items to be rationed. The rationing was complex. There was uniform coupon rationing on things like sugar, meat, and cheese, which were distributed equally to consumers. There was also differential coupon rationing based on various needs, such as gasoline and fuel. Voluntary rationing of gasoline and fuel proved a failure, and coupons were issued starting in 1942.

Gasoline rationing consisted of a normal "A" coupon, which allowed 4 gallons per week, and for those whose jobs were essential to the war effort a "B" coupon, which allowed 8 gallons a week. Further enforcement included a mandatory tire inspection every 5,000 miles. If the government concluded that a car was not in use, its gasoline ration and tire ration could be reduced. Some people—such as truckers, congressmen, physicians, railroad workers, and mail carriers—were allowed unlimited amounts of gasoline. Certificate rationing was imposed on some products that required an application and approval, such as industrial chemicals. In the case of food, rubber, and gasoline, consumers were encouraged through patriotic appeals to reduce their consumption to even lower levels than the coupons allowed.

Much of the rationing centered on the family car, just when the nation had become addicted to the automobile. Gasoline rationing required many people to carpool. This rationing was an economic burden that basically eliminated all but necessary driving. Educational programs were the key to gaining public acceptance. Consumers were encouraged to maintain the "victory speed" of 35 miles per hour. Tire pressure monitoring and tire rotation were encouraged. These suggestions were shown in cartoons at all movie theaters. Educational programs made everyone part of the war effort and capable of making great sacrifices. People were encouraged to plant victory gardens to increase the food supply, and the government issued special cookbooks to help people learn how to save on food. Major advertising campaigns focused on reducing heat levels in homes, having meatless days, and recycling scrap materials.

Scrap steel and rubber were both vital in the production of war equipment. Recycling efforts put things in war terms. For example, Americans were told that a scrap steel shovel could be used to make four hand grenades. The government required 6 million tons of scrap steel alone to keep the war effort going in 1941, and American scrap drives, many of which were led by children, produced that amount in a month. One problem became overzealous collectors who stripped homes of wrought iron fences; tore iron out of cemetery memorials; tore up railroad rails, park statues, historic cannons, and church bells; and aggressively stripped steel signs.

Rubber was considered the most critical war material, followed by starch sources. Cornstarch was one of the most critical items, because at the start of World War II the country was very dependent on cornstarch and imported starches for a large variety of necessary products. Starch imports had been growing since 1922 , and by the start of World War II the country was using more than a billion pounds of cornstarch. Only 250 million pounds were being used for food. The sizing of cotton textiles used 300 million pounds of cornstarch, the laundering of garments used 250 million pounds, and the paper industry used about 200 million pounds. Another 100 million pounds of cornstarch was used to produce dextrin for glues, adhesives, and other industrial uses. On the eve of war, nearly half of this starch was being imported. With the war increasing demand and reducing imports, government chemists and private chemurgists were again studying George Washington Carver's sweet potato research of the 1920s. Sweet potatoes offered a great source of additional starch and chemical bases for glue, adhesives, and dyes.

The government even went into clothing design to save cloth. A 15 percent savings was achieved by shortening hems and removing belts and cuffs on women's clothing. Bridal gowns, maternity dresses, and religious clothing were exempt from cloth rationing. The creative effort of Americans helped achieve major reductions in cloth usage and included the creation of new fibers. Henry Ford announced his opening of a pilot plant to produce soybean fiber as a replacement for wool. Ford predicted that he would cut his upholstery costs for cars by 50 percent, and during World War II, Ford's soybean wool did indeed replace 30 percent of the imported supply of wool that was cut off. The government invested millions of dollars in synthetic and substitute materials programs. Ethanol alcohol was mixed with gasoline to stretch gasoline supplies, but the United States never fully mastered synthetic gasoline as the Germans did during the war. Ford even promoted the use of a 40 percent alcohol/60 percent gasoline mix as the ideal fuel. Similarly, efforts to make synthetic rubber did not fully come to production until after the war.

Oil and fats for soap-making and paint were in short supply, as more than 80 percent were imported. The soap and paint industries were one of the major users of these imported oils, such as palm and coconut. The tropical oils—coconut, palm, and tung—had almost no domestic sources, and the world's major sources were in the Philippines. The Henry Ford lab helped the soap and paint industries use soybean and peanut oil as substitutes. Paint was scrapped and recovered for consumer use. Oil from petroleum was badly needed for machine lubrication, and new recovery processes were developed. Salvaged kitchen fat was used to produce glycerin for explosives.

Although black markets and scams evolved for all rationed goods, the general behavior of the American people proved patriotic. History has shown that shortages on the home front can often break a nation's will to win. The United States in World War II demonstrated a unity rarely seen in nations at war. Organizations and churches helped in recycling drives. Companies voluntarily tried to save on materials and converted over to wartime production. The foundations of Henry Ford's, and later Toyota's, lean manufacturing systems were built during these war years. Government research programs in synthetic rubber, cloth, and alloys would pay huge dividends by the 1950s. The shortages of World War II would again demonstrate the creative motivation of economic shortages.

Preface

When I was in graduate school a professor described the subject of economics as the "clothesline of life." There were several meanings to his phrase. One, there are many ways to approach the world of economics. Two, economics is a living, breathing discipline we use to play out our lives every day. Economics is part art, part science, part history, and all human behavior. If one digs down into the subjects of life, one will find a component of economics in virtually every subject. Economics surrounds us daily. *Economics: The Definitive Encyclopedia from Theory to Practice* has been created in a way to make economics come alive. Within our four volumes, including the comprehensive glossary, document excerpts, and other appendices, *Economics: The Definitive Encyclopedia from Theory to Practice* explores all corners of economic history, the individuals who gave economics life, the economic events that have shaped our world, and the foundational concepts and ideas that make, define, and sculpt our economic world.

We began this project with several goals. Our first, and most important, was to assemble a comprehensive and varied collection of entries on economic history, personal finance, money and banking, environmental, and behavioral economics, to name a few of the subdisciplines that hang from the "economics clothesline." An extension of that first goal was to provide a comprehensive, readable, one-stop resource for the general reader as well as for students, teachers, and researchers of economics, personal finance, and entrepreneurship.

To do so required assembling a diverse collection of economics material. Contained within the four volumes of the *Definitive Encyclopedia* are the people who laid the groundwork for economics as a science, the historical events upon which economics grew, and the concepts and ideas on which they built their legacy. I strongly believe we have accomplished these goals.

Volume 1, Foundations of Economics, is the "economics clothesline." In Volume 1 we present the people, concepts, history, the events, and places and institutions on which economics is built. It includes basic economic concepts such as opportunity cost and marginal analysis. Also included are the business tycoons who shaped the early U.S. economy, such as Henry Ford and John D. Rockefeller. No book on foundations of economics would be complete without the economists who laid the groundwork for economics such as Adam Smith, John Maynard Keynes, and Friedrich Hayek. Not to be forgotten are the political leaders whose contributions to their respective economies during their lives is still with us today, including U.S. president Ronald Reagan, Great Britain's Margaret Thatcher, and the Soviet Union's Joseph Stalin.

Volume 2, Macroeconomics, is our big picture volume. As the title suggests, Volume 2 focuses on the institutions, people, events, and places that have shaped the roles and responsibilities of the economy as a whole—the macroeconomy. Volume 2 presents the different methods and ways in which economies are measured and also explores government's role in the economy. Macroeconomics is about the institutions that measure our economies, such as the Bureau of Economic Analysis (BEA) or the Bureau of Labor Statistics (BLS). Key political figures such as Winston Churchill and President Franklin D. Roosevelt are featured for their economic contributions to world history.

Volume 3, Microeconomics, takes on markets, prices, and looking at the economy under the proverbial microscope. Volume 3 presents how markets function and the institutions that allow markets to work more efficiently and equitably for both the producer and the consumer. In Volume 3 you will find the concepts, economists, institutions, and historical events along with major market events such as the transitioning of the automobile industry and the economic bubbles, such as the "dot-com" bubble, that have determined the behavior and interaction of producers and consumers in today's modern economy. In Volume 3 we explore subfields such as environmental economics with entries such as "Tragedy of the Commons," "Clean Water Act," and "Clean Air Act," along with other environmental issues. Personal finance is a highlighted subfield in the "Annuity," "Debt Credit Counseling," and "Health Insurance" entries.

Volume 4, Global Economics, is the volume of the future. Volume 4 encapsulates the first three volumes in the context of an ever-growing global economy. Barring a cataclysmic event, today's world will continue to get smaller and smaller, translating into a more global economic community. Volume 4 includes concepts such as "Comparative Advantage" and "Balance of Payments." Volume 4 introduces the reader to the individuals changing the world, such as Muhammad Yunus and his Grameen Bank. As the new rules of a global community take shape to include all of the world's 7 billion inhabitants, at the forefront of those conversations and debates are the global institutions: the International Monetary Fund (IMF) and the World Bank, along with the United Nations.

Of equal value to the teacher, student, and researcher are primary documents in economic history; a list of Nobel laureates in economics; a timeline of economic events; and a glossary. The Primary Documents section includes 27 documents, such as the Tariff Act of 1930 and the Financial Reform Act of 2010, better known as the Dodd-Frank Act. The *Definitive Encyclopedia* would not be complete without highlighting some of the most important documents that have shaped the economic landscape of the United States. The Appendix of Nobel laureates highlights those individuals who have changed the course of economics. The Timeline presents key events in the global economy from 1776 to 2016. The Glossary presents a second layer to the all-inclusive nature of the *Definitive Encyclopedia*. Approximately 1,000 additional concepts, people, and events in the Glossary go beyond the four volumes' 850-plus entries.

Throughout my career in economics and economic education one of my main concerns has been that economics often has been presented as a subject beyond the scope of the average reader. In compiling *Economics: The Definitive Encyclopedia from Theory to Practice* we took aim at that notion head-on. Our goal was to bring to both the general and experienced student of economics a readable source to better understand the economic world around them. I strongly believe we have succeeded in this goal.

Of course, a project of this magnitude would not be possible without a team of highly dedicated contributors. I owe a huge debt of gratitude and big thank-you to the contributors without whose efforts this project would not have succeeded. My team of contributors possessed the quality and expertise needed for this project. As some of the best college professors and high school AP economics teachers anywhere, they represent all that is good about economic education. I am humbled they would give of their precious time to be part of the team. I owe them a major debt of gratitude. I owe a debt of gratitude as well to Jillian Davidson for her research and editing assistance.

I would like to thank Brian Romer for bringing me onto this project and then passing the baton into the capable hands of Hilary Claggett, Patrick Hall, and the rest of the ABC-CLIO team who had a hand in this project's development. Thanks for making us look good. I also need to thank my many colleagues, students, and friends who also provided support, feedback, and a kick in the pants when necessary. Most of all I need to thank my family and friends for putting up with me during this time. There were times I was a bit like the candy bar commercial. I owe a big thanks to each and every one of them for their patience and understanding. Finally, I dedicate this project to my mom and my four daughters—Branda, Laura, Jillian, and Mary. They say behind every successful man is a woman. Well, I don't know about being successful but I do have five very precious women behind me. This is for you.

Introduction to Volume 2: Macroeconomics

Because we live in a world of scarcity every individual must make choices. Every choice has a cost. Every choice has a consequence that lies in the future. What can be stated for individuals is just as true for economies—every economy, as a functioning entity, must also make choices, which have costs and consequences. The consequences may be positive or negative but there will be consequences. Where the decisions of economies do differ from decisions of individuals is that the decisions of societies regarding their economic systems determine the context in which individual economic decisions will be made.

Before addressing the questions every economy needs to answer, let's first identify and define an economic system. In its most basic form an economic system is a society's way of allocating and distributing resources (land, labor, capital) to the production of goods and services by sellers (businesses) that will be available to buyers (households) in the marketplace. The allocation and distribution of resources occurs in the resource market and the production of goods and services in the product market. An economic system also encompasses the role of government in an economy, financial institutions to determine the role of money and act as intermediaries, and foreign companies that also provide goods and services to the product market as well as use the economic system's resources from the resource market. This circular flow of economic activity is the makeup of every economic system. How that economic system functions is determined by *how* society answers the following questions and, more importantly, *who* answers them.

Every society must answer three basic questions regarding its economy: what will be produced, how will it be produced, and for whom will it be produced. Who answers those questions and how those three basic questions are answered will determine the economic environment in which individuals, families, businesses, and organizations make their decisions. The answers to the three questions are interdependent. One is no more important than the other. Yet the way in which one is answered will affect how the other two may be answered. Before we get to the "who," let's briefly explore each of these three basic questions.

What to produce is the question that determines how the economy's resources are being allocated to produce goods and services. The answer to this question will determine what goods and services are available in the economy. Is the economy producing three-legged chairs or four-legged chairs? Is the economy producing mostly military goods or private consumption goods?

How to produce is the question of efficiency. Are the economy's resources being used to their most productive level? Is the economy producing chairs one at a time or implementing specialization and division of labor to use labor and capital to their most efficient use?

For whom the goods and services are being produced is a question regarding the distribution of resources within the economy. Are the chairs available to everyone or just to a specific segment of the population? Are the chairs a public good or a private good?

These three basic economic questions have to be answered by every economy, no exceptions. The what, how, and for whom answers are the driving forces behind an economy's efficiency, allocation, and distribution of goods and services, and the use of its valuable limited resources. But there is one additional, even more important, question that needs to be answered by society: who is going to answer the three questions?

The "who" question determines an economy's rules. The answer to this question determines the rules that individuals will use to make their decisions. The "who" question determines the economic system in which society will operate.

An economic system defines the rules of an economy. Determining "who" answers the three basic questions can take on many forms. However, there are two extremes in defining an economic system with many blended or mixed systems in between.

The first extreme is the market system. In a market economic system the three questions are answered in the marketplace through the interaction of the buyers and sellers. In both the product market and the resource market buyers and sellers determine what will be produced, how the goods will be produced or services delivered, and who will be able to participate in the market for a particular good. In a market economy there is a connection between the interaction of buyers and sellers in the product and what action occurs in the resource market.

Referring back to the chair example, in a market economic system the interaction between buyers and sellers would send a message to the resource market indicating the buyers' preference for four-legged chairs over three-legged chairs, because the latter do not stay upright and continually fall over. Buyers in the product market have also signaled they prefer metal chairs to wooden chairs because they last longer. In a market economy these messages from the market product buyers are picked up by the producers who then determine the allocation of resources is in the production of four-legged metal chairs. This results not just in the resource allocation to produce metal four-legged chairs but producers also explore more efficient methods to produce the chairs addressing the "how" question. One producer might be making chairs one at a time, but another producer has figured out how to use specialization and division of labor so they can make many more chairs in the same amount of time and as a result the economy becomes more productive. Because all decisions are determined by the interaction of buyers and sellers in a market system, the "for whom" question is answered in the product market by those who are willing and able to purchase the metal four-legged chairs.

The three-legged chairs no longer have a market so the producer of these chairs goes out of business. This frees up these resources for a more productive use. The wooden chair-makers likewise go out of business, freeing up more resources for a more productive use determined by the product market's buyer and seller interactions. Finally, the four-legged metal chair-maker who was producing chairs one at a time has a choice to make. It may change its method of production to compete with the other, more productive four-legged metal chair producers or it will most likely eventually go out of business.

The market economy functions best when all signals and messages between buyers and sellers and the markets are uninterrupted and unrestricted. There is a free flow of information between the markets and between the participants whether they are buyers or sellers in the product market, resource market, financial market, foreign market, or a government.

The second extreme of "who" is the command economic system. This economic system is at the opposite extreme of the market system. In a command system there is no free flow of information because one central authority, usually government, makes all economic decisions in this society. Referring back to the three basic economic questions of every society, these questions are answered by one voice, the central authority. The central authority decides what will be produced for the product market, thereby determining how the resources will be allocated and ultimately who will receive the goods and services of the product market.

Because all the decisions are made by one central authority there is no connection between the desires of the buyers (households) and sellers (businesses) in the product market with the buyers (businesses) and sellers (households) in the resource market. This bad, or nonexistent, communication between the markets usually results in a misallocation of resources resulting in shortages of products that households desire in the product market. Because the central authority also determines "how" resources will be allocated, a misallocation of resources is highly probable. For example, if an important member of the central authority has a favorite nephew who is making wooden three-legged chairs one at a time, the authority member may push for the decision to allocate more resources to the wooden three-legged chair industry in an effort to help the nephew. The result of such a decision is an inefficient misallocation of resources. The product market now has wooden three-legged chairs made one at a time that no buyer in the product market desired. The central authority also sets the price of those chairs.

Political dictators or populists often accompany command economic systems. Dictators are dictators for a reason. They demand control over all aspects of one's life including the economic decisions individuals can make. A command economic system fits their political style quite nicely. If they want wooden three-legged chairs made one at a time they will have them regardless of messages from the product market, resource market, or other markets of the economy. Dictators and populists generally can have economic success with a command economic system in the short run. Eventually, however, history has shown success is brief and the economic fallout severe.

The third and most popular and varied economic system is the mixed economic system. By its very name it is the hardest to define except to state it is a combination of the market system and a command system. Of course within that are essentially an infinite number of variations. Because of the wide variations of mixed economies the easiest way (not sure that is accurate, either) to define mixed economies is to define them as being either closer to a market economy or closer to a command economy. What is political foundation of the economy in question? If the political system is a democracy (e.g., South Korea) odds are its economic leanings are toward the market system. If the political system is a dictatorship then the economy almost certainly leans toward a command economic foundation (e.g., North Korea).

Mixed economic systems, regardless of the foundation, by definition have a bit of both a market system and a command system. A market-based mixed system can also have the favorite nephew who receives preferential treatment even though he is producing a good or delivering a service the product market buyers have messaged they are not willing or able to purchase. In a market-based system it is called *crony capitalism*. Likewise, in a command system there will be pockets of a market-based system. It may be farmers who are allowed to grow the crops of their choosing and take them to the marketplace to sell.

Mixed economies are a complex array of economic systems. Economists and academics may try to categorize and compare them but the task is very difficult because the political, geographic, and social systems in which they align are often so different.

There is one modern case study to compare economic systems: South Korea and North Korea. Both were established simultaneously following World War II. South Korea chose democracy and a market-based economic system. North Korea chose a Communist and command-based economic system. Both systems are now more than 50 years old and the differences could not be clearer. However a society answers the three basic economic questions, they must answer, and who answers them can have both good and bad consequences for all of the society.

A

AGGREGATE DEMAND AND AGGREGATE SUPPLY

Aggregate demand and aggregate supply are two of the primary concepts in macroeconomics. *Aggregate* means total, and *demand* is the desire and ability to purchase goods and services. *Supply* refers to the desire and ability of producers to provide goods and services. *Aggregate demand* is the total amount of goods and services demanded in an economy during a given time period, while *aggregate supply* is the total amount of goods and services provided. Aggregate demand is composed of all consumer spending, investment spending, government spending, and net exports (exports–imports)—the components of gross domestic product (GDP). Aggregate supply is composed of all income, in the forms of wages, rents, profits, and interest earned.

The British economist John Maynard Keynes (1883–1946) is credited with creating the concepts of aggregate demand and aggregate supply. He used these concepts in the 1930s to explain how governments can recover from recessions by increasing government spending to impact aggregate demand, which in turn would increase aggregate supply. Keynes did the lion's share of his writing and economic thought from 1920 to 1940. Prior to Keynes, market explanations centered on classical economics, popularized by the writings of Adam Smith (1723–1790). Smith emphasized the market concept of *laissez faire*, which is the minimal use of government actions to control economic activity.

Aggregate demand and aggregate supply are graphed on the aggregate demand and aggregate supply graph with the *y*-axis being the general price level, or CPI, and the *x*-axis being real GDP. The aggregate demand curve is downward-sloping to the right while the aggregate supply curve is upward-sloping.

Aggregate Demand

Most economists support the downward-sloping aggregate demand (AD) curve for three primary reasons: the wealth effect, the interest rate effect, and the exchange rate effect. All three of the explanations for the downward-sloping AD curve center around lower prices, which induce greater quantity demanded and the downward slope of the AD curve. When the price level falls, wages do not change immediately, which makes consumers feel wealthier so they purchase more goods and services than before. When interest rates fall, consumer spending on durable goods such as homes and cars and business investments on capital goods will increase. When the domestic exchange rate falls, domestic exports become relatively cheaper to foreign consumers and foreign sales will increase.

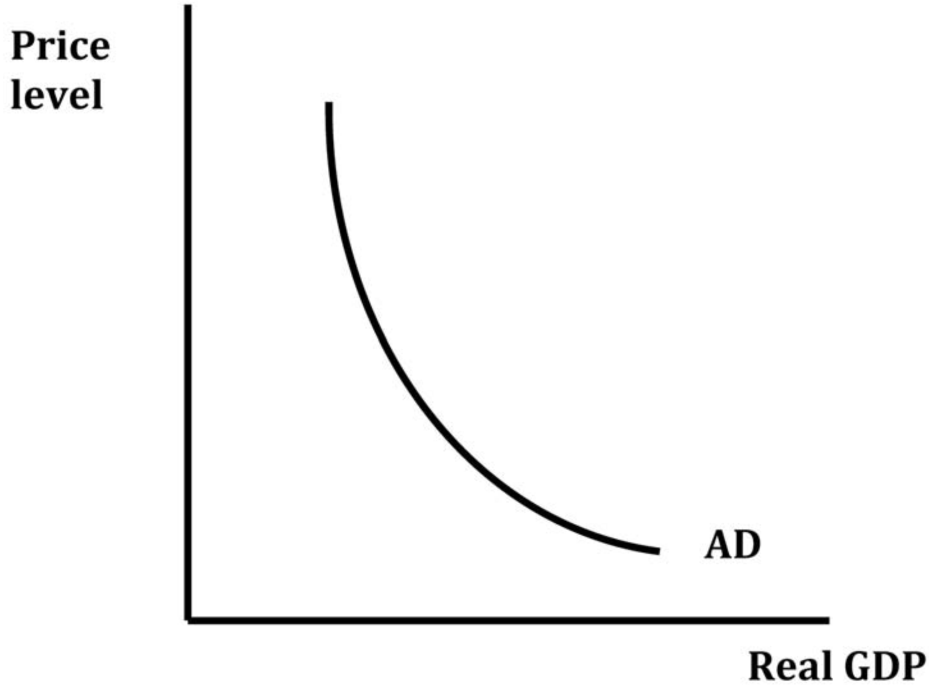

Figure 1. An aggregate demand curve

AD is sensitive to changes in consumer wealth, business investment, government spending, and net exports. When any of these components decrease, AD will shift to the left (decrease), and when any of these components increase, AD will shift to the right (increase). These changes in AD impact the price level; a decrease in AD causes disinflation or deflation, and an increase in AD causes inflation.

Economic systems experience multiple changes like toppling dominos, which create a situation of long-run equilibrium in the AD model. For example, when consumer spending falls (AD decreases), the demand for money will also decrease (because consumers are demanding less money to purchase goods and services), which will lower real interest rates—increasing investment spending (AD increases) and restoring AD to long run equilibrium.

During prolonged contractions and expansions in AD, the government implements fiscal policies and a nation's central bank implements monetary policies to control the price level (inflation, disinflation, or deflation), economic growth, and unemployment (or growing employment) that result from economic contractions or economic expansions due to changes in AD.

The government's fiscal policies include either increases in government spending and/or decreases in taxes to address high unemployment. Conversely, fiscal policies to combat inflation involve decreases in government spending and/or increasing taxes. Government officials often find that the policies to cure inflation are politically unpopular. A central bank's monetary policies can often control changes in AD with more speed and accuracy than the government's fiscal policies. To address high unemployment, the central bank will increase the money supply with the three tools of monetary policy, usually open market operations (buying bonds in the open market). This will decrease key interest rates. To combat inflation, the central bank will decrease the money supply by using one or more of the tools of monetary policy. The most popular tool used is the open market operations (selling government bonds), which increases key interest rate

Economic growth is demonstrated with a rightward shift of the AD curve due to an increase in consumer spending, government spending, or net exports. Keynes's sticky wage/factors of production theory is the idea that when prices change due to increases in AD, wages and the prices of the factors of production do not immediately change. They are "sticky" downward (i.e., they will not decrease) because of labor and or commodity (resources) price contracts. Wages and the prices of the factors of production will eventually adjust with the inflation rate, which results in a leftward shift of the short-run aggregate supply curve back to the original equilibrium point in the aggregate supply/aggregate demand model. This shift to the left of the short-run aggregate supply curve restores real GDP due to the increase in the prices of the factors of production (including wages) and increases the overall price level.

Aggregate Supply

Aggregate supply (AS) shows how changes in both short-run aggregate supply (SRAS) and long-run aggregate supply (LRAS) impact both the price level and real GDP. LRAS is composed of the productive capacity of an economic system or the production possibilities frontier, which is bound to the quantities of the factors of production and technology. SRAS is bound to the prices of the factors of production.

The SRAS curve is upward-sloping because as prices increase, producers are more willing to supply goods and services (law of supply). The LRAS curve is vertical: a constant that is fixed to the quantity of the factors of production and technology or the production possibilities frontier.

LRAS and SRAS are sensitive to changes in the quantities of the factors of production and technology. When there are more productive resources or an increase

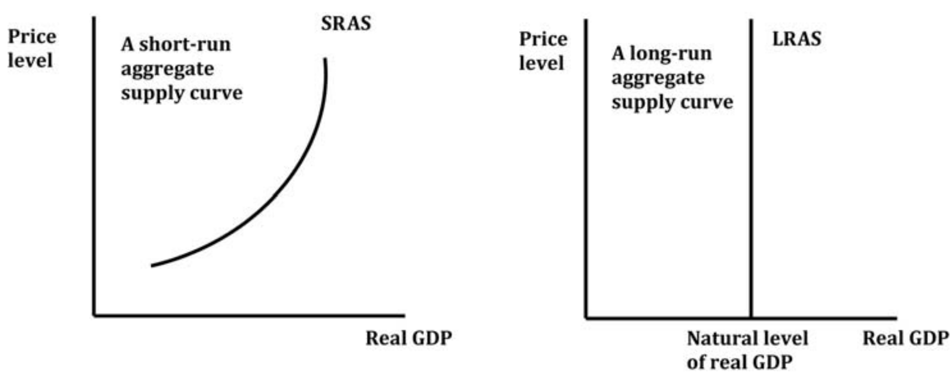

Figure 2. Short-run and long-run aggregate supply curves

in technology, the LRAS and SRAS curves will increase or shift to the right in the AD/AS model, which will increase GDP and decrease the overall price level. The SRAS curve is sensitive to changes in the prices of the factors of production or temporary disruption in a supply-chain of an essential good, such as oil, and expectations about future inflation (this is really producers reacting to what they believe it will cost to replace their inventories). If the prices of the factors of production increase, or if producers expect future inflation, producers will supply less because it will be more costly to produce (some producers will exit the market) and the SRAS cure will shift to the left, resulting in an increase in the overall price level and a short-run decrease in real GDP. This combination of an increase in the overall price level and a short-run decrease in real GDP, called stagflation, is very difficult for the Federal Reserve or the government to cure.

Many economists believe that the best way to combat stagflation is to wait until the prices of the factors of production adjust back down or the disruption in the supply chain is remedied. Conversely, if there is a decrease in the prices of the factors of production or if producers expect lower inflation in the future, SRAS will increase (more suppliers will enter the market) because it is cheaper to produce, which results in a decrease in the overall price level and a short-run increase in real GDP.

The central bank and the government can attempt to increase AS, which would result in lowering the overall price level and increasing real GDP. The central bank can implement monetary policy in an attempt to increase AS by increasing the money supply and lowering key interest rates. Changes in key interest rates will impact other interest rates, which will impact investment spending. As interest rates decrease, producers have an incentive to borrow money and purchase new capital, which will be used to produce future goods and services (this is an increase in the factors of production of an economic system). Additionally, the government can attempt to increase AS through fiscal policy by lowering taxes for producers or by providing direct payments in the form of grants or low-interest loans for creating new capital investments. Both these monetary and fiscal policies are based on the belief that as producers are more willing to produce more goods and services, they will hire more workers—and this increased wealth of the producers will result in increased income levels for households to purchase more goods and services.

As long as producers use their decreases in taxes or direct payments for sound capital investments, AS will increase. The economic and political debate surrounding these ideas is that producers will use their decreases in taxes not to purchase new capital investments but to further their own personal wealth. Additionally, some believe government induces producers to make poor investments in capital that does not yield an increase in AS, resulting in a loss of tax-payer money.

Although AD, AS, and GDP are often viewed as the benchmarks of economic success, they do not say everything about an economic system. They do not measure happiness, leisure time, values, environmental quality, and that many other variables that are unrelated to monetary wealth.

AGRARIAN ECONOMY

Agrarian economy refers to the complexities of economic practices and theories based around agriculture. This topic reaches many levels and different societies. Preceded by hunter–gatherer societies, agrarian systems rely on farming and land as the main source of wealth. In modern times there are mixtures of cultures that still heavily rely on agrarian practices as a main source of their economy. These societies mainly exist in Africa and Asia. Agrarian economies also play a large role in industrialized nations. Within these nations, *agrarian economy* refers to and economically measures the importance of farm and cultivation practices within the scheme of the overall economy. Westernized nations tend to be more industrialized, but they still develop economic notions of agriculture by measuring its relative production, labor movements, and cultivation.

For developed nations, the industrial revolution ushered in a new source of economic strength. Industrialization changed labor movements and goods of production. The manufacture of materials to sustain and promote growth as well as the ability to locate facilities in various places played a large roll in its efficiency. However, agrarian practices are equally important in sustaining economic growth since the products of agriculture, mainly food, are crucial to supporting the growing population. As such, the economics of agriculture are vital in assuring that ample food is available. Agrarian economic patterns have forged theories on trade, surpluses, politics, class structure, and technology.

Throughout history, the advent of certain technologies has vastly increased the productivity of agricultural societies and created greater complexities in anthropological interaction. In this case, simplistic technology—such as advances in storage methods and the application of the wheel to wagons—allowed farmers to increase productivity by addressing the challenges of sustainability and transportation. Originally, agrarianism held values on self-sustenance and preserving simple life needs. However, as empires spread and cultures interacted, transportation became necessary. Value was created by supplying the population with foodstuffs, creating the need for surpluses and preservation of goods. Over the course of history, the external forces of famines, droughts, and flooding have constantly challenged agrarian productivity.

The base of the original concept was the value and products given by the land itself. Different regions were more fertile than others or produced unique products, and this fact led the way to trade. This trade and need for mobility—through the growing concepts of empire, colonialism, and globalization—further led to consumerism. This consumerism was born from the concept of differentiation of product and the demand for specific products, making transportation and even exploration paramount for growing economies. This new need for trade led to the advent of currencies, which in simple primitive agrarian societies existed in the form of barley (Grenier n.d.). Many believe the first accounting principles originated in primitive societies in the measure of agricultural trade.

Today, agrarian economics are crucial in maintaining food source for the growing population. As recently as 1960, nearly 60 percent of the simple agrarian societies still in existence are located in Africa and Asia and are responsible for only 30 percent of the world's food. Many of these societies exist on the brink of starvation. It is believed that total food production must increase by 30 percent in order to fill the world's basic food needs (Georgescu-Roegen 1960). These figures have increased as population growth continues and the gap in economic strength widens. Quantifying these types of theories makes clear that the consumption of products plays a role in determining economic strength as well as the ability to successfully supply efficient and sustainable food for an economy. In that sense, agrarian economics is a vital part of measuring an economy, in that it is a measurable part of trade and value within a given nation. Therefore agrarian economies must be carefully studied and continually developed to help increase productivity and efficiency.

ALASKA DEPT. OF ENVIRONMENTAL CONSERVATION V. EPA

Standards for safeguarding the environment are set at both the state and national levels. Most of the economic burden associated with protecting the environment and economic growth is incurred by local industry. Meeting clean air standards includes expenses that increase the cost of doing business. In a competitive market, these added expenditures to clean up existing factories and build new ones have long-term effects on a state's economic development. In addition, there is a political relationship between economic growth and protecting the environment. In the case of *Alaska Dept. of Environmental Conservation v. EPA,* 540 U.S. 461 (2004), the relationship between the state of Alaska and a federal bureaucratic agency snowballed into a classic battle between states' rights and federal power.

Case Summary

Red Dog Mine is one of the largest zinc mines in the world. It is located in the Northwest Arctic borough of Alaska, almost 50 miles from the Chukchi Sea. Red Dog is operated by Teck Cominco Alaska Incorporated and owned by NANA, a regional Alaska native corporation formed in 1971 under the Alaska Native Claims Settlement Act (ANCSA). NANA (not an acronym) is a for-profit corporation owned by thousands of Inupiat (indigenous people who inhabit northwest Alaska) and is one of Alaska's largest employers. The partnership between Teck and NANA over the last three decades has been a serious contributor to Alaska's economy. Mine operations provide hundreds of jobs for the local and regional economy, as well as key economic benefits to Alaska's Native population through shareholder dividends and community support.

The method Red Dog Mining uses to extract zinc and lead is an open pit process where there is drilling, blasting, and separating. To secure future productivity, a plan for expansion of the mining industry included the completion of a new diesel-fired power generator to fuel operations. Mining can have negative impacts on the surrounding environment, including air, soil, and water. However, this case was concerned with air pollution from the stacks connected with the power generator.

During President Lyndon Johnson's administration, the Clean Air Act of 1963 was signed into law. This act authorized the U.S. Public Health Department to research techniques that would monitor and control air quality. The Clean Air Act of 1970 (CAA) changed the focus from research and monitoring to standard-setting and enforcement. At the same time, the 90th Congress passed the National Environmental Policy Act (NEPA), which took effect in January 1970. This landmark piece of legislation was passed unanimously in the Senate and almost as favorably in the House, reflecting an increased national appreciation for the environment and attention to its safekeeping. Following this stream of legislation, in December 1970 President Nixon signed an executive order (presidential power that enables the operation and management of the federal government) consolidating the administration and enforcement of environmental law to the Environmental Protection Agency (EPA).

At the onset of this case, Alaska had not seen 30 legislative sessions. In terms of developing bureaucratic agencies, statutory history, and political encounters, Alaska is a youngster. The fledgling Alaska Department of Environmental Conservation (ADEC) has a division of Air Quality that manages stationary out-of-stack discharges of air pollution through a permit and compliance program. In addition, it monitors, measures, and alerts the public to any health concerns. These standards were developed with the federal EPA guidelines in mind, but they reflect the unique idiosyncrasies of Alaska, such as an occasional volcanic eruption or glacial ice dust storm. As well as the federal and state duty to the environment, industries such as Teck and Red Dog Mining assert that they also take seriously their responsibility to care for the land and to ensure the future of these natural resource benefits.

Red Dog Mining applied for a permit through ADEC to comply with local and federal air-quality standards at its construction site. The CAA states that new facilities must use the "best available control technology" (BACT) to limit pollution, especially in areas still relatively free of contamination. Alaska had a legal obligation to meet this standard, but on final review, the state decided that the BACT was too costly and gave a permit for a less expensive alternative.

The EPA disagreed and, after much-documented memo tag, ordered a halt to construction of the Red Dog generator in February 2000. Alaska challenged the EPA in the Ninth Circuit Court of Appeals in San Francisco. The appellate court upheld the EPA's authority to require a stricter interpretation of the standards, and it frowned upon the pressure put on states by industries feeling the economic weight of added costs. Alaska appealed to the Supreme Court.

In October 2003, the Supreme Court heard arguments in the case of *Alaska Dept. of Environmental Conservation v. EPA*. The plaintiff argued that the EPA did not have the authority to override a discretionary determination by the state of Alaska. Moreover, it was never Congress's intention to allow such encroachment of the federal government into what should be decided by local priorities and local control. Furthermore, if the EPA did not agree with Alaska's interpretation of the law, the correct procedure was a review by the courts. The EPA disregarded states' rights and overstepped its congressional authority when it barred the construction of the facility.

The EPA responded by stating that nothing in the CAA shielded states from arbitrary and unreasonable decision-making. In the EPA's view, Alaska was arguing the letter of the law—procedure—and ignoring the spirit of the law—clean air. As for the former, the EPA had a due process drill that Alaska chose not to follow. In the EPA's opinion, air quality suffered and procedural due process was not a valid excuse. The EPA recognized that state agencies had the power to make discretionary decisions as to what constituted the BACT based on what the costs would mean to the mine in terms of profitability, employment, or global competitiveness. The problem was that Alaska admitted that the Red Dog Mining Company had failed to bring this evidence to trial. Alaska thereby conceded that it had made the discretionary decision without substantive facts. The EPA claimed the authority to stop such random acts of disregard for air quality, as Congress gave it a mandate to carry out the intent of the law.

The responsibility of the Supreme Court in this case was to determine if under the CAA, the EPA had the authority to overrule a state agency's discretionary decision in determining the BACT. The Court questioned the EPA's implication that in this case Alaska was not the depository of best judgment as to what would work in local communities and federal law requirements. On the other hand, the Court examined the extent of Congress's intention to give the EPA the enforcement authority to prevent significant deterioration of ambient air, especially in areas where early prevention would be key to maintaining air quality.

In January 2004, in a 5–4 vote, the Court decided to uphold the findings of the Ninth Circuit Court. Justice Ginsburg wrote in the opinion of the Court that ADEC should have stayed with its original permit suggestion to Red Dog Mining, whereby emissions would be reduced by 90 percent, as opposed to its final decision allowing only a 30 percent reduction. The Court conceded that states have the discretionary power to make these decisions, though not untethered to the federal requirements of BACT as stated in the CAA. In this case, the justification of this choice lacked evidentiary support and was therefore unreasonable. In addition, it assumed hypothetical usage of various smokestacks to justify the lower standards, again not providing enough substantive evidence. In the opinion of the Court, the EPA properly exercised its authority when it stopped construction at the Red Dog Mine.

James Madison cautioned in Federalist Paper No. 46 that intrusion of the federal government on the power of state governments would be cause for serious alarm. Supreme Court Justice Kennedy echoes Madison's forewarning in his dissent. Kennedy states that the majority opinion rests its findings on principles that do not preserve the integrity of the states in our federalist system. Furthermore, Kennedy continues, the EPA exceeded its power by executing administrative fiat and not allowing a review by the courts to take place. By definition, BACT presumes that the states will take into consideration all criteria and apply a more comprehensive lens to the decision-making process.

However, preceding the federal intervention in Alaska was a chain of events from Love Canal to the publication of Rachel Carson's *Silent Spring*. The balance of environment and economic growth involves an evolution of circumstances. Indeed, the America Invents Act of 2011 (Leahy-Smith Act) continues James Madison's analysis. In Federalist Paper No. 10, Madison stated that the Constitution is a "happy combination" in which the national government takes the aggregate interest and the states care for the local and particular concerns. Whether or not the Clean Air Act anticipated the local and particular concerns to be accommodated by the agents of the state legislatures remains part of this precarious balancing act. The outcome in this case suggests that the federal government must be vigilant in safeguarding standards that Congress established to protect the environment.

ALCHIAN, ARMEN

Born: April 12, 1914, in Fresno, California; Died: February 19, 2013, in Los Angeles; Nationality: American; Professional Interests: macroeconomic theory, inflation, costs and output, property rights; Major Works: "Information Costs, Pricing and Resource Unemployment" (1969), *Choice and Cost under Uncertainty* (2006).

Armen Alchian provided scholars with significant insights into several fields of economics. In macroeconomics, Alchian was instrumental in identifying the relationship between inflation and wages and clarifying why money is necessary for an efficiently functioning economy. In microeconomics, he clarified the relationship between costs and production. He also countered the argument for property rights. While his body of work was not weighty in size, it was impressive in breadth and depth and it broadened the understanding of economics.

Armen Albert Alchian was born in Fresno, California, in April 12, 1914. He attended Fresno State College for two years before transferring to Stanford University. He earned a BA from Stanford in 1936. He continued his graduate studies at Stanford, earning his PhD in economics in 1943. Upon graduation, he had a brief tenure at the University of Oregon as an instructor. During World War II, he served as a statistician for the U.S. Air Force. Following World War II, he joined the faculty at the University of California, Los Angeles.

While often cited for his work in microeconomics, Alchian was also responsible for important contributions in macroeconomic theory. Within the study of macroeconomic theory, he stands out as a contrarian voice to some of the prevailing ideas of his day, particularly on the effects of inflation. Alchian emphasized the importance of detailed historical data when testing economic theories with empirical evidence. An engaged thinker, he would not accept claims without evidence to back them up.

This is most clearly illustrated in the work he did concerning "wage lag" inflation. Wage lag inflation favorably affects firms at the expense of laborers. Many economists believed that labor markets operated differently than other markets. Most of his contemporary economists believed inflation did not have an effect on wages: Wages would not follow as the general price level of goods and services in an economy began to rise. Although economists made these claims, it was Alchian who applied empirical historical data and discovered that in reality there was barely any evidence to support the wage lag theory. He was able to establish that labor markets functioned much in the same way as all other markets.

His work on inflation went beyond his study of the wage lag theory. He also developed detailed ideas about the impact of anticipated inflation versus unanticipated inflation. Alchian conducted much of his work on this area of inflation during the late 1950s and early 1960s, when price indices were showing little inflation. But in subsequent decades when the U.S. inflation rate began to rise, Alchian's ideas became reality as economists witnessed a transition from a world where people expected and experienced price stability to a world with persistently higher-than-expected inflation. His work and experiences showed the need to include inflationary expectations when modeling inflation's effects. He did this by showing that if inflation is unanticipated, holders of cash will behave in a certain way and generate a certain set of implications. If on the other hand holders of cash do expect inflation, they will behave differently, generating an entirely different set of expectations.

A second area Alchian was known for exploring is the role of money in an economy, specifically addressing the questions of what is money and why is it used. In a short essay titled "Why Money?" Alchian explored what money is and why it exists. In this essay, Alchian also demonstrated his ability to use plain language to clarify complicated issues and make them accessible to everyone. For Alchian, a thorough understanding of money serves as an important basis for the understanding of monetary policy. In "Why Money?" he identified three conditions that give rise to the use of a commodity as money. When there is a commodity about which everyone is informed, then everyone will be a specialist in that good and it will be used as money. Alchian also illustrated how what a society considers "money" has a low "recognition cost." As such, its quality and characteristics are readily identifiable by everyone. It can be used to facilitate almost every trade, and therefore it satisfies the characteristics as to what can serve as money.

Even with his important contributions to macroeconomics, his work in microeconomics represents even greater contributions to the field. Two notable areas of his work are developments in understanding the relationship between costs and output in the production process and the implications of private property.

Prior to his work on costs and output in the production process, it was commonly held that a firm's costs depend only on the output. In "Costs and Outputs" (1959), Alchian held that costs are actually determined by several dimensions within a well-defined production process. In his work, he outlines what these dimensions are and describes how costs respond to those variables when they are allowed to change separately. His work in this field was a departure from the classical theory of production.

In his work on private property, Alchian attempted to clarify important issues surrounding property rights by explaining the structure of property rights, the social consequences that result from a particular structure of property rights, and the way in which a particular structure of property rights comes into being. Alchian submitted that what is owned is not the property itself but the right to use it in a particular socially accepted way. Alchian rejected the critics who say property rights take away from human rights, by asserting that property rights are human rights and that a well-defined and enforceable system will lead to better outcomes for society.

Armen Alchian's long career and groundbreaking work qualify him as one of the most important economic thinkers of modern times. His insights into both macro- and microeconomic theory have shed light on the subject in ways that no one previously had. His unique ability to make difficult concepts accessible to any interested party also set him apart as a skilled educator. In 1996, he was named a distinguished fellow of the American Economic Association.

Amen Alchian died on February 19, 2013, at his home in Los Angeles. He was 98.

AUTOMATIC STABILIZERS

Automatic stabilizers aim to lessen the impact of negative business cycle fluctuations or too-rapid economic expansion on individuals. Since the changes in government spending and/or taxation occur automatically to offset recessionary or expansionary economic conditions, government does not have to intervene in the economy.

The contraction or recessionary phase of a typical business cycle is troubled with declining economic growth that often translates to higher levels of unemployment and declining wages. During a recession, government spending (at both the federal and state levels of government) automatically increases in the form of transfer payments. The most common increases in government spending are in the areas of unemployment compensation and welfare payments such as food stamps, Temporary Assistance for Needy Families (TANF), and free and reduced school lunch programs. All of these transfer payments automatically increase during a recession (the contraction phase of the business cycle).

Coupled with the increase in government spending, federal income tax rates and payroll taxes received by the government are reduced. During recessions, individuals pay less in taxes as their incomes decline or they become unemployed. Consequently, payroll taxes paid by businesses also decrease. The automatic increases in government spending help to lessen the negative impact of an economic contraction on individuals.

The goal of automatic stabilization policies is to increase consumer and investment spending, which will increase real gross domestic product, which in turn will decrease the unemployment rate. According to Douglas Elmendorf of the Tax Policy Center, reduced income and payroll taxes offset any decline in real gross domestic product by 8 percent (2008).

Similarly, the expansion phase of the business cycle is filled with increasing economic growth, a decrease in unemployment, and rising wages—which can lead to inflation. The automatic stabilizers that control this part of the business cycle are decreases in government spending and an increase in marginal tax rates. Government spending decreases during the expansionary phase of the business cycle as more individuals are employed, because transfer payments such as unemployment compensation, welfare payments in the form of food stamps, and free and reduced school lunch programs decrease. Additionally, a progressive income tax schedule leads to increased government revenues as incomes increase and to increasing payroll tax revenues from businesses as the economy expands. The goal of these policies is to decrease consumer and investment spending, which will slow economic growth and reduce the potential of an increased inflation rate.

While automatic stabilizers help control the large negative or positive fluctuations of the business cycle, the stabilizers often do not have a large enough impact to reverse a business cycle. Coupled with the above automatic stabilizers, most economic systems rely on additional fiscal and monetary policy measures to control the extreme (severe recession or too-rapid expansion) aspects of the business cycle.

One of the major arguments against relying on the automatic stabilizers of government spending and taxation to control the fluctuations of the business cycle is the impact that these policies have on interest rates. During an economic contraction, government spending automatically increases and taxes automatically decrease, which often results in deficit spending by the government. When a government spends more money than it collects in taxes, it must borrow money by selling bonds in the open market to fund the increase in spending or the shortfall in tax collection. This increase in borrowing by the government has a crowding-out effect on private investments, because the increase in government borrowing tends to increase the real interest rate in the loanable funds market. This higher real interest rate encourages saving and discourages spending or borrowing to purchase goods and services, which has the opposite effect of the intended increase in government spending and decrease in taxes. Similarly, during times of rapid economic expansion, government spending automatically decreases and taxes automatically increase, which often results in a decrease in deficit spending. This decrease in government borrowing will lead to lower real interest rates in the loanable funds market, which will encourage spending or borrowing to purchase goods and services and discourage saving; this is the opposite effect of the intended decrease in government spending and increase in taxation. The movement of interest rates in the loanable funds market that these policies create decreases the impact of the automatic stabilizers of government spending and taxation.

Despite the interest rate effect that automatic stabilizers create, they are viewed as a positive way to control the large fluctuations in the business cycle and to lessen the negative impact these fluctuations have on individuals. This is most likely because these policies target individuals who are negatively impacted by the business cycle. These policies are a transfer of wealth from individuals not impacted by the change in the business cycle to the individuals who are impacted.

BANK OF THE UNITED STATES, CLOSURE AND LOWER TARIFFS, 1833

When Andrew Jackson was elected president in 1828, he faced a major recession, a national debt of $45 million, and a nation divided on tariffs. The real problem was that the United States was a nation of two very different economies in the South and the North that often worked in opposition to each other. In the presidential election, Jackson had faced three opponents: John Quincy Adams, William Crawford, and Henry Clay.

Jackson had run against John Quincy Adams of the National Republican Party who supported high tariffs and an aggressive expansion of business. The election was a split decision and had to be settled by Congress. Jackson's focus had been on the national debt and distrust of the Bank of the United States' ability to resolve the financial crisis. Jackson had hoped to sell government shares in the bank, sell land back to the states, and reform the bank in an effort to eliminate the national debt.

In Jackson's first term, the U.S. economy improved, and he focused on government corruption. He won a second term with 56 percent of the vote, and he took that result as a mandate to take on the Bank of the United States and other economic issues, such as the tariff rates. Jackson was able to effectively shut down the national bank and lower tariffs, but one effect of these successes was a recession in the manufacturing sector. For decades, the bank had been a key element in a robust expansion of manufacturing. Jackson's attack on the bank also set the stage for the panic of 1837 and America's first major economic depression. On the positive side, Jackson paid off the national debt through sales of federal land.

The Bank of the United States and its branches had been popular in the eastern, mid-Atlantic, and western states, where it had financed and expanded manufacturing and business in such cities as Pittsburgh, Cincinnati, and St. Louis. The South generally disliked the bank, believing it favored the North and did little for the South's agricultural society. They believed the government was funding the bank on the backs of cotton and tobacco producers with tariffs. The West often thought the bank did not loan enough money to support land purchases. The scandals and corruption that sometimes surrounded the bank had often upset the general public.

Still, the bank had been the real driving force behind America's rise in manufacturing. It had also performed the function of a central bank, making America more resistant to deep economic depressions. The bank was popular with manufacturers as a source of capital but opposed by farmers and southern plantation owners. Unfortunately, the bank became the focus of a populist political movement. In

1828, Andrew Jackson had won the presidency by running against the bank. As president, his dislike of the bank only grew as the bank remained outside of government control while being funded with government funds.

Early in his second term, Jackson addressed the country's high tariffs with reduced rates in the Tariff Act of 1832. This tariff was still a problem for South Carolina, but Jackson and Henry Clay, his opponent in the Congress, worked out a Compromise Tariff of 1833. The opportunity to end the Bank of the United States came in 1836 when the bank's charter was up for renewal. In 1832, Congress had passed a bill to renew the bank's charter, but Jackson used his veto to stop it. This veto would create a personal fight between Jackson and Nicholas Biddle, the president of the Bank of the United States.

Jackson moved to destroy the bank by launching an investigation into its operations and removing all its government funds. Biddle countered by starting to replace the lost funds with foreign notes. The feud would become known as the "bank war." When the government investigation found no corruption, Jackson ordered his secretary of the Treasury, William Duane, to remove government funds. Duane refused, and Jackson named a new secretary of the Treasury. In September 1833, Jackson stopped all future deposits to the bank. In Congress, Clay opposed Jackson's actions and labeled them as unconstitutional.

Biddle tried to turn the public against Jackson by slowing the economy. The economy in the North had been in a robust expansion. Biddle, using the tools of the Bank of the United States, moved interest rates up, which slowed the economic expansion. The interest-rate increases allowed loans to be called in. This action led to bankruptcies and business failures. Biddle also held back on lending to business. The bank's actions also put financial strain on land purchases and home-building in the West. Unemployment increased, and the public turned on Jackson, then on the bank. The recession hit the manufacturing states hard.

In the long run, however, the Bank of the United States, acting in its self-interest, behaved just as Jackson feared. He was able to convince the public that the bank was out of control and not responsible to the people. Congress finally jumped in to back Jackson, and the bank's charter was not renewed. The Bank of the United States reverted back to its roots as the Bank of Pennsylvania. In 1841, the bank filed for bankruptcy. The closing of the national bank weakened the nation's banking system, which would lead to the great panic of 1837.

BANKING ACT OF 1933 (GLASS-STEAGALL ACT)

The Banking Act of 1933, also known as the Glass-Steagall Act, was introduced as a response to the stock market crash of 1929. It established the Federal Deposit Insurance Corporation (FDIC) and enforced many other banking reforms. The congressional sponsors of this act were Senator Carter Glass, a Democrat from Virginia, and Representative Henry Steagall, a Democrat from Alabama. The Banking Act of 1933 combined two congressional projects: (1) the creation of a federal system of bank deposit insurance, and (2) the regulation of commercial and investment banking. Although at the time, the Roosevelt administration and many in Congress resisted and criticized the act for introducing inefficiency and limiting competition, today many of its supporters consider the act to be the possible explanation for a long period of financial stability in U.S. banking history.

Contrary to the commercial banking theory prevalent during the 1920s, many economists and politicians argue that the stock market crash of 1929 happened mainly because banks were loosely regulated and were actively involved in security market speculation. Following its inception in 1913, the Federal Reserve System had minimal control over the activities of U.S. commercial banks. Senator Glass was one of the proponents of the commercial banking theory, which suggests that commercial banks should limit their lending to short-term loans to finance only the production and sale of goods (versus securities such as stocks or bonds) in commercial transactions. Glass believed that if this theory had been followed and enforced, the crash of 1929 could have been avoided. Senator Glass introduced his first bill on June 17, 1930, to investigate the operations of the National and Federal Reserve banking systems.

Furthermore, Glass and his long-term adviser Henry Willis opposed the engagement of commercial banks in real estate lending, a practice that decades later crippled the U.S. economy during the recession of 2007–2009. Glass criticized banks for lending to stock market speculators and for engaging in risky security transactions, and he criticized the Federal Reserve for not applying better regulatory policy.

In 1933, Senator Carter Glass and Representative Henry Steagall introduced the Banking or Glass-Steagall Act. The main purpose of this historic legislation was to limit conflicts of interest between the banks and individual investors caused by the involvement of commercial banks in underwriting activities related to the security exchange. The new law prohibited commercial banks from underwriting securities. In addition, the banks had to choose between being a commercial bank or an investment bank. The Glass-Steagall Act also introduced the Federal Deposit Insurance Corporation (FDIC) to insure deposits of all commercial banks and to increase the control of the Federal Reserve over them. The deposit insurance and most provisions of the act were severely attacked during congressional debate, mainly for limiting competition and introducing inefficiency into the U.S. banking industry. Despite all opposition, the Banking Act of 1933 was signed into law by President Roosevelt on June 16, 1933.

The law imposed numerous banking reforms and established the FDIC in the U.S. banking system. The Banking Act of 1933 had a significant number of provisions, many of which were changed or repealed over time. The provision that required all FDIC-insured banks to be members of the Federal Reserve System was repealed in 1939. In 1956, the Bank Holding Company Act extended banking regulations by restricting banks that owned other banks from engaging in nonbanking activities or acquiring banks in other states. During the 1960s and 1970s, bank lobbyists persuaded Congress to allow commercial banks to enter the securities market. By the 1970s, a number of investment firms started introducing some of the traditional commercial banking services, offering services such as money market accounts with interest, allowing check writing, and offering credit or debit cards.

In 1986, the Federal Reserve Board bent the law by allowing commercial banks to earn up to 5 percent of their gross revenue from investment banking. Later, the Federal Reserve Board allowed the Banker Trust, a commercial bank, to actively participate in short-term credit transactions and underwriting activities. Finally, in 1987, after more than five decades of strong lobbying of big commercial and investment firms against the Banking Act of 1933, the Federal Reserve Board voted three to two in favor of easing the restrictions imposed by the act. In March 1987, despite strong opposition from Paul Volcker, the Federal Reserve Board chair at the time, the Fed approved an application by Chase Manhattan to participate in underwriting securities. In addition, the Fed increased the limit for participation of commercial banks in securities investment from 5 percent to 10 percent of their gross revenue.

In August 1987, Alan Greenspan became the new chair of the Federal Reserve Board of Governors. A former director of J. P. Morgan, Greenspan firmly advocated for banking deregulation. In 1989, the Federal Reserve Board approved additional applications by J. P. Morgan, Chase Manhattan, and other national banks to allow them to expand their transactions to debt and equity securities. In 1990, J. P. Morgan became the first bank to participate in underwriting activities, with the condition that it not exceed the newly imposed 10 percent limits. After the Senate's numerous failed attempts to repeal the Glass-Steagall Act of 1933, in December 1996, supported by Chairman Alan Greenspan, the Federal Reserve Board increased the limit for engaging in securities business to 25 percent of the gross revenue of commercial banks. Finally, in 1999, Congress passed the Financial Services Modernization Act, repealing the Banking Act of 1933.

BANKRUPTCY REFORM ACT OF 1978

President Jimmy Carter signed the Bankruptcy Reform Act of 1978 on November 6, 1978. However, it was not until October 1, 1979, that the Bankruptcy Reform Act of 1978 took effect. The act made it easier for both businesses and individuals to file bankruptcy and reorganize. This law substantially transformed bankruptcy practices in the United States, and it still serves as the federal law that governs bankruptcy cases today.

The act authorized three main types of bankruptcies: Chapter 7, which allows to liquidation of a business and discharge of debts; Chapter 11, which allows for corporations to continue operations after reorganizations; and Chapter 13, which restructures debt but does not forgive it. While these important changes helped to pave the law of bankruptcy in the United States, they created several controversies in the process.

The most controversial changes were those involving personal or nonbusiness bankruptcy. Some were concerned that the act enhanced the position of debtors in relation to creditors. Others believed the benefits of personal bankruptcy would lead to an increase in the number of bankruptcy cases that would have an adverse effect on the market. Bankruptcy filing rates did increase, but this may have been due more to external factors, including that consumer debt had become more common than it was prior to the enactment of the 1978 act. More people were likely to borrow money, resulting in a greater likelihood of defaulting on their debt and filing for bankruptcy. Consumer protection advocates, however, argued that bankruptcy should be more generous than the legislation established.

As a result, there have been a number of notable developments and judicial clarifications in bankruptcy rules following the 1978 act. One pivotal amendment was made in a 1982 Supreme Court ruling that deemed the extended jurisdiction of the Bankruptcy Court, originally established under the 1978 act, as unconstitutional. The Supreme Court ruling stated that Congress had given bankruptcy judges too much power. The Court asserted that their responsibilities overlapped with the duties of other branches of government. This ruling led to the Bankruptcy Amendment Act of 1984.

Continued debates led to the Bankruptcy Reform Act of 1994 signed into law by President Bill Clinton. The 1994 act is said to be the most comprehensive piece of bankruptcy legislation since the 1978 act, and it contains many provisions to both business and consumer bankruptcy. Specifically, the 1994 act created a National

Bankruptcy Commission to further investigate revision of bankruptcy laws. The law encouraged debtors to use Chapter 13 to reschedule their debts, as opposed to Chapter 7 to liquidate and aid creditors in recovering claims against bankrupt estates. This was encouraged with the intention of expediting bankruptcy proceedings.

Another trend following the 1978 act was the frequency of corporate reorganization. Like the increase in bankruptcy cases, it is unclear whether this was a result of the act. Major changes in the economy took place during the 1980s, and many corporations borrowed money in order to finance their investments. As many corporations took on more debt, they became more likely to default on their loans—with bankruptcy an increasingly appealing option.

These debates, nonetheless, obscure the true intentions and consequences of bankruptcy law. A generous personal bankruptcy law that shields assets and future income can be beneficial as well as detrimental. On the one hand, the law reduces that adversity individuals experience when circumstances prevent them from paying their debt. On the other hand, the law increases the cost of credit by making it harder for creditors to collect their debt.

Similarly, corporate reorganization also involves tradeoffs. A flexible law makes the reorganization of firms easy, and as a result insiders and large creditors might use reorganization as an opportunity to improve their financial position at the expense of small creditors, workers, and other stakeholders. Conversely, if the law makes it hard to reorganize firms, then a firm may be unable to pay and its debts will be liquidated, keeping the firm from executing a potentially good business plan. A good corporate bankruptcy law gives managers, creditors, and other stakeholders some flexibility, but not too much.

BERNANKE, BEN

Born: December 13, 1953, in Augusta, Georgia; Nationality: American; Professional Interests: monetary policy, chairman of the Federal Reserve System 2006–2014; Major Works: "Nonmonetary Effects of the Financial Crisis in the Propagation of the Great Depression" (1983), *Essays on the Great Depression* (2004), *The Federal Reserve and the Financial Crisis* (2013).

Ben Bernanke is an American economist who served as chairman of the Board of Governors of the Federal Reserve System from 2006 through January 2014. Notably, Bernanke directed the Federal Reserve's response to the financial crisis of 2008–2009. He first served as a member of the Federal Reserve Board of Governors from 2002 to 2005. He then served President George W. Bush for a short time as chairman of the Council of Economic Advisers. In early 2006, Bernanke was appointed chairman of the Federal Reserve Board of Governors by President George W. Bush, and in 2010 he was reappointed by President Obama. Prior to joining the Board of Governors, Bernanke was a tenured professor and chair of the Princeton University Department of Economics.

Benjamin Shalom Bernanke was born on December 13, 1953, in Augusta, Georgia. Growing up in Dillon, South Carolina, as the grandson of Jewish immigrants, he graduated as high school class valedictorian. Bernanke earned his BA in economics from Harvard University with honors in 1975. He received his PhD in economics from Massachusetts Institute of Technology (MIT) in 1979. His dissertation adviser was future Bank of Israel central bank counterpart, Stanley Fischer.

Bernanke's dissertation, "Long-Term Commitments, Dynamic Optimization, and the Business Cycle," launched his career as a Depression-era economic historian. Upon graduation from MIT, Bernanke began his academic career in the Stanford University Graduate School of Business. Bernanke joined the faculty at Princeton University in 1985, becoming department chair in 1992—a position he would hold until 2002.

Bernanke's expertise and research on the economic causes and consequences of the Great Depression elevated his reputation as an equal to Milton Friedman and Anna Schwartz. In 1983, Bernanke published "Nonmonetary Effects of the Financial Crisis in the Propagation of the Great Depression." In this piece he made the case that the key cause of the eventual collapse of the economy in 1929 and the subsequent depression of the 1930s was the banking system's failure to provide sufficient credit. This view goes beyond Friedman's response, which laid blame directly on the Federal Reserve and the government. Later, in 2004, Bernanke would provide a summation of his views in *Essays on the Great Depression*.

Beyond his work on the Great Depression, he is the coauthor of two successful economics textbooks, both in their multiple editions. Bernanke has delivered lectures at the London School of Economics on monetary policy and theory. He directed the Monetary Economics Program of the National Bureau of Economic Research and edited the *American Economic Review*.

Ben Bernanke entered public service in 2002 when he accepted an offer from President George W. Bush to join the Federal Reserve Board of Governors. He remained on the Board of Governors till 2005, when he chaired President Bush's Council of Economic Advisers until 2006. In 2006, he was a top candidate to replace the retiring Alan Greenspan as chairman of the Federal Reserve Board of Governors. On February 1, 2006, Ben Bernanke succeeded Greenspan as chair, becoming the most important monetary economist in the nation. He also chaired the Federal Open Market Committee, the committee responsible for key monetary policy decisions.

Although he soundly defended the Federal Reserve's actions, Bernanke was not without his critics. He was criticized for the Federal Reserve's role in backing J. P. Morgan Chase in order for Chase to buy Bear Stearns, and he was further criticized for the Troubled Asset Relief Program (TARP) and for the U.S. Treasury bailout of AIG.

An avowed monetarist and student of the Great Depression, Bernanke feared deflation more than inflation. As a result, he publicly advocated supplying as much money as necessary to the monetary system to avoid a deflationary spiral. Because he used a helicopter analogy in a speech to describe his monetary views, Bernanke was labeled (mostly by his critics) "Helicopter Ben."

On three different occasions (Quantitative Easing [QE] I, II, and III), the Fed went into the business of buying and adding depreciated assets to the Federal Reserve's balance sheet. In return, the Federal Reserve supplies sufficient quantities of dollars into the monetary system, keeping interest rates at historical lows. In responding to these crises, under Ben Bernanke the Federal Reserve took on more direct actions than at quite possibly any time since its inception in 1913.

Bernanke's honors have included being named a fellow of the American Academy of Arts, the Guggenheim, and the Econometric Society. He also was a member of the National Bureau of Economic Research (NBER) and NBER's Business Cycle Dating Committee.

Ben Bernanke was succeeded by Janet Yellen as Chairman of the Board of Governors of the Federal Reserve System and Federal Open Market Committee beginning February 1, 2014. Ben S. Bernanke is a Distinguished Fellow in Residence with the Economic Studies Program at the Brookings Institution.

BUREAU OF ECONOMIC ANALYSIS

The Bureau of Economic Analysis (BEA) is an agency of the Department of Commerce. The Census Bureau and the BEA are two divisions of the department's economic and Bureau of Economic Analysis statistics administration. The BEA's main responsibility is to promote an accurate picture of the U.S. economy by providing key economic statistics, including the national income and product accounts (NIPAs) and gross domestic product (GDP). These estimates are then used to provide important information about essential issues such as economic growth rate, industry-specific and regional development, and, most importantly, the economic strength of the nation in the world's economy. The BEA's mission is to promote an enhanced understanding of the U.S. economy by developing and providing timely, relevant, and accurate economic accounts statistics in an objective and cost-effective manner.

In 1972, the BEA was officially established in the Social and Economic Statistics Administration (SESA) within the Department of Commerce. However, the function of developing and interpreting the economic accounts of the United States goes back to 1820, when the Division of Commerce and Navigation (1820–1866) was responsible for developing and publishing annual statistics on U.S. foreign trade. By 1844, this responsibility had expanded to include domestic trade within the United States.

During the 20th century, the important task of deriving and analyzing national economic statistics evolved and expanded. Today, the BEA is one of the most important statistical agencies in the world and is the main agency of the Federal Statistical System in the United States. The BEA collects and manages data from various segments of the U.S. economy, conducts research, develops statistical estimates, and disseminates statistics to the public. The BEA offers statistical information in five different categories: (1) national, such as GDP, personal income, consumer spending, corporate profits, and fixed assets; (2) international, such as balance of payments, trade in goods and services, international services, international investment, direct investment and multinational companies, and survey forms and related materials; (3) regional, such as GDP by state and metropolitan area, personal income by state and local area, and economic information for coastal areas; (4) industry, such as annual industry accounts, benchmark input-output accounts, research and development satellite accounts, travel and tourism satellite accounts, and supplemental statistics; and (5) Integrated Accounts, such as integrated income, product, and Federal Reserve Financial Accounts, integrated BEA GDP–BLS productivity accounts, and integrated BEA–BLS industry-level production accounts.

GDP and national accounts statistics are used by the White House and Congress to prepare budget estimates, by the Federal Reserve to define appropriate monetary policy, by Wall Street to provide accurate economic projections, and by business communities for financial strategies. The industry data are used by both industry and academia to estimate productivity, by the U.S. International Trade Commission to analyze trade policies, and by national and local leaders to evaluate the impacts of economic shocks. International trade and investment data are mainly used by trade policy officials to negotiate international agreements and by analysts and policymakers to evaluate the effects of international investment. Regional estimates are used by federal and local government agencies as well as businesses to track various economic activities and develop the best strategies for the future.

One of the most closely watched of all economic statistics that is developed by the BEA is the GDP. GDP is the market value of all legally recognized final goods and services produced within a country in a given period of time. GDP per capita is recognized as one of the indicators of a country's standard of living. GDP is also related to national accounts, and it is an important macroeconomic indicator.

Another primary set of macroeconomic estimates that is widely used for economic and policy analysis is the integrated macroeconomic accounts (IMAs). The IMAs consist of several macroeconomic accounts that connect production and income to the change in net worth in the U.S. economy. The accounts define the sources and expenditures of the funds that are made available for capital formation or lending. Furthermore, they track assets and liabilities of the major segments of the economy. IMAs provide enough information regarding changes in the market values of assets and liabilities to be able to draw conclusions regarding changes in the net worth of each economic segment or the entire U.S. economy.

BUREAU OF ENGRAVING AND PRINTING

The Bureau of Engraving and Printing (BEP) is an agency of the Department of the Treasury. The BEP's most important task is to produce paper currency. In addition, the BEP produces treasury securities, military commissions, and a variety of other security documents. The BEP has two large production facilities in Washington, D.C., and Fort Worth, Texas.

Prior to the Civil War, the production process for paper currency was completely manual. A private company produced bills in sheets of four. Then, the sheets were transferred to the Treasury Department, where clerks signed the bills and other workers cut them by hand. In 1861, in order to help fund the Civil War, Congress empowered the secretary of the Treasury to produce paper currency instead of coins. The paper currency served as government IOUs and was redeemable in coins at specific Treasury locations. In 1863, Congress created the Office of Comptroller of the Currency, which was responsible for the production of currency. In 1874, the BEP was officially established.

The BEP has produced a variety of different documents, such as passports, money orders, bonds, refunding certificates, and treasury notes. In 1894, the BEP officially started producing postage stamps for the U.S. government; during its first year, the BEP produced more than two billion stamps. For the next 111 years, the BEP was the sole producer of postage stamps in the United States. Finally, it became more cost-effective for the U.S. Postal Service to move stamp production to the private sector, and in 2005, the BEP produced its last set of postage stamps for the U.S. Postal Service. After more than 100 years of monopolizing stamp production, the bureau terminated its postage stamp production entirely and returned to its original main task of printing paper currency.

In 1918, following World War I, the production of paper currency increased from the initial four notes per sheet to eight. In 1929, the design of the paper currency was standardized and it became much smaller than its original size. The bureau could increase the number of notes per sheet from 8 to 12. Over the years, mainly by reducing the size of the notes, the BEP was able to lower the cost of producing paper money.

Counterfeit deterrence has improved dramatically through the BEP's application of better engraving and security techniques and the general public's improved recognition of paper note features. In 1952, after new developments in the production of non-offset inks, the BEP was able to increase the number of notes per sheet even further. The use of new ink that dried faster enabled the BEP to reduce the rate of damage and distortion in its money production. Because paper notes have to be printed on both the front and the back, this faster-drying ink made it possible for the sheets to be kept moist until both the back and the front were printed. By avoiding the re-wetting process and therefore decreasing the damage rate, in 1952 the BEP was able to switch from 12-note printing plates to 18-note plates.

In 1957, the BEP started using the dry intaglio method, which is a printing technique in which the image is marked into a surface. The areas created by the marked lines hold the ink. The BEP had to use special paper and non-offset inks to switch to the intaglio printing technique. This made it possible to increase the number of notes from 18 to 32 per sheet and to be more efficient. Using the intaglio method made wetting the paper prior to printing an unnecessary step. Since 1968, all paper monies have been printed using the intaglio method. After both faces are printed, the sheets are printed with serial numbers and U.S. Treasury seals.

The Washington, D.C., building is listed in the U.S. National Register of Historic Places. It has a neoclassical architectural style with fireproof concrete. In 1938, because of an increase in number of personnel and in size of production, the BEP added another building, opposite the main building, to its original facility. In 1987, the BEP started building a new facility in Fort Worth, Texas. The Fort Worth facility was built not only because of an increase in production size, but also to be used in case of an emergency in the Washington, D.C., area. In December 1990, the Fort Worth facility officially started production.

BUREAU OF LABOR STATISTICS

The Bureau of Labor Statistics (BLS) is an agency within the Department of Labor. The BLS formed in 1884, and it has been the main statistical agency responsible for collecting, managing, analyzing, and disseminating statistical data to the public, the U.S. Congress, other federal agencies, state and local governments, businesses, and labor representatives. The BLS is the main statistical source of the U.S. government.

On June 27, 1884, the Bureau of Labor Act established the Bureau of Labor within the Department of the Interior. The main purpose of this establishment was to collect information on labor and employment. In 1888, the Bureau of Labor became an independent department, but in 1913, it joined the Department of Labor and has remained there ever since. It is located in the Postal Square Building, close to the United States Capitol in Washington, D.C. A commissioner who serves a four-year term heads the BLS.

The BLS produces a wide range of surveys and statistics that can be divided into three main divisions: (1) prices, (2) employment and unemployment, and (3) compensation and working conditions. The U.S. Consumer Price Index (CPI), the Producer Price Index (PPI), the U.S. Import and Export Price Indices (IEPI), and the Consumer Expenditure Survey (CES) track statistics related to prices. For employment and unemployment, there are various surveys and statistics, such as the Current Population Survey (CPS), the Current Employment Statistics (CES), the Job Openings and Labor Turnover Survey (JOLTS), the Business Employment Dynamics (BED), and the Mass Layoff Survey. For compensation and working conditions, the BLS produces the National Compensation Survey; the Injury, Illnesses, and Fatality (IIF) program; and the Productivity Report. All reports, surveys, and statistics produced by the BLS are categorized into four geographic regions that are known as census regions: Northeast, South, Midwest, and West. Each region then is divided into many census divisions.

The reports and statistics produced by the BLS must be of the highest accuracy, relevance, and timeliness. Furthermore, impartiality in both content and presentation of the reports is of the utmost importance to the Department of Labor.

The following are the main sections within the BLS:

1. Office of Employment and Unemployment Statistics: This office analyzes and publishes data on employment, labor demand, work hours, earnings, and employment by occupation and industry. Every two years, this office publishes a career handbook covering the outlook for employment in many occupations.
2. Prices and Living Conditions: This office analyzes and publishes data on the CPI and the PPI, U.S. import and export processes, consumer spending patterns, and sources of consumer income.
3. Office of Compensation and Working Conditions: This office analyzes and publishes data on wages and benefits (such as health insurance, retirement plans, paid vacations, and paid holidays), and occupational safety (such as workplace injuries or occupational hazards).
4. Productivity and Technology: This office analyzes and publishes indexes of labor productivity for each industry, as well as for large economic sectors. In addition, this office compares U.S. productivity measures, labor costs, and benefits with those of other countries.
5. Survey Methods Research: This office has two centers: (1) the Mathematical Statistics Research Center (MSRC) and (2) the Behavioral Sciences Research Center (BSRC). The MSRC is responsible for the accuracy and efficiency of the BLS survey methods and its statistical analyses. The BSRC is responsible for increasing survey response rates, reducing nonsampling errors, and improving applied survey methods.
6. Publications and Special Studies: This office is mainly responsible for public relations, media contact, and dissemination of all that is produced in the BLS.
7. Field Operations: This office trains field economists who are responsible for collecting data throughout the United States. The office also conducts quality assurance and provides technical direction regarding how to collect data.
8. Administration: This office manages the administrative tasks of the BLS in such areas as financial management and human resources.
9. Office of Technology and Survey Processing: This office uses information technology to promote the mission of the BLS. Project managers and information technology specialists in this office provide a reliable and efficient system to be used for the BLS's advanced and highly technical computational tasks.

BURNS, ARTHUR

Born: April 27, 1904, in Stanislawow, Galicia (now Ivano-Frankivsk, Ukraine); Died: June 6, 1987, in Baltimore, Maryland; Nationality: American; Professional Interests: monetary policy, economic growth; Major Works: *Economic Research and the Keynesian Thinking of Our Time* (1946), *Prosperity without Inflation* (1957), *Reflections on an Economic Policy Maker* (1978).

Arthur Burns was the chairman of the Board of Governors of the Federal Reserve System from 1970 until 1978. Although his record of academic work and government service continued far beyond his time as head of the central bank, he is most commonly remembered for his work at the Federal Reserve, particularly for his part in creating the policies that led to economic stagnation and inflation during the 1970s. Burns died in 1987.

Arthur Frank Burns was born in April 27, 1904, in Stanislawów, Galicia (now Ivano-Frankivsk, Ukraine). He emigrated with his parents to New Jersey when he was a little boy. Burns earned his bachelor's and doctoral degrees from Columbia University. After earning his PhD, he was hired at the new National Bureau of Economic Research, which was located at Columbia. Here, he gathered copious amounts of data on various industries, which he used to predict economic business cycles.

Burns's research during this period focused on booms and busts in the American economy. He carefully measured aspects of the business cycle, looking into the behavior of many different industries to create a complex yet somewhat predictable view of the economy. Burns believed that recessions occurred not so much because of lack of aggregate demand, as the popular Keynesian theory posited, but because several industries happened to slump at the same time. Such a theory promised to be valuable for macroeconomic forecasting, and it gave Burns the reputation as a respectable, impartial scientist.

Burns's nuanced and moderately conservative work got the attention of the Eisenhower administration, and he was recruited to serve on the Council of Economic Advisers in 1953, which he did until 1956. Burns is credited with convincing President Eisenhower not to attempt an aggressive fiscal policy when responding to a recession. When the economy improved in 1954 without significant fiscal stimulus, Burns's fame as an approachable, wise adviser grew. In 1968, this reputation served to elevate Burns as a counselor to the newly elected President Richard

Nixon, and in 1970 Burns was appointed chairman of the Board of Governors of the Federal Reserve System.

Burns inherited an economy beset with both rising unemployment and rising inflation. He embarked upon a policy of fighting unemployment with "easy" monetary policy (i.e., keeping interest rates low in order to stimulate economic activity) while fighting inflation with a variety of schemes to discourage large companies from increasing wages and prices. He failed on both counts, as both unemployment and inflation continued to increase. Throughout his tenure as chairman of the Federal Reserve, Burns kept interest rates at a level that is now considered dangerously low. In 1978, Burns was replaced by G. William Miller—before Paul Volcker fought skyrocketing inflation not with wage and price controls (as Nixon and Burns had done), but with tighter monetary policy. This policy worked, and the Burns era of the Federal Reserve became known as a lost decade.

During the time of Arthur Burns's tenure as Federal Reserve chair, it was not clear that inflation was mostly about money. Many economists believed that inflation had to do with factors such as the power of unions and the price of oil. Attributing inflation to "real" factors such as these made monetary policy of secondary importance. More interesting, however, was the influence of President Nixon and Treasury Secretary John Connally. Nixon was convinced that he had lost the 1960 presidential election because tight monetary policy had raised unemployment, and he did not intend to lose the 1972 election for the same reason. He was recorded in the White House tapes in 1971 as saying, "I've never seen anybody beaten on inflation in the United States. I've seen many people beaten on unemployment." Nixon and Connally cynically urged, threatened, and manipulated Burns to keep an expansive monetary policy. They leaked hints to the press that Burns would no longer be an adviser and that the Federal Reserve might lose its independence if interest rates were not kept low. These threats seem to have been effective in convincing Burns to agree to a looser monetary policy than he would have held without their persuasion.

Thus, throughout the 1970s, inflation surged despite wage freezes, price freezes, and federal anti-inflation councils, and without a significant drop in unemployment. Since that time, economists have refocused on the importance of controlling the money supply as a means to stop inflation. Burns was appointed ambassador to West Germany by President Ronald Reagan in 1981, where he served effectively until 1985.

Arthur Burns died in Baltimore, Maryland, on June 6, 1987.

CHURCHILL, WINSTON

Born: November 30, 1874, in Marlborough, United Kingdom; Died: January 24, 1965, in London, United Kingdom; Nationality: English; Professional Interests: Prime Minister of the United Kingdom 1940–1945, 1951–1955; Major Works: *The Story of the Malakand Field Force* (1898), *The River War* (1899), and *London to Ladysmith via Pretoria* (1900).

Winston Churchill's attachment to the principles of political freedom guided his decisions and was the heart of his ability to inspire through speech. This strong belief in freedom was the product of his experiences throughout his lifetime.

Winston Churchill was born in Woodstock, United Kingdom, on November 30, 1874. His father, Lord Randolph Churchill, was a member of the British Parliament; his mother, Jennie Jerome, was an American heiress. After graduating from Harrow, Churchill was accepted into the Royal Military College, Sandhurst, in 1893. In December 1894, Churchill graduated near the top of his class and was given a commission as a cavalry officer. During his military career he participated in war campaigns in India, Sudan, and South Africa as a war correspondent for *The Morning Post*. During the South African campaign, he was captured and spent a month as a prisoner until he was able to escape. These experiences led Churchill to write several books: *The Story of the Malakand Field Force* (1898), *The River War* (1899), and *London to Ladysmith via Pretoria* (1900).

In the 1920s and 1930s, Churchill observed with unease the collectivism trends that were draining the internal strength of his homeland and threatening to create instability abroad. He opposed such programs; whether they originated on the Left or on the Right of the political spectrum in Britain, Churchill viewed them as destructive of freedom.

Churchill's thoughts as a whole were in agreement with America's first principles of individual liberty and limited government for both Britain and worldwide. Even though Churchill and Franklin D. Roosevelt had a working relationship and supported one another on many foreign policies, a number of scholars wrongly assume that they were also in agreement on domestic policy. Such was not the case. Churchill was opposed to the thoughts and ideas of Roosevelt's New Deal. Churchill opposed FDR's large centralized government that was not based on the founding principle of freedom.

During the 1945 election in Great Britain, Churchill had to defend his strong opposition to socialism. With the end of World War II, the government of Great Britain had assumed many extra controls. Churchill campaigned against these controls and the challenge of the Labour party, claiming that a Labour victory would increase government control over the individual.

Churchill noted that socialism attaches itself onto nationalism and the particular features of the nations it infects. He believed that Germany and the Weimar regime were destroyed and Adolf Hitler propelled to power through national patriotism. In Russia the program of Communism was supported by national sentiment and imperialist aspirations. Churchill went even further to link the United States under the New Deal due to the economic crisis to efforts to increase the power of the central government and to limit the rights of individuals. In his writings, after he described the trends in Germany, Russia, and the United States he often spoke on the opposite view. He always rejected any policy that would use crisis to extend the power of the state and decrease individual liberty. Churchill firmly believed that governments were meant to be servants of the citizens and that states come into existence only by preserving the true power that rests with the individual.

Labor Unions

Another subject about which Churchill had strong opinions was trade unions. As President of the Board of Trade, Home Secretary, and Chancellor of the Exchequer, Churchill had been involved in shaping government policy toward labor disputes and strikes. The General Strike of 1925–1926—and its political implications, in particular—had given Churchill strong negative views on the subject. Churchill's anti-union attitude often suggested that labor unions would reduce England's economic competitive edge. However, Churchill was willing to admit that the trade unions in Britain had become a stable force in the industrial development of Britain.

Redistribution of Income

According to Churchill, economic redistribution through penalties on the wealthy does not benefit a society in the long run. Redistribution drains the wellsprings of economic development. Churchill held that free markets should be allowed to operate without centralized bureaucratic controls. To Churchill, bureaucratic controls destroy the principle of competition that is the mainstay of economic health. Churchill strongly supported limiting the government's ability to make it impossible for private business to thrive by suppressing free market competition.

He and his wife Clementine had five children. Winston Churchill died of a stroke on January 24, 1965, in London, United Kingdom, at the age of 90.

COLONIAL HYPERINFLATION AND CURRENCY DEFLATION, 1749

The American colonial financial crisis of the late 1740s was the confluence of a number of growing currency problems throughout the British colonies, exacerbated by war and trade issues. Periods of hyperinflation, shortages of specie, the uneven quality of colonial paper currencies, the costs of wars with France, and trade issues with Britain all contributed to the colonial crisis.

Hyperinflation was particularly problematic in the colonies of Massachusetts, Rhode Island, Connecticut, and New Hampshire. During the 1740s, the annual inflation rate was above 19 percent. (By comparison, during the period of high inflation in the United States in the 1970s, it never rose above 13.3 percent.) Inflation increased the price of basic commodities, such as molasses, by 60 percent from 1745 to 1749. Extreme increases in the prices of raw goods created a nightmare for British trade, which counted on a supply of cheap colonial raw materials for manufactured goods. Parliament was pressured to enact the Currency Act of 1751, which prevented the colonies from printing their own paper money. The resulting lack of money in circulation, along with the high cost of goods, ultimately caused riots in the streets of Boston.

Currency problems had plagued the colonies from the start. Great Britain promoted a barter system for goods from its American colonies because it gave an advantage to British manufacturing and the goods were carried in British ships. Colonial exports of skins, ginseng, and tobacco were paid for in English goods such as clothing, pewter, and glass windows. The colonists preferred to receive specie (gold and silver coins) as payment, but coins were in short supply. Unlike Spain, Britain did not have colonial gold and silver mines as a source of the precious metals needed to make additional specie.

The best source of coins for the colonies was from piracy, as British and colonial pirates and adventurers captured Spanish treasure ships sailing between Spain and its colonies. The most common coin in the British colonies was the Spanish dollar, which could be divided into eight pieces. The activities of such pirates were welcomed by the colonists and were responsible for the wide circulation of the Spanish dollar. More coins in circulation helped improve the terms of trade for colonial merchants and farmers, because a currency-based trade is more efficient than barter.

The king of England had refused to allow the colonies to mint their own coins. During King William's War (1689–1697), when British colonists first began to pay for their own defense forces, the king had allowed the colonies to pay soldiers in paper money known as "bills of credit." Slowly, the creation of these bills of credit outpaced the silver in circulation, which was needed to lend the bills legitimacy. This resulted in inflation throughout the colonial economies from 1710 to 1750. These bills of credit were backed by the colonial governments and had to be accepted for goods; thus, they had the attributes of paper money. Like our paper money today, the bills of credit were not backed by silver or gold. Inflation increased as spending on King George's War (1744–1748) and on the French and Indian War (1754–1763) put more of this paper money into circulation and created demand for more goods.

The tight trade links between British merchants and the colonies exacerbated colonial inflation. English merchants had begun accepting these bills of credit as payment for the goods they shipped to the colonies. As the value of the bills began depreciating because of inflation in the colonies, British merchants began to charge more for their goods in compensation. A spiral of inflation began.

The currency crisis created local economic turmoil and recession as well as inflation. In the 1740s, the rate of inflation was in the double digits, creating street riots. American traders were at odds with British merchants as their barter system broke down. Another problem arose because the New England colonies could not collect taxes from farmers and merchants who were not making any money. Small farmers found themselves in deep debt to merchants in Boston, who made the currency shortage in the colonies—and thus the recession—worse by shipping much-needed colonial coins to Great Britain in return for goods.

The colony tried another form of bills of credit backed by land, known as the Land Bank. In effect, the Land Bank would create more paper money and allow more money in circulation. The idea was extremely popular with the colonists. The governor and the king did not like the idea of the Land Bank, however, judging that it would further increase inflation and allow colonists to escape full payment for goods. The Land Bank idea went forward because it was popular in elections, but ultimately it failed. The father of Samuel Adams (Samuel Adams Sr.), one of America's founding fathers, was one of those who went bankrupt when the Land Bank failed.

The combination of the economic downturn and inflation made life miserable in the colonies. Shortages of silver required customers to supply their own old silver if they wished to have new silver implements made. The shortage of currency prevented landholders from paying taxes, which in turn often resulted in their property being seized. Merchants could not sell their goods, because their buyers lacked currency.

In Massachusetts, political pressure for reform mounted as tax revenues dropped, trade tightened for lack of money, and street protests continued. In 1750, Massachusetts began currency reforms, which offered a way out of the crisis, but the other colonies refused to join it. Massachusetts worked with Great Britain to retire bills of credit through the payment of specie to the colony. Colonists had four months to turn in the bills, after which they became worthless. No future paper money would be allowed. Shortfalls would be covered by additional taxes. Massachusetts also banned the use of paper money from other colonies. The state could still issue bills backed by specie but retained an exception in case of a major war.

The immediate effect was a shortage of currency, which made things worse in the colony for a brief period. But Massachusetts issued a new type of paper currency called a Treasury Note, which was redeemable in specie and earned interest while it was held. Although Massachusetts had not planned for these treasury bills to circulate, they did—and they became a type of currency. The backing of these bills with specie restored confidence in the colony's currency. The Massachusetts reform proved highly successful as prices fell and inflation declined. By the 1740s, the Boston Land Bank had circulated these new land-backed notes at an alarming rate, and Parliament used the old Bubble Act of 1720 to restrict the practice. Finally, Parliament moved to further restrict paper money in 1751.

Britain passed the Currency Act of 1751 to impose the Massachusetts reform on Rhode Island, New Hampshire, and Connecticut. More wealthy colonists and some farmers who owned bills of credit from the Land Bank were bankrupted. New England once again suffered a mild recession. The Currency Act did not apply to the middle and southern colonies, which at the time had a stable currency. Unfortunately, New York, Pennsylvania, and Delaware continued to print bills to finance the French and Indian War. Eventually, all the colonies would be covered under the Currency Act of 1764. Virginia remained a special case because of its direct tobacco trade with Great Britain. Virginia's high currency demands during the French and Indian War allowed it to continue issuing paper bills.

Economists still use the hyperinflation in colonial Massachusetts as a case study for understanding modern-day inflation. It is striking that this colonial inflation was far more problematic than even America's experience with high inflation in the 1970s. The currency reforms that arose in Massachusetts and that Britain imposed on the colonies helped to return some stability to colonial economies. The failure of individual currencies from each colony would ultimately lead to the use of a common currency, under a common government.

CONFERENCE BOARD

The Conference Board was established during a period of economic turmoil. In 1910, a dynamite bomb exploded in a plant in Los Angeles, killing 20 workers. The following year, in New York, a fire burned the Triangle Shirtwaist Factory, killing 146 workers, most of them young women. In 1914, in Colorado, a strike between miners and the Colorado Fuel and Iron Company led to the "Ludlow Massacre," in which more than 25 people were killed. Following these tragic events, the public largely began to condemn businesses, leading Albert Magnus to found the Conference Board as an idea, not an institution.

An executive at General Electric, Alexander was especially concerned about these events, and he wanted to change people's view of business to a positive one, rather than the current negative one. To do this, Alexander met up with Frederick Fish, who had been a president of AT&T and was at the time an attorney in Boston. Over the next two years, Alexander and Fish held a series of business meetings to discuss ways to reduce the high tensions between businesses. Businesses were notoriously secretive about even their most basic practices, which only made relationships worse.

On May 5, 1916, the National Industrial Conference Board formed (in 1970 the name was officially changed to the Conference Board). It became an official entity, with Alexander acting as the president and Fish as the chairman.

With a $100,000 budget and a new little office, the Conference Board was in business. At this time the board focused on workers' compensation laws and their effect on businesses, employee compensation, labor strikes, and boycotting. In 1917, after World War I started, President Woodrow Wilson asked the Conference Board to bring business leaders together to look at what America could manufacture for the war effort. In 1918, the Conference Board came out with the very first U.S. Cost of Living Index, which instantly began to be incorporated in sessions of planning and strategy.

With the United States engaged in a war with Korea from 1950–1953, the Conference Board Council on Mobilization and Planning took action. The council began producing studies, reports, and surveys on critical issues pertaining to business during wartime. The Conference Board also published a study on how the business and government could protect confidential data in the event of a nuclear war. Today the Conference Board continues its original mission, as an independent source of economic and business knowledge to provide the world's leading organizations with practical knowledge to improve their performance and better serve today's society.

CONGRESSIONAL BUDGET OFFICE

The Congressional Budget Office (CBO) is a nonpartisan agency within the federal government that produces analytical budgetary and economic reports. These analyses are then used to assist Congress in maintaining and balancing the federal budget.

The power to maintain the federal budget is an enumerated power in the U.S. Constitution, and the responsibility is given to the Congress. Despite this, with the passage of the Budget and Accounting Act of 1921, the president became increasingly involved in planning the budget. The Budget and Accounting Act caused two things to occur. First, the Bureau of the Budget was created, giving the president greater authority over budget information. Second, the Budget and Accounting Act gave the president the power to plan a yearly budget that needed to be given to Congress for approval.

Conflicts between the legislative and executive branches of the government gave rise to the Congressional Budget and Impoundment Control Act of 1974, otherwise known as the Budget Act. The Budget Act returned the responsibility of maintaining the federal budget to Congress. As part of retaking that responsibility, Congress enacted several changes.

First, new procedures were established for Congress to develop, coordinate, and enforce budgetary priorities without presidential oversight. Second, the House and Senate Budget Committees were created to direct the budgeting process. Lastly, the Congressional Budget Office was formed, to provide objective and impartial information on budgetary and economic issues for use by the House and Senate Budget Committees and the rest of Congress. The Congressional Budget Office also assists the Appropriations, Ways and Means, and Finance Committees.

The director of the Congressional Budget Office is selected jointly by the president pro tempore of the Senate and the Speaker of the House of Representatives. The rest of the approximately 235-member staff of the Congressional Budget Office is made up of nonpartisan economists and policy analysts who are selected on the basis of their professional competence, not political association. The Congressional Budget Office also employs lawyers, information technology specialists, and editors.

The Congressional Budget Office is organized into the Office of the Director as well as the following eight divisions:

- Budget Analysis Division
- Financial Analysis Division
- Health, Retirement, and Long-Term Analysis Division
- Macroeconomic Analysis Division
- Management, Business, and Information Services Division
- Microeconomic Studies Division
- National Security Division
- Tax Analysis Division

The Office of the Director houses several agents who are essential to running the office smoothly. The Director of the Congressional Budget Office works closely with the following:

- Associate Director for Economic Analysis, who contributes to all aspects of the agency's analytic work;
- Associate Director for Legislative Affairs, who serves as the Congressional Budget Office's central liaison with the Congress;

- Associate Director for Communications and the members of the Office of Communications, who are responsible for all of the public affairs activities of the Congressional Budget Office, including relations with the media and with the public; and
- Office of the General Counsel, which performs the agency's legal work and acquisitions.

Each division is responsible for compiling information based upon its category. Information and data from one agency are often used by other divisions for their reports. The Budget Analysis Division is responsible for gathering both formal and informal cost estimates for every bill proposed or approved by Congress, as well as coming up with a baseline federal budget. This division also makes important contributions to the Congressional Budget Office's reports on items such as the Analysis of the President's Budget and the Monthly Budget Review.

The Financial Analysis Division's responsibility is to focus on the federal government's financial commitments and offer information on financial valuation, modeling, and accounting. The Macroeconomic Analysis Division studies such changes in the economy as labor force participation, international trade, and economic recovery, to name a few.

The Congressional Budget Office produces several reports and economic analyses for Congress. These reports are created with the intent to assist the Congress in making the best decisions to maintain a healthy federal budget. The Congressional Budget Office selects what to research and analyze based upon what is needed by Congress. One of the most important reports created is the Budget and Economic Outlook, which includes projections of spending and revenues over 10-year periods and an economic forecast for those periods as well. These projections provide Congress with a measure of how changes in spending and taxes may affect the future. The Congressional Budget Office generates most of its projections from government-produced data, such as the surveys of labor market conditions and prices, the Current Population Survey, and health care surveys. The Congressional Budget Office also uses information from state and local governments, industry groups, professors, government agencies, and other sources.

CONSERVATION RESERVE PROGRAM

The Conservation Reserve Program, commonly abbreviated CRP, is a large, federally funded program that provides payments to landowners and farmers in exchange for taking their land out of production agriculture and planting native grasses, trees, or other vegetation instead. The United States Department of Agriculture is the primary federal agency that administers the program, but three other agencies contribute to running it: the Commodity Credit Corporation, which is the agency that farmers contract with to enter the program; the Farm Service Agency, which provides support to the commodity Credit Corporation; and the Natural Resource Conservation Service, which provides expert assistance in implementing conservation practices on CRP lands.

The CRP has its roots in farm programs and policies from the Dust Bowl era and the Great Depression. During this period, farmers were struggling to make ends meet and the devastation wrought by the Dust Bowl led to the passage of the Agricultural Conservation Program in 1936, which provided support for farmers who planted perennial vegetation (i.e., grasses, shrubs, or trees) on erosion-prone lands. In addition to helping protect the soil, this had the benefit of reducing the amount of crops grown and harvested. Thus, this early version of the CRP was intended to do more than conserve soil. It was also seen as an important means to improve farm income and rural livelihoods by directly providing money to rural inhabitants and by reducing the supply of agricultural commodities, thereby keeping prices higher than they would be otherwise.

The current version of the CRP got its start in the 1985 Farm Bill, where the program became more focused on a broad set of environmental endpoints—including water quality, wildlife habitat, and general ecosystem health—rather than its previous focus on soil erosion and soil quality. The program also reduced its official focus on income support and rural development. Over 35 million acres of cropland were enrolled in the CRP across the United States in the years following the program's expansion. The number of acres enrolled reached its peak in 2007, when nearly 37 million acres of land were managed under a CRP contract.

Farmers who are interested in enrolling in the CRP identify the acres they would like to enroll; the land's characteristics, such as the type of soil and whether the land is highly sloped; the plantings the farmers are willing to place on the land, and other factors. The information they provide is used to form a score, formally called the Environmental Benefits Index, which is used to determine whether the land will be accepted into the program. Farmers typically sign a contract for 10–15 years; in it they agree to make the changes to the land specified in their bid, in exchange for an annual payment (called the rental rate) and possibly additional compensation to support the costs and maintenance of the new plantings.

There are other conservation programs supported by the federal and state governments that pay farmers to adopt conservation practices. A variety of environmentally friendly agricultural practices can be supported under these programs. Examples include contour farming, buffer strips, and the creation and maintenance of wetlands or other environmentally beneficial open spaces. These programs are sometimes referred to as green payment programs, because they pay farmers to adopt land uses that benefit the environment. Some of these programs provide only a portion of the cost of the conservation practices; others pay the full cost of taking the land out of production, including payments to cover the installation and maintenance of the conservation practices. The CRP has grown to be the largest of these green payment programs. The Environmental Working Group reports that nearly $30 billion was spent on the CRP over the period 1995–2011.

Because the primary motivation of the CRP is to provide environmental services to society, an important question is whether it has achieved its goals, particularly given the high cost of the program to the U.S. taxpayer. Studies by the United States Department of Agriculture and others have identified the CRP as a source of significant environmental benefits, including impressive reductions in erosion; improved habitat for many birds and animals, resulting in larger and more diverse populations; and decreases in agricultural runoff, including less nitrogen, phosphorus, and pesticides. The planting of native plants contributes to preserving ecological diversity and increases the storage of carbon, a greenhouse gas, in agricultural soils. However, research has also indicated that even greater environmental improvements could be achieved if alternative selection rules were used for choosing which land should be enrolled; the idea of improved targeting of conservation dollars to lands that can provide the biggest "bang for the buck" is one of the most important ways that the CRP program could continue to be improved.

The CRP has been criticized for contributing to the decline in rural populations, since if land is taken out of active production, fewer workers may be needed and there may be less business for suppliers of such agricultural products as seed, fertilizer, and machinery. However, studies by the United States Department of Agriculture suggest that such effects are small and that in some areas the additional spending generated by outdoor recreation opportunities has more than made up for these economic losses.

In recent years, the competition for land driven by high commodity prices has put pressure on the CRP. Farmers whose contracts are expiring are increasingly finding it more profitable to replant crops on their fields rather than enter into a new contract to keep the land out of production. This has raised concerns about the environmental performance and sustainability of the program, as the higher prices mean that successfully retaining large areas of land in the program may become increasingly difficult.

CONTRACTIONARY FISCAL POLICY

Contractionary fiscal policy is a policy enacted by the government to slow economic growth by increasing tax rates, decreasing government spending, and lowering transfer payments. This policy is used only when there is fear that very fast

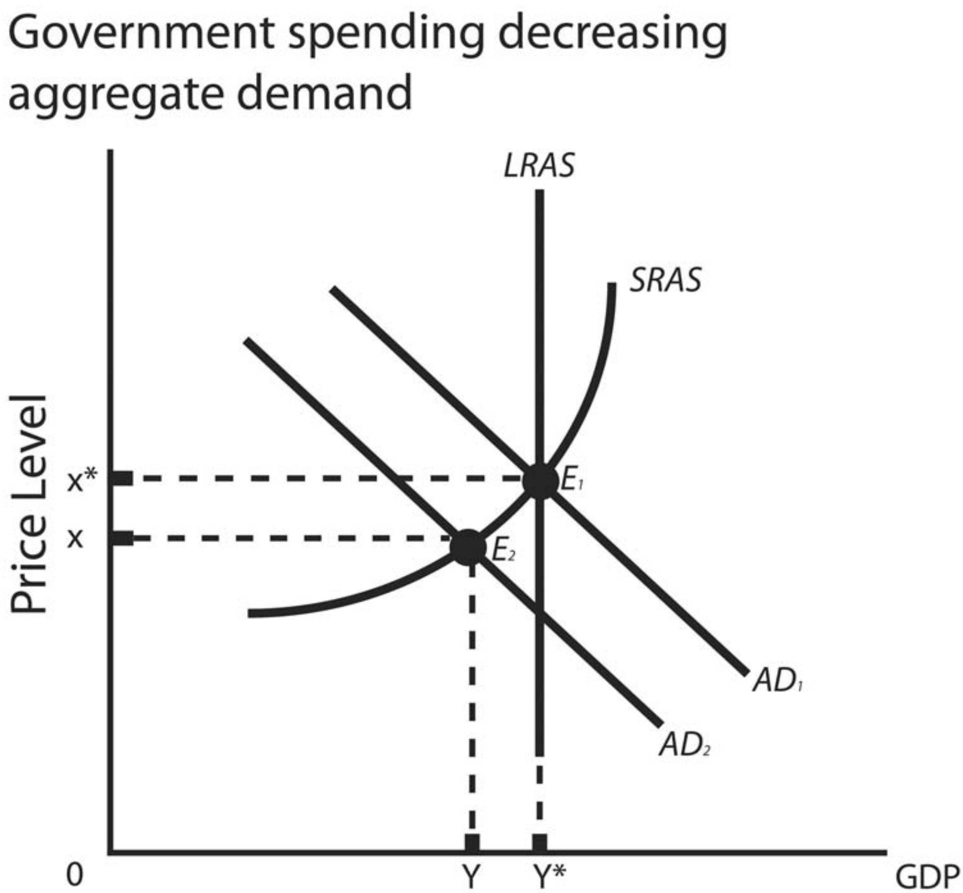

Figure 1. Aggregate demand decreases (AD1 to AD2) when government spending decreases (x* to x)

economic growth is causing inflation, which economists call the inflationary or expansionary gap. The goal of using contractionary fiscal policy is to close this gap. Fiscal policy's ultimate goal is to ensure that the economy is performing at its best.

Aggregate demand (AD) decreases (from AD1 to AD2) when government spending decreases (from x^* to x).

There are two conflicting viewpoints on handling the economy when inflation is high. Classical economists believe that the government should not get involved in the economy—that the market will balance out naturally. However, fiscal policy is based on the theories of the British economist John Maynard Keynes (1883–1946). Keynesian economists believe that the government should step in and make policy changes when the economy is growing too quickly and causing inflation to rise. This approach calls for the government to employ a mix of raising taxes and decreasing government spending in order to slow the economy.

Changes in fiscal policy are made to stabilize inflation, balance employment, and uphold the value of currency. The most important element of fiscal policy is to maintain and balance the federal budget by comparing tax revenues with government expenditures. Contractionary fiscal policy is used when the government is looking to decrease the budget deficit or if it needs to increase its budget surplus.

Economists illustrate the enactment of a contractionary fiscal policy by saying that it shifts the aggregate demand curve to the left, which lowers economic output along with inflation. *Aggregate demand* is the level of demand for goods and services by consumers, businesses, and the government. When contractionary fiscal policy goes into effect, it works to slow aggregate demand for goods and services.

There are three main tools utilized by the government to enact a contractionary fiscal policy: increasing taxes, decreasing government purchases, and reducing transfer payments. When using increased taxation as a contractionary fiscal policy tool, the government typically focuses only on an individual's personal income taxes, though it can also include property taxes and sales taxes. An increase in taxes can be either a one-time payment to the federal government or an overall increase in income tax rates. Either way, when taxes increase, the amount of disposable income an individual has decreases. Thus, with a decrease in disposable income comes less spending power, which in turn causes decreased production of consumer goods.

Overall, this slows the economy and helps to combat inflation. Of the three contractionary fiscal policy tools that can be used, increased taxation is fairly easy to implement, though it is not favored by taxpayers or by politicians. Politicians do not like to implement tax increases, because the politicians are then viewed negatively by taxpayers, who may not reelect candidates who support such a fiscal policy. Another reason that taxpayers view paying more in taxes negatively is that the people with the least amount of disposable income are the hardest hit by this increase.

Reducing government spending means decreasing funds available across several different government agencies, and it can include cuts in military expenditures, teacher salaries, and road construction, for example. When these government agencies have funding cuts, they are no longer able to purchase as much. When an agency has decreased income, its overall production is lowered, and this assists in reducing the inflation rate. Lowering the amount of transfer payments is also a useful tool of contractionary fiscal policy. *Transfer payments* are payments made by the government directly to individuals. Those who receive transfer payments fall into three categories: the elderly and disabled who are on Social Security, people who are unemployed and receive unemployment benefits, and the poor who are on welfare. Transfer payments can be lowered either by decreasing the amount of payment that one or two of the categories receive, or by using a blanket percentage reduction across the three categories.

Decreasing transfer payments lowers the disposable income of those who receive these benefits. Less disposable income means people can no longer purchase as many goods and services; similar to an increase in taxes, this leads to a decrease in production. It also helps to decrease inflation. Although lowering transfer payments can be effective, it usually is not used because the elderly, poor, and unemployed are the ones receiving transfer payment benefits and they are already at a disadvantage economically. Just as with increasing taxes, lowering payments further for those who need Social Security, welfare, or unemployment assistance could have a negative consequence for politicians who vote for these policies.

In summary, contractionary fiscal policy slows the economy to a pace that allows inflation to stabilize by lessening aggregate demand. Using policy tools such as increasing taxes, decreasing government spending, and lowering transfer payments—either separately or together—can work to balance the budget.

CONTRACTIONARY MONETARY POLICY

Contractionary monetary policy is a policy in which the central bank of a country decides that it is necessary to decrease the money supply in order to prevent inflation or slow economic growth. Monetary policy works together with fiscal policy, which is controlled by the government, to ensure economic growth in the economy. The most frequent tool used by a central bank to implement contractionary monetary policy is the selling of government bills, notes, and bonds. The buyer of the treasuries pays the central bank with money, which reduces the amount of money in the system.

In the United States, contractionary monetary policy is under the direction of the chair of the Federal Reserve. The Board of Governors of the Federal Reserve System decides when contractionary monetary policy is necessary. The Federal Reserve accomplishes contractionary monetary policy using three primary tools: raising the reserve requirement; raising the discount rate; or selling government bills, notes, and bonds. This last tool is applied through the Federal Open Market Committee (FOMC). The FOMC implements contractionary monetary policy by raising interest rates.

In order to implement the monetary policy decisions of the Federal Reserve Board of Governors, the FOMC carries out open-market operations. To apply contractionary monetary policy, the Federal Reserve sells government bonds. The decrease in demand decreases the price and increases the interest rate. The higher interest rates create incentives for financial institutions to decrease loans, which slows economic growth but may increase unemployment.

The Federal Reserve sells government bonds by taking cash from the purchasers of the treasuries. With less cash, commercial banks make fewer loans. If any banks are offering loans, the interest rates on these loans are higher, which will restrict business expansion and home purchasing. In this way, the Federal Reserve selling government bonds raises interest rates, which in turn decreases monetary supply.

When increasing the discount rate to accomplish contractionary monetary policy, the Federal Reserve is increasing the interest rate it charges banks to borrow money directly from the central bank—or, more specifically, one of the 12 regional banks. This discourages banks from borrowing more reserves, thus decreasing the money supply. The decreased money supply leads banks to lend less to businesses and households. In summary, increasing the discount rate decreases the money supply, which encourages higher nominal interest rates and brings about decreases in business and household borrowing.

Increasing the reserve requirement increases the amount a bank must have in its end-of-day reserves to satisfy the Federal Reserve's reserve requirement regulations. Reserves include vault cash as well as Federal Reserve deposits. When banks have their reserve requirement increased, the supply of loanable funds is decreased, which raises nominal interest rates. The higher rates create a disincentive for banks to supply more loans to businesses and households.

A risk in utilizing a contractionary monetary policy is an economic slowdown, which leads to higher unemployment. When unemployment is higher, fewer households are participating in the purchasing of goods and services.

Using open market operations to sell government bonds, increasing the discount rate, and raising the reserve requirement are actions that the Federal Reserve can take to decrease the money supply and fulfill contractionary monetary policy. Each is key in contractionary monetary policy to prevent inflation.

COST-PUSH INFLATION

When the higher cost of resources forces producers to raise their prices on the goods and services they produce, cost-push inflation occurs. There are several theories on how and why inflation occurs. One of those is the cost-push theory.

According to the cost-push theory, producers raise prices in order to meet increased input costs, such as land, labor, or capital. The increased costs of these

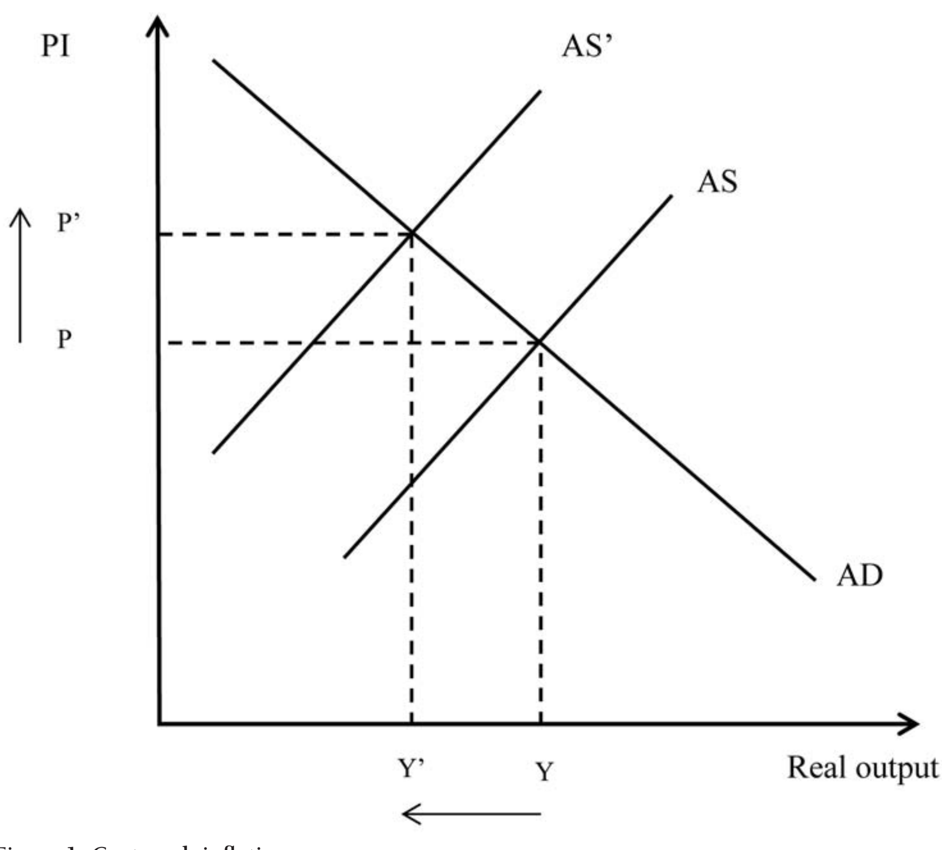

Figure 1. Cost-push inflation

factors of production lead to a decreased supply of goods and services in the short run, with demand remaining constant. The leading cause of the cost-push inflation theory is wage increases. Wages are the leading cause of the theory because wages are the single largest production cost for most companies.

Wage increases can occur for several reasons: when low unemployment leads employers to offer higher wages, as a result of *collective bargaining*, or when the minimum wage increases across the board. This increase in wages leads to an increase in prices, which leads to another increase in cost. This process by which rising wages causes higher prices, and higher prices cause higher wages, is known as the *wage-price spiral*. The wage-price spiral is one reason why some economists are against across-the-board minimum wage increases.

Cost-push inflation causes the purchasing power of the current dollar to decrease. It also negatively affects current income levels, because a person's income can no longer maintain the same level of purchasing power due to inflation. The burden of this falls most heavily on people living on fixed incomes.

COUNCIL OF ECONOMIC ADVISORS

The Council of Economic Advisers (CEA) was established by the Employment Act in 1946. The CEA is a three-person group charged to give the U.S. president advice on both foreign and domestic issues regarding the economy, as well as other economic decisions. The council bases its opinions on economic research and empirical evidence, trying to give the president the best information and statistics available, in order to properly set our nation's economic structure up properly.

Currently the council consists of a chairman and two members. The council includes a support staff of professional senior economists, staff economists and research assistants, as well as a statistical office.

The responsibilities of the CEA include assisting and advising the president in the preparation of the annual *Economic Report of the President*. The *Economic Report* is a follow-up document the president submits to Congress after the president has submitted to Congress the annual budget. The CEA is also responsible for gathering timely and authoritative information on economic developments and economic trends, both current and prospective, and analyzing and interpreting such information.

Other CEA responsibilities include appraising the various programs and activities of the federal government; developing and recommending to the president national economic policies to foster and promote free competitive enterprise; avoiding economic fluctuations, or diminishing the effects thereof; and maintaining employment, production, and purchasing power. The CEA conducts studies, furnishes reports, and makes recommendations on matters of federal economic policy and legislation for the President of the United States.

CROWDING-OUT EFFECT

Crowding-out effect is the term used to describe the result when the government needs to borrow money in order to pay its debts. When government borrows money from the public, the government increases the demand on the money supply. If the money supply does not increase, the increased demand causes interest rates to rise. Together, the additional demand on the money supply and the increase in interest rates make it more difficult for small businesses and individuals to obtain loans for items such as cars and homes. These groups are crowded out of the market for money to borrow.

Crowding out is one risk of using expansionary fiscal policy. In theory, when an expansionary fiscal policy tool is used, the government spends money on programs that increase employment—and by extension increase the demand for goods and services; alternatively, the government decreases taxes, giving consumers more money to spend, which also increases demand for goods and services. Economists call this aggregate demand. *Aggregate demand* is the total demand for goods and services by consumers, businesses, and the government.

One risk of using expansionary fiscal policy tools—specifically, increasing government spending—is that it increases government debt and the government's need to borrow more money. The risk is relatively low in times of a major recession or a depression. The threat of crowding out is greatest when the economy is operating at near-full capacity.

When the government spends its own money to stimulate the economy and it borrows money to pay for this expansion, interest rates go up because of more demand in the money market. Interest rates are the "cost" to borrow money. When interest rates go up, small business owners and individuals do not invest as much, because the cost to borrow money is higher. These groups become crowded out of the market. Without loans during an economic downturn, small businesses that are struggling to continue operating are unable to purchase of raw materials and supplies. Lack of usable resources means that the business cannot produce the goods and services needed to maintain an income. Still worse is the effect that the struggling businesses have on the unemployed. Without raw materials and the means to produce goods and services, small businesses cannot rehire employees who may have previously been laid off; nor can they afford to hire new employees. Without a source of income, those who are unemployed cannot make purchases to help stimulate the economy.

Individuals are also hard hit by the crowding-out effect, as lenders are more likely to give loans to those they believe have the capability to repay the loan, such as the government. If people cannot repay a loan when the "cost" to borrow becomes higher, banks will not lend to them. If consumers cannot take out loans for purchasing a home, a vehicle, or other items that are seen as life essentials, then those people cannot spend on additional items that could help stimulate the economy further. A vehicle, for example, may be a necessity for people who must commute to work. When people cannot obtain a loan for a vehicle, because the interest rates are higher than they can afford, they face additional difficulties, such as keeping their jobs. When small companies and individuals cannot borrow money, economic growth slows down. This is the opposite of what the expansionary fiscal policy tools are intended to do.

The crowding-out effect is a risk that comes from using expansionary fiscal policy tools when the economy is struggling, consumer spending is low, and unemployment is high. In spite of its good intentions trying to stimulate the economy, if the government borrows money to provide the stimulus, lenders raise interest rates. Then, small companies and individual investors are excluded from being involved in the market, and the threat of crowding out remains.

CURRENCY DEFLATION AND INFLATION, 1781

Even before the Revolutionary War ended, the value of America paper money was declining rapidly. France and Holland grew nervous about whether they would receive repayment of their loans, but more pressing was the large amount owed to the soldiers of America's army. The risky floating of paper money during the war could no longer be continued. Parts of the army were in open rebellion. Robert Morris was forced to resign as superintendent of finance of the new country. The nation had piled up too many loans while winning the war against the British, and it was nearing default on its debt to France.

Individual states had their own war debt, and they were imposing high taxes on land to secure money to pay their debts. High taxes and the lack of new credit forced many citizens into bankruptcy and even jail. In the midst of this financial crisis, the states were wrestling with the politics of creating a union. John Adams and Benjamin Franklin were in Europe negotiating a peace treaty, while also working to find more credit to support the young country's finances. America was also in a postwar recession. Merchants and traders on both sides of the Atlantic were trying to collect on debts. In addition, merchants often refused to accept continental dollars as payment for their goods, or they inflated the prices of goods to cover potential losses. British import restrictions and a lack of credit caused massive unemployment in major port cities. In addition, many counterfeit gold and silver coins of diluted base metal were being circulated in the new American economy. Merchants again raised prices to cover their risk. Commerce was at a standstill, and many buyers and sellers returned to the barter system.

Debt, however, was the main issue that had to be resolved before the economy could expand. Alexander Hamilton and James Madison argued for a 5 percent tax or duty on imports. As almost all imports at the time were from Great Britain, a tax on imports was popular. Hamilton and Madison's main concern was to establish the right of the new government to tax its citizens. Hamilton believed the government needed revenue instead of the perpetual loans that it regularly used to push the debt burden into the future.

Hamilton also proposed that these revenues be put into a sinking fund to pay off the country's debt. The sinking fund was to consist of funds set aside from the general budget. The idea was to sequester revenues from the grasp of politicians, who were inclined to use the revenues for short-term gain. Hamilton clearly understood the shortcomings of politicians. Although the North favored the import duties, the South with its plantations feared British retaliation on tobacco, cotton, and rice exports. Western farmers did not want import duties, because they would raise prices on badly needed manufactured goods. As Congress debated the formation of the political union, it refused to address federal funding issues such as taxes. The debt mounted. Politicians clearly preferred to continue issuing perpetual debt to fund the new government, as this would not upset new voters the way raising their taxes would.

John Adams was able to negotiate a major loan with the Dutch, but at a rate of 7 percent. Like Morris's funding during the war, the Dutch loan merely postponed dealing with the debt, because the Continental Congress had no incoming revenues. One success had been the formation during the war of the Pennsylvania Bank, which became the Bank of North America with private investors. It paid shareholders 8 percent in 1782 and 14 percent in 1783. This allowed the bank to raise more capital through a share offering. Bank notes were critical for commerce in a currency-short nation in recession.

Still, the debate in Congress split the farmers, who feared the bank, from the merchants, who demanded it. Eventually, the bank won out, and charters were created for each state. The bank formation addressed the current problems of commerce but did nothing to solve the issue of war debt. New England and the Deep South slipped into depression. Virginia fared the best because of its strong tobacco trade with France, which had started during the war. A number of wealthy Virginia planters were holders of war debt, but as a state, Virginia had paid off most of its war debt. After the war, tobacco prices fell quickly, moving Virginia into recession. By the end of the decade, New York fur trader John Astor reestablished a fur-trading network.

America's war debt was more than $65 million ($90 million with states' debt included). The interest rate on the debt ranged from 4 percent to 6 percent. Britain and the West Indies had closed their markets to the new United States and destroyed the old trade network. Great Britain prohibited the import of American fish, beef, and whale oil. Meanwhile, some American leaders argued that a new government should not be responsible for the debt of the former individual colonies. Men like Thomas Jefferson and James Madison were part of this political group that wanted to ignore the debt.

Even the methods of debt payment were a matter of endless debate among politicians. Some wanted to use land sales to obtain money. New York, for example, had reduced some debt by giving ranking officers land grants. The problem of paying the officers with land grants was that the grants, unlike actual cash payments, did not put currency back into circulation in a badly depressed economy. In addition, few could afford the land taxes imposed by the states. Long-term annuities paying 4 to 5 percent were also suggested as a means to pay off the accumulated debt over time. As the debate continued, prices spiraled out of control in anticipation of the reduced value of continental dollars and other paper currencies.

Many of the debts of the new government and the former colonies were held by citizens and former soldiers, and a currency panic set in. Rumors spread that the new government, as Jefferson and Madison suggested, would not—and should not—honor paper dollars and bonds issued by the former colonies. As Congress debated, wealthy speculators started buying up continental paper for $25 on a $100 face-value note. Many states considered levying taxes themselves to pay off the debt.

Massachusetts, for example, started to enact and enforce the payment of taxes by seizing property. Farmers and ex-soldiers were overwhelmed with debt, and in Massachusetts the conflict over debts led to armed rebellion in 1787. The conflict, which became known as Shays' Rebellion (after Daniel Shays, a Continental Army veteran), happened because the new state government reacted much like Britain had a decade earlier, answering rebellion and violence with strict new laws. A Riot Act was passed with harsh punishments. The state militia and some federal troops finally put down the rebellion, but it sent a clear message to Congress about the uneasy state of the new union. A majority of American citizens, perhaps reacting to difficulties and conflicting solutions within individual states, finally approved the Constitution with a strong central government.

DEBT

The obligation to repay borrowed money is called a *debt*. Individuals, corporations, and nations all borrow money and incur debt.

Individuals and corporations use debt to buy things they otherwise could not afford. When one party borrows from another, the parties draw up a written agreement that specifies how much money is being borrowed, from whom it's being borrowed, to whom it's being loaned, and the repayment terms. Debt repayment usually includes interest payments as well. How the interest is calculated and repaid is specified in the initial borrowing agreement.

There are various types of debts, including secured, unsecured, and revolving debt. Some examples: Consumers take on debt when they use a credit card to purchase dinner at a restaurant and don't repay the credit card bill in full at the end of the month. Corporations take on debt when they borrow money to expand their business internationally. When a consumer borrows $100,000 from a lender to buy a home, the consumer signs a legal agreement to repay that money. This particular type of debt is called a mortgage.

This entry will discuss the various entities that borrow and incur debt, such as individuals, companies, and nations. Types of debt will be covered. Finally, national household debt will be discussed.

Types of Debt

Secured

Secured debt requires the borrower to give the lender collateral or real goods or property (security) if the borrower fails to repay the debt. A mortgage loan is secured by the property, as collateral. If the borrower fails to repay the loan, then the bank takes possession of the real estate. If a pawnbroker loans someone $100, the pawnbroker expects collateral in exchange for the loan. In that case, the collateral might be jewelry or other valuable property.

Corporations might pledge real property for a secured loan. A corporation might also pledge its financial securities, such as stocks and bonds, as collateral.

Unsecured

This type of loan is not secured by such underlying assets as real estate, jewelry, or physical property. Credit card debt is unsecured, as are medical bills or unpaid utility bills. In this case, if the borrower defaults on the loan, there is no home or jewelry or vehicle to seize.

With unsecured loans, if the borrower fails to make the debt payments within the agreed-upon time period, then the borrower must use other remedies to pay the amount owed. The lending party might sue in court for the unpaid debt. If the lender wins the suit, the lending party may be allowed to garnish or take a part of the debtor's future wages.

Because unsecured debt carries higher risk than secured debt, unsecured loans usually charge higher interest rates. For example, a vehicle loan might be obtained for 5 percent, whereas the interest on a credit card can be as high as 18 percent or more.

Revolving

Revolving debt, frequently called revolving credit, gives borrowers, either corporations or individuals, access to credit if they need it in the future. Revolving debt is also called a "line of credit."

In some cases, the borrower pays a commitment fee and then is allowed to use the available funds as needed. The amount available is agreed upon when the original contracts are initiated.

There are various types of revolving credit, including signature loans (which do not require collateral but simply the borrower's signature), credit cards, and home equity lines of credit, to name a few. Credit cards also offer a type of revolving debt. This type of debt is more complicated than a typical loan. The lender approves the borrower for a specific amount of money, or a credit limit. This amount is determined by the borrower's perceived ability to repay the debt, and it considers the borrower's income, assets, and other debt. As the consumer or company repays the debt, the repaid amount is available for the consumer or company to borrow again.

Home equity lines of credit and overdraft protection for checking accounts are also considered revolving debt. This type of debt may have variable interest payments and fees, instead of a fixed interest rate that stays the same for the life of the loan.

What Is the Difference between Debt and Liabilities?

Frequently, the terms *debt* and *liabilities* are used interchangeably, to mean an amount owed to another. More specifically, *debt* has a narrower definition than *liabilities*. In this instance, *debt* refers to monies borrowed with their terms formalized in a written document.

Debt is not a synonym for *liability* when used to describe types of insurance.

Corporate Debt

Corporations frequently borrow in order to grow and expand. A limited amount of corporate borrowing, sometimes referred to as leverage, gives companies a greater amount of financial resources to use in order to grow the company more rapidly. It is a widely accepted business practice for companies to borrow in order to grow.

The percent of debt, as compared with the amount the company owns (equity), should remain within certain constraints so that the company can afford to repay the debt in a timely manner. There are acceptable industrywide debt percentages. For example, a utility company, with a great amount of guaranteed monthly utility payments made by consumers, can afford to borrow more than a small start-up company with uncertain revenue projections.

National Debt

Nations, just like individuals and corporations, borrow money to pay for things they could not otherwise afford. In the case of the U.S. government, the national debt includes public debt such as the Treasury securities (Treasury bonds, notes, and bills) issued by the government. The purchasers of these debt securities are loaning money to the government. This debt might be used to help fund wars or pay for government programs, or for a variety of governmental uses.

When the U.S. government lacks sufficient funds from tax revenues to pay for government obligations, the government must borrow the deficient amount (or deficit) by issuing Treasury securities. Not only do U.S. citizens, corporations, and other governmental entities purchase Treasury bonds, notes, and bills; foreign individuals and governments also buy these securities. That is how the United States develops some financial dependence on international entities.

Consumer Debt Levels in the United States

As previously discussed, debt is a useful tool to finance large purchases such as homes and cars, as well as to assist when times are tough. When layoffs or unexpected expenses occur, consumers use debt to help make ends meet.

According to Vornovytskyy, Gottschalck, and Smith (2011), in 2011, 69 percent of U.S. households held debt. Although 69 percent may seem like a great amount of debt, it represents a decline in household debt from 2000, when households with debt hit a peak of 74 percent. Although the percent of households with debt decreased during the decade, the median amount of debt has increased. In 2000, the median debt level per household was approximately $50,971, whereas in 2011 the approximate median amount of debt per household rose to $70,000.

This increase was caused by a 30 percent rise in both secured and unsecured debt.

The increase in debt may have positive and negative implications. On a positive note, more debt may indicate an increase in consumer confidence. Individuals may feel that the economy is growing and their employment is secure, so they are willing to borrow for new homes, cars, and additional consumption.

The negative impact of increased debt levels includes risks to financial health as well as mental health. When a household incurs a greater amount of debt, relative to its income, there is a repayment risk. In general, total debt percentage, when compared with gross income, should remain below 43 percent, according to the Consumer Financial Protection Bureau. If a consumer encounters financial problems such as a job loss or unanticipated medical expenses, the debt repayment could be in jeopardy.

Home foreclosures and bankruptcies are caused when individuals have greater debt than they can repay. Individuals are at risk for financial difficulty if they have taken on too much debt and unexpected expenses then occur.

In sum, debt, when used responsibly, is a tool to enable individuals, companies, and countries to smooth out consumption and pay for expenses they would otherwise be unable to afford.

DEBT CRISIS OF THE 1980s

In August 1982, a U.S. and international banking crisis developed as a result of least (or lesser) developing countries (LDCs) being unable to service their foreign debt. Latin American countries were forced to borrow heavily to cover budget deficits in the 1970s as a result of spiking import oil costs. Commercial banks in the United States and other world banks acted as intermediaries by loaning the budget surpluses of oil-producing nations to non-oil-producing nations. Monetary policy focusing on inflation reduction contributed to the inability of LDCs to pay their debts.

The Latin American debt crisis of the 1980s was a result of sharp rises in oil prices in the 1970s, which created large current account deficits for LDCs. The increased oil prices created surpluses for the oil-producing countries. With oil bought and sold on the world market in U.S. dollars, the quantity of loanable funds at large U.S. banks increased significantly. In an effort to expand overseas profits, and with encouragement from the U.S. government, U.S. commercial banks began to reinvest the U.S. dollar deposits from the oil-producing nations into developing countries, especially in Latin America. Latin American countries aggressively borrowed from these U.S. banks, and their outstanding debt rose dramatically. From 1970 to 1978, foreign debt by Latin American nations had risen from $29 billion to $159 billion.

Despite warnings from economists and government officials that the rapid growth of LDC debt was putting the banks' capital and the entire banking system in jeopardy, commercial banks continued to assume these excessive risks. By 1982, Latin American debt had reached $327 billion. Lower interest rates allowed the Latin American countries to initially service the loans without much trouble.

However, in an effort to slow inflation, the United States began to tighten the money supply. Interest rates rose and the economy entered a recession. Commercial banks began to shorten loan repayment periods and increase interest rates, which increased the cost of debt for the Latin American nations. The interest rate payments rose to a level that the Latin American nations could not sustain. Demand for exports from the Latin American nations fell due to a global recession, which further worsened their balance-of-payment difficulties. In August 1982, Mexico announced that it could no longer make the interest payments on its debt, and within a year, 27 other nations were attempting to renegotiate their debt payments.

In an attempt to avoid a major financial crisis, the Federal Reserve worked with other central bankers around the world to provide a bridge loan to Mexico and encouraged U.S. banks to reschedule Mexico's debt. As the crisis spread, the United States—along with commercial banks, central banks, and the IMF—conditionally agreed to lend the funds necessary for the Latin American nations to pay the interest on their loans. The conditions for the funds included structural reforms to their economies and efforts to eliminate their budget deficits. It was found that the high debt levels, high domestic consumption, excessive government control, and unsustainable currency values were are all responsible for the Latin American debt crisis. The goal of restructuring was to allow the nations to increase their exports and generate the trade surplus they needed in order to pay off their debts. The practice, however, was to cut spending in infrastructure, education, and health but continue to subsidize the state-owned enterprises. The result was increased unemployment and negative economic growth. By the end of 1989, it became apparent that the Latin American nations would not be able to repay the loans. The commercial banks began loan loss provisions for the Latin American debt. The U.S. government, under the Brady Plan, established permanent reductions in principal and interest obligations, while the commercial banks forgave $61 billion—approximately one-third—of Latin American debt.

DEFICIT

A *deficit* means you have more cash leaving your account than coming into the account. You can determine if there is a deficit by taking your cash inflows and subtracting your cash outflows; if the difference is a negative number, then you have a deficit. For example, if you are bringing in $1,000 a month in income and your expenses are $1,200 a month, then you have a deficit of $200 a month.

The concept of a deficit can be found anywhere that money is going and out, including—but not limited to—personal finances, corporate finances, and government.

How Deficits Are Financed

When you have a deficit, you need to pay for the difference between the cash coming in and the cash going out. Most entities have three ways to finance the difference: equity, existing savings, or debt.

Governments have the added ability to create new money supply in order to pay their existing bills.

Having a deficit might be sustainable for a short amount of time, but in the long run it will create a situation that can be escaped only by bankruptcy. This happens because after you use all your existing savings, you must turn to debt to continue to cover a deficit.

Debt comes with a payment that must be made every month. As you borrow money and increase your payments, your expenses increase, making the deficit every month even bigger. This creates more debt, and more payments—so eventually the debt payments become bigger and creditors will no longer allow you to take on more debt through them. This ends the ability to borrow to cover the deficit. The final outcome is that someone will not get paid because you are unable to cover the deficit.

It is a vicious cycle that you can correct only by increasing the cash coming in every month so that it's more than the cash going out every month, thus eliminating the deficit.

Personal Deficit

If you are creating a deficit on a personal level, you may begin by paying for it with your existing savings. Once your savings has run out, you will have to use debt to manage the difference, including credit cards and other loans.

Eventually your debt payments combined with your existing expenses will become too big, and no additional credit will be given to you. At this point, you will approach bankruptcy as you are no longer able to pay all your expenses. You can eliminate the deficit, however, by bringing in more income.

Corporate Deficit

A corporate deficit occurs when a company is not selling enough to cover its costs. The company's revenue minus costs is less than what is needed to pay the bills.

A company has three ways to cover the deficit: They can utilize savings that they have; they can take out debt to cover the difference; or they can sell shares of stock, otherwise known as equity, in the company to raise more money.

As with personal debt, a company cannot maintain a deficit for a long time, as savings will dry up, debt providers will stop loaning money, and possible new shareholders won't be interested in buying into the company due to the status of the company's finances. This will either cause the company to go through bankruptcy and rework its existing debt or force the company to close its doors permanently.

Government Deficit

A government deficit occurs when incoming funds from taxes do not cover the expenses the government is paying out during a given time period. An accumulation of deficits creates a debt.

A government can cover the deficit by using savings if it has any, by issuing bonds as a debt instrument to get money, or by printing new money.

Government savings may occur from one part of the government bringing more than they need to cover their own costs. This money can then be reallocated to other branches to cover their expenses. For example, the Social Security surplus funds were shifted to other areas to cover costs, in the form of bonds issued to the Social Security Trust.

The government issues its own debt in the form of bonds, instead of using credit cards and other loans. Depending on the type of bond, the government has to pay interest on an ongoing basis, or all at once when it pays back the borrowed amount. Either way, the expenses of the government are increased in the same way that a loan to an individual would be.

Printing new money is the least desirable of the options available to the government, since increasing the supply of money causes inflation, which will raise the prices of goods, thus eliminating the benefits of the new printed money since the value of each dollar goes down.

Governments or countries may also experience a trade deficit. This occurs when a country is importing more goods than it is exporting. More dollars are leaving the country than are coming in, causing an increase in the price of goods coming into the country if the countries holding the currency decide to sell. This has no direct relationship to the expenses of a government, but instead has the indirect effect of causing the cost of items to increase.

How to Eliminate a Deficit

To eliminate a deficit you must do one of two things: increase the incoming cash flow or decrease the outgoing money. On a personal level, this means increasing your income and decreasing your expenses. On a corporate level, it means increasing revenues or lowering costs. For a government to get the desired reduction in the deficit, the government can increase taxes or decrease spending.

DEFLATION

Deflation occurs when prices fall instead of rising as they do in inflation. Deflation makes the value of your dollar greater tomorrow than it is today—thus creating a desire to not spend money today, and instead to wait and buy items in the future as the price continues to drop.

For example, if prices were falling and one dollar would buy you five pieces of gum today but would buy you seven pieces of gum tomorrow, then you would wait to buy, because your dollar would have more purchasing power in the future.

How Deflation Occurs

Deflation typically occurs for three reasons: a decrease in demand, an increase in operating efficiency, or a reduction in the money supply. When deflation does occur, it might include one or all of the elements that are contributing to the downward pressure of prices.

The most common cause of deflation is a decrease in demand. When demand for a product or service goes down, because of the decreased demand the company selling the item will need to lower the price in order to sell the product. For example, if a company ordered too many winter boots, when spring comes around the company may have to lower the price of the unsold boots to get customers to purchase them. Those boots are no longer worth what they were when it was cold outside.

While this example is for a single product, deflation can occur on a national level with most prices decreasing. This has occurred a handful of times in the history of the United States, the most recent being in the recession of 2008–2009.

Deflation can also occur when there are great improvements in the efficiency of the production or delivery of goods. For example, when a new technology first comes out, it is expensive. As the manufacturer perfects the process, the costs to produce the item decrease, and the seller can lower the price it charges consumers and maintain its profit.

The automobile is an example of this improved efficiency. Before Henry Ford created the assembly line, building a car took days and sometimes months, because cars were made one at a time. The assembly line enabled cars to be assembled in a matter of hours, thus lowering the overall cost to produce the item and allowing more to be made.

Deflation can also occur because of a decrease in the money supply. The *money supply* is the amount of monetary assets available in an economy at a specific time—in other words, how much cash is available in people's checking accounts, and and how much is available for access in tools such as bank loans. As the amount of money available for consumption decreases, the ability to pay for goods and services decreases, thus decreasing demand and lowering prices.

Impacts of Deflation

When we encounter deflation across the entire economy, a few things are impacted, including unemployment and wages, the desire of consumers and businesses to spend, and a worsening position of debtors.

As prices fall, people become less willing to purchase items. They know the price will go lower, so they are in a position to ask why they should spend $5 today when that same item might cost $3 next week?

Another way of saying this is that your dollars are worth more tomorrow than they are today, so you want to save as much cash as you can. Unfortunately, as this occurs it worsens the deflationary cycle, also known as deflationary spiral.

When no one is buying, the retailers must lower the price if they want to move the product off the shelf. This makes buyers want to wait, which makes the retailers have to lower the price even more. It becomes a cycle that is hard to stop.

As this desire to spend decreases, it causes unemployment and falling wages. Since the factories don't have to run as much to produce products since they are not selling, there is no need for workers to run the plants and therefore they are laid off.

With fewer people working, demand decreases again as those that are not working have little or no money coming in and are not able to buy as much.

The deflationary spiral continues to worsen. This will also decrease the level of wages being paid by employers, since when unemployment is high wages go down because of more workers being willing to work for less money.

Finally, people who owe money on loans find that the burden of their debt is consuming more of their dollars. Because debt represents items they purchased earlier, those items become more expensive because money is worth more today than it was yesterday. Thus they must also reduce spending in order to make up for the increased portion of their dollars that is going to debt repayment, yet again decreasing the level of demand for goods.

How to Stop Deflation

There are a few ways to get out of the deflationary spiral, including increasing government spending and increasing the money supply. In order to create more demand for goods and services, governments and the Federal Reserve Bank may use a mixture of these tools to get demand moving. By increasing spending on the government's side, they increase the demand for goods and services immediately, allowing retailers to sell their products.

An example of this tool being used comes from the Great Depression: The federal government started a program called the New Deal, which began public works projects. These projects not only increased demand for products for construction, but also they employed workers. These workers could then increase their spending because of an increase in their wages. New government spending and increased wages for consumers helped stop the deflation of the Great Depression.

The government can also increase the money supply by modifying reserve requirements for each bank or by lowering interest rates to encourage borrowing and lending. Also, the Federal Reserve can purchase bonds on the open market, thus putting more money into the system for people to spend.

DEPARTMENT OF COMMERCE

The U.S. Constitution states in Article 1, Section 8, Clause 3, that Congress has the power "[t]o regulate Commerce with foreign Nations, and among the several States, and with the Indian Tribes." In the latter part of the 1800s, the United States made huge strides in business and economic development. Many businesspeople and industrialists felt they needed closer ties to and protection by the federal government. They pushed the government for a specific department to fulfill their needs and interests. Congress called for the creation of such a department.

Thus, on February 14, 1903, under the presidency of Theodore Roosevelt, the Department of Commerce and Labor was founded. Overtime, however, the Department of Commerce and Labor grew too large to be contained under one secretary, and on March 4, 1913, it was split into two separate entities: the Department of Labor and the Department of Commerce. The Department of Commerce is dedicated to promoting economic growth, job creation, and a higher standard of living for all Americans.

The Department of Commerce is a cabinet-level department of the federal government's executive branch. As a cabinet position, the secretary of commerce reports directly to the president of the United States. The department works with businesses, communities, universities, and workers. The Commerce Department employs over 47,000 employees worldwide and operates with an annual budget of over $7 billion (see www.commerce.gov/about-department-commerce).

Throughout its history, the Commerce Department has grown and changed as required to accommodate the needs of the American society and people. In response to these needs, the Commerce Department established several subagencies that are designed to, among other things, support businesses, promote economic growth, and protect the environment.

The Department of Commerce is made up of 12 bureaus: the Bureau of Economic Analysis (BEA), the Bureau of Industry and Security (BIS), the Economic Development Administration (EDA), the Economics and Statistics Administration (ESA), the International Trade Administration (ITA), the Minority Business Development Agency (MBDA), the National Oceanic and Atmospheric Administration (NOAA), the National Telecommunications and Information Administration (NTIA), the National Institute of Standards and Technology (NIST), the National Technical Information Service (NTIS), the U.S. Census Bureau, and the United States Patent and Trademark Office (USPTO).

Each of these bureaus serves a specific function within the Commerce Department. The U.S. Census Bureau shows the Commerce Department's commitment to maintaining a wide array of useful data on and about the economy, people, and population residing within the United States, and this information has a variety of functions. Some examples of how the U.S. Census Bureau data are used include how Congressional districts are created; how over $400 billion in federal funds are allocated within communities; and what community services to provide, such as the building of schools and roads, and services for the elderly.

The U.S. Patent and Trademark Office highlights the Commerce Department's promise to protect American businesses by granting patents and generating trademarks. Patent and trademark security ensures that intellectual property created by Americans nationally and internationally is not infringed upon. Patents and trademarks emphasize an economy's property rights. Protection of property rights through patents and trademarks helps to create a strong economy through job creation.

The National Oceanic and Atmospheric Administration (NOAA) reflects the Department of Commerce's commitment to maintaining economic and environmental health by monitoring weather patterns, preserving coastlines, and supporting marine commerce. NOAA's products and services affect more than one-third of the United States' gross domestic product.

DEPARTMENT OF LABOR

In 1903, President Theodore Roosevelt established the Department of Commerce and Labor. In response to labor's growing lobbying efforts for a position of influence within the president's cabinet and the growth of responsibilities of the Department of Commerce and Labor, the decision was made to separate the department into two cabinet posts. The Department of Labor was created by President William Howard Taft on March 4, 1913, when he signed the Organic Act. This was the same year that the Federal Reserve Act was signed by President Woodrow Wilson.

When the Department of Labor was created in 1913, its main charge was to promote and advance working conditions and employment opportunities for the average working person. The responsibilities and scope of the department have expanded significantly since those early days.

Four bureaus became the center of activity within the Department of Labor: the Bureau of Labor Statistics, the Bureau of Immigration, the Bureau of Naturalization, and the Children's Bureau. The Bureau of Labor Statistics (BLS) is the oldest, established in 1884. The BLS produced its first report in 1886, while it was a part of the Department of the Interior. With the creation of the new Department of Labor, the BLS was moved to its new home in the Labor Department. As it is today, the primary function of the BLS is to collect, assemble, report, and analyze economic and employment data on the labor force. The Bureau of Immigration was responsible for the laws that applied to foreigners. It also served as an employment agency, helping new immigrants find employment. The Bureau of Naturalization administered the laws for foreigners who wanted to become naturalized U.S. citizens, and the Children's Bureau, as its name suggests, had oversight of the welfare of children; the newest of the bureaus, it was established in 1912, serving as a predecessor to Child and Protective Services in caring for the welfare of children.

As the department grew in those early years, it took on the footprint of its first secretary, William B. Wilson. Wilson was not related to President Woodrow Wilson, who appointed him, but he was a former labor leader and one of the members of Congress responsible for the creation of the department. Secretary Wilson was always quick to point out that while the department was created to serve the average wage earner, it was first and foremost a federal department devoted to fairness for everyone.

With Wilson as secretary, the department conducted many mediation and labor dispute interventions early in its existence. This one function grew so much that by 1916, conciliation had become a single item budgeted for by Congress. A second major charge early on was unemployment. Using existing personnel and resources from other bureaus, Secretary Wilson built a national framework for finding jobs for the unemployed. President Wilson was so impressed he funded the effort out of the president's office, not Congress.

As the need for the United States to join in World War I became more and more certain, and as Secretary Wilson shifted the department's resources to aid the war effort, labor became in short supply and labor disputes increased. The Department of Labor became the primary source for administering labor policies during the war. The department was charged with the bulk of the government's programs on labor, including the all-important War Labor Board. The Department of Labor was also responsible for interring German sailors from German ships captured in U.S. harbors.

During the presidency of Warren G. Harding, the Department of Labor took on much less of an activist role in labor disputes, and new restrictive immigration policy implementation took on a more prominent role. President Harding and the new labor secretary, James Davis, expanded the role of the Children's Bureau. The Women's Bureau, which had been created during the war and made permanent in 1920, advanced the welfare of women in the workforce. In 1931, during the Depression, the department was responsible for passage of the Davis-Bacon Act, which required federal contractors to pay the local standard rate on federal construction projects.

The first woman to serve in a president's cabinet was a secretary of labor. Appointed by President Franklin Roosevelt in 1933, Frances Perkins became the new secretary of labor and the first female member of the president's cabinet. The Bureau of Immigration and Naturalization had, in the view of some people, become overzealous in its deportation strategies. Secretary Perkins took on a popular special corps devoted to deportation and disbanded the group. The Bureau of Immigration and Naturalization was eventually transferred to the Department of Justice.

As President Roosevelt's secretary of labor, Frances Perkins was instrumental in creating and implementing many of the president's New Deal programs as they related to labor. She was especially involved in the development of the Civilian Conservation Corps (CCC) and Social Security. The CCC was a labor program for young men to work on federal projects in rural America. Secretary Perkins was instrumental in the promotion and eventual passage of the Social Security Act in 1935. Perkins also revitalized the United States Employment Service (USES), instituting a nationwide network of employment services. As opposed to its involvement in World War I, the department's role in World War II was minimal.

Following World War II, the department's energies were mostly devoted to leveling the workplace landscape between labor and management. Subsequent presidential administrations added their individual agendas, and Congress added laws to retain collective bargaining and maintain adequate working conditions. New programs for the Department of Labor began to emerge under President Lyndon Baines Johnson and his Great Society initiatives. President Johnson created the Manpower Administration to oversee new programs that focused directly on labor issues. The passage of the Civil Rights Act of 1964 also changed the landscape of the department. It now devoted its energies to enforcing new nondiscriminatory policies in the workplace and within federal contracts.

Through the 1960s and 1970s, major restructuring occurred within the Department of Labor. President Johnson's Manpower Administration was restructured in 1969. That same year, the Job Corps, whose programs were aimed at youths, was moved to the Department of Labor. The Comprehensive Employment and Training Act (CETA) was created in 1973 as a training and revenue-sharing mechanism for local activities. In 1971, during an economic downturn, the Emergency Employment Act was created, providing jobs in the public sector. A second 1971 initiative for the Department of Labor was a new charge of job safety, with the creation of the Occupational Safety and Health Administration (OSHA) to oversee workplace safety. The Employment Retirement Income Security Act (ERISA) was created in 1974 to protect private retirement systems.

One of the main responsibilities of the Department of Labor is to administer and enforce more than 180 federal laws regarding employment and wages. The Wage and Hour Division, for example, regulates the Fair Labor Standards Act (FLSA), which requires employers to pay their employees the federal minimum wage for most public- and private-sector jobs. This division also administers the Family Medical Leave Act (FMLA), guaranteeing employees up to 12 weeks of unpaid, job-protected leave for the birth, adoption, or serious illness of a loved one. The Veterans' Employment and Training Service (VETS) protects deployed service members by administering the Uniformed Services Employment and

Reemployment Rights Act. This act ensures that members of the military who are deployed can return to their jobs when they return from duty.

While most of the programs have been revised or altered over the years and presidential administrations, the Department of Labor continues to administer many programs to protect, educate, or provide access for the U.S. labor market. The Department of Labor serves a very important role through the various programs, services, and acts it administers. At some point, every person's life is probably somehow affected by a Department of Labor–administered program. By protecting workers and workers' rights, these programs help ensure that the American public is able to maintain gainful employment in a safe, ethical environment.

DEPOSITORY INSTITUTIONS, DEREGULATION OF

Depository institutions are financial institutions that are legally allowed to accept deposits from consumers. On March 31, 1980, President Jimmy Carter signed the Depository Institutions Deregulation and Monetary Control Act. The act changed how depository institutions were regulated and intended to improve the control of monetary policy for the Federal Reserve. The law was passed during a period of high inflation when the depository institutions needed a great deal of reform. The key points that helped to change the way depository institutions were functioning were the elimination of interest rate ceilings, changes to the checking account system, and new disclosures and changes for customers.

The most important aspect of the Depository Institutions Deregulation and Monetary Control Act came under Title II—Depository Institutions Deregulation Act of 1980, which led to the elimination of interest rate ceilings. Due to high levels of inflation, interest rates rose to double-digit levels. Because of the regulations that were in place at the time, the banks were unable to raise the level of the interest rate high enough to compete with the market, since Regulation Q made the banks unable to raise the interest rate beyond 5.25 percent. As a result of this difference in interest rates, customers were moving their money to less regulated accounts such as mutual funds in order to achieve a higher rate of savings; this was creating disintermediation for the banks. Lower-income households that were unable to move their savings to mutual funds were forced to accept the lower interest rate at the bank despite the fact that the market interest rate paid much higher. The decrease in deposits left banks with less funds to operate with, making it difficult for banks to compete in the marketplace. In the act, the interest rate controls that were being abolished were to be slowly phased out over a period of six years. The six-year period was intended to allow for an orderly phase-out that would not add to problems in the marketplace. The act was also designed so that the interest rate would increase gradually, until it eventually was abolished in the sixth year.

Under Title III—Consumer Checking Account Equity Act of 1980 there were regulations that allowed banks to provide automatic transfer services from savings to checking accounts. This change made it possible for banks to provide better service for their customers since the banks were able to transfer funds for the customer to use. This let customers leave their primary money in an account that had a higher interest rate and move it to a checking account that had a lower interest rate only when necessary. Under this title the amount insured by the FDIC increased from \$40,000 to \$100,000 for customers. The increase in insured deposits made it easier for customers who were looking to have their deposits insured but were reaching the limit. Previously, customers would need to have their funds placed at multiple banks in an effort to keep their funds insured and avoid the limit. This increase allowed banks to build higher amounts of funds with their customers and develop relationships because many customers would now be able to have all of their accounts at one bank.

The act also made it possible for banks nationwide to offer Negotiable Order of Withdrawal (NOW) accounts. These accounts are deposit accounts that earn interest for the borrower, and the borrower is also able to write checks from this account. The new accounts helped customers open the new type of checking accounts since customers would be able to earn interest while they were using the funds to pay their bills.

Title VI—Truth in Lending Simplification and Reform Act is still in effect today, and it has been strengthened due to problems with banks and other financial institutions lacking clarity with their customers. The Truth in Lending Simplification was aimed at helping customers understand the financial documents to the best of their ability. The title regulated what would be required for disclosure, since many financial institutions were releasing information that was confusing to the customers or was inaccurate. The Truth in Lending Simplification forced banks to use language that was more easily understood by the majority of the public rather than using finance terms that needed to be explained to the customer in order to be understood. The Truth in Lending was mainly aimed at helping customers that were lacking in a financial background. By regulating the disclosures that the bank would give, and how much information it should disclose, this helped to clarify information for the customers.

DETROIT BANKRUPTCY, 2013

In 1950, Detroit, Michigan, was the fifth-largest U.S. city, with 1.85 million people. After the General Motors bankruptcy in 2009, only 770,000 people were left; by 2013, there were only 680,000. Those left had the lowest average literacy rate in the nation, if not in the world. Crime and drugs were so bad that police refused to enter many of the city's neighborhoods. In July 2013, Detroit filed for bankruptcy, crushed by the unsecured debt owed to union public employees and by its overall debt of $18 billion. Like most cities of the period of great American prosperity, Detroit's finances became overextended because of promised wages and benefits owed to public employees.

The unions in Detroit resisted any settlement to reduce their pensions and health benefits, unlike the United Auto Workers a decade earlier. Detroit's situation in 2013 illustrates the future of many American cities that now lack the once-plentiful tax base of industry. Detroit learned the hard way that increasing the tax rate on its businesses and citizens only accelerates a city's decline. The state of destruction in Detroit went far beyond the destruction of New Orleans after Katrina, yet the American media has given the city's problems little coverage in comparison. America has never known the crime, devastation, lawlessness, poverty, and hopelessness that existed in Detroit.

One variable associated with the decline of Detroit was the transformation of the automobile industry in America. In 1954, Detroit had the highest per-capita income and the highest rate of home ownership in the United States. As of 2013 it ranked lowest. At its peak in the 1960s, Detroit had more than 290,000 manufacturing jobs, a number that by 2013 had fallen below 27,000. Even in the first few years of the 2000s, the Detroit area lost an additional 150,000 auto industry jobs. In 2009, the unthinkable happened with the bankruptcy of General Motors. Many of those who lost their jobs and other Detroit residents took advantage of state and local retraining programs either for the new automobile industry or for other new jobs in non-auto industries.

In 2013, crime was so bad in Detroit that the police barely tried to deal with most of it, and police response time averaged 58 minutes. Homicides hit 386 in 2012, and 90 percent of the crimes went unsolved. Gangs controlled most of the city. Some neighborhoods were too dangerous for even police patrols. Drug dealers found the area dangerous, too. More than 50 percent of the city's children were classified as poor and illiterate. Less than 40 percent of students graduated from high school, and those who did could barely read. The infant mortality rate of 16 per 1,000 was higher than in the Dominican Republic.

More than 40 percent of the city's streetlights were broken; most were stripped of their copper wiring for drug money. Old houses were broken up and used as firewood by the homeless. The city halted most road and sidewalk repair. More than 30 percent of the ambulances and emergency vehicles did not run. Detroit's crime rate in 2013 was five times that of New York City. Real unemployment was still around 50 percent. At least 30 percent of the buildings were vacant, and many houses sold for less than $500.

The median house price was $6,000. Often only a single house per block had a living occupant. It was hard to sleep in the downtown hotels as the night sounds of sirens and gunfire continued until daybreak. Many Michigan residents would not even drive near Detroit after sunset. City blocks started to revert back to forest. Politicians promoted farming in downtown Detroit. In what were considered their worst days, from 1990 to 2000, the industrial bad neighborhoods of Detroit were Eden compared with 2013's neighborhoods that fell victim to deindustrialization. Detroit still pays the highest tax rates in the state and has the lowest level of public services. Over the decades several efforts were made to save the downtown, but without an industrial base these efforts amounted to corporate welfare. Eventually the decline of General Motors and Chrysler brought an end to even this corporate welfare.

In January 2013, Governor Rick Snyder of Michigan declared a financial emergency and took over the city's operations to restructure its debt. At that time the debt breakdown was $9.5 billion in pension and health care costs, $6 billion in water and sewer debt, and $2 billion in bonds. The emergency financial manager was able to obtain contract concessions from the AFL-CIO, but it was too little too late. Bankruptcy became the only option as Detroit lacked the money to pay for basic services.

Without welfare support, Detroit lacked a stable income source and barely had the infrastructure necessary for people to live. Detroit became a ward of the state of Michigan and of Washington, D.C. Lacking money, and with an illiterate voting population, Detroit has received little support from politicians. Detroit's issues with local government corruption and cronyism added to Detroit's recovery problems. The federal government surprised many by choosing to ignore social service aid to Detroit. People from the city continue to move to the South, reversing the Great Migration of the 1930s, 1940s, and 1950s.

After bankruptcy, Detroit was hit by a new increase in crime as gangs took over some of the city's 80,000 vacant homes. In addition, an estimated 30,000 wild dogs roam the city in packs. The unions, which had negotiated one of the best pension benefits in the nation, received 20 to 30 cents on the dollar.

On December 10, 2014, Detroit declared it was out of bankruptcy. Major business leaders purchased and renovated much of the downtown office spaces, with new occupants and several suburban businesses moving downtown. Detroit's professional sports teams have built new fields and arenas downtown; the city's professional sports have proved to be anchors to a renewal of the downtown area. The downtown river area has been transformed into a park and scenic walkway more than a mile long.

Detroit still has many problems, including a significant drop in population from approximately 2 million to 150,000 city residents, leaving major tracks of vacant land and homes. Condensing Detroit to a city serving only 150,000 as opposed to the historically 1 to 2 million will be legacy issues and challenges that will continue long into the future The larger question is how many American cities face a future like Detroit's?

DIGITAL CURRENCY

Digital currencies (or cryptocurrencies) are created with a complex algorithm and are stored electronically. There is no government control or monitoring. All transactions and storage are governed by protocols that are set when these currencies are established. The most popular and largest in valuation is Bitcoin, which was conceptualized by Satoshi Nakamoto (Nakamoto n.d.). When one writer claimed to have found the creator of the popular digital currency, the person cited denied any such association (Goodman 2014). The creators of these digital currencies have a common goal: to use the currencies as method of payment via a peer-to-peer (P2P) network, bypassing financial institutions. However, these digital currencies are not money in the traditional sense. They are more like commodities (such as gold and silver). To understand why these digital currencies are not money, we have to understand what money is.

In economics, money has three essential functions. First, it is used as a unit of accounting (or measurement). Second, it is used as a medium of exchange. Third, it is used as a store of value.

The first function of money is easily fulfilled by digital currencies and by most other commodity monies. For any commodity to be considered “money” in terms of its function as a unit of measurement, all that is needed is some form of agreement on the measurement. This is the main reason why gold and silver have served as commodity monies for most of human history.

The second function is where digital currencies experience a little difficulty gaining mainstream acceptance. Unless digital currencies can be used to meet daily transaction needs, it will be difficult for them to be accepted as money. While there has been efforts to make purchases with digital currencies possible at some online retailers and even some physical stores (via digital price tags), the use of digital currency is largely limited to transactions that are linked to the digital world. Imagine shopping in the fresh food markets in Vietnam, and you can see how well this type of currency would function. The large volatility in price also makes these currencies a poor payment choice for businesses that are increasingly demanding more precision in production and sales planning.

The high degree of variation in value also makes digital currencies a poor store of value. For example, consider Bitcoin’s “price.” Bitcoin started with a value of a few cents, and it skyrocketed to over $1,000 in a matter of a few years. Within a year, the value can fluctuate between a few hundred USD to more than a thousand. Imagine if you work for a company that accepts Bitcoin as payment for the goods and services you provide and your compensation is also in Bitcoin. Because the value of Bitcoin fluctuates frequently, the amount of income available to you also fluctuates widely. Imagine that you go to a restaurant and you have to decide what to order, or whether you have enough money to tip the server, depending on the value of the Bitcoin you have? It is simply impractical. The problem gets worse if you think about long-term planning in the world of highly volatile value. Hyperinflation and deflation are major problems for any economy. Having a highly volatile currency is like having hyperinflation and deflation all the time. The economy would simply stall.

Furthermore, for goods or services to have value, a certain amount of resources have to be put into them. Once those goods and services are created, their value might change depending on the supply and demand for those goods and services. But in general, only goods that can generate more cash flow/value in the future should see their price go up in the future. Goods that have limited supply could see their value increase if the demand for them increases. If many people are bidding on a limited supply of certain goods that generates less value than the selling price, we have a speculative bubble.

We must also note that Bitcoins have a price. So, the value of a Bitcoin still depends on the value of existing currencies. The value of Bitcoins changes based on the last price in which a transaction/exchange has been made at one of the Bitcoin exchanges. If Bitcoin is to replace all other currencies, the value of all goods and services will be measured in Bitcoin—in which case, Bitcoin will become another good with value depending on the relative values of other goods and services. In that scenario, we would be back to a barter system, with Bitcoin serving as the reference value/unit. In a barter system, credits cannot be created easily. The complex capital markets we have today would not be possible under such a system.

Controversies

Due to the nature of how Bitcoin is transmitted, Bitcoin became a tool for illegal drug trades, money laundering, and other illegal activities. The biggest online illegal drug dealer, Silk Road, was shut down by authorities in October 2013. Silk Road used only Bitcoin for transactions and charged commissions in Bitcoin. Silk Road 2, the reincarnation of Silk Road, was shut down for a different reason in February of 2014. Hackers attacked Silk Road 2 and stole all the funds (in Bitcoin). Hacker attacks were also the reason behind the closure of the biggest Bitcoin exchange, Mt. Gox, in February 2014. Another Bitcoin exchange, Flexcoin, also closed in March 2014 for similar reasons. The closure of these exchanges caused large variations in the value of Bitcoin. More importantly, they show that Bitcoin is far less secure than believers claimed. Hacker attacks on the online exchanges or businesses that use Bitcoin are similar to robberies of trains/wagons/banks that carry gold/silver.

Should You Invest in Bitcoin?

Bitcoin is not money or any currency. Instead, it is a speculative asset that varies in value depending on demand and supply. In other words, Bitcoin can be viewed as an alternative asset. The Internal Revenue Service defined it as such in March 2014. The main question is whether the average investor should invest in such an asset. The famed investor Warren Buffett advised investors to stay away from Bitcoin. He may have good reasons for that. There are two main driving forces behind the value of Bitcoin. First, different exchanges have different values for Bitcoin, and the variation in value is not small. The value of gold or silver is fairly standardized, because they have established exchanges, with rules and regulations for setting proper value depending on market transactions. Bitcoin has no such mechanism. Second, demand and supply (or speculations) are the main driving force in variation of value for Bitcoin. The surge in value from 2012 to 2013 was due to a large influx of speculators. Many believe that Bitcoin reached a speculative bubble in late 2013 and since then is likely worth far less. For prudent investors, it is best to stay away from assets that have volatile value. Bitcoin is such an asset.

Conclusion

Digital currency is a new class of speculative asset that has emerged quickly in recent years. While a more efficient payment system might emerge in the future due to this movement, it is at an early stage of its development. Regulatory changes in financial systems around the world will be required in order to make this possible. Until then, the value will continue to fluctuate widely. Because there are many competitors for the title of most dominant digital currency, most of the existing ones will likely have no value once the development stage is settled.

DISCOURAGED WORKERS

A *discouraged worker* is an individual of working age who is unemployed and is not pursuing a position in the current job market. Usually this person is willing and able to work but has given up finding gainful employment due to a variety of factors. Due to these real or perceived limitations in the job market, these individuals have become "discouraged." Discouraged workers are not included in the unemployment rate, and they are not considered to be in the labor force.

The Bureau of Labor Statistics of the U.S. Department of Labor compiles information on the labor force using the monthly Current Population Survey, or CPS. The CPS assesses data including and pertaining to unemployment, employment, those not in the labor force, and labor force characteristics. Based on a recommendation by the Committee to Appraise Employment and Unemployment Statistics, the CPS began gathering information on people not in the labor force starting in January 1967. Since these individuals were considered neither employed nor unemployed, the CPS sought to gather reasons why they were not in the labor force.

To determine why individuals are not in the labor force, the CPS asks four specific questions to gauge a person's ability to work, desire to work, job search process, and reasons why the person has not looked for work in the previous four weeks. The answers to the questions are then used to decide whether these individuals should be a part of the marginally attached labor force measure. Those who are *marginally attached* to the labor force are available to work, want to work, and have been looking for work within the last 12 months.

Discouraged workers are a subsection of those who are marginally attached to the labor force. The difference between those who are marginally attached to the labor force and discouraged workers is that discouraged workers state that they have not looked for unemployment in the previous four weeks despite wanting to work and being able to work. The CPS has determined four reasons discouraged workers give as to why they are not seeking employment. These reasons include the following:

1. They believe no job is available to them in their line of work or area.
2. They had previously been unable to find work.
3. They lack the necessary schooling, training, skills, or experience.
4. Employers think they are too young or too old, or they face some other type of discrimination.

Discouraged workers are sometimes referred to as the "hidden unemployed" because they are not counted in the total unemployment number since they are not in the labor force. During times of economic growth when businesses are doing well and are hiring workers, discouraged workers are motivated to seek employment. When this happens, the CPS reports slightly higher levels of unemployment, as discouraged workers are then stating they are looking for work. During periods of recession when employers are laying off employees, discouraged workers are even more dejected and the CPS reports even higher levels of unemployment.

DIVIDEND INCOME

A *dividend* is a transfer of part of a company's earnings to its shareholders (stockholders). In general, the dividend is stated in terms of a percent of the current market price. This is referred to as the dividend yield. For example, if a stock is selling for $10 per share and pays a dividend of $.50 per share, the dividend yield would be 5 percent (0.50 × 10).

Investors in mutual funds also receive dividends passed through from the individual stocks and or bonds held within the mutual fund.

Investment Income

When investing in stocks, investors can realize gains in two ways. The first type of gains is called capital gains and is calculated as the difference between the sale price of the stock and the buy price of the stock. In other words, capital gains are realized when the price of stock appreciates and the shares are sold. If the stock price depreciates, the investment in the stock will yield a loss. For example, on January 1, investors buy the stock ABC at $12.00 per share. One month later, they sell the stock at $25.00 per share. The investors' capital gain is calculated as $25.00 – $12.00 = $13.00. They realized a profit of $13.00 per share, or a percentage gain of 108 percent [(25 – 12)/12].

The second type of gain that investors can realize when buying a stock is dividend income. From the investor standpoint, dividend income is an amount of cash received per share of stock held. For instance, if the dividend associated with stock ABC is $2.00 per share, investors will receive $2.00 dollars for every share of stock ABC they hold. The total gain for the investors will be the sum of the appreciation of the stock and the dividend income. Continuing with the same example, if investors realize $13.00 in capital gains and $2.00 in dividend gains, the result is a total of $15.00 of profit for every share of stock they have been holding.

Dividend Income: What Does It Represent?

From an investor's perspective, the dividend income is an additional source of gain when investing in equities. In order to invest in stocks that offer dividend income opportunities, it is important to be familiar with the concept of dividends. A *public corporation* is a firm that has the ability to raise money in the public capital markets by allowing public investors to own shares of its firm called stocks. Dividends are cash payments that public corporations pay to these public investors as a return on their capital investment in the firm.

Investors inject capital in the firm in the form of equity. This capital allows the firm to run its operations and invest in growth opportunities. The firm makes profits in the form of revenues. After subtracting all the operational and financial costs associated with these revenues, the company is left with the final profit—or net income. If the net income is a profit, the company will retain a portion of it. The part of earnings that a corporation keeps and doesn't pay out to shareholders is called retained earnings. The residual amount of net income not retained in the firm will be paid out to investors in the form of dividend payments. The percentage of net income paid out to investors is called the payout ratio.

For example, company ABC realized net income of $200 million this year. The company's management decided to retain 45 percent of the earnings to invest in new projects next year. The amount of retained earnings is $90 million. As a result, the payout ratio is equal to 55 percent, and the amount of dividends paid out to investors is $110 million. The dividends are divided proportionately among all the shareholders. If the company has 55 million shareholders, then each shareholder will receive a $2.00-per-share dividend.

The retained earnings can vary tremendously depending on growth and investment opportunities offered to the firm. If it appears that an investment opportunity will return significant value for the shareholders, management might decide to retain all the earnings instead of paying cash dividends to the investors. Mature companies usually pay more dividends than growth companies do. For investors looking for dividend income as a primary source of investment gains, investing in mature companies with a history of dividend payments could be a good option. Investors need to keep in mind that a history of dividend payments is not a guarantee of future dividend payments.

Valuing a Company Based on Dividend Payments

For mature companies that have been consistently paying dividends to investors, the dividend cash flows can be used to value a company—or, in other terms, to calculate the intrinsic value of the stock. Investors will seek to invest in stocks that are undervalued by the market—that is, stocks that are selling cheaper than their intrinsic value. One way to calculate the intrinsic value is to calculate the preset value of future dividend payments that a company is expected to pay out to investors. To complete this calculation, investors need to forecast future dividend payments based on historical data for the firm. Readers interested in this calculation should consult literature around the dividend discount valuation model.

Taxation of the Dividend Income

Dividends can be taxed either as ordinary income at ordinary income tax rates or at the preferred long-term capital gains tax rate. Readers should consult the IRS website for comprehensive information on the taxation of dividend income. The taxation of dividend income has been criticized because of the double-taxation problem. Indeed, the company pays corporate taxes for profits realized, and the investor pays taxes for dividend gains, which is a double taxation that shareholders have to bear.

DOUBLE-DIGIT INFLATION, 1974

The United States had not experienced double-digit inflation at the rate seen in the 1970s since colonial times. The period from 1972 to 1980 is often called the "Great Inflation." In the United States, the inflation rate peaked at 12 percent in 1974, declined to 6 percent in 1976, and again peaked in 1980 at 13 percent. President Nixon's wage and price controls in 1971 were shorted-lived and did little to remove the underlying price pressures. By 1972, inflation quickly returned after price controls were lifted. The great wave of inflation returned in 1974, fueled by the Arab oil embargo and the Federal Reserve's pushing of the money supply to keep unemployment low. The elimination of the gold standard had freed the Federal Reserve to pump unlimited amounts of money into the U.S. economic system. There was a worldwide run on the dollar, causing it to become devalued. Initially, American consumers showed little fear of inflation; the major fear in the American psyche had always been the deflation experienced in the 1930s. Countries like Germany had learned to fear inflation more.

The American public had a mixed view of inflation. The big unions were protected by automatic cost-of-living adjustments to their wages and salaries, and workers saw large increases in their pay on a monthly basis. Even nonunion workers benefited from the wage inflation. People on fixed incomes or employees lacking cost-of-living adjustments faced a major loss in purchasing power, but they enjoyed the high rate of return on their savings. Most homeowners were pleased with the rise in housing prices, which brought new wealth to homeowners. However, prospective new owners were being priced out of the market. Food and consumer-goods price increases were looked at as a major negative. Food prices rose 30 percent between 1974 and 1975. The nine-month period of food price increases beginning in February 1974 is often referred to as "food shock." Food shock created panic-buying in meat, coffee, and flour. Used car prices rose 38 percent in the peak period of 1973–1976, while new car prices lagged but rose after the peak period. Fuel prices doubled. Strange shortages occurred at times, as goods such as coffee and toilet paper became unavailable. Consumers found new money by cashing in gold and silver goods. Consumers were slowly forced to deal with the problems caused by high inflation as the bills for big-ticket purchases came due or the items needed replacing. Probably those with the real concern were the wealthy, who were stuck with investments in bonds and high-dividend stocks that were being devalued by higher interest rates.

The U.S. government was running large deficits, but the economy was picking up as the Federal Reserve was easing monetary policies. Inflation was causing major problems in international markets as the United States moved off the gold standard. More accurately, there was a de facto gold standard that allowed the Federal Reserve to continue to print money beyond the point where it had 100 percent gold backing. The dollar was losing value, causing Arab oil barons to watch as their petro-dollars were devalued. The gold coverage of the dollar dropped to 22 percent, which created a lack of confidence in the dollar by foreign countries. The dollar was further eroding as foreign countries demanded gold for dollars, and the U.S. Treasury was being drained of gold reserves. Over the decade, Americans adapted to rapid inflation. Many middle-class Americans actually profited from the period, assuming they remained employed.

The bigger problem for the United States became stagflation, a combination of high unemployment and high inflation, which hit the unemployed, citizens on welfare, and those on fixed incomes particularly hard. The government, in an effort to slow inflation, actually moved the country into a recession. During the 1976 presidential campaign, the "misery index" was developed—a measure that combined the unemployment rate and the inflation rate into one gauge of economic misery. Although the causes of stagflation are still being debated, it is considered a relatively modern phenomenon. Certainly, the oil crisis of the 1970s was a major contributing factor. Thus, this type of inflation would also become known as "cost-push inflation," where a rise in the price of natural resources drives inflation higher.

DROUGHT

Winston Churchill's description of Russia—a riddle wrapped in a mystery inside an enigma—could very well apply to the issue of drought. That is, there is rarely agreement or understanding as to when a drought begins or ends (which is why it is often referred to as a creeping phenomenon), nor is there a single definition that can be agreed upon. Indeed, there are a multitude of definitions, including meteorological droughts, hydrologic droughts, agricultural droughts, and socioeconomic droughts, to name a few. There seems to be universal agreement that drought involves a decrease in precipitation relative to an identified norm over an extended period of time. Yet, even here things are not so clear in that what constitutes a drought differs across regions and seasons. For instance, a two- or three-week period of dryness in an arid region such as California's Imperial Valley may well be within the norm of weather patterns, whereas the same duration and intensity of dryness in Portland, Oregon, or in a tropical region such as Malaysia may trigger serious concerns of drought. Finally, drought is often identified by three characteristics: duration, intensity, and spatial coverage. None of these is known in advance, and past experiences of them are not necessarily good predictors of future events. When coupled with the rarity of drought events within any particular region, the lack of certainty and agreement in what constitutes a drought and its indeterminate impacts pose challenges to planners, particularly with regard to their ability to garner support for adequate planning and preparation for drought.

Despite these challenges, it is easy to find motivation for drought planning in light of the far-reaching and potentially devastating impacts of drought. With respect to the natural environment, the impacts of drought on ecosystems can be dramatic, with the capability to change biotic community composition and markedly alter ecosystem function. From an anthropocentric perspective, arguably the most recognized impact of drought is on agriculture, with images of the 1930s Dust Bowl in the United States as memorialized in the writings of John Steinbeck coming to mind. And while drought can significantly impact industry, municipalities, and residential households, possibly the largest impacts of drought arise from its impact on hydroelectric power and recreation. Given a future that portends more frequent and intense drought worldwide, the motivation and benefits associated with drought planning and preparation should surely rise.

Of course, the necessary amount of planning and preparation for drought—or from an economic perspective, the efficient level of mitigation and adaptation—will depend on the benefits or avoided damages of strategies to mitigate and adapt to drought relative to the costs of such strategies. These strategies, which vary considerably across regions, can be placed into three general categories: water supply augmentation, demand-side adaptation/mitigation, and institutional adjustments.

Water supply augmentation generally consists of modifying the impact of the meteorological event on water supply availability. Historically, and successfully, water supply augmentation has consisted of the development of water storage and conveyance structures that reduce a region's vulnerability to drought by modifying the spatial and temporal distribution of its available water supply. As such, a region's available water supply is a function not only of the precipitation that falls within that region at any particular point in time, but also of past precipitation events whose excess has been stored. Lake Mead and Lake Powell, which combined can store four times the mean annual flow of the Colorado River, serve such a purpose for the Lower Colorado River Basin, including southern California. Such storage and conveyance structures allow water to move to its highest valued use, temporally and spatially, thereby reducing the economic impacts of drought. While ample opportunity for storage and conveyance still exists in many developing countries, many if not most low-cost opportunities have been appropriated in developed countries. The future usefulness of this approach is therefore limited, with one notable exception: the use of aquifers to store excess water, in what is termed conjunctive use. The other historically reliable method to augment supplies has been pumping groundwater. While groundwater will continue to be heavily relied upon, contentious and ill-defined property rights, groundwater overdraft, and increases in groundwater pollution can severely limit its ability to further augment future water supplies in any appreciable manner. Ocean desalinization is an alternative that has met with some success in particular regions worldwide, although widespread adoption is limited by proximity to the coast, energy requirements, and environmental concerns surrounding air emissions and the potential marine impacts arising from water intake and brine disposal. More recent augmentation opportunities being considered and implemented by governments include stormwater capture and wastewater reuse, both of which are viewed as locally reliable and potentially low-cost supply options to reduce drought vulnerability.

Drought planning also can consist of reducing the impacts of drought by increasing resilience and/or decreasing reliance on water. For instance, the development of drought-tolerant crops increases the resilience of agricultural production to drought events by reducing damages on yields. Similarly, agricultural operators and urban residents can implement crop combinations and landscape designs (e.g., xeriscaping) that serve to reduce the effects of drought either directly by reducing impacts on overall farm/landscape production, or indirectly by reducing water requirements. Obviously the change in value associated with altering crop composition or landscape design should be balanced with the benefits such actions provide. In an effort to reduce reliance on water and exposure to drought, water agencies regularly encourage the adoption of water-conserving practices and technologies. Encouragement has often taken the form of subsidies for the adoption of water-efficient technologies such as drip irrigation in the agricultural and landscape settings, or through rebates for the installation of more water-efficient indoor appliances (e.g., shower heads, toilets, and clothes washers). While such nonprice measures have been successful in reducing water use, they can be very costly. As an alternative, agencies increasingly are turning toward water pricing, and tiered-rate pricing in particular, to encourage more efficient water use. A significant benefit of using prices rather than subsidies or rebates for water conservation is that the use of subsidies or rebates typically leads to losses in revenue that agencies rely upon to cover their costs, while the use of prices may actually increase revenues, given that the demand for water has been shown to be price inelastic.

From an institutional perspective, water markets and water banks are two strategies that offer potentially large gains in reducing the economic impacts of drought, because they can facilitate the movement of water toward its highest valued uses. Acknowledgment and awareness of possible third-party effects from water trades should be considered when the overall net benefits surrounding the efficiency of water trading are being calculated. Another equally important development with significant potential from an institutional perspective is the collection and dissemination of real-time information related to drought indictors (for example, precipitation and evapotranspiration, as well as surface, groundwater, and storage supplies). Further development of information systems will allow water users and agencies to have accurate and up-to-date information upon which to monitor their drought risk and base their decisions.

ECONOMIC EMBARGO AND DEPRESSION, 1807

The embargo of 1807 remains a valuable reference tool for economists, politicians, and businesspeople. It offers a study of the effects, both positive and negative, of restrictions on trade, and it clearly demonstrates the interaction of politics, trade, and business. In many ways, the embargo was an extension of the decades-long war between Great Britain and France in the early 1800s.

Starting during the colonial period in America, trade restrictions of one kind or another had plagued the new nation. Although the embargo of 1807 initially created an economic recession and led to depression in 1809, it would launch new American production of textiles, iron, tools, tinplate, glass, hemp, hats, and nails. Overall, while this embargo was in force from 1807 to 1809, American imports dropped from $30 million to $15 million, while exports dropped from $107 million to $22 million.

In the years before the embargo, Europe was struggling with the Napoleonic Wars. France's advantage on land was checked by Britain's advantage on the seas, and Great Britain used blockades and seizures to enforce its naval advantage. British ships blocked key foreign ports, forcing American ships to first go through British ports. In addition, the British navy boarded American ships, looking for deserters. At times, France would also board American ships and take cargo and sailors. This system of impressments of American sailors created a public outcry in the United States. President Thomas Jefferson hoped to avoid war and demonstrate economic alternatives to war. The United States was a major importer of British manufactured goods and an exporter of raw materials such as cotton, furs, pig iron, lumber, farm goods, and tobacco. Still, Jefferson believed he could restrict imports while continuing to export to Great Britain.

In December 1806, Congress passed the Nonimportation Act of 1806, which declared a "Prohibition of the importation of certain goods and merchandise from the kingdom of Great Britain." America depended on Great Britain for such imports as iron nails, tinplate, tin, glass, hats, clothing, silk, paper, wool, hemp, and leather. Initially, Canadian and American smugglers found ways around this embargo. In January 1807, Congress passed a supplementary act to close embargo loopholes that had excluded the whaling, fishing, and coastal boats that were economically important to the New England states.

The act was met with mixed opposition. Dependent on shipping, New England opposed any restriction of trade, as did the South, which exported agricultural goods to Great Britain. New England favored military action. The initial economic impact of the embargo was to move the country into a recession and increase unemployment. Treasury receipts dwindled, wiping out a surplus that had accumulated from the earlier policies of Alexander Hamilton and the Washington and Adams administrations. More than 30,000 seamen were put out of work, creating a true depression on the New England seaboard.

President Jefferson stuck to the policy, believing it was a social experiment on how to avoid war. The Federalists, the party out of power in Washington, rallied political opposition to the embargo and revitalized their party. Meanwhile, the middle states started to benefit from the restrictions on British imports as domestic iron production expanded. Textile manufacturers started to expand in New England as well. Still, overall the embargo had suppressed the U.S. economy further. A bigger problem was that the federal government was dependent on import tariffs for its operating capital. Fewer imports meant a smaller operating budget for the U.S. government.

Reduced tariff receipts meant that Jefferson had no money for federal projects, such as the canals and roads wanted by the Federalists. The reduction in federal spending made the recession worse. Despite these concerns, in March 1808, a new Embargo Act was passed to stop all ships leaving for foreign ports. From the standpoint of restricting trade, the act was successful, and U.S. exports fell from $80 million in 1808 to $22 million in 1809. This worsened economic conditions across the nation.

Poor economic conditions replaced public anger over British impressments as the deciding factor is U.S. elections. In the presidential election of 1808, James Madison of Jefferson's Democratic-Republican Party won the presidency, but the Federalists won the House of Representatives and took it away from Jefferson's party. The economies of the South and New England were hurt badly by these embargos. Both regions considered it America's first depression. Cotton prices dropped from 51 cents a pound to 24 cents. Tobacco prices also fell by 50 percent. The election, with the Federalists replacing the Democratic-Republicans over the issue of the embargo, was one of the first examples of Americans voting their pocketbooks over international affairs.

After Jefferson left office, the Embargo Act was repealed, and the embargo was lifted on all countries with the exception of Great Britain, France, and their possessions. The act was replaced with the Non-Intercourse Act in 1809, which extended the embargo until it was safe for trade. The decision on when to lift the embargo was left to President James Madison as a discretionary authority. The embargo was hurting Great Britain far more than America, as its manufacturing growth was based on exports to America.

One positive side effect of the embargo was the development of domestic manufacturing in the United States. Jefferson played on this success by dressing in homespun clothes for the Fourth of July celebration in 1808. The lack of imported British iron, in particular, caused the startup of America's iron furnaces, which had been dormant for decades. Saltpeter and gunpowder mills were also restarted. American manufacturing was reborn as the foundries and forges of the Revolutionary War opened again. Americans would prove to be adaptive and creative. Textile mills opened in New England to process southern cotton, and a new industry was born. The application of new machinery in American factories would also give the domestic industry a new productivity advantage over British producers. Francis Cabot Lowell would also develop a whole new system of textile manufacture. The success of textile production created a machine industry as well.

New England would ultimately emerge as a more economically balanced region after the embargo. As the War of 1812 approached, the manufacturing Connecticut Valley became America's armory. In the middle states, the iron industry, which was still suffering from the colonial Navigation Acts, started to awaken. In Pittsburgh, nail and tinplate mills were built to supply the growing needs of the west. Iron foundries also started to supply the needs of an industrial boom.

The glass industry came alive in New England and New Jersey. Western Pennsylvania and eastern Ohio opened hundreds of iron smelting furnaces, rolling mills, nail factories, tinplate manufacturers, and forges. Pittsburgh Foundry would become the producer of cannons for the War of 1812. In 1810, Great Britain wisely tried to end the naval problems that had led to the U.S. embargo; but it was too late: the War of 1812 between Britain and the United States was already beginning.

ECONOMIC GROWTH, MEASURES OF

Economic growth is the measure of an economy's productivity. Along with price stability and low unemployment, economic growth is one of the three goals every economic system aims to achieve. Economic growth is measured by several methods. Which method is dominant often depends on the purpose for the measure and what specific measure is important. Each economic growth measure has its own characteristic and personality. While there are several other methods for measuring economic growth of an economy, three measures receive most of the attention: gross domestic product, gross national product, and the personal consumption expenditures.

Gross Domestic Product

Gross domestic product (GDP) is the leading report and is considered the most important indicator on the health of an economy. GDP is considered the best indicator of an economy's achieving economic growth, one of the three major goals of every economy (along with price stability and low unemployment). GDP measured over time (quarter to quarter, year to year) is considered the major indicator of how fast or slow an economy is growing or contracting. In the United States, virtually all participants of the economy are impacted by the GDP reports. GDP is closely related to the other major economic goal of low unemployment. A growing GDP reflects the need for labor, capital, and land resources, which reflects lower unemployment in the future.

GDP measures the final value of goods and services produced within the borders of a nation, irrespective of who produced the good or service. GDP is not a measure of what is sold, but of what is produced within an economy's borders. Toyota, even though a Japanese company, assembles automobiles in the United States. Those Toyota automobiles are counted as part of the U.S. GDP data. Conversely, a Chevrolet automobile the final assembly of which is in Canada is not counted.

Another example of what counts as GDP would be a tire company that has produced eight tires. Four of the tires are shipped to an automobile manufacturer and used in the assembly of an automobile. The other four tires are shipped to a tire company's retail outlet for sale. Only the four tires sold at the tire company's retail outlet are counted toward GDP. If the four used on the automobile were counted at the time they were produced, they would be double-counted, as their value to the economy is counted in the final value of the automobile, assuming the automobile was assembled in the United States. If the automobile was assembled outside the United States, they would not be counted.

In the United States, GDP data are collected, measured, and reported by the Bureau of Economic Analysis, a part of the Department of Commerce. GDP is reported quarterly (at the end of January, April, July, and October) with revisions each month. The monthly revisions report marginal changes—with an annual revision in July, the completed report for a given year. GDP is reported in both nominal dollars (present dollars) and real terms (constant or "chained" dollars).

The Bureau of Economic Analysis collects information and data from thousands of an economy's governments and private companies within its borders—including home purchases, retail sales, and auto sales—to report initial GDP estimates.

GDP is measured in two ways. One measure is the expenditures of an economy in four major areas of the economy's products of goods and services: the personal consumption by households (C) on durable and nondurable goods and services; the gross private investment of businesses, including changes in inventory (I); government's purchases of goods and services and investment (G); and the net trade balance between exports and imports of an economy's foreign participation ($X - M$). This is often shown as GDP = $C + I + G + (X - M)$. GDP measures what is produced, not what is sold. Unsold inventory is a measure of GDP at the time of its production. *Government* is defined as all government entities, including federal, state, and all local governmental entities.

The second measure is the income earned by laborers (w), profits earned from capital (p), interest earned by savers and investors (i), and the rents earned by landowners (r). This is often shown as GDP = $w + p + i + r$. Economists often measure an economy's health based on an equilibrium model of GDP = $C + I + G + (X - M) = w + p + r + i$ and the discrepancy between these two measures.

Gross National Product

Gross national product (GNP) is similar to GDP with one significant distinction. GNP is more concerned with "who" is producing, not with "where." GNP measures a U.S. company's production anywhere in the world that the production occurs. Using the above GDP example, a Toyota automobile produced in the United States is not counted as GNP for the United States because Toyota is a Japanese company; it would be counted for the GNP of Japan. Likewise, the Chevrolet automobile is counted in the U.S. GNP as a product of General Motors, a U.S. company.

Personal Consumption Expenditures

In the United States, the largest component of GDP is personal spending on goods and services. It comprises up to 70 percent of the U.S. GDP. By contrast, China's personal spending as a component of GDP is only about 30 percent. Consumer expenditures are the key dynamic influence of the U.S. economy. If consumers are not purchasing goods and services, businesses are not using resources (including labor) to produce goods and services—and the economy does not grow, or it even regresses. The stock market and other economic indices react to the reports of how much households are spending on goods and services.

As a component of GDP, the reporting of personal consumption expenditures (PCE) is a function of the Bureau of Economic Analysis (BEA). Personal spending is reported monthly, with several months of revisions. The monthly reports are also annualized to reflect yearlong income or expenditure trends. A major revision in data may occur to reflect new reporting and/or data-collecting methodologies. Personal income is measured before taxes are deducted. The BEA measures income from several sources: wages and salaries, rental income, interest and dividend income, income of the self-employed (proprietor's income), transfer payments, and other income. PCE and personal income are reported in nominal dollars (current dollars) and real dollars (adjusted for inflation).

PCE are measured in three major categories: durable goods (goods lasting three or more years), nondurable goods (goods lasting less than three years), and services. Durable goods are major items purchased by households, such as cars, refrigerators, and televisions. Because these are items that households do not purchase often, they account for only 12 to 14 percent of PCE. Nondurable goods, such as food and clothing, account for approximately 30 percent of PCE, as they are purchased more often. Services, the fastest growing component, make up the remaining spending, as much as 60 percent, accounting for purchases of haircuts, movie tickets, medical expenses, etc. Services spending is up from the 1960s, when it was only around 40 percent.

People either purchase goods and services (expenditures) or save income. Personal savings is also calculated from this information. Once all spending is measured, interest on credit cards and car loans is taken into account, and taxes are deducted, leaving disposable income, the remainder is considered personal savings. It has been calculated that over time the average household spends 95 cents of each dollar received and saves 5 cents. This very high percentage of consumption is the key reason the PCE receives attention from the media and economists.

Collecting personal income data is one of the most complicated tasks the BEA undertakes. The BEA collects data from many sources to calculate both personal consumption and personal savings. Wages and salaries are collected from employment reports, and transfer payments are reported by the Social Security Administration along with the Departments of Treasury and Labor. Interest and dividend payments to households are estimated from reports of the Internal Revenue Service (IRS), the U.S. Census Bureau, the reports of corporations that pay dividends, and the Federal Reserve.

Measuring PCE is also complicated and involves many government departments, organizations, and companies. For example, medical expenses come from the Labor Department (a government agency), but expenditures on automobiles involve the manufacturers. Many measures of consumer expenditures are estimates that are reached after many years of data-collecting.

ECONOMIC OPPORTUNITY ACT OF 1964

On August 20, 1964, President Lyndon B. Johnson signed the Economic Opportunity Act (EOA) into law to fight poverty. The EOA was a key component of President Johnson's Great Society programs and War on Poverty. Although most of the EOA was slowly eliminated, core programs such as Job Corps and Head Start still exist today.

The EOA was not passed to create a wealth redistribution system. It was created to provide people in poverty with decent wages and a basic standard of living. The act provided funding to public outlets to address the community needs of low-income families. The EOA provided resources to community-action organizations for job training, adult education, and small-business loans. A 1964 poll revealed that 20 percent of U.S. families of four had incomes under $3,000 per year. Of special note was that over 50 percent of U.S. non-whites lived in poverty.

The EOA had 11 programs, all of them administered by the Office of Economic Opportunity (EOP):

- Adult Basic Education—education grants for low-income individuals over 18 or adults whose first language was not English
- Assistance for Migrant Agricultural Employees—financial assistance to state and local governments for travelling workers and families for housing, education, and children resources support
- Employment and Investment Incentives—loans under $25,000 for small-business startups
- Financial Assistance to Rural Families—financing of microloans (under $2,500) to low-income families to increase their disposable income
- Job Corps—basic education and work training for young people ages 16 to 21
- Neighborhood Youth Corps—training and employment opportunities for young people ages 16 to 21
- Urban and Rural Community Action—technical and financial assistance to public and private nonprofit groups to develop community action programs
- Voluntary Assistance for Needy Children—an information center to encourage voluntary assistance for needy youths
- Volunteers in Service to America (VISTA Program)—volunteer training for local and state agencies and nonprofit organizations in the United States
- Work Study Programs—education grants to higher education organizations to provide part-time employment for students in low-income families
- Work Experience—financing for trial, demonstration, and experimental projects to expand opportunities for work experience and training of individuals who are unable to support their families

ECONOMIC POPULISM

The term *populism* refers to taking a stand that is said to reflect the general public or the general populous. Therefore, *economic populism* refers to a position that supports economic measures that fit the needs of the majority in the public. This might include stimulus packages, environmental regulations, universal health care, or any policy or economic measure that represents the people. *Populism* is frequently misused as a term to criticize a public figure for pandering or making general remarks with the intention of appealing to the basic instincts of voters. In this sense, candidates often make hollow promises or undetailed remarks, leading the opposition to label them as populist. Recently, actual populism has gained momentum in politics, specifically in Latin America. Populism is also on the rise in the United States. In 2016, presidential candidate Bernie Sanders ran on a populist platform.

Historically, populism came about during the 1870s when farmers felt unfairly burdened by high costs, debts, and small profits. At the time, the chief antagonist of restrictive policies was the railroads. In 1874, the Granger Laws were passed, creating a price ceiling for costs of freight shipment and making the pricing of railroad rates more favorable to farmers. The Grangers, much like the Masons, were a secret society with local chapters, passwords, and rituals. Around the same time, the Farmer's Alliances came into existence. In 1889, the Farmer's Alliances became involved in politics and gained positions of power in order to represent the needs of the common man.

The emergence of populist arguments had a deep economic connection. Many of the aggrieved had been saddled with debt due to the government's shift to backing money with gold rather than silver. At the time, this contracted the money supply and worked to the benefit of the wealthy. Therefore, farmers and merchants wanted to create inflation in order to recover their debts. Out of these initial organizations rose the Populist Party. This party led the charge in the Free Silver Movement, which attempted to allow money to be backed by both silver and gold, thus increasing the money supply and creating inflation. The Populist Party ran on other political reform platforms as well, such as demanding a graduated income tax that would tax the wealthy more. The party also advocated for affording citizens greater rights in politics, such as the ability to democratically elect senators (at the time, senators were elected by the state legislatures) and the ability to bring forth debate on various social issues.

Historically, Latin America has had large roots in populism. More recently, some Latin American nations are experiencing a rebirth of populism. Frequently, a charismatic dictator represents the populist cause. The common thread of these populist dictators has been their appeal to the masses of people through the promotion of policies that would help the working man. This type of populism has often been seen as a way to strengthen nationalism and fend off the corrosive aspects of capitalism. Latin American populists have often favored inflationary policies and monetary distribution with the goal of quick turnaround growth. With a number of leaders clearly military-backed, many of these forms of populism actually operated more like fascism than populism.

In modern times, populism has taken on a new form in Western politics, where it is seen more as a modern iteration of democratic socialism. Core concepts of "fighting for the little guy" and equitable representation and policies have led the charge. Modern politicians often base their election campaigns on economic populist policies such as raising the minimum wage, increasing Social Security benefits, making college free, and regulating Wall Street.

Recent recessions have made Americans more aware than ever of their social standing. Their perspectives on how government should represent the people have also shifted. Formulating policies and strategies to win votes has been strongly influenced by populist trends. There has also been an evolution in the application of these theories with the growing connectivity of the world. With innovations in communication and trends shifting toward sustainability and responsibility, populism has taken on new forms that include embracing a global society and has shifted farther away from classical nationalism.

ECONOMIC PROBLEMS OF THE 1970s AND 1980s

The U.S. economy experienced a rapid transformation in the late 1970s and early 1980s, with a shift away from manufacturing and toward an information-based service economy, an increasing participation of women in the labor force, and the emergence of a trade deficit. In addition, inflation proved to be persistent. The economic policies that were adopted to address these issues had long-lasting social implications. An understanding of these periods will help individuals appreciate the nature of contemporary American economy and society.

Economic Problems in Late 1970s and Early 1980s

In the post–World War II years, many Americans enjoyed a period of unprecedented prosperity, characterized by high employment, stable prices, and rising income. This prosperity was interrupted by the food and energy shock in 1973–1974, resulting in a rapid rise of inflation. The Consumer Price Index (CPI), one of the key measures of inflation, rocketed from 3.4 percent in 1972 to 12.2 percent in 1974 (Blinder 1982, 265) and stunned many Americans.

Inflation fell in intervening years, but from 1977 it climbed steadily, before reaching a new height in 1980 at 13.5 percent. Unemployment also rose hand in hand with inflation, puzzling policymakers due to the widespread belief of a trade-off between inflation and unemployment (when inflation is high, unemployment is low, and when unemployment is high, inflation is low). With unemployment reaching 7.4 percent in 1980, America suffered from classic symptoms of stagflation, characterized by both high unemployment and high inflation.

For Americans growing up in the postwar years, accustomed to low inflation rates (less than 2 percent in the first half of the 1960s and about 4 percent in the early 1970s), the rise of inflation to over 12 percent in 1979 and 1980 tainted their economic optimism. By 1980, opinion polls revealed that the American public saw inflation as the problem of greatest concern, and many were willing to tolerate drastic measures to reduce it (Feldstein 1994, 4; Wells 2003, 111).

Factors Contributing to Inflation

One theory traces the rise of inflation in the late 1970s to food prices, which rose 22 percent between 1977 and 1979. Much of the increase is attributed to "meat inflation." Meat prices as measured by the CPI were extraordinarily high and variable during 1978 and 1979, partly because of a sharp drop (over 16 percent) in the total cattle herd (Blinder 1982).

The high oil prices and the energy shock in 1979 ensured a continued acceleration of inflation. The political turmoil in Iran and the downfall of Shah Pahlavi caused disruptions in supply and chaos in the world oil market, resulting in queues at gasoline stations in various locations in the spring and summer months of 1979 (Blinder 1982, 270). Between December 1978 and March 1980, the average cost per barrel of imported crude oil to U.S. refiners rose from about $15 to over $33. As a result, the CPI energy component rose 56 percent (a 43 percent annual rate) between December 1978 and March 1980 (Blinder 1982, 271).

The increase in mortgage rates also fueled inflation. Mortgage interest rates were about 6 percent in the 1960s; throughout 1977 they stood at 9 percent, before increasing dramatically to 10 percent by December 1978 and 12 per cent by 1980.

Interest rates have a huge impact on monthly mortgage payments, and the rising costs of borrowing (in addition to the rapid rise in prices) inflicted economic hardship on many American families in the 1980s as their household budgets were badly squeezed. This had a long-term social impact, forcing many women to enter the labor market to help their families with the rising costs of living. (Women also entered the workforce as part of the women's liberation movement.)

The factors named above do not tell the whole story. Inflation was a persistent problem in the 1970s because, with the Great Depression fresh in people's minds, unemployment had been the government's economic priority. Inflation was tolerated because it was thought that inflation would keep unemployment low. The United States, unlike countries such as Switzerland and West Germany, saw its inflation rates rise significantly in 1979 because it did not make a more determined effort to reduce inflation after the first oil shock in 1973 (Mussa et al. 1994). When the second oil shock came, inflation was already at more than 9 percent; inflation would jump to new peaks during 1979 (Mussa et al. 1994, 93).

President Reagan's Government and Economic Policies

It is generally agreed that the major economic success of President Ronald Reagan's policies (along with those of Federal Reserve Chairman Paul Volcker) lay in their triumphant battle against inflation. The CPI fell from 13.5 percent in 1980 to 3.9 percent in 1982, and it remained at around 4 percent for the rest of Reagan's presidency.

The battle against inflation was won because inflation became the government's number one priority. In dealing with inflation, the government's strategy was influenced by Milton Friedman's theory that sees the control of the money supply as an essential weapon.

From November 1980 (when President Reagan was elected president) and for 21 months until 1982, the Federal Reserve pursued a very tight monetary policy to combat inflation, even at the expense of business activity (Mussa et al. 1994). As a result, the American economy was plunged into a recession in 1981–1982, with an estimated loss of output of more than \$200 billion–\$300 billion (in 1982 dollars). Consequently, unemployment soared to new heights in January 1983, with more than 11.5 million people unemployed, or 10.4 percent.

Taming inflation was only half the battle; higher standards of living required higher productivity. To get the American economy moving again, President Reagan believed it was essential to give people incentives to work, save, and invest by reducing federal expenditure and personal taxes. Social Security spending was cut by \$40 billion, top tax rates were reduced from 70 to 50 percent, and income tax rates were reduced by 25 percent over three years (Wells 2003, 115). During the 1980s 18 million new jobs were created, the economy grew by about 3.5 per cent per year, and real disposable per capita income rose by 18 percent (Sloan 1999, 7). Unemployment, however, remained at 5 percent throughout the 1980s, reflecting structural shifts in the economy.

The sharp appreciation of the dollar from the mid-1980 through to mid-1981 may have helped reduce inflation rate. It also accelerated the decline of manufacturing.

The United States had low savings, and high interest rates were intended to encourage savings—but high interest rates led to the appreciation of the dollar. Between 1980 and 1985, the dollar appreciated by more than 60 percent against other industrial democratic currencies. This made U.S. exports expensive and uncompetitive, and exports fell from 8.1 percent to 5.1 percent of gross domestic product (GDP) in this period. For the first time, the United States became a net debtor. The trade deficit peaked in 1987 at \$152.13 billion (Wells 2003).

Social Consequences—Women in the Workforce and Growing Inequality

There is a general consensus that economic progress in the 1980s was accompanied by a growing inequality in American society. In 1980, there were 4,414 millionaires in America, rising rapidly to 34,944 by 1987 (Sloan 1999, 252). The number of persons living below the official poverty line, on the other hand, increased from 26.1 million in 1979 to 32.5 million in 1987 (Sloan 1999, 100).

The reasons for this are less clear. One theory holds that the enterprise culture of the 1980s, the philosophy of limited government intervention, and low taxes contributed to the growing inequality in U.S. society (Wilber and Jameson 1991, 119) while other theories point to the significant social and economic changes (Wells 2003). Between the 1970s and 1980s, for example, single-parent households became more common and at the same time the rising cost of living encouraged many women to enter the workforce, therefore widening the gulf between single-income and two-income families. The economy was increasingly shifting away from heavy industry toward the information technology sector, thus disadvantaging older workers in the declining industry while richly rewarding those in the growing sector. These changes led many to question American economic power and the ability of the United States to maintain its global role.

From a personal finance standpoint, it's important to understand the economy within a historical context. Although early in the 21st century the United States is experiencing historically low interest rates and high unemployment, these conditions should be viewed in a broader context. By understanding the cyclical nature of the economy—with highs and lows in interest rates, inflation, and employment rates—citizens are better equipped to understand the changing nature of their own economic lives as well as the life of the national economy.

EMBARGO ACT OF 1807

The Embargo Act of 1807, signed into law by President Thomas Jefferson on December 22, 1807, was created as an attempt to stop France and Britain, which were at war with each other, from restricting American trade. The purpose of the Embargo Act of 1807 was to introduce a form of nonviolent resistance to British and French interference with U.S. merchant ships. It effectively restrained American trading overseas until March 1809.

The Napoleonic Wars (1803–1815) can be viewed as the origin of the Embargo Act. Emperor Napoleon Bonaparte of France was determined to build a great empire. Beginning in 1803, a series of wars erupted between the French under Napoleon and the British. Each side possessed very different military strengths: With Napoleon's power based on the strength of his land armies, and British strength displayed in its naval fleet, it was difficult for the parties to engage each other in battle. Therefore, the French and the British ventured to inflict damage in another way: by attacking each other's trade and commerce. To illustrate, the British attacked the French by declaring Continental ports closed to commerce. As retaliation against the British, the French declared all British commerce to be unlawful. These circumstances meant that neither British nor European ships could carry on trade.

However, the two enemies' attacks on one another created a rather lucrative situation for American ships. As a result of the French and British policies, the United States could make profits by trading without any competition. Unfortunately, British shipowners were enraged and demanded that the British government put an end to trading with America. Old British laws were resurrected and enforced, and any American ships that violated these laws were to be seized by the British. Both the French and the British would seize any U.S. ship that was caught entering harbor.

Additionally, the British had a long history of using the system of impressment. Similar to what would be the U.S. draft, impressment to the British was the hijacking or conscription of men into military service in order to inflate the ranks of the sailors in the British Navy. British warships began to stop American merchant ships and remove any sailors who looked like Englishmen and were unable to prove their U.S. citizenship. The captured men were then forced to serve in the Napoleonic War. It is said that thousands of American seamen were captured this way and used as forced labor on British warships.

A monumental instance of impressment is known as the Chesapeake–Leopard Affair. (A similar incident, called the Chesapeake Affair, took place in 1863, during the American Civil War.) As time went on, tension between Britain and the United States grew. It was reported that some British deserters joined the ranks of the USS *Chesapeake*. Specifically, three men aboard the British HMS *Melampus* escaped and joined the American ship *Chesapeake*. The Secretary of the U.S. Navy conducted an investigation, and it was reported that the men in question were, in fact, American citizens. Despite this, the British ordered all captains and commanders of all British ships to search the USS *Chesapeake* for the deserters should any of them come in contact with the ship. On June 22, 1807, the *Chesapeake* and the HMS *Leopard* crossed paths, and the captain of the *Chesapeake* refused to allow British seamen to search his ship. The British forcefully boarded the U.S. ship, which resulted in the suspected deserters being removed, three U.S. seamen killed, eight seriously injured, and 10 more suffering severe injuries.

President Jefferson, enraged to hear about the instance, had to decide to declare war on both Great Britain and France. Instead, President Jefferson believed that if the United States refused to trade with France and Great Britain, both nations would be forced to treat American trade and commerce with respect. Thus, Congress passed the Embargo Act in order to ensure the neutrality of the United States in the wars in Europe. The Embargo Act forbade American merchant ships to leave American ports after a specified day and effectively closed all U.S. ports to exports from foreign vessels.

With the embargo in place, American imports and exports both declined significantly. Many parts of the country were hit hard, especially the South, where cotton growers lost the British market and merchants in New England. The law ultimately failed to achieve its objective, and it wound up doing more damage to American merchants than to European governments.

ENERGY POLICY

As an essential input into most economic activity and a long-term driver of economic growth, energy commodities are a focus of politicians and other policymakers. When striving to implement energy policy, these policymakers have different objectives, sometimes even conflicting. They also face incentives and institutional contexts that make achieving a coherent national energy policy difficult.

Energy policy is dominated primarily by concerns about production, distribution, and consumption. A country's energy policy typically focuses on the policy environment surrounding the availability and use of nonrenewable and renewable fuel sources, and the economic, social, and political consequences of that use. Such decisions are usually made through private market processes and transactions, so energy policy sits at the intersection of economics, politics, and science. That intersection can often be uncomfortable, because these perspectives can lead to different expectations, time frames, and objectives. Energy policy is further complicated by its intersection with other areas of policy, such as transportation policy, which can create layers of potentially mutually incompatible objectives.

An overarching goal of energy policy is to implement strategic planning regarding future energy use and availability, with a goal of meeting several subsidiary objectives simultaneously: supply security, environmental quality, and future planning for investment and infrastructure construction. These objectives are frequently in conflict with each other. One of the most substantive challenges in energy policy is bargaining among the various policymakers and other stakeholders (such as the firms whose existence or profitability would be affected by the policy specifics) who prioritize the energy policy objectives differently. Not only do interested parties have different priorities, but they also advocate different means of achieving their preferred objectives. In combination with the ability of specific policies to shift revenues and costs, the competing and sometimes incompatible objectives of energy policy mean that the policy process is usually contentious, and lobbying and rent-seeking are likely.

The instruments of energy policy are instruments of policy in other areas as well.·Legislation can enable regulation and its enforcement in an attempt to meet policy objectives (such as Corporate Average Fuel Economy standards for vehicles); it can authorize taxation or tax credits to change the incentives of energy producers and consumers at the margin; and it can enact taxpayer funding to subsidize particular activities that legislators see as compatible with meeting the policy objectives, including research. In international transboundary issues, treaties are often used, with varying degrees of success; well-known examples include the Montreal Protocol for the reduction of chlorofluorocarbons (a success) and the Kyoto Protocol for greenhouse gas reductions (not a success).

Market design can also be a policy instrument, again with varying degrees of success. The Acid Rain Program's success at reducing sulfur dioxide emissions, after the Clean Air Act Amendments of 1990 passed by the Congress, did not translate into a similarly successful market for greenhouse gas emission permits in the European Union's Emissions Trading Scheme.

Energy policy is not solely a 21st-century phenomenon. While energy use has always been associated with economic growth and increased living standards, the role of energy in economic activity changed meaningfully in the 19th century, with industrialization and the growing use of steam power. The English economist William Stanley Jevons wrote his seminal book *The Coal Question* in 1865, arising out of concern that England's accelerating industrial activity would be limited by its coal supply. In the burgeoning days of industrialization, the primary energy policy question was supply availability and supply–demand imbalance as a potential limiter of economic growth (a concern that persists to this day in industrialized and industrializing countries).

In the 20th century, this supply security question took on a geopolitical dimension, as fuel use shifted toward oil and strategic conflicts at the nation–state level led to such dramatic conflicts as the Organization of Petroleum Exporting Countries (OPEC) embargo of 1974, precipitated by the 1973 Yom Kippur War, and the supply restrictions arising from the Iran–Iraq War in 1979. Increasingly, nation–states with substantial oil reserves saw those reserves as a strategic asset in geopolitical interactions, and through organizations like OPEC they started to act strategically, although incentives to cheat and undermine cartel agreements to reduce output and maintain high prices continue to lead to cartel instability. These actions led to an increasing belief, particularly in oil-importing countries, in the need for national-level energy policy to ensure supply security and enable planning for future economic activity in which oil supplies did not create a material constraint.

While these supply security objectives persist in energy policy, environmental objectives now join them more so than in the 20th century. The environmental consequences of fossil fuel use—and ways to manage those consequences using the policy instruments of regulation, taxation, subsidies, or market design—now form a substantial share of the emphasis of energy policy. Thus energy policy in the early 21st century focuses on balancing the potentially conflicting objectives of maintaining supply security while ensuring that the current and future environmental consequences of fossil fuel use are manageable, both through mitigation and through adaptation to global warming. Increasingly, policymakers interested in achieving this balance emphasize promoting and accelerating innovation, whether in production, distribution, consumption efficiency, or environmental harm mitigation.

Energy policy involves producers and consumers and their economic interests, legislators and bureaucrats and their interests, environmental interests, and the scientific process, all interacting in a political environment. Not surprisingly, then, the political economy of energy policy is particularly complicated. The combination of self-interested policymakers and firms attempting to influence legislative and regulatory outcomes can lead to rent-seeking and regulatory capture. The combination of firms trying to raise their rivals' costs through regulation and environmental groups interested in using regulation to achieve their objectives can lead to a "bootleggers and Baptists" dynamic of coalition-formation that may bring regulations into existence that would not pass a benefit-cost analysis. And the presence of concentrated benefits to those interests in combination with diffuse costs of inefficient policies can lead to policies that favor politically powerful groups and do not necessarily achieve one of the general policy objectives outlined earlier. These aspects of the political economy of energy policy can yield persistent unintended consequences and failures to achieve policy objectives of supply security, environmental quality, infrastructure planning, or breakthrough research.

A national energy policy is often presented as a desirable goal, to reduce the extent to which individuals work at cross-purposes toward energy development and environmental objectives. In a complex and dynamic world of diverse individuals and constant technological change, though, achieving a stable, coherent national energy policy is unrealistic, and it may more often lead to unintended consequences. A better approach to national energy policy may be to focus on reducing transaction costs and reducing distorted investment and innovation incentives. General policies may perform better that align economic and environmental incentives in the face of unavoidable uncertainty about the scientific, economic, and political future.

ENGELS, FRIEDRICH

Born: November 28, 1820, in Barmen, Germany; Died: August 5, 1895, in London, England; Nationality: German; Professional Interests: socialism, Marxist; Major Work: *Manifesto of the Communist Party* (with Karl Marx) (1848).

Friedrich Engels was a 19th-century German philosopher and a founder of Marxist theory. Engels was the main partner of Karl Marx in bringing communism and socialism to the forefront of economic thought. The son of an industrialist, growing up in an upper-class lifestyle, young Engels befriended many of his father's workers and became familiar with their working and living conditions. Writing of these experiences led him to meet Karl Marx, his intellectual soulmate. Engels and Marx worked together to organize workers to join the Communist League in Belgium, Germany, and Prussia. In 1848, Engels and Marx published the *Communist Manifesto*. Engels would later become the main financial support of Marx's later works. Engels died in 1895.

Friedrich Engels was born on November 28, 1820, in Barmen, Germany, the son of a German industrialist who owned a number of textile companies. A rebellious young man, he was writing political tracts by the age of 18. As was required of all young German men, he served his mandatory military enrollment and completed it honorably. While serving in the military in Berlin, he became familiar with the works of Friedrich Hegel and embraced a leftist ideology. It was also here that his agnosticism would grow to militant atheism.

Young Engels persuaded his father to send him to a mill in Manchester, England, in which the elder Engels was a partner. Friedrich told his father that this would help further his knowledge of the family business. The elder Engels saw this as an opportunity to remove his son from exposure to the radical ideas afoot in Germany in 1842, so he gladly sent him. En route, Engels and Marx would meet briefly for the first time. Neither was impressed with the other.

While Friedrich participated in the upper-class lifestyle enjoyed by the Manchester industrialists (he was particularly fond of fox hunting), he pursued his studies of the working men and women who were his employees. He frequented their clubs and their workers' meetings, even developing an ongoing relationship with one of the women who worked in his mill. His tours of the working-class slums and his growing knowledge of their living and working conditions would result in his writing and publishing *The Condition of the Working Class in England* in 1844.

Early that same year, Engels began contributing to a radical journal edited by Karl Marx. Upon leaving the family business to return to Germany, Engels went to Paris to meet Marx and this time found his intellectual soulmate. They began working together, and in January 1845, when Marx was expelled from France for his radical writings and ties to a radical organization, later to become the Communist League, both would end up in Belgium. In Brussels, Marx and Engels worked together to organize workers in Germany, joining the Communist League. The workers' movement was already taking place in England and France, and both men felt it was time for German workers to join ranks. It was while in Belgium that Engels and Marx would work on and publish their most famous collaboration: the *Manifesto of the Communist Party.* However, in 1848 revolution struck France and soon spread across much of Europe. Marx and Engels were expelled from Belgium, again for their radical writings and work with the Communist League. They returned to Germany.

Once back in Prussia, Engels continued working to organize workers and writing with Marx. Marx would lose his Prussian citizenship and again be expelled, but Engels stayed on to take part in fighting against Prussian troops in an uprising against the government. When the Prussian army emerged as the winner, Engels barely managed to escape into Switzerland. From there, he rejoined Marx, this time in England.

While in England, Engels and Marx tried to resurrect the now-defunct Communist League, but their finances were stretched thin and Marx was beginning to work on *Das Kapital.* It is here that Engels would again play a crucial role in the development of economic theory—this time, not as a writer or thinker but as a supporter. Engels went back to work in the Manchester mills, providing funding for Marx and his family, while Marx worked on his major work. Engels also provided insights for Marx on economic and business matters, but his largest contribution was financial. However, despite Engels's support, the Marx family continued to live in relative poverty. In 1869, Engels sold his interest in his business and moved to London to be near Marx. He and Marx worked together for another 14 years, until Marx's death.

Engels continued to be a force in the workers' movement. For the first five years after Marx's death, Engels spent much of his time writing. He wrote *The Origin of the Family, Private Property and the State,* a work in which he claimed that monogamy was a recent invention that kept women in a state of near-slavery. He claimed that with the rise of communism, the institution of monogamy would fall in an era of sexual freedom, and that private property and the state would join monogamy as outmoded ideas. But he also spent much of his time editing the second volume of *Das Kapital.*

Upon completing that work, Engels visited the United States at about the same time that the American edition of *The Condition of the Working Class* was published. While visiting the United States, he did not address workers' groups or tend to organize; instead, he opted to travel quietly, making notes as he traveled from place to place. He likened his visit to New York City to visiting Dante's Inferno.

Engels returned to England and spent much of the rest of his life editing the final volume of *Das Kapital,* which he finished shortly before he died on August 5, 1895, in London.

ENTITLEMENTS

Entitlement is a term used to describe a group of government programs in which recipients satisfy a set of criteria to qualify to receive the benefits of the particular program. If one meets the eligibility requirements for one of these programs, one is "entitled" to receive the benefits the program provides. Examples of federal government programs that fit into this category of programs are Social Security, Medicare, Medicaid, the Supplemental Nutrition Assistance Program (SNAP), and the National School Lunch Program. State government programs include housing assistance, the federal–state partnership for unemployment insurance, and special college tuition programs. Local governments may offer some housing assistance if one qualifies, but generally local governments do not offer programs that can be considered entitlements.

As government programs, entitlements are usually funded through either tax revenues or, in the case of Social Security, a combination of individual and employer contributions. Entitlements are considered automatic government expenditures because receiving the benefits is based on qualifications, not selection. Because increases in benefits are automatic, entitlements are often labeled the “uncontrollable” part of government budgets. Entitlements at both the federal level and the state level are components of their general budgets. Especially at the federal level, entitlement programs have become a significant percentage of the general budget. The government funds certain programs through offering bonds.

The most notable entitlement programs are the federal programs Social Security, Medicare, and Medicaid. Recipients must meet the requirements for each. For Social Security and Medicare, age is the major criteria. To qualify for Social Security, one must be at least 62 years old to qualify for minimum benefits and must have paid into the Social Security System for a minimum of 40 “credits,” or 10 years. Social Security benefits also extend to the family survivors from a death in a family, or if one becomes disabled and cannot work. A second Social Security eligibility requirement is that of paying into the Social Security insurance program for a minimum of eight quarters through one’s employment. For Medicare, one becomes eligible on one’s 65th birthday. Medicaid eligibility is based on a minimum income level. While Social Security and Medicare participation is not limited by income level, Medicaid is a medical insurance program designed to aid low-income individuals and families.

Federal spending on the entitlement programs or Social Security, Medicare, and Medicaid makes up the largest part of the federal budget. These programs are also the fastest-growing. Since the 1990s, entitlement programs have been growing between 7 and 8 percent per year, with Medicare and Medicaid growing the fastest. The Congressional Budget Office projects that entitlement programs—especially Social Security, Medicare, and Medicaid—will continue growing as a percentage of the federal budget as more citizens qualify.

Social Security

Social Security was established in 1935 when the Social Security Act was passed by Congress and signed by President Franklin Roosevelt. When the act was passed, the intent was for Social Security to be a retirement supplement or social safety net for those whose retirement savings were not sufficient. Today, Social Security is not just for older U.S. citizens. In 1956, the law was amended to include benefits for people with disabilities. Social Security benefits also extend to workers who become disabled and the survivors of a family in which either a spouse or a parent has died.

Social Security was originally established to replace approximately 40 percent of one’s income at retirement. Of every Social Security tax dollar, 85 cents is paid to retirees or their dependents, and 15 cents goes to those receiving disability benefits and their families.

How Social Security Works

When an employer participates in the Social Security System, an employee pays taxes into the Social Security System. The money pays the benefits to those who are entitled to receive retirement, disability, or survivor’s benefits from the Social

Security System. All Social Security taxes paid are held in a single federal government trust fund, not in individual accounts. The taxes are used to pay those receiving benefits. As of 2013, Social Security taxes are paid on income up to $113,700.

Employees become eligible to receive Social Security benefits when they have earned a total of 40 “credits” ($1,160 per credit, maximum 4 credits per year). Those 40 credits equate to 10 years of employment and participation to qualify for the Social Security retirement entitlement. Fewer credits are needed to qualify for the disability and survivor benefits.

Medicare and Medicaid

The other two major entitlement programs, Medicare and Medicaid, were signed into law on July 30, 1965, by President Lyndon B. Johnson. Medicaid was originally part of the Social and Rehabilitation Services Administration. In 1977, Medicare and Medicaid were combined into one federal agency: Centers for Medicare and Medicaid Services (CMS). While there have been many changes to the original program since 1965, the most significant change occurred on December 8, 2003, with the signing of the Medicare Modernization Act (MMA) by President George W. Bush. The MMA added several changes, the most significant being the outpatient prescription drug benefit.

Medicare is a federal health insurance program for individuals 65 and older. Younger individuals may qualify due to disability or End-Stage Renal Disease (ESRD). Medicare has four parts: Part A covers hospital, skilled nursing, hospice, and some home health care costs; Part B covers medical costs, including doctor’s services, outpatient care, medical supplies, and some preventive services; Part C covers health maintenance organizations (HMOs), preferred provider organizations (PPOs), or private fee-for-service, special needs, or Medicare medical savings accounts; and Part D covers prescription drugs. Parts C and D are offered by private companies that have contracted with federal government for Medicare services.

Individuals, including the self-employed, pay Medicare taxes on all earned income. Those who work for someone else pay half (6.2 percent) and employers pay half (6.2 percent). Self-employed workers pay the entire 12.4 percent. Medicare taxes go into a trust fund to pay for hospital costs and other medical costs of Medicare recipients. Medicare and Medicaid are managed by the CMS.

States are required by federal law to provide Medicaid health coverage to qualifying individuals with disabilities, seniors, children, pregnant women, and parents who are entitled under income requirements. The entitlement is based on the federal mandate to cover certain population groups, with the states having the option to include other groups. States set the eligibility requirements based on federal minimum income standards. One income eligibility standard is based on a percentage of the federal poverty level (FPL). In 2013, the FPL for a family of four was $23,550; the level is changed annually. Many state minimum eligibility levels exceed the federal minimum. Other nonfinancial criteria, such as U.S. citizenship, immigration status, or residency, are used to determine Medicaid eligibility.

Beginning in 2014, the Affordable Care Act of 2010 expanded Medicaid eligibility. Signed by President Barack Obama on March 23, 2010, the minimum eligibility level nationally became 133 percent of the federal poverty level. In 2011, the poverty level for a family of four was $29,700. While the new guidelines went into effect January 1, 2014, states had the option to accept the federal guidelines earlier if they chose to do so.

EQUATION OF EXCHANGE (QUANTITY THEORY OF MONEY)

The Equation of Exchange is the basis for the demand of money. Developed by Nobel laureate Irving Fisher, the Equation of Exchange is used by monetarists to view the role of money in an economy. Monetarists espouse the view that the quantity of money in an economy directly influences output, gross domestic product (GDP), employment, and prices. Changes in an economy's money supply will influence other economic variables as well. By way of comparison, the Keynesians believed that changes in the money supply influence changes in interest rates directly and employment and output indirectly.

The Equation of Exchange is also known as the Quantity Theory of Money. There are many different views of the Equation of Exchange, but all involve several of the same variables: money supply (M), velocity of money (V), price level (P), and output (Q): $MV = PQ$.

Defining Variables

The *money supply* (M) is the amount of currency and funds immediately available for use in the economy. A checking (demand deposits) account is an example. The funds of a checking account are not currency, but they are funds available for immediate use to purchase goods and services.

The *velocity of money* (V) is the average times that one dollar will circulate throughout an economy in a given year. If $V = 5$, this represents a one-dollar bill circulating throughout the economy five times during a year, or $5 worth to the economy.

The *price level* (P) of an economy times the economy's output (PQ) equals nominal GDP; that is, $P \times Q$ = nominal GDP. This represents how much people spend on goods and services during a given time period. Therefore, for an economy to have enough money to buy the goods and services purchased, represented by (PQ), MV must equal PQ. Because this equality always exists, this is also known as an accounting identity: $MV \cong PQ$.

Output (Q) is the amount of goods and services produced in an economy during a specific period of time.

Classical View

The Classical view emphasizes the microeconomics of an economy and the interaction between buyers and sellers. This is in contrast to the Keynesian and Monetarist views. In the Classical view, the income velocity of money (V), price level (P), and output (Q) are constant and the money supply (M) is fixed. As a result, only a change in the money supply (M) will change price (P). While similar to the Monetarist view, the Classical view is a long-run view only, where all resources are variable and can change with the economy. A second distinction between the Classical and Monetarist views is that the Classical view is based on a currency with a fixed value, such as a currency's value pegged to a gold standard.

Keynesian View

In contrast, the Keynesian view takes a macroeconomics view. This different perspective leads to several distinctions between the Keynesian view and the Classical view, specifically. In a macroeconomic view of the economy as a whole, aggregate output (Q) takes on another meaning. Output under the Keynesian philosophy equates to production of the entire economy, which Keynes's expenditure approach measured as GDP. For Keynes and the macroeconomists, short-run output (Q) became GDP.

The second distinction Keynes asserted was that a macroeconomy in equilibrium needed an income level equal to its production level (its GDP). Keynes's income approach asserted that for an economy to be in equilibrium, aggregate income (Y) needs to equal total output—or, for Keynes, GDP.

Under Keynes, the money supply (M) is fixed. The relationship between price level (P) and real output (real GDP) determines the aggregate demand curve. Keynes's focus was on stimulating the economy through increased aggregate demand, and interest rates are a significant tool for doing so. Changes between price level and real GDP create simultaneous changes in interest rates (R). The velocity of money (V) is a function of interest rates. Real GDP (Q) is changed by holding money supply (M) and income price level (Q) constant, since $V(R)$ is a function of R (interest rates): $M = PQ / V(R)$.

Monetarist View

Like the Keynesian view, the Monetarist view is a macroeconomic perspective of the economy. Again, output (Q) is also a measure of the aggregate output as measured by GDP. Monetarists also accepted an equivalency between macroeconomic output (as measured by GDP) and aggregate income (Y).

In the short run, when the money supply (M) changes it causes real GDP (Q) to change, since price level (P) does not change.

In the long run, when money supply (M) changes it causes only the price level (P) to change, since the relationship between real GDP and income (Y) is determined by other real factors of production.

Income velocity of money (V) is a function of interest rates and asset returns.

Quantity Theory of Money

With the addition of two assumptions using this same equation identity ($MV = PQ$), the Quantity Theory of Money model was developed. The Quantity Theory of Money helps explain the relationship between the price level in the economy (P) and the money supply (M). The first assumption is that over time velocity of money (V) is stable so can be assumed to be constant. The second assumption is that output (Q) is also constant over time. The Classical model also assumed that wages and prices were flexible, so that employment was always at full employment for the output of the economy at the time.

As a result, the Quantity Theory of Money appears as $MV = PQ$ with V and Q constant; money supply (M) is directly proportional to price level (P). Therefore, as the money supply (M) changes, so will the economy's price level—resulting in inflation, disinflation, deflation, or even hyperinflation if the relationship is too severe.

EXCESS RESERVES

Excess reserves are the extra money that banks hold beyond the required reserves that the Federal Reserve mandates. When a deposit is made at a bank, the bank must keep a percentage of the deposit as a required reserve, mandated by the Federal Reserve, to ensure the safety of the banking system. With a fractional reserve banking system, the bank has several options: to loan the remainder of the deposit to the public, to purchase bonds, or to keep the excess as cash reserves. Any amount of the deposit that is not kept as a required reserve and loaned to the public or used to purchase bonds is kept as cash and is classified as excess reserves.

There are many reasons why a particular bank or the banking system may have excess reserves. Perhaps the most significant reason is perceived economic instability. A financial institution would fight this negative perception by holding excess reserves to meet the withdrawal demands of its depositors. This would protect the financial institution from a rash of defaulted loans, and would provide financial security. An example of this type of economic instability is depicted in the bank run scene in the classic 1946 movie *It's a Wonderful Life*.

A second reason to keep excess reserves is if the bank is having difficulty finding qualified borrowers to lend their excess reserves.

Interest rates can also have an impact on excess reserves. While extremely low interest rates encourage borrowing, they also discourage lending—and some banks will evaluate their lending practices using cost–benefit analysis. While very low interest rates can be an incentive for borrowers, some banks may view the opportunity cost of lending at low interest rates very high and they choose not to make loans in those circumstances. Some banks choose instead to hold excess reserves until interest rates rise. This would increase their benefit of future loans.

In a fractional reserve banking system, a money multiplier effect is realized when banks loan out available excess reserves. The *money multiplier* is calculated as 1 divided by the reserve requirement (1/rr). For instance, if the reserve requirement is 10 percent, the traditional money multiplier would be 10; thus, (1/.10 = 10). If $1,000 of excess reserves are loaned out, $10,000 of money would be created in the economy ($1,000 × 10 = $10,000).

The multiplier effect can also be used to contract the money supply by increasing the reserve requirement. An increase in the reserve requirement from 10 percent to 20 percent would force financial institutions to hold more in required reserves, and consequently to have less excess reserves to loan.

During times of economic contraction or expansion, the Federal Reserve can increase or decrease excess reserves and the money supply by changing the reserve requirement. If banks choose to hold excess reserves, economic growth will be slower compared with a situation in which banks loan out all available excess reserves.

Consequently, one major concern with respect to economic activity is how to encourage banks to lend out more excess reserves during periods of economic contraction and instability, when it may be in their best interests to keep additional excess reserves. Some economists have suggested that banks could either be fined or pay a tax on excess reserves as a means of providing an incentive for banks to loan out their excess reserves. Many other economists support the belief that the market for loanable funds will cure the problem of banks holding excessive reserves, if interest rates are allowed to adjust to market conditions rather than being held down by the Federal Reserve.

The Federal Reserve can also increase excess reserves through the use of open market operations. The central bank purchases bonds from banks, increasing the money supply with the intent of increasing economic activity. Through the fractional banking system, excess reserves are created that can be loaned to the public. If banks choose to keep excess reserves as cash for financial security rather than loaning them out, the money supply and economic activity will not increase as much as the Federal Reserve had intended.

EXPANSIONARY FISCAL POLICY

Expansionary fiscal policy occurs when the government attempts to stimulate the economy by decreasing taxes, increasing government spending, and increasing transfer payments. This policy is used when unemployment is high, when consumer spending is low, or when the economy is in a recession.

There are two conflicting viewpoints on handling the economy when inflation is high. Classical economists believe that the government should not get involved in the economy—that the market will balance out naturally. However, current fiscal policy is based on a theory developed by the British economist John Maynard Keynes: Keynesian economists believe that the government should step in and make policy changes when the economy is not growing—or worse, is in decline—and unemployment is high. This approach calls for the government to lower taxes along with increasing government spending to "prime the pump" of the economy. Expansionary fiscal policy is aimed at stimulating the economy and increasing employment. The most important element of fiscal policy is to maintain and balance the federal budget by examining tax revenues compared to government expenditures. Expansionary fiscal policy is used when the government seeks to increase the budget deficit or when it must decrease the budget surplus.

When enacting an expansionary fiscal policy, economists say that it shifts the aggregate demand curve to the right, which encourages economic output. *Aggregate demand* is the level of demand for goods and services by consumers, businesses, and the government. When an expansionary fiscal policy goes into effect, it works to increase aggregate demand for goods and services. The government uses three main tools to enact an expansionary fiscal policy: decreasing taxes, increasing government spending, and raising transfer payments.

When *decreasing taxes* is an expansionary fiscal policy tool, the government typically focuses only on an individual's personal income tax rates, though it can also include property tax and sales tax. A decrease in taxes can be in the form of either a one-time stimulus payment or an overall decrease in income tax rates. Either way, when taxation decreases, an individual's amount of disposable income is increased. Thus, with an increase in disposable income comes more spending power, which in turn causes increased production of consumer goods. When more production is necessary, businesses hire employees to meet the growing consumer demand. Overall, this causes the economy to grow. The increase in disposable income indirectly causes an increase in aggregate demand when consumers make more purchases of goods and services.

Increasing government spending means raising available funds across several different government agencies, and it can include giving more money for military expenditures, teachers' salaries, and road construction, for example. When these government agencies have increased available funds, they are able to make more purchases; this then increases an agency's income and raises its overall production. Aggregate demand is increased directly when the government spends more money because of increased output.

Raising the amount of transfer payments is also a useful tool of expansionary fiscal policy. Transfer payments are payments made by the government directly to individuals.

Aggregate demand (AD) increases (from AD1 to AD2) when government spending increases (from *x* to *x**)

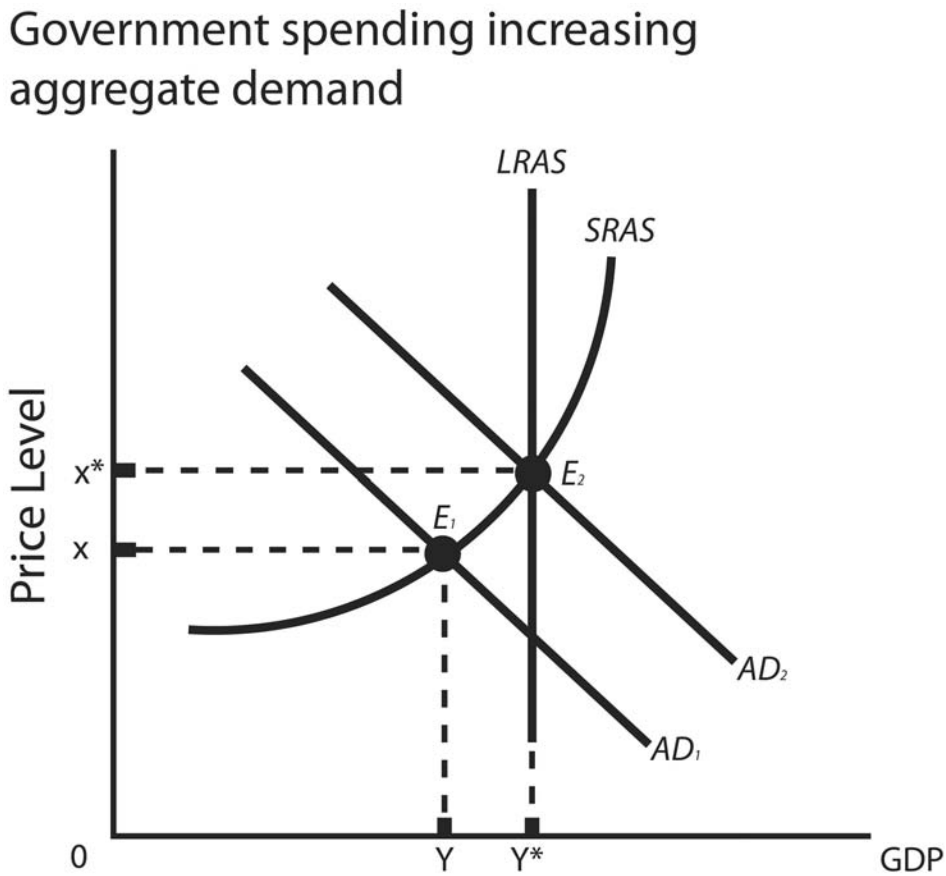

Figure 1. Aggregate demand increases (AD1 to AD2) when government spending increases (x to x*)

Those who receive transfer payments fall into three categories and include the elderly and disabled who are on Social Security, people who are unemployed and receive unemployment benefits, and the poor who are on welfare. Transfer payments can be raised either by increasing the amount of payment that one or two of the categories receive or by applying a blanket percentage increase across the three categories. Increasing transfer payments raises the disposable income of those who receive these benefits. More disposable income, such as when taxes are decreased, leads to an increase in production when people are able to purchase more goods and services. Once again, an increase in production means that more people can be hired to meet increased consumer demands. This also is an increase in aggregate demand indirectly.

One issue with using expansionary fiscal policy is known as the "crowding-out effect." Whenever the government spends its own money to stimulate the economy and borrows money to pay for the stimulus, interest rates go up because of greater demand in the money market. When interest rates go up, people do not invest as much, which means that economic growth slows down. While the crowding-out effect is more evident when the private sector's demand for money is high, it also poses a risk when expansionary fiscal policy tools are used.

EXPANSIONARY MONETARY POLICY

Expansionary monetary policy is a policy in which the central bank of a country decides that it is necessary to increase the monetary supply to prevent recession, decrease unemployment, or increase economic growth. Monetary policy works together with fiscal policy, which is controlled by the government, to ensure economic growth in the economy. The most frequent tool used by a central bank to implement expansionary monetary policy is the buying and selling of government bills, notes, and bonds.

In the United States, expansionary monetary policy is under the direction of the chair of the Federal Reserve. The Board of Governors of the Federal Reserve System decides when expansionary monetary policy is necessary. The Federal Reserve accomplishes expansionary monetary policy using three primary tools: lowering the reserve requirement; lowering the discount rate; or buying government bills, notes, and bonds. This last tool is implemented through the Federal Open Market Committee (FOMC). The FOMC implements expansionary monetary policy by lowering interest rates.

In order to implement the monetary policy decisions of the Federal Reserve Board of Governors, the FOMC carries out open-market operations. To apply expansionary monetary policy, the Federal Reserve buys government bonds. The increase in demand increases the price and decreases the interest rate. The lower interest rate creates incentives for financial institutions to increase loans, which promotes economic growth and reduces unemployment.

The Federal Reserve pays for government bonds by giving a credit to the purchasers in the form of deposits at regional Federal Reserve banks. Commercial banks then use the deposits to make more loans and accept more deposits. If many banks are offering loans, the interest rates on these loans are lowered in order to maintain competition between banks. In this way, the Federal Reserve purchasing government bonds lowers interest rates, which in turn increases monetary supply.

When decreasing the discount rate to accomplish expansionary monetary policy, the Federal Reserve is decreasing the interest rate it charges banks to borrow money directly from the central bank—or, more specifically, one of the 12 regional district banks. This encourages banks to borrow more reserves, increasing the money supply. The increased money supply allows banks to lend more to businesses and households. In summary, decreasing the discount rate increases the money supply, which encourages lower nominal interest rates and brings about increases in business and household borrowing.

Reducing the reserve requirement decreases the amount a bank must have in its end-of-day reserves to satisfy the Federal Reserve's reserve requirement regulations. Reserves include vault cash as well as Federal Reserve deposits. When banks have their reserve requirement decreased, the supply of loanable funds is increased, which lowers nominal interest rate. The lower rate creates the incentive for banks to supply more loans to businesses and households.

A risk in utilizing an expansionary monetary policy is overstimulation of the economy, which leads to inflation. When inflation is high, the purchasing power of money is decreased.

Using open market operations to buy government bonds, decreasing the discount rate, and lowering the reserve requirement are actions that the Federal Reserve can take to increase the money supply and fulfill expansionary monetary policy. Each is key in expansionary monetary policy to prevent a recession and increase economic growth.

EXPECTATIONS (RATIONAL AND ADAPTIVE)

Expectations about the future have an influence on practically all economic decisions. Investors, consumers, and firms all form expectations about such variables as income, interest rates and inflation for the purpose of making advantageous choices among available alternatives. Firms, for example, consider which additions to the capital stock and which hiring decisions will be profitable. The outcome in this case depends on the return that the additional resources will generate in the future. All such economic decisions with consequences in the future—according to the dominant theory of expectations—are formed rationally. Although it took more than a decade for the concept of rational expectations to take hold in economics, this notion has now become so ingrained in economists' thinking that many find it difficult to even conceive of an alternative. This difficulty stems from the fact that the notion of rational expectations is simply an extension of maximizing behavior to the formation of expectations. Those who believe that as economic decision-makers we always make the very best of our possibilities find it logical that we also form expectations in an optimizing way.

With respect to expectations or predictions, when we're looking into the future, *optimal* means not only that we use all available information but also that we use this information correctly. Accordingly, believers in rational expectations assume that economic agents understand exactly how past events and current decisions determine future outcomes.

One would expect that such an unrealistic view of human behavior would quickly be disproved by reality. For sure, contradictions between the theory of rational expectations and reality were documented in a large number of empirical studies. However, many studies assuming rational expectations were able to empirically predict stable relationships among observed variables. This begs the question why reality does not show more resistance to such a quixotic assumption. First, it is important to note that prediction is not the same thing as causation. That rational expectations are often consistent with the data does not imply that this theory actually explains the data.

By way of an answer, the following thought experiment should be helpful: Imagine a Martian civilization that wants to understand life on Earth. The technological possibilities and perhaps the physical form of these Martians permit them only to perceive and measure rectangular objects. In their endeavor to study life on Earth, these aliens make quick progress. In meetings at their academies, they listen to presentations about the spatial distribution of a long-living and stationary species (buildings). They have award-winning scientific publications dealing with the issues of whether reproduction of this observed earthly species is sexual or nonsexual and whether the small and quickly moving objects (cars) are excrements, food, or even parasites. According to several criteria, these alien investigations should be considered serious science. Their insights are verifiable and may be used for making predictions. Still, this unworldly science misconceives reality in fundamental ways. It misjudges the organic and inorganic basics of biology on Earth as well as life's potential and limitations. Moreover—thus returning to economics—such fundamental mistakes in understanding lead to misjudgments concerning the possibilities and dangers of interventions into the system thus studied. How can such misjudgments be avoided in economics when investigating expectations?

An answer starts with the detailed empirical study of expectations and decision-making (Simon 1959; Katona 1968). Research relying on survey data of expectations elicited from consumers and firms and laboratory studies has documented that human expectation formation is susceptible to systematical flaws. Inflation expectations, for example, have been documented to underestimate (or overestimate) actual inflation for extended periods of time. Laboratory experiments indicate that people fail to use all of the relevant information. Instead, subjects show a strong tendency to use simple forecasting heuristics. Simple rules of thumb like adaptive (error-learning) expectations or extrapolative expectations (which state that expectations are a weighted mean of past observations) had been considered even before the advent of rational expectations. While these earlier models of forecast heuristics have been largely pushed aside by rational expectations, recent developments like the notion of pattern-based extrapolation have proved to be valuable alternatives and have led to renewed interest in the hypothesis of extrapolative expectations (Rötheli 2011).

EXTERNALITY

When the market works, the incentives of market participants—that is, consumers and producers—align with those of society as a whole. In this case, a socially optimal allocation of resources is achieved. An *externality* occurs when there is a misalignment of these incentives, or in other words when the incentives that drive the choices of consumers and producers are different from those that affect other members of society. In this case, a third party who is external to the market transaction bears a cost (in the case of a negative externality) or receives a benefit (in the case of a positive externality) from the interaction between the consumer and the producer. Because the market participants fail to account for this external cost or benefit when making their choices, they choose to consume and produce at levels that are not optimal from society's perspective. Thus, an externality represents a market failure. In the case of a negative externality, the market outcome (i.e., the outcome that results from the choices of consumers and producers) results in too much of a good being consumed (and produced). With a positive externality, the market outcome leads to too little of a good being consumed (and produced). Externalities can result from consumption or production activities. A consumption externality occurs when there is a misalignment of incentives on the consumption or demand side of the market, whereas a production externality arises from misalignment on the production or supply side.

Pollution is a classic example of a negative externality. Firms that generate pollution do not set out to do so; rather, pollution is a by-product that results when firms produce other goods and services. How do firms decide how much of a good to produce and therefore, indirectly, how much pollution to generate? When firms seek to maximize profit, they produce at the point where the extra cost of producing one additional unit of a good (the marginal cost) is equal to the additional revenue the firm receives from selling that unit (the marginal revenue). The marginal cost reflects the cost of the materials, labor, etc. that the firm incurs to produce that additional unit of the good. However, from society's perspective, these are not the only costs of producing an additional unit of a pollution-generating good. Air pollution, for example, can lead to adverse health outcomes and poor visibility, among other effects. Water pollution can result in reduced recreational opportunities, negative impacts on aquatic life, and adverse health outcomes. The firm fails to account for these additional external costs when making its production decision to maximize profit and, as a result, chooses to produce too much of the pollution-generating good relative to what would be optimal from society's perspective. The socially optimal outcome involves the firm fully internalizing, or taking into account, these external costs when deciding how much of a pollution-generating good to produce.

How does this story change if firms have objectives other than maximizing profit? Many firms now devote significant resources to reducing the environmental impact of their production activities. The motivation for firms to pursue these activities varies; some firms may do so in response to regulatory pressure, others to consumer demands, or even to the preferences of the firm's owners. While these actions may reduce the magnitude of the negative externality associated with pollution, they are unlikely to completely eliminate the externality. Unless these activities result in the firm fully internalizing the external costs associated with pollution, then the externality will remain.

A flu shot is a useful example of a positive externality, albeit one outside the realm of environmental economics. Have you ever considered getting a flu shot? If so, then you likely weighed the costs and benefits of doing so in making your decision (even if you were unaware you were making this comparison). On the cost side, you may have considered the monetary costs of the flu shot (e.g., your insurance co-payment or the out-of-pocket cost of the shot), the pain you might feel from the injection, the chance of side effects, and perhaps the forgone time (the time you could spend doing something other than getting a flu shot). The most obvious benefit to you of getting a flu shot is your reduced chances of contracting the flu. In making your decision, you may have even recognized and factored into your decision the reduced chances your roommates or family members would face as a result of you getting a flu shot. If you viewed your personal benefits as exceeding your personal costs, then you got a flu shot.

Otherwise, you did not. From society's perspective, the optimal outcome involves flu shots for those individuals for whom the social benefits exceed the social costs. The social benefits of your getting a flu shot include your personal benefits as well as the benefits to all other individuals who face a reduced chance of contracting the flu because you received a shot. Thus, the social benefits of getting a flu shot are likely to exceed the personal benefits. In this case, the market outcome—that is, the outcome that results when people make decisions based on their personal costs and benefits—results in too few people getting flu shots. Like the pollution example discussed earlier, the socially optimal level of flu shots involves people fully internalizing the external benefits of the activity.

Whether positive or negative, stemming from production or consumption activities, an externality results in an inefficient allocation of resources. The inefficiency is corrected and the socially optimal allocation of resources achieved only when market participants fully internalize the external costs or benefits of their actions. Environmental economists recognize two fixes for externalities. The first applies under specific conditions and relies on coordination among market participants and those impacted by the externality. The second involves regulation—specifically, the use of taxes, subsidies, or other instruments—to force internalization of the external costs and benefits. In general, these fixes work by realigning private and social incentives and therefore eliminating the market failure associated with the externality.

FEDERAL DEPOSIT INSURANCE CORPORATION

The Federal Deposit Insurance Corporation (FDIC) is a federal agency created in 1933 under the direction of President Franklin D. Roosevelt. The FDIC was created to insure customer deposits in the event of a bank failure. At first, FDIC insurance covered losses up to $2,500. The amount has grown over time, and is currently at $250,000 per depositor, per insured bank.

During the 1920s, U.S. banks loaned large sums of money to many high-risk businesses. Many of these businesses proved unable to pay back their loans. The October 1929 stock market crash caused many panicked investors to sell their stocks, resulting in the collapse of the stock market. Banks had invested heavily in the stock market, and they lost huge sums. Farmers were also unable to pay back loans due to crop failures and hard times on the nation's farms. Fearful that banks would run out of cash, people rushed to their banks demanding their money. To pay back these deposits, banks had to recall loans from borrowers, but they could not do so fast enough to pay all the depositors.

The combination of the stock market crash, unpaid loans, and bank runs resulted in the failure of thousands of banks across the country. By the early 1930s, the Great Depression had hit the United States. Many people lost their life savings due to bank failures and closings, and the American people lost their faith in the banking industry.

When Franklin D. Roosevelt took office in 1933, he needed to encourage citizens to deposit their money in banks once again and restore confidence in the nation's banking system. On March 5, 1933, Roosevelt declared a national "bank holiday" and closed the nation's banks. The bank holiday was not a time of festivities or celebration, but a desperate last-resort move to restore trust in the nation's financial system. The "holiday" was a time for the banks to replenish their reserves and reestablish a healthy money system. Within a matter of days, sound banks began to reopen. As a result of the many bank failures of the Great Depression, banks were closely regulated from 1933 through the 1960s.

Later in 1933, Congress passed the Banking Act, which established the Federal Deposit Insurance Corporation. Roosevelt was hopeful that with this act citizens would trust the banking industry again and be willing to deposit their money in the nation's banks. The act guaranteed that even if a bank failed, deposits would be guaranteed by the federal government.

Meanwhile, banks became extremely cautious. They made fewer loans and kept enough cash on hand in case depositors all came at once to withdraw their funds. Banks began to hold substantial reserves, far in excess of those required by the Federal Reserve.

The FDIC is an independent agency of the federal government. It employs more than 7,000 people. It is headquartered in Washington, D.C., but it conducts most of its business in six regional offices and field offices throughout the nation. The FDIC is managed by a five-person board of directors, all of whom are appointed by the president and confirmed by the Senate. No more than three can be from the same political party as the president.

In addition to insuring deposits, the agency identifies, monitors, and addresses risks with deposits in participating banks. It directly examines and supervises more than 4,500 banks and savings banks for operational safety and soundness. It also monitors banks to make sure they are in compliance with any consumer protection laws that have been created by the federal government.

To protect insured depositors, the FDIC responds immediately when a bank fails. Failed institutions are generally closed and the FDIC helps to resolve the failure, usually through the sale of deposits and loans to other thriving banking institutions. Customers of the failed institution automatically become customers of the bank that acquired the deposits and/or loans. Most of these transitions are seamless from the customer's point of view. Since the start of the FDIC insurance on January 1, 1934, no depositor has lost a single cent of insured funds as a result of a bank failure.

FEDERAL OPEN MARKET COMMITTEE

Following World War I (1914–1918), there was a significant economic contraction in the United States, and a result of this contraction was a significant decrease in reserves in the banking system. To remedy this situation, during the first half of 1922 the Federal Reserve began to purchase government securities from commercial entities to improve the reserves of commercial banks. The Federal Reserve observed that as it purchased bonds, interest rates in the credit market and on loans decreased, which resulted in an increase in economic activity.

The Banking Acts of 1933 and 1935 created the Federal Open Market Committee (FOMC), and active monetary policy as a means to control economic activity was born. The Federal Reserve has a long history of using open market operations to fulfill its dual mandate of controlling inflation and maintaining high levels of employment. However, the power of open market operations by the Federal Reserve was an accidental discovery.

Open market operations is the buying and selling of government securities or bonds by the Federal Reserve, and it is the primary monetary policy tool used to control bank reserves, the money supply, and ultimately interest rates. The Federal Reserve specifically targets the *federal funds rate*, which is the interest rate that banks charge each other to borrow money on a short-term or overnight basis. The Federal Open Market Committee (FOMC) of the Federal Reserve determines the target for the federal funds rate, and the Federal Reserve Bank of New York conducts open market operations (the buying and selling of government securities) to satisfy the federal funds rate target established by the FOMC.

Typically, open market operations are conducted on a daily basis to maintain the federal funds rate target. The federal funds rate can be viewed as the first domino of interest rates, as most other interest rates follow the federal funds rate. The ability to control interest rates provides the Federal Reserve with the power to achieve its dual mandate of stable prices and maximum employment. Low interest rates encourage borrowing and spending while they discourage saving, which increases economic activity and employment in the short run. High interest rates discourage borrowing and spending while they encourage saving, which decreases economic activity and inflation in the short run.

During a business cycle contraction, the FOMC will typically lower the federal funds rate target, requiring the Federal Reserve Bank of New York to purchase of government securities. These purchases directly increase bank reserves, reducing the federal funds rate, and stimulate economic activity. The securities that banks hold represent previous deposits that cannot be loaned to the public because the value of those excessive reserves or deposits is held in the form of bonds. As the Federal Reserve purchases these securities from banks or individuals, the Fed deposits the sale price of the securities into the accounts of the banks or individuals, and the excess reserves that banks hold will increase. As a bank's excess reserves increase, the interest rate incentive encourages banks to loan out their newly acquired excess reserves, which stimulates the money multiplier effect of the fractional reserve banking system—and ultimately it stimulates economic activity. The goal of this expansionary monetary policy is to increase employment.

When the Federal Reserve owns government securities, the interest earned from these securities is ultimately transferred to the U.S. Treasury.

During a business cycle expansion, when inflation increases beyond the desired amount, the FOMC will typically increase the federal funds rate target and will require the Federal Reserve Bank of New York to sell government securities. The sale of these securities directly decreases bank reserves, increasing the federal funds rate, slowing economic activity, and ultimately slowing the rate of inflation. The excess reserves that banks hold come from the deposits made by individuals, and these reserves are used to purchase the securities from the Federal Reserve. A bank's purchase of securities from the Federal Reserve directly reduces the amount of loans that can be made in the banking system, decreasing the money multiplier effect of the fractional reserve banking system and ultimately slowing economic activity to control inflation. The goal of this restrictive monetary policy is to reduce the rate of inflation.

During times of high levels of unemployment and high inflation (stagflation), the Federal Reserve is limited in its ability to fulfill the dual mandate of stable prices and high employment. In times of stagflation, the Federal Reserve must choose to either control inflation or control unemployment.

The ability of the Federal Reserve to control economic activity through open market operations is directly linked to the banking system's treatment of excess reserves and the public's desire to hold cash. If banks do not loan out excess reserves or if the public holds cash rather than depositing their excess cash into banks, the impact of open market operations on economic activity will be limited.

FEDERAL RESERVE ACT OF 1913

Popular call for a central U.S. bank began after Americans experienced the severe inflation of Continental currency during the American Revolution. It was not until 1791 that Treasury Secretary Alexander Hamilton helped Congress establish the First Bank of the United States in Philadelphia. The 20-year charter was not renewed when it expired, as some Americans were uncomfortable with the idea of a large, powerful bank. Public opinion later shifted, and in 1816 Congress created the Second Bank of the United States. Congress did not renew this charter when it expired in 1836, however, as Andrew Jackson (elected president in 1828) led the fight against central bank power.

The United States suffered a severe depression in 1893, and again in 1907, after severe banking panics and bank runs arose from a liquidity crisis. New York financier J. P. Morgan stepped in both times, using his vast resources and wealth to stabilize the American economy. Many Americans realized the need for reform of the banking system.

However, debate between the conservative "money trust" financiers of New York City and the "progressives" continued over the necessity of a nation's central bank. The progressive solution, endorsed by William Jennings Bryan, suggested public control of a central bank, while conservatives like Senator Nelson Aldrich of Rhode Island advocated a banker-controlled plan.

In May 1908, Congress passed the Aldrich-Vreeland Act, establishing the bipartisan National Monetary Commission to study central banking and monetary reform. In November 1910, Aldrich and others—including Paul Warburg, Frank Vanderlip, Harry P. Davison, Benjamin Strong, and A. Piat Andrew—traveled to Jekyll Island off the coast of Georgia to create a U.S. banking and currency reform plan known as the Aldrich plan.

The American public elected Democrat Woodrow Wilson president in 1912 before the Aldrich Plan could be enacted into law. Yet it became the foundation for the Federal Reserve Bill, along with another bill that Senator Robert Latham Owen proposed: the Glass-Owen Bill. H. Parker Wills, an economics professor from Washington and Lee University, and Carter Glass, Virginia Democrat in the House of Representatives, worked to create this version of a central banking plan. Glass was later to chair the House Committee on Banking and Finance.

After much deliberation and revision, the 30-section Federal Reserve Act passed the House with 298 yeas to 60 nays, and it passed the Senate with 43 yeas to 25 nays. The Democrats supported the act, while the banker Republicans opposed it. Bankers were concerned because only one of seven members of the board could represent the banking community. On December 23, 1913, President Woodrow Wilson signed the Federal Reserve Act into law.

The Federal Reserve Act called for a central bank that could make decisions it felt were in the best interests of the country, without political or private pressure—a compromise of public and private interests. A second compromise was for there to be at least 8 but no more than 12 private regional Federal Reserve banks, each with its own branches, board of directors, and district boundaries.

The Federal Reserve System required a seven-member Board of Governors consisting of officials appointed by the president and confirmed by the Senate. They would serve 10-year staggered terms to govern the central bank. Two board members would be the Secretary of the Treasury and the Comptroller of the Currency. This was changed in 1922 to become eight members, before a final settlement of seven was again restated in the Banking Act of 1935. The permanent member requirement was later also eliminated, and terms were extended to 14 years.

The act encouraged diversity, as the president was to seek a fair representation of the different commercial, industrial, and geographic divisions of the country when selecting the five remaining board members, none of whom should be selected from any one Federal Reserve district. In addition, two of the members had to have banking or finance experience (although this experience requirement was later dropped).

The president would select the governor and vice-governor of the board—later called the chair and vice-chair of the board—each serving four-year terms. The Federal Reserve Act of 1913 determined that bank assessments would pay the salaries of the board members and that the board would be required to submit an annual report to Congress. In addition, the act specified a 12-member Federal Advisory Committee and a single U.S. currency of the Federal Reserve Note (the U.S. bank notes or bills used today).

Membership was mandatory for all national or federally chartered banks and was optional for state-chartered banks. All nationally chartered banks were required to purchase nontransferable stock in their regional Federal Reserve banks and to keep a specific amount of reserves with their respective banks. Member banks would now be subject to supervision, limited to earning no more than a 6 percent dividend on their stock, and authorized to offer discounted loans.

The act was also later changed to create the Federal Open Market Committee (FOMC), consisting of the seven board members and five representatives from the Federal Reserve Banks, one of which is always from the New York Federal Reserve. They direct all open-market operations of the Federal Reserve banks.

In the 1970s, the act was amended again to promote the goals of maximum employment, stable prices, and moderate long-term interest rates. The chair was now required to report at semiannual hearings to inform Congress of policy objectives and plans concerning monetary policy, economic development, and future prospects.

Today, the Federal Reserve continues to conduct the nation's monetary policy; supervise and regulate member banks; maintain the stability of the financial system and contain systemic risk that may arise in financial markets; and provide financial services to depository institutions, the U.S. government, and foreign official institutions.

FEDERAL RESERVE AND TREASURY, RELATIONSHIP BETWEEN THE

The U.S. government has a vested interest in the welfare of its economy. The Department of the Treasury and the Federal Reserve work together to maintain U.S. economic stability. To understand the relationship between the Federal Reserve and the U.S. Department of the Treasury, one must first understand the dynamics of each body.

The U.S. Department of the Treasury was established in 1789. The mission of the U.S. Treasury is to create and maintain a strong economy, combating threats and protecting the integrity of the U.S. financial system. Among its many obligations, the department is responsible for advising the president on economic and financial issues and fostering improved management of financial institutions. The department also operates the financial systems that are responsible for the production of coin and currency and for payments made to the U.S. public, as well as for collection of the taxes and revenues needed to operate the federal government. Basic Treasury functions also include managing federal finances, supervising national banks, and enforcing federal finance and tax laws.

Created by the Federal Reserve Act, the Federal Reserve System was established in 1913. The system is commonly referred to as "the Fed," and it has a mixture of public and private elements. The system is overseen by a Board of Governors located in Washington, D.C. The Federal Reserve System comprises a network of 12 regional banks with 25 branches under the oversight of the board. The 12 regional reserve banks are the operating arms associated with the Fed System.

There are more than 8,000 commercial banks in the United States, and about one-third of them are members of the Federal Reserve System. Member commercial banks are investors of the regional reserve banks, and they must hold 3 percent of their capital as stock in their reserve branch.

The Federal Open Market Committee is responsible for managing the nation's money supply. The FOMC is the monetary policymaking body responsible for the creation of policies designed to promote economic growth and stable prices. In short, the Federal Reserve ensures that lenders and borrowers have access to money and credit.

With the common goal of obtaining and maintaining a stable economy, the Fed and the Treasury have plenty of opportunity to work cohesively. When the government needs cash, the Fed and the Treasury work together to borrow money. Working on behalf of the Department of the Treasury, the Fed issues U.S. Treasury securities and conducts Treasury securities auctions. The congressional act governing the Fed specified that securities transactions must take place in the open market. Thus, instead of securities being bought or sold directly with the Treasury, transactions take place between the Fed and a group of primary dealers. Transactions undertaken in an open market, rather than directly with the Treasury, ensure the independence of the central bank when it conducts monetary policy. The prices of new securities are set by the demand and supply conditions of the private market.

Not only does the relationship include organized policymaking, but also it generates a portion of the revenue needed to run the country. The Federal Reserve is a nonprofit organization; once its operating expenses are paid, the remaining profits are paid to the Department of the Treasury. The Treasury uses the funds for spending by the federal government.

Recessions are a natural part of the cyclical economy. When a recession occurs, the Fed and the Treasury work together to formulate and implement economic policies to stimulate the economy. During recession, the optimal response is to reduce interest rates and make money available to banks and consumers. When the government issues rebate checks, the Treasury is responsible for debiting the money from the Federal Reserve System.

When government-sponsored entities and private companies get into trouble, the Fed can discount borrowing rates and provide funds to the companies; in addition, the companies' lines of credit can be increased and the Department of the Treasury can purchase their stocks. Recent bailouts include the financial system during the recession that began in 2008. With the near collapse of Bear Sterns, the Fed and the Treasury worked together to provide J.P. Morgan Chase funds to purchase Bear Stearns. Taxpayer assistance was also given to Chrysler and General Motors during the same time period.

FEDERAL RESERVE SYSTEM

Financial panics were frequent occurrences during the 19th and early 20th centuries. These panics led to banking failures and businesses frequently going out of business. The monetary system of the day was highly disruptive to the economy. Banks were often unstable and not able to consistently provide the intermediation services and liquidity necessary for an economy to grow. The financial crisis of 1907 caused Congress to pass the Federal Reserve Act. The act became law when it was signed by President Woodrow Wilson on December 23, 1913.

The idea of a central bank in the United States was a hotly debated political issue at the time of the act's passage. As a result, the Federal Reserve Act of 1913 included a political compromise: While the act established a central bank for the nation, many of the responsibilities of a central bank were to be conducted by a network of regional banks.

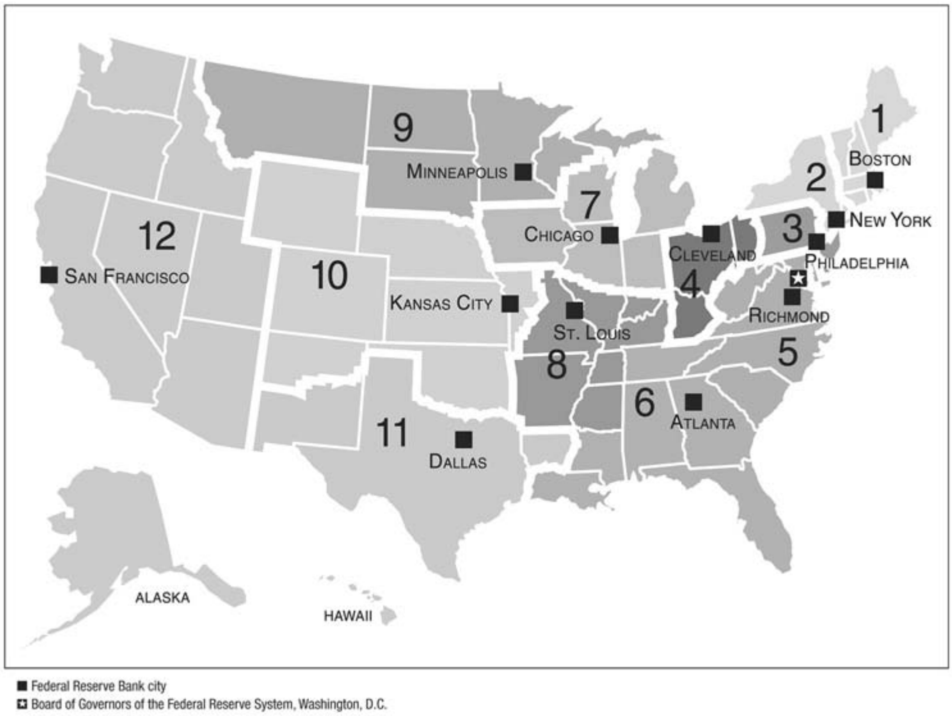
The Federal Reserve (commonly referred to as "the Fed") had two key purposes: to create a more stable central banking system, and to provide the U.S. economy with a stable monetary system. As time has passed, the monetary and banking system duties and responsibilities of the Fed have expanded several times. Today's Federal Reserve System has four major themes: overseeing the nation's monetary policy; supervising and regulating the nation's banks; creating a stable banking system; and providing banking services to the nation's banks—that is, serving as the banks' bank. Economists for the Federal Reserve Board are known for their innovative research on many economic and finance topics and issues, and also for their high-quality research at conferences, published articles in journals, their presentations to many political representatives.

Even though the Fed was created by an act of Congress and signed into law by the president, the Federal Reserve System was established as an independent central bank. The decisions of the Fed are not subject to any approval or rejection by either Congress or any agency of the executive branch, including the president. However, the Fed must still conduct its business within the framework of government and the government's overall financial and policy goals, and the chair of the Federal Reserve Board of Governors does report to Congress. This independence of decision-making has often been the subject of debate within both Congress and the executive branch.

Since 1913, several laws have been enacted to refine, revise, or expand the responsibilities of the Federal Reserve System. First was the Banking Act of 1935, followed by the Employment Act of 1946, and then the Bank Holding Company Act of 1956. The second half of the 20th century saw further revisions of the Fed with the International Banking Act of 1978; the Depository Institutions Deregulation and Monetary Control Act of 1980; the Financial Institutions Reform, Recovery, and Enforcement Act of 1989; the Federal Deposit Insurance Corporation Act of 1991; and the Gramm-Leach-Bliley Act of 1999.

Board of Governors

The Board of Governors of the Federal Reserve System has seven members. The members are appointed by the president and confirmed by the Senate. Each board member is appointed for a 14-year term. The seven terms are staggered so that one term will expire on January 31 during even-numbered years (2010, 2012, 2014, and so on). Board members are appointed for only one 14-year term, and they cannot be reappointed. New members appointed to complete a former member's term may be appointed to their own 14-year term.



Map 1. Federal Reserve regional banks

Current members of the board are eligible to serve as the chair and vice chair of the board. A selection by the president for chair or vice chair may be double-appointed to the board and to chair or vice chair at the same time. These positions are also appointed by the president and confirmed by the Senate. Each chair or vice chair position serves a four-year term and may be reappointed.

The Federal Reserve System is a network of 12 regional banks and their branches; each regional bank is responsible for a specific geographic region, or district. (See Map 1.) The district banks are the operational extensions of the central banking system. These banks are responsible for the duties of a central bank. These duties include maintaining a national payment system, distributing the nation's money supply, and serving as a regulator and supervisor of banks and as the banker for the U.S. Department of the Treasury. Each regional bank also serves its region with various district duties. The district banks also report to Congress.

Each district bank has its own board of directors. The district boards are made up of nine members from outside the bank, representing business, agriculture, labor, banking, and labor sectors of the district bank. Each district board of directors employs a president and first vice-president to serve as chief executives of the district bank.

Federal Open Market Committee

A major component of the Federal Reserve System is the Federal Open Market Committee (FOMC). The FOMC members are members of the Board of Governors and are presidents of four district banks on a rotating basis, excluding the New York district bank (the Federal Reserve Bank of New York president is a continuous member of the FOMC). The FOMC is responsible for the open market operations of the Fed. The Fed uses this monetary policy tool to influence interest rates and money supply.

FEUDALISM

Most commonly associated with the European Middle Ages, *feudalism* represents the economic, political, and social system that supplanted the empire as a centralized form of governance. Feudalism served to protect the king and subservient high-ranking nobles from uprisings. It also allowed for a system to manage and maintain large expanses of land. The lower classes also gained security and protection from robbers and marauders, while also owning and working small land plots.

Feudalist economics centered on *manorialism*, where lords presided over self-sufficient estates, or fiefs, in exchange for providing services to high lords and the king. These services mainly consisted of fees (taxes) and soldiers. *Manors* consisted of a structured social system where peasants or serfs would be given land within the manor in exchange for service to their lords. This service consisted of taxes paid in the form of crops and military service in wartime. The peasants or serfs were also able to use their crops to pay for use of the mill or for other necessities within the manor. Since manors were self-sufficient, there was very little trade between manors, and serfs were tied to their land—although not explicitly as slaves, since they could not be bought or sold.

The basic concept of nation–states and decentralized power structures arose from feudalism. By bestowing ruling power to separate entities across large spaces, fiefs acted as separate entities with their own laws, but also served the purpose of enforcing the overarching laws of the king. Therefore, precedence of power came from a centralized government, but the feudal system spread this power geographical and ideologically, creating an embryonic version of the nation–states. For example, in the event of war, soldiers would be provided from manors to fight for the central power. Similarly, the United States armed forces serve not only their states, but also the nation as a whole.

Many theorists believe that we are in a state of modern feudalism, termed *neo-feudalism*. The basic concept relies on the majority of the power being in the hands of a few and the delegation of duties being passed down the social ladder. Even though society has progressed from beheadings and antiquated taxing methods, neofeudalism asserts that the basic principle still exists—of protection against rebellion and maintaining a workforce for a centralized gain. One of the main aspects of life in the Middle Ages was the need for crops and labor as an economic force. Today, farming and the food supply are equally as crucial in maintaining the needs of a nation. However, people have greater freedom of choice for employment. Farmers also experience greater control in their products. Similarly, labor is still essential in modern economics.

A counterargument to neofeudalism is represented by democracy. People in general have more power of choice and are more empowered in terms of political, social, and economic issues. Neofeudalism asserts that even within modern structures of labor and economics, major decisions are still controlled by a hierarchy of influential peoples and their subsequent nobles.

FINANCIAL INTERMEDIATION

Financial intermediation is the process performed by banks of taking in funds from a depositor and then lending the funds out to a borrower. It essentially paints the picture of what banks are purposed to do, yet it can be observed on a much more complex scale. In contrast to financial intermediation, *direct finance* refers to savers and borrowers meeting directly in financial markets; *indirect finance* involves the use of a financial intermediary. While the stock and bond markets play a most important and indispensable role in this allocation of funding, it is evident that in the United States and many other countries indirect financing is much more important.

Financial intermediation plays five major roles that make it much more relative than direct financing. First, financial intermediaries pool the resources of small savers. This refers to the fact that many borrowers rewire large sums, while many savers offer small sums. Banks pool a multitude of small deposits and use this pool to be able to make large loans. Second, banks provide safekeeping, accounting, and payment mechanisms for resources. Services are standardized and automated on a larger scale, so transaction costs are minimized. Third, financial intermediaries provide liquidity by making it easy to transform various assets into a means of payment through ATMs, checking accounts, debit cards, etc. The fourth and fifth functions are diversifying risk and collecting and processing information.

The banking business thrives on the process of financial intermediation's abilities. Financial institutions lend out money at comparatively high rates of interest, while receiving money on deposits at relatively low rates of interest. Since the loans offered by banks tend to be of longer maturity than the liabilities that fund those loans, the spread is indicative of the marginal profitability of an extra dollar of loans on intermediaries' balance sheets.

While central banks expand their balance sheets, the market price of risk falls. "Expanding a balance sheet" is another term for *quantitative easing*: infusing fresh capital into the financial system by using newly printed money to purchase loans from commercial banks. In exchange, the commercial banks receive cash, which appears as an increase in reserves on their own balance sheets. As a result, the ratio of reserves to loans increases, as does the ratio of reserves to deposits, better enabling the commercial bank to bear losses on any nonperforming loans and still meet depositor demands. In turn, the commercial bank can now make new loans to businesses and individuals, thereby stimulating the overall economy.

Conversely, despite their importance, financial markets are often described as being among the least efficient of all markets. This is due to the fundamental fact that the lender and debt/stock issuers know much more about their likelihood of success than potential borrowers and investors do. This unbalanced information causes one group with better information to use this advantage at the expense of the less-informed group. If not controlled, asymmetric information can cause markets to function very inefficiently or even to break down completely.

FINANCIAL MODERNIZATION ACT OF 1999.

FINANCIAL REFORM ACT OF 2010 (DODD-FRANK ACT)

The Financial Reform Act of 2010 was an effort to reform financial regulation and avoid a financial crisis similar to the crisis of 2008. President Barack Obama signed the act into law on July 21, 2010. The law is also known as the Dodd-Frank Wall Street Reform and Consumer Protection Act, or simply "Dodd-Frank," in reference to the significant work of Senator Christopher J. Dodd (D-Conn.) and Representative Barney Frank (D-Mass.) to create and pass the bill through their respective chambers of Congress. Dodd-Frank is one of the most extensive financial reforms since the Banking Act of 1933 (Glass-Steagall Act), which was created after numerous bank failures due to excessive speculative investment ventures.

Specifically, it ends the possibility of taxpayers being asked to write a bailout check to failing businesses. Dodd-Frank, also known for its massive length, establishes new agencies and reorganizes the roles and responsibilities of others to preempt future large-scale financial woes. The act established the Financial Stability Oversight Council, consisting of a chair (the Secretary of the Treasury), along with 10 voting members (federal financial regulators, and an independent member) and five nonvoting members (OFR, FIO, state banking, insurance, and securities regulators). The council's purpose is to identify risks for U.S. financial stability from financial and nonfinancial organizations, promote market discipline, and respond to emergency risks to the U.S. financial system.

The Orderly Liquidation Authority and Fund monitors companies that have been deemed "too big to fail" and assists in the liquidation of failing companies to prevent widespread economic problems. The tough new capital and leverage requirements make it undesirable to be too big.

The new Office of Financial Research, headed through presidential appointment and Senate confirmation, works within the Department of the Treasury to support the council's work collecting financial data and conducting economic analysis. It monitors emerging risks to the economy and makes information public in reports and testimony to Congress. The director reports to and testifies before the Senate Committee on Banking, Housing, and Urban Affairs and the House Committee on Financial Services of the House of Representatives.

The Federal Insurance Office, working within the Department of the Treasury, serves to monitor the insurance industry for gaps in regulation that could cause systemic risk, gaps in access to affordable insurance for underserved communities, and in other insurance matters.

The act also creates the “Volcker Rule,” named for Paul Volcker—former chair of the Federal Reserve and proposer of the rule. The Volcker Rule restricts the trading that financial companies can do with their own accounts and limits their ability to take excessive risks. It restricts financial companies with regard to owning, investing, or sponsoring hedge funds, private equity funds, or proprietary trading for their own profit. Some have considered the Volcker Rule as a semi return to the banking regulations that were in effect under the Glass-Steagall regulations, while others claim that the Volcker Rule did not go far enough.

The new Consumer Financial Protection Bureau, housed and funded within the Federal Reserve, consolidates the functions of many different agencies. It works to write rules, supervise companies, and enforce federal consumer financial protection laws. It also serves to promote financial education and monitor financial markets for new risks to consumers. In addition, it works to enforce laws that outlaw discrimination and other unfair treatment in consumer finance. Its director is appointed by the president and confirmed by the Senate, and it has an independent budget paid for by the Federal Reserve. New rules for the Federal Reserve allow it to provide systemwide economic support (but not for individual firms) and to establish uniform standards and supervision for the management of risk. It also creates a vice-chair for supervision—a member of the Board of Governors—to develop policy recommendations regarding supervision and regulation for the board, reporting to Congress semiannually.

The act requires the Securities and Exchange Commission (SEC) or the Commodity Futures Trading Commission (CFTC) to regulate credit-rating agencies to avoid overrating such risky derivatives as credit default swaps.

To streamline bank regulation and oversight, the act eliminates the Office of Thrift Supervision.

FISCAL POLICY

Fiscal policy is a government's intentional use of spending and tax policy to influence the economy. Fiscal policy is the responsibility of the federal and state governments. Government's involvement in an economy, using the tools of fiscal policy, was first suggested by John Maynard Keynes in his 1936 classic, *The General Theory on Interest, Money, and Employment*. Keynes suggested the use of fiscal policy during two economic periods. One was during economic recessions, when government should serve as a third partner in a market economy and stimulate demand, increasing incentives of individuals and businesses to consume and invest. The second period was during times when an economy is "overheating" (demand was outstripping supply), and government should implement fiscal policy to slow down the economy. The primary tools of fiscal policy are government spending and taxes. Which tool to use is determined by the incentives that government would like to promote and the economic problem that needs to be solved.

To address a lack of consumer spending, government would likely implement a reduction in taxes to stimulate consumer spending and business investment. If the government would like to decrease unemployment, it would increase its spending on public structures such as roads, bridges, dams, and schools. This was a popular use of fiscal policy by President Franklin Roosevelt. Many of his New Deal initiatives involved government spending on the public's infrastructure.

Fiscal policy has its greatest influence during times of recession or when economic expansions are moving too fast for the economy to absorb. During times of recession, government can implement fiscal policies using one or both tools. A government could increase its spending, enabling more people to be employed and resulting in households having more money to buy goods and services. A second option for the government would be to cut taxes, increasing the amount of people's take-home pay to spend on goods and services.

However, if the economy is growing too fast, that threatens inflation. The government can decrease government spending, leaving fewer opportunities for jobs and thereby decreasing people's ability to buy goods and services. If taxes are used as the fiscal policy tool, the government would increase taxes, leaving people with less money to spend on goods and services.

The main problems of fiscal policy deal with time lags between identification, implementation, and the time between identifying and the effects of a fiscal policy solution impacting the economy. The first time lag occurs in recognizing that an economic problem needs to be addressed. This leads to the time lag created by the political process in approving a fiscal policy solution: the implementation time lag. As a result of fiscal policy being determined through the political process and with different economic philosophies of fiscal policy represented in the Congress or a state legislature, this lag can be significant. Once a need for a fiscal policy solution is identified, a proposed solution needs to pass through the legislative process quickly enough to be effective. This implementation lag time may lead to a fiscal policy solution being implemented after the crisis that required it has passed.

The time taken during the implementation lag leads to a third lag: the impact or effect lag. Beyond recognizing the problem and implementing a solution, and the solution impacting the economy, this lag may make the fiscal policy solution worsen the economic crisis or create a new economic problem.

As part of fiscal policy responsibility, Congress has instituted automatic stabilizers for an economy. These are programs that automatically go into effect when the state of the economy warrants it. Two programs that automatically impact the economy without actions from either Congress or the president are unemployment benefits and the progressive tax structure for income taxes.

FISHER, IRVING

Born: February 27, 1867, in Saugerties, New York; Died: April 29, 1947, in New York City; Nationality: American; Professional Interests: money, monetarism, inflation, interest, econometrics, index numbers; Major Works: "The Equation of Exchange, 1896–1910" (1911), "The Debt-Deflation Theory of Great Depressions" (1933).

Irving Fisher fundamentally shaped the profession of economics. Early on, Irving showed a proclivity for mathematics and invention. His interest in mathematics was instrumental in making the study of economics more quantitative, with a stronger mathematical foundation. Fisher developed and designed some of the first economic indexes—including the first weekly newspaper publication of a wholesale price index. His inventiveness was manifested by his invention of a rotary index card system, the Rolodex. Fisher died in 1947.

Irving Fisher was born on February 27, 1867, in Saugerties, New York. His father was a teacher and minister. Fisher went to Yale and studied a variety of topics, including science and philosophy. But his greatest concentrations were in mathematics and economics. He received his BA in mathematics in 1888. Despite there being no economics department at Yale, in 1891 Fisher was the first Yale student to receive a PhD in economics. As part of his dissertation, Fisher actually developed a price machine that used water and levers to show the circulation of money and capital throughout an economic system. Fisher remained a member of the Yale faculty until he retired in 1935.

It was Fisher's interest in mathematics that helped shape the economics profession. Through Fisher's influence, the study of economics became more quantitative, with stronger mathematics-based research. Fisher is perhaps best known and remembered for two simple equations.

The first is the equation of exchange, which linked money supply to prices. It was well known that too much money led to rising prices. The relationship had been observed, commented on, and even exploited for centuries. What was missing was a sense of why and of what constituted too much. Fisher provided answers for those questions with his equation of $MV = QP$: money supply (M) multiplied by velocity (V) equals transactions (Q) times price level (P). The equation tied the supply of money and its circulation to the production side of the economy—the exchange of goods and services at a price level. This equation has become instrumental in the development of modern central banking, and it provides a foundation for the modern monetarist school.

Fisher's second important equation is the one that bears his name. The Fisher equation states that the nominal interest rate (the interest rate charged consumers or paid savers) is affected by the rate of inflation. By deducting the inflation rate from the nominal rate of interest, one can arrive at the real rate of interest to be paid. This is a truer measure of interest, as it shows the amount of forgone real consumption that is necessary to service a debt. Thus, only when inflation is zero is the nominal interest rate the same as the real interest rate. More importantly, this equation offers insights into how unanticipated inflation or deflation can impact the debtor-creditor relationship. Accelerating inflation can actually lower real interest rates below zero on longer-term debt bearing a fixed interest rate—effectively transferring wealth from the lender to the borrower. Likewise, a significant reduction in inflation can result in the debtor paying a higher real rate of interest than was originally anticipated in an agreement. It is the combination of the two equations that links price-level changes to the perceived return on financial assets. This in turn becomes a factor in the boom-bust cycle.

This connection manifested itself in his debt-deflation theory. Fisher's debt-deflation theory was one of the first theories offered as a cause of the Great Depression. It would be discredited and discarded in favor of Keynes's view of the economy. Nevertheless, it is gaining favor once again as a tool for explaining the Great Recession that followed the collapse of the housing bubble in 2007.

Despite these important ideas, unfortunately Fisher is remembered for some of his failures. Prior to the 1929 stock market crash and the onset of the Great Depression, Fisher was one of the best known and sought-after economists in the United States. His pronouncements were as widely circulated as those of any other economist of his day. However, a few days before the crash, Fisher was assuring investors that stock prices were not overinflated but rather had reached a permanently high plateau. After the October crash, Fisher spent the next few years trying to return a sense of confidence in the market, to no avail. He lost a fortune, and when he went broke he had to sell his home to Yale University and rent it back from the school.

An early bout of tuberculosis made Fisher a lifelong advocate of healthy lifestyles. He was a vegetarian and a backer of Prohibition. He also dedicated significant energy to the study and promotion of eugenics as well as being active in the movement.

Fisher was a cofounder of the American Econometrics Society in 1931 and was its first president in 1932.

Irving Fisher died on April 29, 1947, in New York City.

FRACTIONAL RESERVE BANKING

Banks serve an economy as intermediaries, bringing together savers and borrowers. Banks take in money from the savers and loan out money to borrowers for homes, cars, business expansion, and other mostly durable goods. *Fractional reserve banking* is the banking practice in which banks need to retain only a small portion (a fraction) of the money they take in as reserves, allowing them to loan out most of the money they take in. This expands an economy's money supply through extending additional credit in an economy.

Historically, the story on the origin of fractional reserve banking is considered by some to be more folklore and myth than fact. As one story goes, many eras ago precious metals such as gold were stored in vaults by goldsmiths. The goldsmiths figured out they could loan or invest the gold to gain a rate of return on the gold. They could make a profit and then return the gold to the vaults, with the owners none the wiser. This story is probably myth, or folklore, but it does exemplify the point that anything of value stashed under a mattress or in a vault or a hole in the backyard does not have any value for the economy.

As banks and their role in an economy evolved, the banks came to understand this concept—that money sitting in a bank vault was not being put to work to expand and grow an economy. Fractional reserve banking as a banking practice uses the money that sitting in the vault just waiting for a customer. Putting this money to use expands the money supply through the expansion of credit. The following example shows how fractional reserve banking does this.

A customer deposits \$100 into a checking account at the bank. That bank credits the \$100 to the customer's checking account. Since the checking account is a demand deposit, the customer essentially can go back to the bank, write a check, or use a debit card the next day and withdraw that same \$100. The customer can "demand" (this the term *demand deposit*) the use of the \$100 at any time. So far, the economy has the customer's $100, so there is $100 in the economy. In the practice of fractional reserve banking, the bank now has a choice. With that $100, the bank can do one of three things: (1) do nothing, and leave the $100 in the bank until the customer uses it; (2) deposit the entire $100 into the Federal Reserve, so the Fed credits that bank with reserves of $100; or (3) apply the rules of the fractional reserve banking system to make loans to other bank customers.

Enter fractional reserve banking. If the bank chooses option (3), the fractional reserve banking practice provides to the bank with a set of different rules. Under fractional reserve banking, the bank is required to maintain only a fraction of the $100 on its books. If the requirement is 10 percent, then the bank books $10, freeing up $90 to be loaned to other customers. The $10 is required reserves and the $90 is excess reserves. The bank loans the excess reserves to another customer, and the economy just grew by $90. The original customer still has access to the $100, while the new customer now has $90. The economy now has $190: an increase of 90 percent. The second customer spends the $90 at a store, and that store deposits the money in a second bank.

The process continues, and new money is created for the economy each time a deposit is made and the accepting bank uses the rules of fractional reserve banking. How much money is added to the economy in total? That can be calculated by using the money multiplier:

$$1 / (1/\text{reserve requirement}) = \text{money multiplier}$$

Using our example above, with a reserve requirement of 10 percent, the money multiplier is equal to 1 divided by (1 divided by 10% = 0.1), or 1/.1 = 10. Starting with the first customer's $100 and using the money multiplier, it can be calculated that an additional $1,000 can potentially be added to the economy.

The alternative to fractional reserve banking is full reserve, or 100 percent reserve, banking. With full reserve banking, deposits are to remain fully with the bank or financial institution. In essence, the money is held as if in a trust for the customer. The funds could be loaned by the first bank in the example above, but only after a significant holding period. In the short run, with 100 percent reserve banking the story essentially ends with the first customer's $100 and an economy of $100, or it grows only after a lengthy holding period. Compare this to the $1,000 of new money created in the short run through the fractional reserve banking practice.

Fractional reserve banking has been criticized with economic arguments as well with moral and ethical ones. It has been likened to a Ponzi scheme, as it allows early depositors to gain at the expense of and using later depositors' money. The moral and ethical arguments mostly stem from the idea that several people have a claim on the same money. Fractional reserve banking has been termed "embezzlement" by some economists (mostly adherents to Austrian Economic Thought). One economic argument is that it twists and blurs the capitalist notion of the property rights of money. This claim rebukes the system, claiming that no two people can own the same money at the same time.

FREE RIDER

A *free rider* is anyone who benefits from a public good or service without paying for it. In economic terms, free riders are considered beneficiaries of a market failure. Economists view free riders as beneficiaries of market failure, because in many instances, no one can be excluded from using the public good and everyone can enjoy the good without taking it away from someone else.

The free rider problem stems from the use of public goods and services. Street lights, police services, and national defense can all be considered public goods and services. At one time or another, everyone will need the use of these goods and services, but the problem lies in the fact that not everyone who benefits from their use actually contributes to paying for their cost. Unlike private goods and services, which can be used only by the person who purchased them, public goods and services are available to everyone, and one person using those goods and services does not stop another person from enjoying those same goods and services at the same time.

For example, streetlights that illuminate a neighborhood at night are a public good used by everyone who lives in or visits the neighborhood. Everyone within the neighborhood benefits from having the streetlights, regardless of whether they live in the neighborhood or are just visiting. Yet only those who live in the neighborhood have paid the taxes to provide the streetlights. Everyone else within the boundaries of the neighborhood benefitting from the streetlights is a free rider, as they have not paid for the streetlight.

No one can stop people from using the streetlights, regardless of who pays the taxes that supply them. For one person to the streetlight does not mean that others in the neighborhood cannot use it. If the electrical company tried to get money from residents on the street based on their consumption of the benefit provided by the streetlights, the company would be unable to see who used the lights the most and who used them the least.

All public goods, including national public goods such as national defense, have a free rider problem. The military defends the nation in times of need, and everyone in the nation enjoys the benefits of this defense. The military receives its pay from the government, which in turn taxes citizens in order to pay for these costs. The free rider problem occurs when those who do not pay taxes enjoy the benefits of national defense alongside those whose taxes go toward funding the cost of this protection.

FRIEDMAN, MILTON

Born: July 31, 1912, in Brooklyn, New York; Died: November 16, 2006, in San Francisco, California; Nationality: American; Professional Interests: monetary policy, price theory, public policy, monetary history, Nobel Prize (1976); Major Works: "The Methodology of Positive Economics" (1953), *A Theory of the Consumption Function* (1957), *Capitalism and Freedom* (1962), *A Monetary History of the United States, 1867–1960* (with Anna J. Schwartz) (1971), *Free to Choose: A Personal Statement* (with Rose Friedman) (1980).

For his ability to explain and defend the merits of free markets and individual freedom, Milton Friedman is considered one of the most influential economists of the 20th century. Friedman was also considered the embodiment of the Chicago school of economics, with an emphasis on monetary policy, free markets, and less government intervention. He was instrumental in the economic policies of President Ronald Reagan and Prime Minister Margaret Thatcher. Milton Friedman won the Nobel Prize in Economics in 1976, and President Reagan honored him with the Presidential Medal of Freedom in 1988. Friedman died in 2006.

Milton Friedman was born in Brooklyn, New York, on July 31, 1912. Growing up in New Jersey in the home of immigrant Hungarian parents, Milton graduated from the local public high school when he was 15, a month before his 16th birthday. He was destined for college, but the untimely death of his father during his senior year of high school narrowed his college direction to Rutgers University. Financing his own education, along with a small scholarship, Friedman graduated from Rutgers University in 1932. Originally a mathematics major planning on becoming an actuary, he became interested in economics. Friedman graduated from Rutgers with majors in both mathematics and economics.

Encouraged to pursue graduate work in economics, Friedman accepted a scholarship to the University of Chicago. His early experiences at the University of Chicago framed his economics and research philosophies. During this time there, he met the woman who would become his wife and lifelong working professional partner, Rose. After one year at the University of Chicago, Friedman received a fellowship to Columbia University. Even though he returned to the University of Chicago after only one year at Columbia, he received his PhD in economics from Columbia in 1946.

In 1935, Friedman was recruited by his friend W. Allen Wallis to join him on the National Resources Committee in Washington, D.C. Friedman s role on the committee was to continue earlier work on a consumer budget study. It was this work on the consumer budget study that became the basis for one of the two key components for his later groundbreaking work, *Theory of the Consumption Function.*

In 1937, Friedman accepted a position with the National Bureau of Economic Research (NBER). At NBER he worked with Simon Kuznets, publishing *Incomes from Independent Professional Practice*. Kuznets and Friedman introduced the concepts of permanent and transitory income. They also initiated a debate among Washington bureaucrats by asserting that the incomes of physicians were higher than those of dentists due to the monopoly power of physicians. For Friedman, this study also provided the second key component of his own later work on the consumption function.

Friedman continued his work in Washington during World War II. From 1941 to 1943, Friedman directed his efforts on tax policy at the U.S. Treasury. In 1943, he joined his friend Wallis again, this time at Columbia University, applying his mathematical and statistical expertise on military tactics, design, and metals. After teaching at the University of Minnesota for a year, Friedman returned to the University of Chicago in 1946. He remained at the University of Chicago until he retired from active teaching in 1977. Another close friend, Arthur Burns, who was directing NBER, persuaded Friedman to rejoin NBER. Friedman remained with NBER until 1981.

In 1953, Friedman wrote "The Methodology of Positive Economics," in which he argued that the validity of economic theories should be based on their ability to predict human behavior. He followed this in 1957 with his classic, A *Theory of the Consumption Function.* Friedman's case was that it was necessary to think of individuals making rational spending and saving decisions over a lifetime. The basis was a return to his earlier work with Kuznets and the permanent-income hypothesis. His thesis in *A Theory of the Consumption Function* was also a return to classical economic thinking, which had been replaced in the middle of the 20th century by the economic philosophies of John Maynard Keynes.

Friedman's launching of the Money and Banking Workshop at the University of Chicago set the academic and research foundation for his next target in economic research: monetary policy. The research and publications that originated from the workshop highlighted the Chicago school of economics' emphasis on the role of monetary policy as the key determinant to inflation and business cycles.

Friedman's work explaining the role of the money supply and monetary policy on an economy earned him an international reputation. His monetary policy theories were highlighted in 1969 with *The Optimum Quantity of Money and Other Essays*. The workshop provided the environment for many contributors and researchers to generate significant work on monetary policy. Through his work with the workshop and NBER, Friedman began a collaboration with economic historian Anna J. Schwartz. In 1971, they wrote the classic *A Monetary History of the United States, 1867–1960*.

Another groundbreaking accomplishment in economic theory for Milton Friedman came when he suggested that the popular inflation-unemployment rate trade-off was not necessarily a long-run trade-off as most assumed. In 1967, while he acknowledged a short-run trade-off, he asserted that government intervention to keep inflation high to promote low unemployment would eventually fail, with ultimately both unemployment and inflation rising. This argument would later be proven correct in the 1970s and the ensuing period with the economic condition that became known as stagflation.

In 1976, Milton Friedman was awarded the Nobel Prize in Economics for his scientific work on consumption, monetary history, and stabilization policy. In 1988, he received both the Presidential Medal of Freedom from President Reagan and the National Medal of Science. Earlier in 1986 he had received the Japanese government's Grand Cordon of the First Class Order of the Sacred Treasure.

After his retirement from active teaching, he became involved in public affairs and public policy. He assisted presidential candidates Barry Goldwater, Richard Nixon, and Ronald Reagan as an economic adviser during their campaigns. He would later serve as an economic adviser to both presidents Nixon and Reagan. He also began writing columns for the popular news magazine *Newsweek*, promoting the virtues of individual freedom and markets unfettered from government intervention.

In 1981, he served on President Reagan's Economic Policy Advisory Board. Friedman is given significant credit for the economic philosophies of President Reagan and Prime Minister Margaret Thatcher in the later decades of the 20th century. Friedman was viewed as the opposition to the popular theories of John Maynard Keynes that dominated economic thought and political economic policy from post–World War II through the 1970s.

Milton Friedman's popularity with the general public reached its pinnacle in 1980 with the release of the popular 10-part television series, *Free to Choose*. Coauthored with his wife Rose, the series was accompanied by a book of the same name. The book was the nonfiction bestseller in 1980, a rare occurrence for someone with the high academic stature of Milton Friedman. Since its release, the series and book have been translated into 14 languages, and the series can be seen in many foreign countries.

Milton Friedman concluded his career at the University of Chicago as the Paul Snowden Russell Distinguished Service Professor Emeritus of Economics. He also served the Hoover Institution at Stanford University as a senior research fellow.

Milton Friedman died on November 16, 2006, in San Francisco, California.

G

GALBRAITH, JOHN KENNETH

Born: October 15, 1908, in Dunwich Township, Ontario, Canada; Died: April 29, 2006, in Cambridge, Massachusetts; Nationality: American; Professional Interests: general economics, economic policy; Major Works: *American Capitalism: The Concept of Countervailing Power* (1952), *The Great Crash of 1929* (1954), *The Affluent Society* (1958).

John Kenneth Galbraith was quite possibly the most widely read economist of the mid-20th century. He authored over 30 books. His most widely read, *The Affluent Society*, published in 1958, became popular with the general population as well as academics. Galbraith is credited with penning economics phrases that are now part of the economics and political lexicon, including "conventional wisdom," "countervailing power," and of course "the affluent society." Galbraith was known for his writing style of addressing the economics topics and issues of the day as part of everyday life and not as an esoteric science. Galbraith died in 2006.

John Kenneth Galbraith was born on October 15, 1908, in Ontario, Canada, and raised on a small farm in Dunwich Township in Ontario. Of Scottish descent, his father was a farmer and schoolteacher who had a major influence on his son's early views of politics and his liberal philosophy. The young Galbraith attended Ontario Agricultural College (OAC), taking courses to be a farmer. While at OAC, he became more interested in the economics of farming than in farming itself. He completed his undergraduate work at the University of Toronto and went on to complete his master's and doctorate in agricultural economics at the University of California, Berkeley, in 1934.

Galbraith's writing notoriety started early in his academic career, while he was at the University of California, Berkeley. This early success led him to Harvard University, where he joined the faculty as an instructor in 1934. In 1937, he received a fellowship to attend Cambridge University in England and study under John Maynard Keynes. During the Depression, the theories of Keynes were dominating both the economic and political landscapes. This one year under Keynes was to be the turning point in Galbraith's career. Yet he admits that his economic philosophy was also influenced by Thorstein Veblen.

Returning to Harvard from Cambridge, he remained at Harvard only one more year. In 1939, Galbraith joined the economics faculty at Princeton University. He also became an American citizen. With the outbreak of World War II, Galbraith joined President Roosevelt's administration, becoming an administrator in the Office of Price Administration. As administrator of wage and price controls, he gained a contentious reputation with industry. He resigned his post in 1943.

After holding various positions both in and out of government, including a brief term as a writer for *Fortune* magazine—which introduced the United States to both John Maynard Keynes and his U.S. protégé, John Kenneth Galbraith—he returned to Harvard in 1949. This began what was to become his period of famous lectures and even more famous writings.

In 1952, Galbraith wrote *American Capitalism: The Concept of Countervailing Power.* In *American Capitalism,* he submitted the idea that U.S. economic power was concentrated between corporations on one side and unions on the other. These countervailing forces kept the U.S. economy in equilibrium. Also in 1952, Galbraith wrote *A Theory of Price Control.* In 1954, Galbraith wrote *The Great Crash of 1929,* suggesting that the same errors made in 1929 were being made in 1955. He went so far as to testify to the U.S. Senate that another “crash” was likely to occur.

His influence reached its zenith in 1958 when *The Affluent Society* was published. With *The Affluent Society,* Galbraith became a global success. He suggested that U.S. businesses had overproduced, leading consumers to overspend without thought to solving the social issues of the day. He went on to predict inflationary and recessionary dynamics, with the overemphasis on private goods and with public goods being the trade-off.

One area where Galbraith was ahead of his time was in thinking about economic progress and its impact on the environment. He blamed advertising for frivolous spending at the expense of addressing environmental concerns as well as the social benefits to society. Along with several other writers of the 1950s, Galbraith began to change the public views of an economic system that would best suit a postwar United States.

Beyond his work in the Roosevelt administration, John Kenneth Galbraith had a significant influence in the later political arena. An avowed political liberal, he was influential in shaping the ideas and views of the Democratic Party in the 1950s and 1960s. He advised presidential candidate Adlai E. Stevenson and eventual president John F. Kennedy on the Keynesian view of how to best deal with the economy. He was also instrumental in devising and promoting President Lyndon Johnson’s Great Society program. During this period he was also a speechwriter for Roosevelt, Kennedy, and Johnson. Galbraith served as ambassador to India under President Kennedy.

John Kenneth Galbraith was not without his critics. As popular as he was with the general public, the economic academic community regarded his writings as often too simplistic to be highly regarded. Others regarded his blatant liberal political views as interfering with his economic objectivity. One area where his ideas were later disputed was advertising. As he submitted in *The Affluent Society*, he blamed advertising as the cause of an overly consumption-oriented economy. This notion was later countered by Nobel laureates Gary Becker and George J. Stigler, using mathematical proofs that advertising was indeed informative to consumers and was not leading them to undesired consumption.

In 1967, in *The New Industrial State*, Galbraith called for a new class of policy decision-makers. In 1973, he wrote *Economics and the Public Purpose*, in which he called for an increase in central planning, socialism, increasing tax progressivity, and more public housing and medical care, along with a move to nationalize some corporations that serve the federal government. In 2004, at the age of 95, Galbraith published *The Economics of Innocent Fraud,* a short book that questioned much of standard economic wisdom.

John Kenneth Galbraith received many awards, the most prestigious of which was the Presidential Medal of Freedom, which he received twice, first in 1946 from President Harry Truman and again in 2000 from President Bill Clinton. In 2001, Galbraith received India's second-highest civilian award, the Padma Vibhushan. In Canada, he was conferred the Officer of the Order of Canada in 1997, and in Dutton, Ontario, the library was renamed the John Kenneth Galbraith Reference Library. In 2010, posthumously, he was the first economist to have his popular works included in the Library of America series.

John Kenneth Galbraith died on April 29, 2006, in Cambridge, Massachusetts.

GEITHNER, TIMOTHY

Born: August 18, 1961, in New York City; United States; Nationality: American; Major Work: U.S. Secretary of Treasury, 2009–2013.

Timothy Geithner's most notable role may be his appointment as U.S. Secretary of Treasury under President Barack Obama, but he has held several noteworthy positions throughout his career.

Timothy Geithner was born August 18, 1961, in New York City. His father Timothy was a U.S. government representative for international development, and his mother Deborah was a professional pianist. Due to his parents' occupations, he lived in several foreign nations during his youth, including Zimbabwe, India, and Thailand. Exposure to so many different areas of the world from such a young age grew his interest in international affairs. While attending high school at the International School of Bangkok, he pursued an interest in photography. Through opportunities presented at his high school he was able to travel to Cambodia and take photographs of refugees.

While attending Dartmouth College he continued to pursue his love of photography and worked as an event photographer. At Dartmouth, his professors noticed he had a natural talent for language—learning Mandarin and Japanese. He graduated from Dartmouth in 1983 with a B.A. in government and Asian studies.

After earning a bachelor's degree from Dartmouth, Geithner continued his passion for international affairs at Johns Hopkins School of Advanced International Studies. While pursuing his master's degree, he met his wife, Carole Marie Sonnefeld. He was awarded his master's degree in International Economics and East Asian Studies in 1985.

After graduation, Geithner worked as a consultant for Kissinger and Associates. He continued his consulting work until 1988, when he began his political/civil servant career with the Treasury Department. He held different positions within the department, including financial attaché and advisor and eventually a member of the executive branch's senior team.

He worked under Treasury leaders Robert Rubin and Lawrence Summers during the Clinton administration. He joined the International Monetary Fund (IMF) in 2001 as the director of the Policy Development and Review Department.

Geithner joined the Federal Reserve Bank of New York as its president and chief executive officer in 2003. His role as CEO of the New York Federal Reserve Bank included serving as vice-chairman and permanent member of the Federal Open Market Committee (FOMC), which develops monetary policy strategies for the country and determines the interest rate. During his time at the Federal Reserve Bank of New York, he worked closely with Federal Reserve Chairman Ben Bernanke and Treasury Secretary Henry Paulson to respond to the U.S. financial crisis of 2008. He assisted in the highly controversial rescue of Bear Stearns (one of the largest investment banks and brokerage firms) and collapse of Lehman Brothers.

President Obama nominated Geithner to be 75th Secretary of the Treasury, confirmed by the Senate in January 2009. Geithner stepped into the position in the midst of the greatest economic downturn since the Great Depression. The programs he developed assisted in shaping the financial system and reviving the economy during the Great Recession. The Treasury was able to successfully return profits to taxpayers from the investments they made during the emergency financial programs that resulted from the financial crisis.

Secretary Geithner established a mix of short-term tax cuts and public investments, followed by longer-term spending and tax reforms to help sustain the fiscal position of the United States. He was the main advocate of the Dodd-Frank Act (Wall Street Reform and Consumer Protection Act), aimed at restructuring and reforming the financial system. The comprehensive Dodd-Frank Act protected investors and consumers with the creation of the Consumer Financial Protection Bureau. These efforts were much needed to assist in the recovery of the nation's financial system and overall consumer confidence.

Geithner was a significant participant and leader during the European financial crisis and in U.S. economic relations with China. He was instrumental moving China to a more flexible exchange rate system. U.S. agreements with developed and emerging economies were strengthened under Geithner.

He resigned his position and left the Obama administration in January of 2013. He wrote a memoir about his time as Secretary of the Treasury, titled *Stress Test: Reflections on Financial Crises* (2014).

Geithner was the first former member of the Treasury's career civil service to become Secretary of the Treasury. Geithner now serves as president and managing director of the private equity firm Warburg Pincus. He and his wife Carole have two children.

GENERAL EQUILIBRIUM ANALYSIS

General equilibrium analysis is the study of equilibrium price and quantity in multiple or all markets in the economy. The analysis of supply and demand on equilibrium price and quantity in a single market ignoring events in other markets is referred to as *partial equilibrium analysis*. While partial equilibrium analysis can be very useful, there are times when it is necessary to analyze the impact a change in one market has on other markets. General equilibrium analysis has developed through the work of such economists as Léon Walras, William Stanley Jevons, Kenneth Arrow, and Gérard Debreu.

General equilibrium analysis looks at the interdependence of markets. There are two common relationships between markets: the spillover effect and the feedback effect. The *spillover effect* refers to a change in equilibrium in one market having an effect in other markets. The *feedback effect* is when the change in equilibrium in one market (A) causes a change in another market (B) and that change in Market B will result in a change in equilibrium in Market A. The following scenario will help to illustrate these effects.

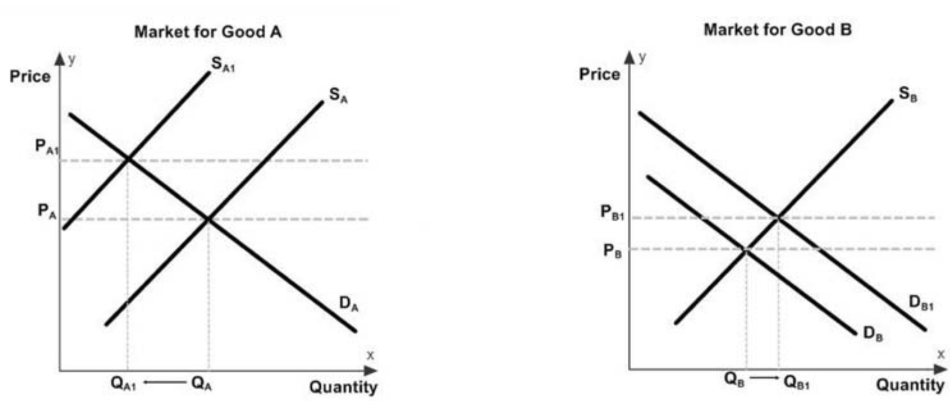

Figure 1. General equilibrium analysis A

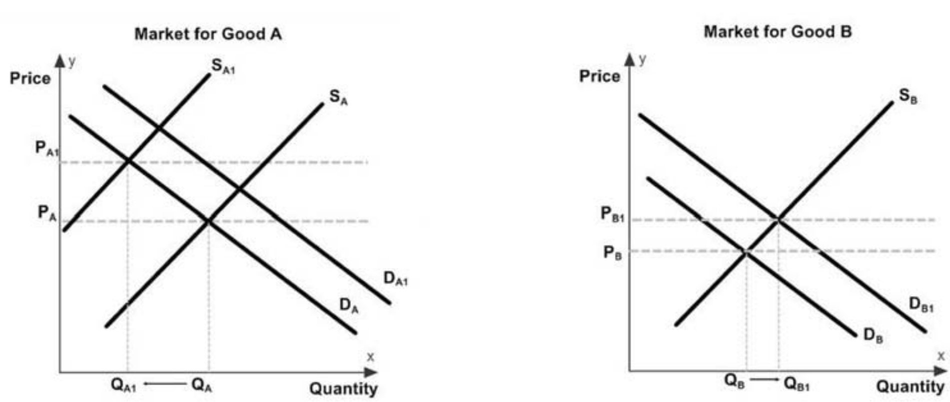

Figure 2. General equilibrium analysis B

There are two interdependent competitive markets, Market A and Market B. Both markets start in equilibrium. Assume that a tax is placed on Good A. This tax results in a decrease in supply, which is represented by the shift from S_A to S_{A1}. The price has increased from P_A to P_{A1}, and the quantity has decreased from Q_A to Q_{A1}. The changes in the Market for Good A have a spillover effect into the Market for Good B. Since the goods are substitute goods, the higher price of Good A initially increases the demand for Good B with the shift from D_B to D_{B1}. D_{B1} represents the demand for Good B when the price of Good A is P_{A1}. The price will increase from P_B to P_{B1} and the quantity will increase from Q_B to Q_{B1}.

Analysis of the markets does not end here. The change in Market B has a feedback effect on Market A. The tax in Market A led to a higher price for Good B. Since the price for Good B has increased, the demand for the substitute good, Good A, will increase. The feedback effect is shown by the shift from D_A to D_{A1}.

General equilibrium analysis shows the interdependence of markets by including not only the spillover effect but also the feedback effect. Partial equilibrium analysis and general equilibrium analysis are both useful tools for economists. Typically, partial equilibrium analysis is sufficient if the change in the market primarily affects one market. General equilibrium analysis is more appropriate when the change affects many markets at the same time.

GIBBONS V. OGDEN

Gibbons v. Ogden, 22 U.S. 1, is an 1824 Supreme Court case that gives the federal government the ability to maintain uniform and equal rule of law within the whole of the United States. The Court addressed the issue of monopoly in transportation. In addition, it addressed the issue of states' responsibility versus the authority of the federal government to make laws regarding business and commerce, specifically interstate transportation. As on many occasions throughout history, this case was also a case of creative destruction, as technology was changing the face of an industry, in this case the transportation industry. *Creative destruction* is an economic concept allowing old methodologies of manufacturing, production, or distribution to be replaced with new methodologies.

Economic Summary

In the late 1700s, the introduction of steam to drive boats spurred a rush of innovation. A race began to build a better engine—from which someone could develop a profitable industry from this new power source. Among the many entrepreneurs and inventors in this race was Robert Fulton; in 1807, he was the first to make steamboating a commercial success. Between 1807 and 1814, the *North River Steamboat* (also known as the *Clermont*) operated as a commercial transportation vessel on the North River (now known as the Hudson River). This commercial success was due in part to Fulton's partner, the former chancellor of New York, Robert R. Livingston (1746–1813), who negotiated with the state legislature to pin down the legal details that would give Livingston and Fulton exclusive rights to operate steamboats on waters within the state of New York—in other words, a monopoly.

Fulton and Livingston sold franchises to rivals who wanted a part of the industry. Aaron Ogden bought a license from them in 1815, and Ogden's business associate, Thomas Gibbons, began operating steamboats between Elizabethtown, New

Jersey, and New York City. In 1818, much to Ogden's annoyance, Gibbons began an independent steamboat line.

To stop Gibbons, Ogden sued him in a New York court and won. Gibbons appealed to the United States Supreme Court. The greatest questions in this case were how to interpret the commerce clause and the boundaries to the supremacy clause of the U.S. Constitution. Finally, in an era of invention and growth of industry, what is the responsibility of the state and federal government to make laws regarding business, industry, and commerce?

The Court addressed these questions, and Chief Justice John Marshall clarified commerce and supremacy.

Case Summary

Robert R. Livingston was one of the committee of five who wrote the Declaration of Independence. As the chancellor of New York, he held the highest judicial position in the state and swore in George Washington as the first president of the United States. With this political clout, it was not a stretch for Livingston to secure for his partner, Robert Fulton, the exclusive authority to navigate the waters of New York with steam-powered engines. This created a legal monopoly of navigation by steam on all waterways in and around New York.

Establishing rule of law and property rights in a free enterprise system is fundamental. Early in the history of the United States, the Articles of Confederation allowed such laws and rights to be maintained by state legislatures. In the federal system established by the U.S. Constitution, the question of states granting legal monopolies for commerce between states was brought forth. *Gibbons v. Ogden* solved the dilemma of who was the legitimate authority to regulate interstate commerce.

Thomas Gibbons was a former Tory (colonist who was loyal to the British King during the Revolutionary War), lawyer, businessman, and mayor of Savannah, Georgia. In 1801, Gibbons left Georgia for New Jersey, where he went into business with Aaron Ogden. Aaron Ogden was a former Revolutionary War hero and governor of New Jersey who, after a license fee, secured from Livingston and Fulton a franchise to operate a steamboat business between Elizabethtown, New Jersey, and New York City.

By 1818, Gibbons and Ogden were at odds with one another. Gibbons started his own steamboat business with a license obtained from Congress under a 1793 law that pertained to the regulation of trade along the coastline. Gibbons partnered with Commodore Cornelius Vanderbilt to operate a steamboat from New Jersey to New York. Ogden sued Gibbons in a New York State court to stop him. The state court held that securing navigational rights to waterways was a concurrent power, not one expressly given in the Constitution to the federal government. Gibbons's lawyer, Daniel Webster, argued that the Constitution did in fact give the power to regulate trade between the states explicitly to the federal government and that this state law conflicted with the U.S. Constitution.

The New York court ruled in favor of Ogden, perpetually enjoining Gibbons from navigating the waters of the state of New York with steamboats the *Stoudinger* and the *Bellona*. Gibbons appealed this case to the Supreme Court.

The Supreme Court heard arguments in February 1824. By this time, Fulton and Livingston were deceased, while Ogden was heading to debtors' prison and Gibbons was determined to succeed. The appellant maintained that the laws allowing a state to regulate interstate commerce were in opposition to the U.S. Constitution.

The state of New York disagreed, contending that New York was the legitimate authority in such business matters. New York defined *commerce* as traffic and the buying and selling of commodities. Chief Justice Marshall defined *commerce* differently. The Court's definition of *commerce* included navigation and the power to regulate the vessels of one state into the port of another state to engage in buying or selling or barter. This was the definition the writers of the Constitution had intended when they expressed this power in Article I, Section 8. Consequently, New York argued that regulation of the coastal waters surrounding the state was a concurrent power.

The Supreme Court disagreed with this as well. Chief Justice Marshall's opinion stated that concurrent powers were such that by their practical operations, they needed to reside in different levels of government. For example, the power to lay and collect taxes is essential to maintaining government function at any level and therefore is concurrent. By contrast, the power to regulate commerce is appropriate in the hands of the federal government for the purpose of maintaining a more perfect union and securing domestic tranquility within the nation. However, the Court did recognize that there would be gray areas where states may pass laws that interfere with or are contrary to an act of Congress.

The framers of the Constitution foresaw this collision of powers and provided for it in Article VI of the U.S. Constitution, declaring the supremacy not only of the Constitution, but also of the laws made in pursuance of it. Finally, New York laws pertained only to vessels with steam engines, not to vessels with sails. The Supreme Court expressed the opinion that steam-propelled vessels were entitled to the same privileges and protections as vessels with sails. The rule of law includes a level playing field for innovation in a free enterprise economy. Hence, requiring only steam-powered vessels to obtain a license from private citizens who possessed exclusive legal monopolies on certain technologies was construed as a hindrance.

This case established the federal government as the legitimate authority to determine regulation of commerce among the states and the U.S. Constitution as the supreme law of the land. On March 2, 1824, a unanimous opinion of the Court reversed and annulled the decree of the Court of New York, ruling in favor of Gibbons. This case illustrates the supremacy clause of the Constitution, which gives the federal government the ability to maintain uniform and equal rule of law within the whole of the United States.

GLASS-STEAGALL ACT. *See* Banking Act of 1933

GOLD STANDARD

England adopted a de facto gold standard in 1717 after the master of the mint, Sir Isaac Newton, overvalued the guinea in terms of silver, and the nation formally adopted the gold standard in 1819. The United States, although formally on a bimetallic (gold and silver) standard, switched to gold de facto in 1834 and de jure in 1900 when Congress passed the Gold Standard Act.

In 1834, the United States fixed the price of gold at $20.67 per ounce, where it remained until 1933. Other major countries joined the gold standard in the 1870s. The period from 1880 to 1914 is known as the classical gold standard. The gold standard is a fixed exchange rate system, with gold being pegged as the basis for the exchange rate.

The gold standard was abandoned in the 1930s during the Great Depression. Research shows that the first countries to end the gold standard were the ones that escaped the Great Depression. After World War II, Western economies adopted a modified gold standard under the Bretton Woods exchange rate system (1947–1971); this too was abandoned, in the early 1970s. Under a pure gold standard, nations keep gold as their international reserve. Gold is used to settle most international obligations, and nations must be prepared to trade it for their own currency whenever foreigners attempt to "redeem" the home currency they have earned by selling goods and services. The nation's money is backed by gold.

There are three rules a country must follow in order to maintain a fixed gold exchange rate system. The first rule is that the country must fix its currency unit in terms of gold. This fixes the exchange rate. For example, under the modified gold standard of the Bretton Woods exchange rate system, the U.S. dollar was fixed at $35 per ounce and the British pound was set at £12.5 per ounce. Because both currencies were fixed in terms of gold, they were implicitly set in terms of each other: $35 = one ounce of gold = £12.5, or 2.80 dollars per pound.

The second rule of the gold standard is that nations must keep the supply of their domestic money fixed in some constant proportion to their supply of gold.

This requirement is necessary to ensure that the domestic money supply does not grow beyond the capacity of the gold supply to support it.

The third rule of a gold standard is that nations must stand ready and willing to provide gold in exchange for their home country currency. Instead of holding currency in the reserve, in a pure gold standard currency system countries hold gold in reserve. As countries sell their gold reserves, there are two outcomes: (1) the demand for gold is satisfied and the pressure on the currency eases, or (2) the country began to run out of gold. If the country runs out of gold, the country may be forced into a devaluation, which is accomplished by changing the price of its currency. For example, if the dollar is fixed at $35 per ounce of gold, devaluation would shift the price of gold to something more than $35—say, $50—and each ounce of gold sold by the United States would buy back a greater quantity of dollars.

GOVERNMENT BAILOUTS OF PRIVATE COMPANIES

Government bailouts in the United States have been around for almost as long as the United States has been a sovereign nation. Some of the most costly and famous bailouts in American history took place in the past several years, due to the Great Recession of 2007–2009. Government bailouts of private companies have been spread across many industries.

Bailouts in the United States can be dated back to the Panic of 1792, when the federal government bailed out the 13 states, which were overwhelmed with debt stemming from the Revolutionary War.

The Great Depression that followed the stock market crash of 1929 is one of the best-known economic disasters in world history. When President Franklin D. Roosevelt took office, the U.S. unemployment rate was near 25 percent. Combating the drastic times called for drastic measures. The Roosevelt administration enacted many precedent-setting government bailouts, with the goal of easing the economic disaster that had taken over. One of the primary government bailout efforts of the Depression was handled through the Home Owners' Loan Corporation (HOLC). The HOLC refinanced mortgages by purchasing defaulted mortgages from banks.

Because there wasn't another market for package mortgages, the government held the mortgages until they were paid off.

Following World War II, a national group of fiscally conservative lenders helped stimulate the housing boom by creating savings and loan associations (S&Ls). Government oversight on S&L lending was nearly non-existent. Their investments were reckless, and many S&Ls ended up going bad, leading to one of the most costly bailouts of all time. Almost half of America's S&Ls failed, and loan default totaled billions of dollars. Congress enacted the Financial Institutions Reform, Recovery and Enforcement Act in 1989 to address this crisis, which ended up injecting the industry with nearly $293 billion.

All previous bailouts were surpassed in size and scope by hundreds of billions of dollars thanks to the Emergency Economic Stabilization Act of 2008. The U.S. Treasury bought risky and nonperforming debt in the form of mortgages, auto loans, college loans, and other types of loans. It was hoped that this bill, along with a $250 billion cash infusion into the banking system, would spur interbank lending and cause a trickle-down effect in the economy—all the way down to small businesses and consumers. The U.S. government planned to borrow some of the money by issuing Treasury bonds and bills. The government also planned to print additional currency to help pay for the plan.

The subprime mortgage fiasco of 2007–2008 caused the giant investment bank Bear Stearns to collapse. In 2008, J. P. Morgan Chase was given $29 million to buy the financially troubled firm. The government predicted disaster and economic devastation if the United States allowed one of the largest securities companies in the world to go bankrupt.

In 2008, the U.S. government committed $200 billion in taxpayer money to Fannie Mae and Freddie Mac to protect the two mortgage lenders from collapse. Both of these giant companies were brought down by the subprime mortgage crisis. They issued mortgage loans to unqualified borrowers, and when borrowers defaulted on the loans, Fannie and Freddie experienced great financial trouble. Eventually the federal government bailed them out.

One of the world's largest insurance companies, American International Group (AIG), was taken over by the U.S. government and guaranteed a loan of $85 billion when private lenders declined to assist. The government took an equity position in the company. AIG's assets, its hefty insurance revenues, were collateralized by the government, which diminished the government's risk in the company. The loan was conditioned with the requirement that AIG sell many of its unprofitable businesses to shed some of its nonperforming debt. This marked the first time in history that the federal government took over a private insurance firm.

During the same period, the three major automobile companies in the United States asked the government for a $50 billion bailout. The auto companies stated that they feared their demise would push the economy further into recession. During the vetting process it was determined that Ford really didn't need a bailout; in truth, Ford was worried it wouldn't be able to compete with government-subsidized companies. Initially, Congress declined to assist, stating that the industry had created its own problems. Finally, in 2009, Chrysler and General Motors were allotted $23.4 billion. In return, the companies were required to fast-track environmentally friendly vehicles and consolidate operations, along with other requirements specific to each of the companies.

General Motors pledged to cut its debt and sell stock ownership to the government. The bailout led to a managed bankruptcy in which GM emerged as two separate companies. One company held the assets and the other held the liabilities. A few years later, on two separate occasions, the government sold its shares of the company. Chrysler also went through a managed bankruptcy. It emerged partly owned by Fiat and partly owned by the United Auto Workers Retirement Medical Benefits Trust. Intense negotiations eventually led the United Auto Workers Trust to relinquish its ownership in the company. Today, Chrysler has a new identity: Fiat Chrysler Automobiles. Five years after the bailout, the government had recouped nearly 70 percent of the money it spent on the auto industry bailout, mostly by selling it shares of General Motors. Chrysler repaid its debt to the government six years ahead of schedule.

Many economists believe the U.S. government is overextending itself with the numerous bailouts. Rescuing private companies has led to trillions of dollars in debt; resources to pay off the debt are limited, and there are few resources available to fund future bailouts. The most recent round of bailouts was also politically unpopular, as many people believe the government shouldn't interfere with the free market. With the most recent regulatory legislation and stringent oversight, it's possible that bailouts of the size seen in 2008 may not be necessary again.

GOVERNMENT FAILURE

When markets fail to provide the right amount of a good or service or when they provide too much of a bad thing, that is, an externality—in other words, when a market failure occurs—citizens expect the government to step in and provide the remedy. Consumers expect government to supply the desirable quantity of a good or service or protect the consumer/citizen from harm or economic hardship caused by others. Often, government will interfere with those markets successfully.

There are times, however, when a government interferes with a market and the expected outcome is not the one achieved. These consequences are known as government failures. Even though people usually think of government failures as occurring at the national level, government failures occur at the state and local levels of government as well.

Government failures occur for many reasons. Some are the result of the influence and political self-interest of special interest groups, the self-interest of political and civil servants attempting preserve programs or jobs, or government intervention that results in overregulation at the expense of consumers. Government actions often create disincentives or cause avoidance activity by businesses or consumers, or sometimes a government action falls victim to the law of unintended consequences.

When government failures occur, several consequences may arise. One consequence is that the economic costs of a government decision outweigh the economic benefits realized. Many times, the components of the economic costs and economic benefits of an activity are estimated and fairly subjective, leading to disagreements about whether a government action was a failure, a success, or some of both.

Trade policies that are intended to protect an industry or a special interest group are one example of this type of government failure. On the one side, consumers would view the protectionist policy of the sugar tariff as a government failure, because it makes consumers pay a higher price for sugar and other food items. For the consumer, the economic costs outweigh the economic benefits. Yet the corn industry would view this government action quite differently, as the industry receives significant economic benefits from higher corn prices, relative to the production of corn-based ethanol versus sugar-based ethanol.

Another type of government failure occurs when a government action to change behavior does not produce the desired change of action. For example, a government may act to curtail pollution through fines and penalties. While the governmental unit may impose the fine or penalty on a polluting company, if the fine or penalty is not severe enough to alter the company's behavior, the company will be inclined to pay the fine and continue polluting. While the government may collect the fine, it did not accomplish the purpose of the fine by altering the company's polluting activity. If the fines and penalties are too heavy, the penalized company may close its facility and move elsewhere. While the closed or moved company would certainly not pollute anymore, the negative economic impact on the locale would most definitely be a heavy and unwanted consequence of the government action.

There are times when government failure occurs because the regulations being imposed are outdated. In those cases, it is up to the government to update or eliminate its policies. Sometimes this occurs through the government itself taking action, as happened when the federal government deregulated the airline industry and eliminated the Civil Aeronautics Board. At other times, the courts have imposed actions on the government to take, as with the communications industry and the federal government giving monopoly power to AT&T (see 1994 Supreme

Court case *MCI Telecommunications Corp. v. American Telephone and Telegraph Co.*). This type of government failure is also seen at the local level, as communities grow, or shrink, and current local policies either inhibit growth or prevent a community from addressing a changing demographic or geographic disparity. Many Midwest communities—such as Detroit, Michigan, and Dayton, Ohio—have experienced this type of government failure as they have tried to transform themselves for the future economy.

Interestingly, there have also been times in history when government action can be seen as a government failure through government interfering and regulating a market that did not exist. The famous Yak Fat Caper of the Interstate Commerce Commission (ICC) is one example. While it could be considered a government failure, there were no serious consequences to the action outside of some embarrassing moments for the ICC.

GOVERNMENT FINANCE, STATE AND LOCAL

Without taxes, state and local governments would not have the revenue to provide public goods and services. With no money, state and local governments could not function and provide the goods and services that are used every day.

Public goods and services are important components of every economy at every level. All governments—federal, state, or local—need money to function and to provide the public goods a society has entrusted a government to provide. To finance public-sector activities, state and local governments have these sources of funding available: user fees, taxes, and borrowing.

One revenue source that is implemented by most state and local governments is user fees. These are fees that citizens pay directly to the government for the use of public facilities, including highway tolls, fines, public golf course green fees, fishing and hunting licenses, and state and local park entrance fees. While all of these are important to financing government activities, they do not bring in a very large part of the overall funding that state and local governments need to operate.

A more effective method of funding is taxation. In fact, taxation is the most common source of funding for state and local governments. Every tax has a tax base; there are three of them: consumption (sales tax); current income (income tax); and accumulated wealth, or property (property tax). The primary tax bases for *state* governments are current income (income tax) and consumption (sales tax), while the primary tax base for *local* governments is property (property tax). Some major cities also use current income (income tax) and some consumption (sales tax) to generate revenue.

A third source of public funding for state and local governments is to borrow through the financial markets. Often, a state or local government or governmental entity (for example, the public school system) will want to build a new building or add infrastructure such as new roads or bridges. To fund such a large project would not be possible through normal annual budget channels. The governmental unit will offer a bond (a loan) to the public through the financial markets to generate additional revenue for the construction of the public infrastructure. Both citizens and other countries may loan the state or local governmental unit money by purchasing the bonds. A bond is a loan, and it must be paid back with interest, so borrowing is only a temporary solution to be used for special circumstances. All money borrowed must be returned eventually, and at an even greater expense.

GRAMM-LEACH-BLILEY ACT

The Gramm-Leach-Bliley Act (GLB Act, or GLBA), also known as the Financial Modernization Act of 1999, is a federal law enacted in the United States to control the ways in which financial institutions handle the private information of individuals. In its entirety, the act consists of three sections: the "Financial Privacy Rule," which regulates the collection and disclosure of private financial information; the "Safeguards Rule," which guarantees that financial institutions must implement security programs to protect such private information; and the "Pretexting Provisions," which prohibits the practice of accessing private information under false pretenses. Additionally, the act requires financial institutions to give customers a written privacy notice that details all aspects of the institution's information-sharing practices.

Historically, the GLB Act can be traced to the separation of banks, brokerage companies, and insurance companies. In 1933, after the financial failures of the Great Depression, Congress passed the Glass-Steagall Act, which prohibited national and state banks from affiliating with securities companies. Then, in 1956, Congress passed the Bank Holding Company Act, which prohibited banks from controlling nonbank companies. This act was amended in 1982, when Congress forbade banks from partaking in general insurance underwriting or agency activities. This changed in 1999, when the GLB Act repealed different sections of these prior acts, ultimately allowing banks to engage in a wide range of financial services.

The problem with such mergers had to do with significant privacy risks. With these mergers being permitted, new financial institutions would gain access to an enormous amount of customers' personal information with virtually no restrictions upon its use. To illustrate, prior to the GLB Act, the finance company that maintained ones' health records was distinct from the bank that mortgaged ones' house, or the stockbroker that traded ones' stocks. Yet after the GLB Act, these institutions would be able to consolidate the private, personal information of their customers, in addition to being able to analyze and sell that personal information. As a result of these potential privacy risks, the GLB Act contains several elements that protect the personal data of individuals.

Because of the GLB Act, financial institutions are required to develop safeguards to ensure the security and confidentiality of customer records and information, to protect against any potential threats or hazards to the security or integrity of personal records, and to protect against unauthorized access or use of such private records or information that could result in harm or inconvenience to a customer. This regulation is required, whether financial institutions choose to disclose personal information or not.

Also because of the GLB Act, financial institutions are required to provide customers with notice of the institution's sharing policy. The notice should outline the details of the institution's policies on disclosing nonpublic personal information (NPI) to third parties, disclosing NPI after the customer relationship is terminated, and protecting NPI. *NPI* is described as all information on applications to obtain financial services and all information on account histories, as well as the simple fact that the individual was a customer.

The GLB Act gives consumers the right to opt out from a limited amount of NPI sharing. Specifically, a customer has the right to direct the financial institution to not share information with unaffiliated companies. However, customers have no right under the GLB Act to stop institutions from sharing NPI among affiliates. An *affiliate* is any company that controls, is controlled by, or is under common control with another company. Under this jurisdiction the individual consumer has no control over the trading of personal information among these related entities.

Financial institutions are also prohibited from disclosing access codes or account numbers to any nonaffiliated third party for the purpose of telemarketing, direct mail marketing, or other marketing through electronic mail. Even if a customer fails to "opt out" of a financial institution's transfers, personal information such as credit card numbers, PINs, or other access codes cannot be sold.

The GLB Act prohibited specific types of pretexting. *Pretexting* is the practice of collecting personal information under false pretenses. As an example, a pretexter would be an individual posing as an authority figure—such as a law enforcement agent, a social worker, or a potential employer—and attempting to lure people with fictitious stories in order to obtain personal information about the person. The GLB Act prohibits the use of false, fictitious, or fraudulent statements or documents to get customer information either from a financial institution or from the individual customers themselves. The GLB Act also prohibits the use of forged, counterfeit, lost, or stolen documents to get customer information from a financial institution or from individual customers of the financial institution.

The GLB Act prohibits asking an individual to retrieve someone else's information using false, fictitious, or fraudulent documents.

GRANT'S RECESSION, 1869

Grant's recession, named after President Ulysses S. Grant, was one of America's mildest recessions. Some of it was the result of the natural contraction in the economy after the Civil War, but it is best remembered for the first "Black Friday," when the gold market in New York crashed on September 24, 1869. The crash was the result of an economic scam and a political scandal. The stock market plummeted 20 percent, and agricultural products plummeted 50 percent. The crash caused a short but severe disruption in the economy. The railroad industry slowed as well, in part due to overexpansion and railroad industry's role in the gold market. Grant's recession would eventually lay the groundwork for the panic of 1873.

The crisis of 1869 was rooted in the expansion of credit to finance the Civil War. The North had large gold reserves before the war, but these were quickly used up in the first two years of the war. In 1862, the Legal Tender Act permitted the use of paper money and took the government off the gold standard. The act authorized the printing of more than $150 million in paper money, known as "greenbacks," issued with little gold or silver backing. Such a rapid expansion of credit created massive inflation as the war ended. After the war, greenback dollars dropped in value to 35 cents in equivalent gold. The low gold value of the greenback gave the government an opportunity to use its remaining gold to pay off the war debt.

The Grant administration decided to start using gold for a debt payback plan. Because the government controlled most of the gold market, it, in turn, controlled the price. However, speculators could make money if they could discover when the government planned to sell. The government's general plan for selling gold was far from secret, but speculators such as railroad barons James Fisk and Jay Gould had an insider in the administration, financier Abel Corbin, who was Grant's brother-in-law and was close to him. Fisk and Gould arranged that Corbin would, in Grant's presence, argue against the government selling gold. Corbin also persuaded Grant to appoint his friend Daniel Butterfield assistant treasurer of the United States. Butterfield then plotted with Fisk and Gould to corner the gold market by tipping them off when the government was to sell gold. Quietly, Fisk and Gould proceeded to corner the gold market by buying massive amounts.

By the end of August 1869, the government payback plan had proven very successful. The money supply and the price of gold remained steady as $50 million of the national debt was reduced. The government varied its moves in the market, believing, based on the market indicators, they had held off speculation. Fisk and Gould, however, with their inside information, were sitting on a mountain of low-priced gold. It was only with the rapid rise in the gold price in late September that the government became aware of their scam. One tip-off was the brazen attempt to include more government officials in the scam.

As Grant implemented his payback plan, gold had started to drop in value. Fisk and Gould would move in and buy at these low prices, which reached $130 an ounce. Prices started to rise as the Fisk and Gould group hoarded gold. The government had hoped to sell about $4 million of gold, but the total gold market was small, around $15 million. Fisk and Gould had gained control of the market. They could now drive the price of gold up, making a huge profit.

Slowly the price of gold started to rise, with the aid of hoarding by speculators. By late in the year, a Double Eagle $20 gold piece was worth $26 in gold. In September, gold hit a high of $162 an ounce (a high that would take 100 years to hit again). Once the government fully realized (or discovered) what was happening, Grant ordered $4 million of gold to be sold. As the government gold hit the market, a selling panic set in. The price plummeted in a few minutes, destroying many uninformed speculators. Grant's brother-in-law went bankrupt, though Fisk and Gould were able to escape with little harm. The stock market followed with its own crash, spreading the harm to innocent investors. A large number of brokerage houses were pulled into bankruptcy.

The crash of the gold market caused a major decline in wheat prices. In 1869, the American harvest had been bountiful, and farmers had hoped to sell wheat in Europe at high prices. Instead, farmers found a depressed wheat market that resulted in major financial losses for many of them. As the stock market crashed, industrial orders were canceled, and industry would be paralyzed until the start of 1870. Because the underlying foundation of the economy was strong, however, industry returned to production once the stock market also returned to normal.

The railroads, however, were severely slowed in their expansion. In addition, the government corruption would hurt the ability of the United States to get cheap money for its rebuilding after the war.

GREAT RECESSION OF 1896

The great recession of 1896, better known as the Panic of 1896, was a slight economic depression pre–World War I, caused by the drop in gold reserves and the market concerns about the effects the drop would have on the gold standard. During the panic, business activity declined across the economy and unemployment rates increased. The panic dated from December 1895 to June 1897.

The panic can be characterized as a slowing rate of increase of the world's stock of gold, an increase in the number of countries on the gold standard, and a higher growth rate of total economic output. These several factors resulted in a deflationary period from 1875 to 1896. Additionally, the growth rate on real output was greater than the growth rate of the money supply during this period, which resulted in pressures on the nominal price.

Prior to the deflationary period, the United States was under a *bimetallistic* standard, a monetary standard established as a fixed rate of exchange using both gold and silver. However, the Coinage Act of 1873 demonetized silver, and the Resumption Act of 1875 further established the gold standard. During this deflationary period, political movements urging departure from the gold standard were increasing, as the United States needed an increase in the money supply in order to stop deflation. As farmers started to become unable to pay their debts without lower prices, and silver producers were hit by lower silver prices, people formed the People's Party and the National Silver Party. As the Treasury's gold reserve continued to drop, the public began to worry about the maintenance of the gold standard, established by the Sherman Silver Purchase Act of 1890. This resulted in even more pressure on the gold reserves.

In July of 1986, the Democratic Party nominated William Jennings Bryan as its candidate for the 1896 presidential election. This nomination further intensified the movement toward silver because of Bryan's "free coinage of silver" position. After Bryan's nomination, the demand for foreign exchange increased as dollar holders wanted to convert their dollars to gold first, resulting in more pressure on gold reserves. The election simply made matters worse and accelerated the net gold outflows.

Another differing theory on the cause of the panic is the fluctuations in the cotton harvest due to such external variables as weather. The poor cotton harvest of 1896 caused a decrease in the export of cotton and a decline in the inflow of gold. Therefore the cotton harvest could have contributed to the panic through the decrease in reserves and stock price decline. The revenue resulting from the export of cotton accounted for a large portion of the country's total merchandise export revenue, so it could very well be one of the factors that changed the business cycled and resulted in the panic.

Ultimately, in order to stop the gold outflows, a group of gold-shipping and foreign exchange houses agreed to blow the outflows of gold. The group borrowed funds in foreign currencies and exchanged it with the American investors wanting foreign currency. People transferred their other currencies without first converting them to gold, and the decline in the gold reserves was managed. Additionally, when the cotton harvest came to an end in 1896, crop export season started and resulted in an inflow of gold.

GREAT RECESSION, 2009

The stock market crash of 2008 was driven by the collapse of subprime mortgage investments throughout the world. The next few years would be known as the "Great Recession." The Great Recession would rival the Great Depression of the 1930s in many aspects. It has produced misery approaching the levels of the 1930s, and a full analysis of the causes will continue for years. Still, the origins and effects of the Great Recession have many similarities to those of previous recessions.

The official start of the Great Recession has been tagged as December 2007 after a real estate bubble evolved into a financial crisis. But for Main Street America, it was the crash of the stock market in November 2008 that signaled the recession's start. The full accounting of negative effects of the recession is not complete; but based on the drop in U.S. gross national product, it is the greatest recession since the 1930s. The unemployment rate would approach 9 percent, and other measures of unemployment and underemployment saw rates at Depression levels. Although the analysis of the causes and effects is incomplete, the place of the Great Recession in history is ensured.

The stock market hit a record high of 14,164 on the Dow Jones Average on October 11, 2007, before starting its decline. In October 2008 the stock market continued to slide and bank failures increased. In November 2008, the crisis came to Main Street as unemployment claims jumped to a seven-year high. The decline in market value by as much as 40 percent or more had small investors with individual retirement accounts in shock. Declines in housing and the stock market had slowed consumer spending to a trickle. AIG and other financial companies needed more money to prevent bankruptcy, and Congress was looking at loans for American carmakers facing potential bankruptcy. Citigroup needed a government loan of $20 billion to keep it from going under. The carmakers got their loans in December, and Citigroup was forced to merge with Morgan Stanley.

The stock market declined in 2009, plunging below 7,000 on the Dow. Runs at money market mutual funds required the government to insure them. The Federal Reserve used all its tools to flood cash into the system. Congress passed the Economic Recovery and Reinvestment Act in February 2009, and it was signed by President Obama. The cost was more than $800 billion and spread money in various directions. Some of the largest spending, more than $100 billion, went to education; health care received more than $150 billion and renewable energy more than $70 billion. Infrastructure, which focused on job creation, directly received more than $47 billion. Another $50 billion targeted aid to low-income and unemployed workers. Total spending exceeded $520 billion. Tax changes accounted for another $270 billion.

In addition, the Federal Reserve moved to push interest rates to near zero by putting more money in circulation and buying Treasury bonds. Many suggest that the movement of money via the Federal Reserve and government spending prevented the economy from going over the cliff. European countries had to implement similar plans and bailouts. This huge influx of government funds into the system was based on the lessons of the Great Depression, when the government had been slow to react.

Most agree, however, that the stimulus did little to prevent the Great Recession. The total damage of the Great Recession to employment has eluded traditional measures. Employment losses to college graduates and American youth far exceeded those of the 1930s. The basic calculations were changed, and the large number of workers who gave up job-hunting or took Social Security early was not fully accounted for in the figures. Many other workers escaped the unemployment rolls by filing for disability or welfare payments, both of which saw dramatic increases during the recession. The unemployment rate did not bounce back quickly, as it had in earlier recessions, but behaved more like unemployment in the 1930s. Some of that resistance to improvement was that America was operating in a global market and the recession drove consumers to buy cheaper imported durable goods instead of American-made products. Globalization and deindustrialization had greatly reduced the resiliency of the American economy.

The problems of the recession would continue even as the banking system was stabilized. *Bloomberg News* estimated that more than $14 trillion of global company value was eliminated in 2009. Although the recession continued worldwide into 2010, China, South Korea, and India appear to have avoided recession. Iceland suffered a total collapse of its banking system. The United States lost more than 4 percent of its total gross domestic product (GDP). Europe was hit much harder, with GDP losses in excess of 6 percent. One feature of the prerecession problems was the rise of a worldwide housing bubble.

GREAT SOCIETY

There are moments in history when time seems to stand still. For people who are old enough to remember, those moments are etched in their memory—exactly where they were and what they were doing. The day President John F. Kennedy was assassinated—November 22, 1963—was one of those days. History took a turn with that fateful event. With the assassination of President Kennedy, Lyndon Baines Johnson became president of the United States. The new president began to implement his agenda for civil rights, urban renewal, and lifting the general welfare of U.S. citizens. The Great Society is commonly seen as the most far-reaching agenda of domestic legislation since the New Deal. The beginnings of this new agenda can be found in speeches President Johnson gave in 1964 at Ohio University and the University of Michigan.

The 1964 election was a definite choice between different approaches to government's participation in the U.S. economy. President Johnson's Great Society initiatives and Barry Goldwater's promise to reduce the size and reach of the federal government in the 1964 presidential election were both ideologically and pragmatically polar opposites. The voters' choice was clear. Johnson won 46 states, capturing 61 percent of the popular vote. Johnson was secure with such a margin of victory; he had a mandate and the support of the American people. In his 1965 State of the Union address, he proposed his plans for a Great Society. With a cooperative Congress, his plans moved quickly, and many new government programs were legislated. Roosevelt had introduced society to the New Deal; Johnson introduced it to the Great Society. First, however, he completed the legacy of President Kennedy with the passing of the Civil Rights Act in 1964.

As expected, many aspects of U.S. life were impacted by the programs Johnson launched in the name of the Great Society. Foremost was the Economic Opportunity Act of 1964. The act created two new agencies to address the economic and social needs of those in poverty. The Job Corps and Volunteers in Service to America (VISTA) were created to fight poverty at home. The Job Corps was initiated to help young people ages 16 to 24 receive vocational training. VISTA had the look of President Kennedy's Peace Corps, only with a domestic agenda, as young people were trained and placed in the poverty-stricken urban and rural areas of the United States to assist with uplifting the living standards regarding the most basic human needs. The Economic Opportunity Act of 1964 also made loans available to farmers, small businesses, and community programs to fight poverty.

A second major area of American life impacted by the Great Society was the entire educational spectrum—from primary to secondary to higher education. At the preschool level, Head Start was launched as a preschool summer program to prepare low-income children for school, with focus on such areas as basic early childhood education, the importance of parental involvement, health, hygiene, and nutrition. In 1965, the Elementary and Secondary Education Act funded federal programs for the first time in elementary and secondary education. The Higher Education Act provided financial assistance to those wishing to pursue a college education. The private sector had the Job Corps; education now had the National Teacher Corps through the Higher Education Act.

In the 1960s, the United States was changing from an urban society to a suburban one. The civil rights movement was having an impact on the nation's urban areas. A third area addressed by the Great Society was urban renewal and conservation. With the signing of the Housing and Urban Development Act of 1965, Johnson created the Department of Housing and Urban Development (HUD). This act greatly increased federal funding for public housing in urban areas and addressed the needs of blighted urban areas. On the conservation side, Johnson increased federal funding to regulate water and air quality with the Highway Beautification Act.

Access to health care was another endeavor of the Great Society, especially for two specific groups: low-income families and senior citizens. For many, these two groups were one and the same. For the low-income population, the Great Society provided Medicaid, and for senior citizens it provided Medicare. Medicaid and Medicare made medical care both accessible and affordable for these two groups. In the case of Medicare, all evidence through the years has shown that it has positively impacted the standard of living of senior citizens.

The architect for much of Johnson's Great Society was Republican John Gardner. Gardner was selected by Johnson to lead the Department of Health, Education, and Welfare. President Johnson had the vision and ideas for the Great Society. John Gardner, as head of Health, Education, and Welfare, had the implementation know-how.

Many of the programs started during the Johnson administration as part of the Great Society are still operational federal programs. Programs such as Medicare and Medicaid, Head Start, and the Elementary and Secondary Education Acts are government programs that are part of the American fabric. Of course, many of these programs, as with any government program, have their critics, who believe government is overreaching into these areas of our life. But their impact on American life since the mid-1960s cannot be denied.

GREENSPAN, ALAN

Born: March 6, 1926, in New York City; Nationality: American; Professional Interests: monetary policy, chairman of the Federal Reserve System, 1987–2006; Major Works: *The Age of Turbulence: Adventures in a New World* (2007), *The Map and the Territory 2.0: Risk, Human Nature, and the Future of Forecasting* (2014).

Alan Greenspan served an unprecedented five terms as chairman of the Federal Reserve System ("the Fed"). While chairman, he experienced the stock market crash of 1987, fallout from the savings and loan (S&L) scandal, a record increase in the market, and finally the bursting of the dot-com and housing bubbles. He is a fiscal conservative, believing in free-market economics. He believes in creative destruction—that is, allowing some companies to fail, freeing resources for newer companies.

Alan Greenspan was born in Washington Heights, New York City, on March 6, 1926. He received training at the Juilliard School in 1943 (clarinet) before enrolling at New York University (NYU) in 1944, receiving his bachelor of science (1948) and master of arts (1950). His pursuit of a PhD from NYU was interrupted by his work experience, but he would earn the degree in 1977.

Greenspan began his career in 1950 with the National Industrial Conference Board. He gained political attention for his research of the Defense Department's use of metal, twice published in the *Business Record.* In 1953, he formed a partnership with William Townsend called the Townsend–Greenspan Company. During this time, he met Objectivist and author Ayn Rand, and he was greatly influenced by her views. He wrote several articles in the 1960s for Rand's *The Objectivist Newsletter*, and she included essays by him in her collection called *Capitalism: The Unknown Ideal.*

Greenspan's first political post was in 1967, working as a volunteer economic and domestic policy adviser for Richard Nixon's 1968 presidential campaign. He worked on the Commission on an All-Volunteer Armed Force that worked to abolish the draft in 1970. Just before President Nixon resigned in 1974, Greenspan became chairman of the Council of Economic Advisers, serving as an economic adviser to the president. He remained on the council through Gerald Ford's administration, helping to devise policies to fight inflation and unemployment. In 1980, he helped Ronald Reagan's campaign. He served on the Economic Policy Board and later worked to overhaul Social Security.

When President Reagan appointed him chairman of the Fed in 1987, Greenspan inherited a national situation that had seen vast increases in the stock market and a tripling of the federal deficit under Reagan, plus an increase in inflation, measured by the Consumer Price Index (CPI). When Greenspan increased interest rates in September 1987, the stock market experienced its largest single-day drop (508 points)—on Black Monday, October 19, 1987. The Fed responded by buying billions of dollars of Treasury securities (increasing liquidity), encouraging lending by the Fed's member banks. The markets began to stabilize by November, and growth resumed in the first quarter of 1988.

Greenspan continued his role as chairman of the Fed into the George H. W. Bush administration, though his relationship with the president was more strained under a difficult economy. Greenspan worked with the Resolution Trust Corporation to resolve issues with the savings and loan (S&L) scandals of the late 1980s, which resulted in the federal government being saddled with about $87 billion in losses, less than expected. The recession continued into the 1990s despite the Fed lowering interest rates. The administration wanted rates cut lower, but Greenspan believed that the short-term benefit would quickly lead to a long-term inflation problem. Bush reappointed Greenspan as chairman of the Fed in 1991.

Under President Clinton, Greenspan encouraged passage of a 1993 budget that would begin to reverse the trend of steadily rising national debt. Greenspan believed this was necessary to encourage businesses to invest more, and he allowed the Fed to lower rates to sustain long-term growth. Under pressure from Congress to allow more transparency, Greenspan agreed to announce immediate moves of the Federal Open Market Committee. The Fed raised interest rates a quarter point in 1994 as a preemptive strike against inflation, the first increase in five years. The stock market grew amid the dot-com boom of the late 1990s, and Greenspan warned of irrational exuberance in investing. He believed the boom would not last long. Clinton reappointed Greenspan in 1996 and 2000 under a strong economy. As the dot-com bubble was bursting in 2000, Greenspan believed that the growing surplus of the federal budget should be used to pay down the national debt, and that "triggers" should be implemented to prevent a reversal in the surplus.

Under George W. Bush, following the attacks on the United States on September 11, 2001, and in response to recession, the Fed cut interest rates several times to stimulate the economy. Greenspan disagreed with the president's plans to continue to cut taxes to stimulate the economy, figuring it was more important to control the deficit, and he was displeased with the president's unwillingness to veto spending bills.

Greenspan is often criticized for politicizing the Fed. Despite being a libertarian Republican, he often praised both parties when they acted in a fiscally conservative manner. He also received criticism for the economic downturn of the 2000s, with many claiming his monetary policy was too lax. Since finishing his record fifth term as Fed chairman, Greenspan has accepted some responsibility for the problems related to the economy that could be linked to the Fed.

GRESHAM'S LAW

Simply put, *Gresham's Law* states that if a new coin is assigned the same face value as an older coin whose contents contain a larger amount of precious metal, then the new coin or "bad money" will be used in circulation while the old coin or "good money" will be saved and will vanish from circulation.

Sir Thomas Gresham lived from 1518/19 to 1579 as an English merchant and financier. Although Gresham was not the first to discover the "good" and "bad" money instability, he was responsible for informing Queen Elizabeth I of the principle, and thus, the law has been associated with him. Gresham worked for the English government; it is believed that he provided intelligence, smuggled precious metals, and negotiated with England's foreign creditors. Gresham operated a foreign-exchange market in England to relieve exchange fluctuations caused when the country repaid its loans and interest to foreign creditors. The government has the power to affect the exchange rate, and Gresham might have been ahead of his time in understanding that power.

To understand this rationale, we must first examine the history of coins as money. Coins were originally made from precious metals such as gold and silver. This is how they received their value. However, it was realized that these precious metals have a much higher value in their natural state than they have when they are contorted into coins.

Money isn't just a medium of exchange; it is also used as a commodity and a store of value. Given money's intrinsic dual role, if a particular kind of money is worth more due to its precious metal content, that money will be set aside and used as a store of value as opposed to a medium of exchange.

In today's society, an example of Gresham's Law can be seen in the U.S. nickel. The coin has a nominal value worth five cents. However, the value of the amount of nickel used to produce that five-cent coin in 2010 was actually valued at six cents. To combat this difference, the U.S. government was expected to alter the composition of the nickel. Ultimately they used less nickel and more of another metal, copper, to prevent Gresham's Law from taking over the currency.

In the 2001 U.S. budget, a provision was established to address the composition of coins and to prevent the application of Gresham's Law. While the law was not referred to directly, the provision authorized the Department of the Treasury to research and analyze new materials considered to be less expensive, in order to create a coin with real value at a cost-effective price to the government.

GROSS DOMESTIC PRODUCT

Gross domestic product (GDP) is the main measurement of the size of a nation's economy. It represents the market value of all final goods and services produced within a country in a given year. It is an important economic indicator that measures the total economic output of a country. In general, a growing GDP is considered a sign of positive economic health.

In the United States, the job of calculating GDP falls to the Bureau of Economic Analysis (BEA), within the Department of Commerce. The BEA publishes its findings quarterly, and its comprehensive report is closely watched by the chief architects of both fiscal and monetary policy, as well as by the business sector. The economists who measure GDP can do so through an income method, a value-added approach, and an expenditure method.

In the *income* approach, GDP is measured as the sum of the incomes earned and the costs incurred in production. In the *value-added* approach, economists add the "value added" at each stage of the production process (equivalent to the total sales minus the value of the intermediate inputs).

In the *expenditure* method—the most common of the three methods—GDP is calculated by adding together the final value of goods and services in the four main sectors of the economy: household consumption (C), business investment (I), government purchases (G), and the net of exports minus imports (NX): GDP = $C + I + G + (NX)$.

Only "final" products are calculated: goods or services that are at the last stage before consumption, rather than intermediate goods, which are inputs in the production process. If intermediate goods were included in the GDP calculation, it would overstate the value of production by counting products several times before they reached their final form in the market. So economists rely on the final value of goods and services only. The calculation results in a figure known as nominal, or "current dollar," GDP, which reflects the output of the economy in current prices, demonstrating the purchasing power of dollars in the year they are spent.

Nominal GDP does not take inflation into account, so it is impossible to know, when comparing nominal GDP from year to year, how much of the growth is a result of inflation and how much is an increase in real output. To compensate for the effects of inflation, the BEA also calculates real GDP, which shows the value of an economy's output in constant dollars. Real GDP allows economists to compare GDP from year to year to show the rate of growth. For example, the Commerce Department's report for the second quarter of 2013 showed that real GDP increased at a rate of 2.5 percent. This means that even accounting for inflation of the dollar, there was growth in the overall size of the U.S. economy from the first quarter of the year to the second quarter. Each GDP report also explains the reasons for the growth or decline by identifying the segment(s) of the economy that changed the most, such as business investment, consumer spending, or government expenditures. Real GDP is the best measurement for showing economic growth over time.

It is also important to note that GDP includes only those goods produced within the United States. It includes the output of foreign companies producing within the United States, but it does not include the output of U.S. companies producing in foreign countries.

Economists can also adjust the GDP for population, which allows them to compare the economies of individual countries. Per capita GDP takes population into account by counting GDP "per person," rather than the total amount for the country as a whole. This calculation involves taking a country's real GDP and dividing it by the population. This calculation is often used to determine a nation's standard of living. It is the most accurate measurement when comparing the GDPs of various countries, because it averages it out over the number of people living in that country. An example: China's GDP may seem significant at over $8 trillion (2012), but when that number is dividing up over the substantial number of people living in China, it averages to a per capita GDP of $6,188. When compared to the total GDP of the United Kingdom, which is $2 trillion, China's GDP might appear larger, but upon calculating the U.K.'s per capita rate of $38,000, China's GDP is considerably lower (see http://data.worldbank.org/).

While GDP is a widely accepted calculation for determining a country's economic health, there are limitations to GDP as an economic indicator. For instance, GDP does not take all productive activity into account. Economic activity that is not completed in the market, such as a homeowner's work on his or her personal home or an unpaid volunteer's work, is not included in the calculation. It also does not include leisure time, which is indicative of the overall well-being and satisfaction within a nation. Thus, GDP is understated. GDP also does not include the underground, or black market, economy—such as the activities of gamblers, smugglers, or drug dealers—in its calculations. Additionally, GDP does not take into account improvements in product quality over time. It does not consider the by-products of increased production, such as environmental harm. The calculation also does not identify how the output is actually distributed, so even per capita GDP fails to indicate the size of the gap between the wealthy and the poor.

It is commonly noted that as per capita GDP increases, so too do other factors associated with a higher standard of living, including the literacy rate and life expectancy. The infant mortality rate also tends to decrease as GDP increases.

GDP varies throughout the phases of the business cycle. It increases during periods of growth, stops increasing at the peak of economic growth, decreases during periods of contraction, and stops decreasing at the trough. If GDP falls for more than six months (two consecutive quarters), economists define that as a recession. Periods of depression tend to be identified with an even more substantial plunge in real GDP.

GROSS NATIONAL INCOME

Gross national income (GNI) is the broadest measure of national income. The GNI, previously called the gross national product (GNP), is the people's total income derived from domestic and foreign sources. Thus, GNI includes gross domestic product (GDP) plus the net receipt of income from abroad. The *net receipt of income* is the difference between income inflows and income outflows each year. The cross-border income flows stem mainly from wages or salaries, and property income. The GNI per capita states people's average annual income by dividing the GNI by the country's population. Since 2000, the World Bank has used the GNI and GNI per capita to classify countries, to assess the relative size and economic well-being of countries, and to determine eligibility for loans or other assistance. The gross domestic product (GDP) and GDP per capita measurements are also widely used to determine the relative size of economies and the economic well-being of people.

The World Bank classifies the world's 208 economies by GNI per capita. This classification scheme identifies four categories of countries: low-income, lower middle-income, upper middle-income, and high-income. GNI per capita is not the sole criterion for determining a country's development status. Other development criteria include the size and sophistication of a nation's economic system. In 2004, all low-income and middle-income economies were classified as "developing countries or other emerging market economies." Some high-income economies, such as Bahrain, Brunei, Kuwait, Monaco, Qatar, Slovenia, and the United Arab Emirates, were also identified as developing countries or other emerging market economies, because their economies lacked the size or sophistication to be considered advanced. Just 29 high-income economies out of 208 total economies were classified as advanced.

Measuring income inequality in the global economy is a tricky business. Measurements that use the traditional exchange rate GNI per capita show that people in high-income economies ($38,352) had nearly 7 times the average income of people living in the upper middle-income countries ($6,247), 20 times the income of people in lower middle-income countries ($1,716), and 63 times the income of people living in the low-income countries ($526).

Measurements of GNI per capita on a purchasing power parity (PPP) basis narrow the income gap between rich and poor nations. PPP accounts for differences in money's buying power around the world. The PPP GNI per capita shows that people living in high-income countries ($38,392) were just 3 times richer than people living in upper middle-income countries ($6,247), 5 times richer than people in lower middle-income countries ($5,640), and 14 times richer than people in low-income countries ($2,260).

The GNI per capita offers a basis for national comparisons of economic well-being. Yet, there are limitations to this approach to national income accounting. First, national income data ignore most business activity in the informal sector. As a result, official GNI data often understate national income. Second, income data are often unreliable. In recent years, the International Monetary Fund (IMF), World

Bank, and other multilateral organizations have extended technical assistance to strengthen data collection and analysis in the developing world. Third, GNI per capita does not assess the actual distribution of national income. The uneven distribution of income within nations is especially severe in African and Latin American countries.

GROSS NATIONAL PRODUCT

Gross national product (GNP) is the measurement of all the final goods and services produced by the companies of a country regardless of where the goods and services are produced. There are several differences between GDP (gross domestic product) and GNP. It is important to understand why GNP is such an important factor for a country's economy purposes. GNP measures the total output of a nation's economy regardless of geography. GDP measures total output within a nation's borders. A Ford car built in England counts toward U.S. GNP because Ford is a U.S. company. However, that same car built in England does not count toward GDP because it was built outside the borders of the United States. Conversely, a Honda built in the United States counts toward U.S. GDP but not GNP because Honda is not a U.S.-headquartered or U.S.-based company. GNP is more concerned with the "by whom" and GDP more concerned with the "where."

Although they both measure the amount of final goods and services that are being produced, GDP and GNP are different concepts in the way that each infers what constitutes an economy. GDP focuses on levels of domestic measurements, while GNP focuses more on how much the companies of a country produce. GNP is often referred to as the national output count. Depending on a country's comparable measure between the domestic and foreign manufactures, occasionally GNP will change between being higher or lower than GDP. Although GDP is more commonly used to measure the goods and services, GNP is also important because it shows the country's overall economy.

GNP is usually measured once a year, at the same time each year. It measures all of the goods and services that were produced within that year. There are two options for taking that measure. First, there is the buyer's point of view, also known as the aggregate demand (AD). This method adds the following: consumption (C), investment (I), government purchases (G), and net exports ($X - M$) where X are exports and M are imports.

The second method, also known as the income approach, is from the seller's side. The major components include employee compensation (w), rental income (r), corporate profits (p), and interest income (i). This is based on payments due to labor, and an estimated 60 percent of U.S. employees are included in this.

Finally, GNP is a lot more valuable than most people think. The main point of GNP is that it shows the overall health of a country's economy. It shows the size and growth of a country's economic system. It is one of the most accurate indicators of whether a country's economic system is functioning well. It also is a way to compare one nation's economy with the economies of other nations. This could benefit some countries that are struggling, as they could seek advice from the countries with a healthy GNP. It helps economists find solutions to factors such as poverty or identify causes for low points in economic systems, such as inflation or deflation. Governments can cooperate with each other to improve the economic conditions of each country.

HAZLITT, HENRY

Born: November 28, 1894, in Philadelphia, Pennsylvania; Died: July 8, 1993, in Fairfield, Connecticut; Nationality: American; Professional Interests: economics, literary criticism; Major Works: *A New Constitution Now* (1942), *Economics in One Lesson* (1946), *The Failure of the "New Economics": An Analysis of the Keynesian Fallacies* (1959).

Henry Hazlitt was a journalist, writer, public intellectual, and determined supporter of free market and Austrian economics. Over his career, he wrote for several of the United States' leading newspapers and magazines, proving to be an eloquent expositor of the sometimes arcane arguments of his classical liberal heroes. Henry Hazlitt was a rare personality in the field of economics, having never earned a college degree. Nevertheless, he had an amazing talent for clearly and persuasively communicating complex ideas. Hazlitt died in 1993.

Henry Stuart Hazlitt was born November 28, 1894, in Philadelphia, Pennsylvania. His father, Stuart Hazlitt, died shortly after Henry was born. He was sent to Girard College, which was (and still is) a home and school for disadvantaged children. His mother remarried when he was nine, and the family moved to Brooklyn, New York. Henry sought to attend university to become a psychologist, but financial considerations led him to attend night classes at City College. Though the tuition was free, taking classes came with an opportunity cost. When his mother's second husband died, he quit college to support her.

Initially, Hazlitt went from job to job, unable to stay employed. In 1915, at the age of 20, he got a job with the *Wall Street Journal* as a stenographer. At about the same time, he wrote his first book, *Thinking as a Science*. In 1916, he joined the *New York Evening Post*. He served in World War I with the Army Air Services, and when the war ended he went back to being a newspaper columnist.

Hazlitt's most enduring work is *Economics in One Lesson*. The lesson itself is only five pages long and is explained in the chapter "The Lesson." He asserts that economics can be reduced to a single sentence. The art of economics consists in looking not merely at the immediate but at the longer effects of any act or policy, tracing the consequences of a policy to the consequences to all groups. The rest of the book proceeds to show how a lack of thinking through the side effects of policies impacts all kinds of real-life situations. He was critical of minimum wage laws, government price fixing, protectionism, stimulus spending, and make-work programs. He goes on to explain the role of prices and profits in coordinating economic activity, writing that the economy is like a giant machine made up of thousands of smaller machines. Each machine has its own self-correcting mechanisms, and tampering with the machine risks jamming or breaking it.

As an adherent of the Austrian School of economic thought, he deplored inflation. He became friends with Ludwig von Mises, who was a fugitive from Nazi-dominated Austria. Mises had experienced the post–World War I hyperinflation in Austria firsthand, and he promoted the view that inflation was a greater evil than unemployment—an opinion that was difficult to sell in an era when the United States was suffering from the Great Depression and the accompanying deflation. Hazlitt was one of Mises's few supporters at the time. Through Hazlitt, Mises's anti-Keynesian, anti-inflation, and pro–free market views appeared in the nation's newspapers every week.

Hazlitt's uncompromising support for free enterprise occasionally got him into trouble with his editors. Throughout the 1930s, Hazlitt used his column to criticize the New Deal. In the 1940s, his target became the Bretton Woods conference, a post–World War II effort to create a global money system based on the U.S. dollar. He regarded it as inflationary, and wrote as much in the *New York Times*. His editor indicated that Hazlitt was embarrassing the *Times* by writing against Bretton Woods when 43 governments were in favor of it. Hazlitt departed soon after this incident for employment at *Newsweek*.

By the end of his life, Hazlitt had written and edited for the *New York Evening Mail*, the *New York Sun, The Nation*, the *New York Times*, and *Newsweek*. He was also instrumental with start-up journals such as *The American Mercury* and *The Freeman*. He was a prolific author, writing 18 books over the course of his life in addition to thousands of newspaper and magazine articles. Not limiting himself to economics, he also wrote book reviews and literary critiques.

Henry Hazlitt died on July 8, 1993, in Fairfield, Connecticut, at the age of 98.

HECKMAN, JAMES

Born: April 19, 1944, in Chicago, Illinois; Nationality: American; Professional Interests: labor economics, econometrics, Nobel Prize (2000); Major Works: *Handbook of Econometrics* (2007), *Longitudinal Analysis of Labor Market Data* (2008), *Giving Kids a Fair Chance* (2013).

James Heckman is another in a long line of University of Chicago professors who were recipients of the Nobel Prize in Economics, winning the prize in 2000. Earlier, Heckman also received the John Bates Clark Medal in 1983. Heckman is one of the preeminent econometricians in economics. His economic models focus on a variety of economic topics: life cycle skill, inequality, behavioral, labor, social programs, income distribution, and regulation.

James Joseph Heckman was born on April 19, 1944, in the Hyde Park area of Chicago. Growing up in Chicago and Kentucky, Heckman attended high school in the Lakewood area of Denver, Colorado. While in high school he was introduced to the distinguished experimental physicist Frank Oppenheimer. A cattle rancher in Colorado, Oppenheimer introduced Heckman to physics, experimental science, and linking theory and evidence. Heckman has credited this relationship and these early experiences as a major experience in his intellectual development. Even though he chose economics over physics, his ability to bring theory and evidence was to serve him well in the field of econometrics.

Heckman's interest in economics was spawned at Colorado College, where he read the works of Adam Smith and David Ricardo and Paul Samuelson's *Foundations of Economic Analysis*. Heckman completed his doctoral work at Princeton University in 1971 and began his career at Columbia University. While at Columbia, Heckman was invited to join the National Bureau of Economic Research (NBER). Heckman was in his intellectual element at NBER, surrounded by a group of high-powered empirical scholars. The empirical environment was very exciting to a young Heckman. At NBER he was able to hone his econometric skills; data and theory were the priority for all the scholars at NBER. Heckman's research career and topics were formed during his time at NBER and Columbia.

In 1973, Heckman left Columbia and returned to his birthplace, Chicago, where he joined the faculty at the University of Chicago. Heckman found the environment at the University of Chicago intellectually stimulating and demanding.

During his career there, he developed a prestigious list of collaborators for both research and publishing, directing the University of Chicago's Economics Research Center and the Center for Social Program Evaluation at the Harris Graduate School of Public Policy Studies. Heckman also holds the Henry Schultz Distinguished Service Professor in Economics endowed chair. In addition, Heckman is the professor of science and society in University College Dublin and a senior research fellow at the American Bar Foundation. In 1991, the American Bar Foundation approached Heckman to research the impact of law on the economy.

While Heckman's research extends to a number of areas, one area that received public attention was his work on early childhood education. At NBER, Heckman took a special interest in researching the investments in early childhood programs and the impact of such programs. He determined that early intervention can make a difference in the life skills development of young children. Heckman's focus was on noncognitive skills of determination, social skills, and motivation, which lead to success.

Heckman devoted his career to the development of scientific foundations to evaluate economic policies. Specializing in models that focused on individuals and disaggregated groups, he was able to create new econometric models to address the special topics of his research. Heckman is especially recognized for his work in labor economics, as well as his work on the effectiveness of early childhood education programs. Policymakers have new understandings in areas of education, labor markets, civil rights, and job training because of the econometric modeling developed by Heckman.

Beyond receiving the 2000 Nobel Prize in Economics, Heckman is one of most honored and prized economists of the late 20th century. He won the prestigious John Bates Clark Medal in 1983. In 2005, Heckman was honored with the Jacob Mincer Award from the Society of Labor Economists and the Ulysses Medal from the University College Dublin. He has been granted prestigious fellow status of the Econometric Society, American Statistical Association, Society of Labor Economists, International Statistical Institute, and American Association for the Advancement of Science.

HELLER, WALTER

Born: August 27, 1915, in Buffalo, New York; Died: June 15, 1987, in Seattle, Washington; Nationality: American; Professional Interests: Keynesian, Council of Economic Advisers (1961–64); Major Work: *Monetary vs. Fiscal Policy* (with Milton Friedman) (1968).

Walter Heller is best known from his time working on the Council of Economic Advisers under presidents John F. Kennedy and Lyndon B. Johnson, from 1961 to 1964. He also was influential in the reconstruction of the West German economy after World War II while working as a tax adviser to the U.S. military government in Germany in 1947 and 1948. Heller returned to an earlier post with the University of Minnesota's Economics Department and retired a year before his death. Heller died in 1987.

Walter Wolfgang Heller was born on August 27, 1915, in Buffalo, New York, to German immigrant parents. His family moved to Washington State, before settling in Milwaukee, Wisconsin, when he was six. Heller received his BA in economics from Oberlin College in Ohio in 1935. He completed both an MA degree in 1938 and a PhD in 1941 at the University of Wisconsin, studying finance and taxation. He focused on state income tax laws for his dissertation, which he researched by touring 31 states, the District of Columbia, and Canada over the course of a year.

Heller spent the next 20 years varying his experience between government work and the education field, while becoming an expert on taxation. Between 1941 and 1945, he worked in tax research as a senior analyst in the Department of the Treasury. From 1945 until 1960, he was an associate professor at the University of Minnesota, missing time on occasion to perform various government jobs. In 1947, he spent a year in West Germany as chief of finance for the U.S. military government in West Germany, and he spent another year in West Germany in 1951 studying West German fiscal problems.

Heller's work in the 1950s acquainted him further with the U.S. government. During Eisenhower's administration, Heller appeared before Congress on several occasions to encourage more federal spending on education and other programs, while also encouraging Congress to raise taxes. In 1952, he began to consult the United Nations on issues of encouraging growth and development of underdeveloped countries. From 1955 to 1960, he was an economic adviser and consultant to the governor of Minnesota and that state's Department of Taxation. In a 1957 article, he criticized the Committee for Economic Development's plan to create flexible tax rates and expenditures to adjust for inflation and deflation as a plan that failed to adequately consider short-run economic forecasts. In 1960, he assisted the nation of Jordan in reforming its taxation and fiscal policies.

Heller was sought out by President-elect Kennedy in 1960 to become the chairman of the Council of Economic Advisers. One of Heller's main tasks would be to implement strategies to help the country get out of a slight recession that it had been in for about six months, though Heller linked the problem to a recession in 1957–1958 that the nation had not fully recovered from. Kennedy's main focus was to use the Employment Act of 1946—which stated that the federal government should enact fiscal policy to maintain high employment and which also created the Council of Economic Advisers—to its fullest potential.

Heller viewed the problem of recession was that an economy was not recovered until the nation's gross national product continued to rise above previous levels—and not just bounce back to what it was before. To do this, he was not concerned with a balanced budget but rather wanted to see more economic growth and unemployment down to around 4 percent, as opposed to the 7 percent in March 1961. One way he sought to attack this problem was by adjusting tax rates to eliminate loopholes and tax advantages for certain groups and lowering the tax range from 20–91 percent to 14–60 percent.

While working with Kennedy, Heller believed it was important to use forecasting tools to estimate how the economy was going to work. He also believed in the federal government's power to correct small problems with inflation and unemployment by spending more. He supported cutting taxes in 1962 to pick up the lagging economy, a measure that was also supported by Kennedy, who promised that it would be enacted as necessary. The actual cut in taxes did not occur until February 1964, after Kennedy's assassination.

Heller maintained his position initially as Lyndon Johnson finished Kennedy's term, but he resigned by the end of 1964. Early in the year, when Heller realized that cutting taxes was leading to higher inflation, he reversed his position and called for a tax increase, especially as U.S. involvement in Vietnam increased. Johnson did not take his advice. Heller's decision to leave his post, however, has been attributed more to his personal circumstances and not his disagreement with Johnson. He returned to teaching at the University of Minnesota.

One of Heller's best-known books, *Monetary vs. Fiscal Policy*, is a record of his debate with Milton Friedman at New York University in 1968: a friendly give-and-take between a supporter of monetary policy and a Keynesian. Heller also contributed to the *Wall Street Journal* and *Time* magazine. His ideas about the use of tax cuts to stimulate the economy would be embraced by Republicans in the 1980s, specifically by Ronald Reagan and "supply-side economists." He had been called an "educator of presidents."

Walter Heller died on June 15, 1987, in Seattle due to a heart attack at the age of 71.

HELVERING V. DAVIS

In *Helvering v. Davis*, 301 U.S. 619 (1937), the Supreme Court upheld the constitutionality of the Social Security Act of 1935. In upholding the Social Security Act, the case also expanded the role of the federal government into economic areas previously reserved for states and local and private entities.

The case must be viewed through the lens of the Great Depression. The devastation of this extreme market collapse brought social as well as economic and political changes to the fabric of American life. President Roosevelt offered the nation a "New Deal." Congress passed the Social Security Act of 1935, which provided income to the elderly, blind, unemployed, widowed, or orphaned, and launched other state health initiatives. Funds were appropriated that originated from employee income taxes as well as employer excise taxes. As a shareholder of a corporation subject to these taxes, Davis opposed them, claiming that they were in conflict with the 10th Amendment to the Constitution. Whether or not Social Security is the best remedy for business cycle aliments in a free market economy remains to be seen, but the constitutionality of the issue was resolved. This case set the stage for cooperative federalism and a new era in government involvement in the economy.

Case Summary

Historically, the city of Boston has not been a stranger to citizens who stand up to defend their property from governments that are eager to tax. George P. Davis may be a footnote in history, but his stand as a citizen to defend his property from what he believed was an unconstitutional tax is reminiscent of the Sons of Liberty dumping tea into Boston Harbor. In 1936, Davis owned a small number of stock shares in Edison Electric Illuminating Company in Boston, Massachusetts. Although he lacked large amounts of wealth, what assets he did possess he tended with diligence. At a time when many Americans sought governmental assistance to deal with the desperate consequences of the Great Depression, Davis was focused on keeping his equities clear of government encroachment.

In January 1937, Davis knew that Edison Electric was preparing to accommodate the employers' share of the payroll tax to fulfill its responsibility to the Social Security Act of 1935. This additional expenditure would diminish the company's bottom line—and Davis's equity. His objection to this tax was based on the Tenth Amendment to the Constitution, which reserves powers not delegated to the federal government to the states.

It was Davis's opinion that taking care of the elderly in a financial capacity was the domain of the state, and that therefore a federal excise tax was beyond the scope of the national government's powers.

Meanwhile, back in Washington, D.C., Congress and President Franklin Roosevelt were fighting to keep New Deal legislation alive. The president's landslide reelection signaled public support for Roosevelt's new economic policies. However, the Supreme Court, insulated from the necessity to respond to public opinion, continued to rule legislative reforms unconstitutional. In 1935, the Court declared the National Industrial Recovery Act and the Frazier-Lemke Farm Bankruptcy Act void. In 1936, the Court struck down the Agricultural Adjustment Act, stating on the same judicial principle that the federal government had overstepped its constitutional boundaries as set by the Framers.

Regardless of these setbacks, President Roosevelt proposed that Congress pass legislation that would give it the power to provide direct aid to states for the "general welfare." The 74th Congress passed the Social Security Act in an effort to assist indigent elderly, abandoned wives and children, and people suffering from the effects of extremely high unemployment and health issues, at both an individual and a public level. The plan included augmenting incomes and matching state monies with equal or greater federal assistance to alleviate hardships and stimulate a stagnant economy.

In summary, the Social Security Act looked like this: Title I covered grants for old-age assistance. Title II set up an account within the National Treasury to handle the monthly payments to qualified recipients. Title III spelled out details of the unemployment compensation. Title IV granted state aid to children who were abandoned or orphaned. Title V gave assistance to states for the health and welfare of crippled children. Title VI provided states money to set up public health facilities and to train workers. Title VII established a three-member Social Security Board, appointed by the president and confirmed by the Senate, to carry out the spirit of the law. Title VIII explained the Employee Income Tax and the Employer Excise Tax. It also detailed several jobs that are exempt from these taxes. Title IX explained the payroll exemption for employers with fewer than eight employees, or who employ their family. Title X granted assistance to blind people. Title XI defined all the terms of the act and included Alaska, Hawaii (both not yet states), and Washington, D.C. It also defined the separability of the act, whereby if any one part is found invalid it doesn't invalidate the other parts.

Until the Great Depression, with the exception of veterans' benefits, most of the aforesaid economic programs were the prerogative of state, local, or private endeavors. In 1936, the judiciary under the leadership of Chief Justice Charles Hughes adhered to a strict constitution doctrine (James Madison's idea of limiting federal usurpation of state powers). However, these were extraordinary times, and President Roosevelt proposed that Congress add one justice to the Supreme Court for every justice currently serving who had reached the age of 70. Increasing the Court from 9 justices to 15 would swing the balance in the president's favor. This proposal was met with bipartisan suspicion and indignation.

In the meantime, George Davis filed suit in district court to stop Edison Electric from paying the employer payroll tax and void the act. The government intervened on Edison's behalf, and Guy Helvering, commissioner of the Internal Revenue Department, took the case. The district court upheld the tax, and Davis appealed. The Federal Court of Appeals for the First Circuit reversed the district court, and Helvering requested that the Supreme Court take the case in order to establish the validity of the tax. The Court granted *certiorari* (request for a lower court to send the records of the case to the Supreme Court) and heard the case in May 1937.

In *Helvering v. Davis*, it was the responsibility of the Supreme Court to determine whether Social Security taxes were valid exercises of the taxing power in Article I, Section 8; whether providing the benefits was valid under the general welfare clause; and if Titles II and VIII of the Social Security Act were a valid use of the taxing power granted to Congress in the Constitution. Title II established the parameters for the payment of benefits for old-age assistance. Title VIII describes an income tax on employees and an excise tax on the employers that will fund the old-age assistance. Both taxes are with respect to income from wages for workers and having people in their employment and are measured by wages. Both taxes are paid to the U.S. Treasury and into the general revenue. No funds are earmarked. There are penalties for nonpayment. The federal government argued that the nation could not solve current complex issues facing the economy if it remained in 1789. Flexible interpretation of the Constitution allows the nation to progress and provide for the general welfare. New to the previous discussions advocating old-age assistance was the clarification by the government that these were indeed true taxes, and therefore valid exercises of Congress's power to tax. In addition, it concluded that the desperate situation of the elderly at this time was a problem too big for private charity or the state, and therefore needed to be addressed by the federal government to fulfill its obligation to promote the general welfare.

The respondent countered with the argument that if these taxes were truly intended to raise general revenue, taxing the lowest wage earners and stopping at an income of only $3,000 seemed counterintuitive. In addition, leaving out several categories of wage earners—for example, agricultural and domestic workers, government workers, and those who worked for charitable organizations—segregated the laborers who would be eligible to receive benefits. Furthermore, because the Tenth Amendment clearly reserves the power of the states to cover what is not expressly given to the federal government or denied to the states, the respondents concluded this was an unconstitutional power grab by Congress in violation of states' rights.

In a 7–2 vote, the Hughes Court broke from its previous conservative judicial philosophy. The Court disagreed with the respondent that Title II violated the Tenth Amendment. Congress is charged with maintaining the general welfare, and what defines that is apt to fluctuate with current events. More importantly, the Great Depression of the 1930s had created a national situation that demanded a national solution, and the wisdom of Congress, which heard testimony and reviewed evidence, should be deferred to. Justice Cardozo wrote the majority opinion, and Justice McReynolds and Justice Butler dissented.

Whether or not the Court acquiesced to Roosevelt's political arm-twisting due to the court-packing initiative is open to debate. Regardless, the decision ushered in the era of cooperative federalism, in which national, state, and local governments interacted collectively to solve problems. New Deal programs increased the flow of federal money to the states for a variety of purposes. These matching funds or grants of large sums of money often pulled states away from their priorities and made the national agenda more of a reality. This new relationship between the federal government and state governments that was ushered in with the New Deal and Social Security Act can be viewed through either a lens of coercion or one of cooperation. It remains to be seen if one lens is more accurate, or if indeed either has merit.

HYPERINFLATION

Hyperinflation does not mean just an increase in the supply of money. Hyperinflation occurs when a nation's increase in the money supply accelerates at an abnormal rate. The domestic currency loses significant value in a short amount of time. The loss of value impacts households buying power, value of savings and retirement accounts, and the real value of assets, such as homes and businesses, minimizes the amount each household is able to hold.

Hyperinflation occurs when a government significantly increases the money supply by borrowing money from its central bank or printing new money and investing the new money into the domestic economy. The new money is created when the bank buys bonds from the government, giving the central bank more money for the government to spend.

As the money supply of the country continues to increase, hyperinflation becomes real when citizens' holdings lose significant value. This constant movement of currency and increasing levels of pricing force the government to attempt to stabilize the country's economy. To stabilize the economy, most governments resort to printing more physical currency. Mismanagement and fraud within a government cause the cycle to continue until the currency has lost virtually all its usable value.

A 21st-century example of a country in the grips of hyperinflation is Zimbabwe. Zimbabwe's inflation is currently unlike inflation anywhere else in the world. Zimbabwean President Mugabe continued to print money to pay for his political promises. In 2008 the inflation rate was as high as 79,600,000,000 percent. One U.S. dollar is equivalent to nearly two and one-half billion Zimbabwean Kwacha. President Mugabe used the power of printing money to fulfill campaign promises such as land reform programs and war funding. In addition to these expenditures, the country's economic management was extremely poor, leading to a famine and the plummeting of foreign exchange profits.

Zimbabwe ultimately eliminated the Zimbabwean Kwacha and adopted the U.S. dollar. Later Zimbabwe also adopted the euro and the Chinese yuan for domestic economic transactions. The situation in Zimbabwe continues to be a monetary and fiscal challenge. Its official unemployment rate is in the area of 20 percent, its life expectancy is the lowest in the entire world, and the spread of HIV and malaria in Zimbabwe is increasing rapidly. The effects of hyperinflation create complete economic collapses.

INFLATION

Inflation is an important measure for investors, because the risk-free rate is approximately the sum of real growth rate and inflation rate. So, inflation rate will play a large role in determining the rate of return for investments.

The broad definition of *inflation* in economics is increases in general price level. With increases in price level, the purchasing power of the same unit of money/income/wealth diminishes. In other words, inflation can be viewed as either an increase in price level or a decrease in purchasing power. Thus, it is important to understand some of the basic issues on the construction of the price level index and how changes in the construction will affect purchasing power differently. Also important to this is hyperinflation and the impact of hyperinflation on productivity.

In the United States, inflation is measured by changes in the Consumer Price Index (CPI). The CPI is produced by the Bureau of Labor and Statistics (BLS). It is based on a theoretical basket of possible goods and services that best represents an average household based on 1990 U.S. Census data (1990 was the base year set by the BLS; this date changes infrequently). Each item in the basket has a point value, and changes in a particular item's price level multiplied by its point value will result in the effect of price change in that particular item.

The content of the basket is determined by a survey of two-week purchasing habits of 7,000 families in the United States over two years. The BLS recognizes the following broad categories:

- Food and beverages (e.g., breakfast cereal, milk, coffee, chicken, wine, full-service meals, snacks),
- Housing (e.g., rent of primary residence, owners' equivalent rent, fuel oil, bedroom furniture),
- Apparel (e.g., men's shirts and sweaters, women's dresses, jewelry),
- Transportation (e.g., new vehicles, airline fares, gasoline, motor vehicle insurance),
- Medical care (e.g., prescription drugs and medical supplies, physicians' services, eyeglasses and eye care, hospital services),
- Recreation (e.g., televisions, toys, pets and pet products, sports equipment, admission to entertainment venues),
- Education and communication (e.g., college tuition, postage, telephone services, computer software and accessories), and
- Other goods and services (e.g., tobacco and smoking products, haircuts and other personal services, funeral expenses).

It is important to note that not every item on the basket is purchased by every family in the survey; in fact, some families will never purchase any of those items, so price increases in some of those items will have very little impact on the rest of the population. College education provides one such example: The cost of attending college has been increasing at a rate more than twice the general level of CPI increases. Thus, the cost of a college education will have no impact on a family that has no one attending college during this period, while a family with two children in college will likely feel a large impact of college tuition increases.

Other BLS categories will also affect individual families differently; For example, the cost of a new vehicle, gasoline, and automobile insurance will have little impact on someone who lives in an urban setting with convenient public transportation and therefore has no need to own a car. In contrast, most low-income families spend a large portion of their income on food and other basic necessities, so price increases in basic necessities and food will have a much higher impact on those families than on families with higher income levels.

So, depending on a family's consumption habits, inflation will affect one family's purchasing power differently than another family's. Most families do some form of price comparison and make changes to their consumption habits by substituting lower-price items for similar, higher-priced ones. To be responsive to this, the BLS created what is known as the Chained CPI, which takes the substitution effect into account and results in a lower inflation rate. Some entitlement programs are considering using Chained CPI as the basis for adjustment. A new measure called the Cost of Living Index (COLI), which is more reflective of actual cost of living, is being proposed as a substitute. But the COLI has its shortcomings as well. It is based on the relative cost of living for typical mid-management households in more than 300 U.S. cities, but midmanagement households are no longer the norm in the United States. So both the Chained CPI and the COLI are facing criticism.

Moderate Inflation versus Hyperinflation

A moderate level of inflation is generally seen as a good thing for the economy. Producers will produce more goods and services only if they know they can sell those goods and services for higher prices in the future. A moderate level of inflation—around 3 percent—will encourage production growth. If inflation is too low or is in the negative territory (deflation), the monetary authority will generally relax monetary policy to induce a higher level of inflation.

Hyperinflation, where the price level increases at a rapid rate, hinders economic activity. Since inflation reduces purchasing power, in a hyperinflationary period the income and wealth of households declines rapidly. During a period of hyperinflation, one of the key functions of money (as a store of wealth) is essentially gone, so consumers will try to spend their money as quickly as possible, exchanging their income for food and other basic necessities as soon as they receive a paycheck. Not only does this place a constant demand on people's time (from consumers waiting in line to buy goods to store owners constantly changing the prices on all the items), but also it increases the velocity of money. According to the Quantity Theory of Money, an increase in velocity results in a higher price level—creating a vicious cycle.

For an extended period after World War I, Germany had an inflation level of more than 2 billion percent a year. The money was not worth the paper it was printed on, and the economy was basically destroyed. Images of people pushing around a cartload of paper money, looking for bread to buy, still bring chills to people from older generations. A more recent example can be taken from the 1980–1997 Brazilian economy. The CPI went from 4 to 5,080,300,000,000! Something that cost 1 Brazilian real (BRL) in 1980 would cost 1 trillion BRL in 1997!

By late 1997, inflation was under control in Brazil and the economy started to recover very quickly. With modern knowledge about the effect of monetary policies on inflation, periods of hyperinflation like those experienced by Germany and Brazil are likely not going to occur again in developed countries.

Inflation is an important piece of data in that it tells investors the lowest level of return they must obtain in order to maintain the purchasing power of their wealth/income. Inflation, however, affects purchasing power differently across demographics and consumption habits. While hyperinflation is bad for the economy, a low level of inflation—or *deflation*—is also bad. Since the risk-free rate is tied to the inflation rate, knowing the inflation rate will help consumers understand the real rate of return for various risky investments. Having a better understanding of this important piece of data will help ensure smarter investment decisions.

INFLATION, MEASURES OF

Inflation is the general rise of prices in an economy—and the number one issue in many economies. Inflation reduces the real value of an economy. It depreciates the value of a currency, reducing the confidence of holding the currency. Very high inflation, or hyperinflation, can destroy an economy and be a catalyst for civil and political unrest.

There are three key measures of inflation: the Consumer Price Index, the Producer Price Index, and the Personal Consumption Expenditures. Each measure provides a separate picture of the economy. When taken together, these key measures provide a broad measure of an economy's price level. Other measures that economists study for inflation indicators include import prices, unit labor costs, and the gross domestic product (GDP) deflator.

Consumer Price Index

The most watched and most popular measure of inflation is the Consumer Price Index (CPI). The CPI data are collected, analyzed, and presented by the Bureau of Labor Statistics (BLS), an agency of the Department of Labor. The CPI is reported monthly, and unlike the GDP measure, there are no monthly revisions. There are, however, annual revisions that can revert back five years. There are many versions of the CPI for different geographical areas. While the CPI is used to determine the "cost of living" index to determine increases in Social Security and other government entitlement programs, the best use of the CPI is to view price trends and to measure retail prices over time.

The BLS constructs a market basket of goods and services by surveying over 20,000 retail outlets in over 85 urban areas. It collects prices on 80,000 goods and services, from medical and dental services to computers, beer, and rental housing. The data collected on 200 categories of goods and services are divided into eight major categories, each weighted to reflect its impact on a household:

1. Housing, which includes shelter, utilities, household furnishings, and operations, is weighted at 42.2 percent.
2. Transportation is the second most weighted category, at 17.4 percent. This category includes new vehicles, motor fuel, maintenance and repair, and used cars and trucks. It also includes the use of public transportation.
3. Food and beverages are a third category, accounting for 15 percent.
4. Medical care is weighted at 6.2 percent.
5. Just below medical care is education and communication, at 6 percent.
6. Recreation is 5.6 percent of the market basket.
7. Apparel is weighted at 3.8 percent.
8. Other goods and services, such as tobacco and smoking products, are 3.5 percent.

The CPI is an index, and therefore it uses a base year upon which to measure growth over time—usually a period of one year. The current CPI base year is the time frame from 1982 to 1984, which has a value of 100. Each month, the CPI is calculated and measured against the base year (1982–1984) along with the previous year; if in a current year, the CPI is calculated at 150, the general price level of the market basket of goods and services has risen 150 percent of the 1982–1984 price level (150/100 = 1.5 × 100 = 150%). So based on the CPI, if an item cost $1.00 in 1982, it would cost $1.50 today. Of course, the CPI is only an average, so some items may have fallen in price, while others may have risen more than 50 percent. If in the following year the measured CPI is 155, the annual inflation rate would be 25 percent (155 – 150 = 5/150 = 0.033 × 100 = 3.3%).

The BLS computes several measures of CPI. One measure is CPI-W, which measures the price index for wage earners and clerical workers. A second measure is the CPI-U, which measures the price index for urban professionals, including the self-employed, managers, and technical workers. The BLS measures the price index for 14 specific geographic areas as well. The BLS also takes into account seasonal factors, such as specific growing seasons, that impact a product's price—for example, oranges.

The BLS press releases also identify a CPI in two versions: "headline inflation" and "core inflation." *Headline inflation* is the inflation measure using all items in all categories, as described above. *Core inflation*, however, is the CPI measure minus the food and energy categories; the core inflation measure was invented in the high-inflation 1970s to minimize the high prices of the two volatile categories of food costs and energy costs.

Producer Price Index

First used officially in 1902, the Producer Price Index (PPI) is the oldest of the government's measures. It is the first monthly measure announced by the BLS. The PPI measures changes in the prices that businesses pay for the intermediate goods they use in producing goods and services. The PPI is announced by the BLS monthly, often several weeks after the month being measured. It is updated four months after the initial release, and updated annually in February from the January measure.

The Department of Labor requests prices on approximately 100,000 products from approximately 30,000 companies nationally. The weighting of each product is based on its value to the economy. The products are reweighted every five years based on changes in the economy. Imported goods are excluded from the PPI, as are services. Like the CPI, the PPI has an established baseline. The PPI baseline year is 1982.

The PPI is actually a combination of indexes. The PPI measures the price level of three separate goods in production: commodity prices, intermediate goods, and finished goods just prior to being sent for retail. *Commodities* are the natural resources used in the production process. *Intermediate goods* are the manmade goods used in the production of final goods and services, such as machinery. *Finished goods* are the final product, ready to be sold to consumers. This last measure is the one most publicized in the news and of interest to investors and businesses. The finished goods measure is determined by the other two and it makes them a leading indicator of finished goods prices. Because the PPI measures these early prices and costs in the production process, it is a leading indicator of future retail inflation, as businesses are inclined to pass along cost increases to consumers.

The PPI for crude goods measures the cost of raw materials, such as agricultural products; oil and copper are examples of commodities. These product prices are often based on the supply of the product, making them subject to significant changes in such variables as weather, labor costs, or political uprisings. The PPI for intermediate goods includes the price changes in items just before final production, such as automobile parts, cotton, flour, or machine parts. These two components make up approximately 40 percent of the total PPI measure.

The PPI for finished goods includes prices in 11 categories, including automobiles, groceries, fuels, and clothing. This component is similar to the CPI components. The components for the finished goods PPI make up approximately 75 percent of finished consumer goods (20 percent finished consumer foods and 55 percent finished consumer goods), with 25 percent finished capital equipment. As with CPI, a core PPI of finished goods is measured removing food and energy costs. This removes the volatility of weather and geopolitical situations in the inflation predictors.

Economists and investors are especially interested in price changes as they occur—from crude products to intermediate products to finished products. Price changes through this process are key signals of what sectors of an economy are experiencing inflation. Knowing where the inflation is originating allows economists and investors to know which stage inflation is present and which sectors and businesses can predictably experience inflation in the future.

Economists often claim that there is no relationship between the PPI and the CPI. Experience during the 1970s and 1980s does not often support that claim; measures during the end of the 20th century were not as consistent. Most economists agree that in the long term the two measures will ultimately converge.

Personal Consumption Expenditures

In the United States, the largest component of GDP is personal spending on goods and services, or personal consumption expenditures (PCE), which accounts for up to 70 percent of the U.S. GDP. By contrast, China's personal spending as a component of its GDP is only approximately 30 percent. Consumer expenditures are the key dynamic influence of the U.S. economy. If consumers are not purchasing goods and services, businesses are not using resources (including labor) to produce goods and services, and the economy does not grow or even regresses. The stock market and other economic indices react to the reports of how much households are spending on goods and services.

As a component of GDP, the reporting of PCE is a function of the Bureau of Economic Analysis (BEA). The PCE is also a critical component of the Federal Reserve's inflation calculations. Personal spending is reported monthly with several months of revisions. The monthly reports are also annualized to reflect yearlong income or expenditure trends. A major revision in data may occur to reflect new reporting and/or data-collecting methodologies. Personal income is measured before taxes are deducted. BEA measures income from several sources: wages and salaries, rental income, interest and dividend income, income of the self-employed (proprietor's income), transfer payments, and other income. PCE and personal income are reported in nominal dollars (current dollars) and real dollars (adjusted for inflation).

PCE are measured in three major categories: durable goods (goods lasting three or more years), nondurable goods (goods lasting less than three years), and services. Durable goods are major items purchased by households, such as cars, refrigerators, and televisions. Because they are items that households do not purchase often, they account for only 12 to 14 percent of PCE. Nondurable goods, such as food and clothing, account for approximately 30 percent of PCE, as they are purchased more often. Services make up the final 40 percent, accounting for the purchases of haircuts, movie tickets, medical expenses, and so on.

One either purchases goods and services (expenditures) or saves income. Personal savings is also calculated from this information. Once all spending is measured, interest on credit cards and car loans is taken into account and taxes are deducted, leaving disposable income; this remainder is considered personal savings. It has been calculated that over time the average household spends 95 cents of each dollar received and saves 5 cents. This very high percentage of consumption is the key reason the PCE receives attention from the media, economists, and, as mentioned earlier, the Federal Reserve Board of Governors. Measuring PCE is also complicated, and it involves many government departments, organizations, and companies.

THE IRAQ WAR'S IMPACT ON THE U.S. ECONOMY, 2003–2011

The Iraq war began in 2003 when President George W. Bush launched an invasion of Iraq. After the September 11, 2001, attacks, the United States was determined to retaliate. The war was initiated due to the belief (which was later disproved) that Iraq possessed nuclear weapons of mass destruction. The Iraqi leader Saddam Hussein had killed many of his own people and was considered one of the worst dictators, further fueling the desire to remove him from power. The war officially ended in December 2011, although the country still suffers from conflict and unrest. Further, the United States is still feeling the economic repercussions of the Iraq war.

This entry will focus less on the war itself and more on its economic impact. There is a widely held belief that fighting a war and increasing military spending will improve a county's economy. According to Dean Baker from the Center for Economic and Policy Research, military spending diverts resources from more fruitful uses and in the end decreases employment and slows economic growth.

Problems Calculating the Cost of the Iraq War

Many sources explain that it is difficult, if not impossible, to accurately tabulate the economic costs of the Iraq war for the United States. In 2008, Fred Foldvary of Econ Journal Watch attempted to quantify the costs. As of 2008, the United States was estimated to have spent $3 trillion on the war in Iraq. The dollar amount is just one input into the economic costs of the war to the nation. The additional economic costs are far-reaching and include both tangible and intangible economic costs.

An exceptionally difficult cost to quantify is the costs for the returning military. Returning military personnel experience tremendous reentry issues, and those costs impact the country through medical, psychiatric, and employment damages.

The government has also been accused of poor accounting and reporting with regard to the Iraq war, making it difficult to calculate the cost of the war. Unlike prior wars, this war did not have a separate account, and the war payments were mixed in with other types of spending. The war was funded through many emergency allotments, not factored into the government's budgets. There was no specified budget category for Iraq war spending, so a complete accounting of all financial war costs is exceedingly difficult.

Opportunity Costs of War

Opportunity cost is an economic term that refers to the cost of the choice that was not made. When one choice is made, the decision-make must forgo other choices, and those are called the "opportunity costs." Spending on the war meant that many other projects had to remain unfunded due to lack of resources. For example, if the United States had not spent money on the Iraq war, those funds could have been directed to reduce the federal debt, cut taxes, and/or increase funding for domestic programs.

For 10 years, trillions of dollars went to fund the war. It is difficult to calculate how those dollars—had they been spent on, for example, other domestic programs, debt, or tax relief—would have affected the economy of the country. This is an example of an intangible economic cost of the war.

Costs to U.S. Citizens
