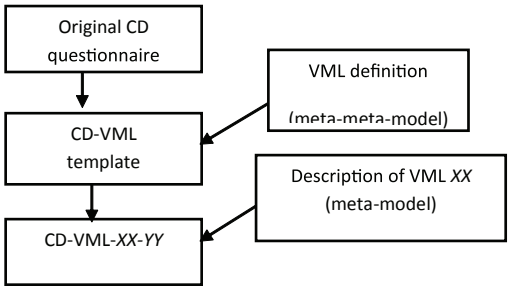
In order to give an example, we present questions from the section of the questionnaire related to error-proneness. It starts with questions to find common mistakes whilst modeling and using diagrams: 'Whilst modeling, what kinds of mistakes are particularly common or easy to make? Which kinds of mistakes you must be careful not to make? Whilst using diagrams, which misunderstandings are very likely to happen?' They were followed by a table with listing of all model elements and notation elements and space for problem descriptions. The table was headed with the questions: 'Which model elements or constructions or notation element or visual mechanisms are these mistakes concerned with? What are the problems?' Below the table there was a space for explanations, examples, comments and suggestions for improvement of the VML or suggestions for special features of the CASE tool.

This method was verified in an experiment with students as participants. Students confirmed simplicity and usefulness of use cases, but they also discovered a large number of problems, gave reasonable explanations to them and quite often made suggestions for improvements. Their discoveries covered all the problems reported in the

Figure 2. Schema of the CD-VML methodology (©2007 Anna Bobkowska. Used with permission)



related work. The level of detail of the individual answers was satisfactory: problems usually were described with details and examples and even simple diagrams for illustration of the problem were added. In the section of comments they stated the following strengths of the methodology: the precision of questions, large area of covered issues and ease of use. Usefulness of the method was evaluated as high and results were considered as important for use case model improvement.

FUTURE TRENDS

In our opinion, the following areas need to be integrated into the research on quality of software models:

- Proper configuration of modeling tasks and artefacts in the context of software project;
- Integration of reuse technology with modeling technology;
- Need for methods which enable evaluation of the fit between the problem and modeling technology;
- Usability of the modeling technology;
- Visual modeling language engineering.

There is a need for knowledge which would enable proper configuration of the modeling artefacts and modeling tasks within the software project depending on the type of project. Modeling takes time and often does not result in increase of code (except from the situation where the full code is generated by tools). Thus, the suggestion is that the use of models is efficient and beneficial only to certain limits. Furthermore, unlike suggestions in pure modeling solutions, in realistic projects still a lot of documentation is made in the textual form. It is worth to mention that quality of models and thus the quality of the system which is represented by these models depends on whether analysts and developers have enough time for making them. It depends also on the proper scope of modelling. Understanding of this impact requires more research and should result in guidelines on the scope of application of models in the software project depending on the project characteristics. Once the development process is customised, the proposed methodology of designing methods of model evaluation can be used to create proper methods of evaluation.

Integration of the reuse technology with the modeling technology is the next of the challenges. We have a lot of evidence about benefits of reuse for both efficiency and quality of software. However, there are some risks as well. The most important reuse solution related to modeling are patterns and components. The related questions include: How to use patterns effectively for the purpose of software development? How to study their impact for software quality? How the fit between a problem and the applied patterns matters? How components could be incorporated into models? How to analyse their impact for quality of software? The proposed method can facilitate approach to evaluation, but several new factors must be defined e.g. fit of the reuse method to the solution of the problem.

There is a need for methods which enable evaluation of the fit between a problem and given technical modeling solution. It is not a surprise that a problem which can be difficult in one technology can be easy to solve in another. Expert's knowledge is necessary to evaluate modeling solutions against the problem at hand. Examples of decisions include: whether to use UML or a domain specific language, object-oriented or aspect-oriented solutions; how to choose between several technical spaces? It is worth to remember that this perspective sets the space of achievable effects.

Much more work should be done on the usability side of modeling methods. Most decisions so far are technology-driven and result in difficult to use methods and tools. Focus on users of the modeling technology could surely result in better

fit of the technology to support several roles of software development process and their activities. This area of research can use pragmatics by the means of identifying pragmatics profiles and their tasks and then evaluating how they are supported by modelling technology.

And finally, we would like to support the research in the discipline of visual modelling language engineering. The technology changes, modeling paradigms are passing by, but the activity of modeling is useful anyway. The role of visual modeling language engineering would be to capture the knowledge about modeling which is technology invariant. It could collect universal and consistent knowledge about models in the areas including:

- understanding the role of models;
- quality of models;
- guidelines for creating visual modeling languages;
- quality of visual modeling languages;
- guidelines for use of modeling technology in the software project.

The proposed method could be a part of visual modeling language engineering.

CONCLUSION

The objective of this chapter was to present an approach to dealing with model quality in a way which integrates quality criteria and methods of evaluation. The methodology for designing methods of evaluation customized for selected objectives and objects under evaluation which check out these objects against desired quality criteria fulfills the requirements which were stated before it. It is explicitly configurable to different objectives and objects under evaluation and thus it fits to configurable software development process in which particular models, modeling and model checking activities are results of decisions made by process engineer. With integrating quality criteria and methods of evaluation it is easy to manage scope of inspection and enable better fit to the objects under evaluation. Inspirations from linguistic theories provide a framework for understanding impact of given criteria for the quality of software under development and software development process. The proposed methodology is flexible and universal. The case studies have delivered an evidence of feasibility of the methodology and its coverage for a diversity of cases as well as usefulness of the results achieved with the use of designed methods of evaluation.

Chapter 7.7
Software Security Engineering:
Towards Unifying Software Engineering and Security Engineering

Mohammad Zulkernine
Queens University, Canada

Sheikh I. Ahamed
Marquette University, USA

ABSTRACT

The rapid development and expansion of network based applications have changed the computing world in the last decade. However, this overwhelming success has an Achilles' heel: almost every software controlled system faces threats from potential adversaries both from internal and external users of the highly connected computing systems. These software systems must be engineered with reliable protection mechanisms, while still delivering the expected value of the software to their customers within the budgeted time and cost. The principal obstacle in achieving the above two different but interdependent objectives is that current software engineering processes do not provide enough support for the software developers to achieve security goals. In this chapter, we reemphasize the principal objectives of both software engineering and security engineering, and strive to identify the major steps of a software security engineering process that will be useful for building secure software systems. Both software engineering and security engineering are ever evolving disciplines, and software security engineering is still in its infancy. This chapter proposes a unification of the process models of software engineering and security engineering in order to improve the steps of the software life cycle that would better address the underlying objectives of both engineering processes. This unification will facilitate the incorporation of the advancement of the features of one engineering process into the other. The chapter also provides

a brief overview and survey of the current state of the art of software engineering and security engineering with respect to computer systems.

INTRODUCTION

With the proliferation of connectivity of computer systems in the applications where the quality of service depends on data confidentiality, data integrity, and protection against denial of service attack, the need for secure networks is evident. In these applications, the consequences of a security breach may range from extensive financial losses to dangers to human life. Due to heavy dependence of computer network based applications on various software and software controlled systems, software security has become an essential issue. Almost every software controlled system faces potential threats from system users, both insiders and outsiders. It is well accepted that "the root of most security problems is software that fails in unexpected ways when under attack" (McGraw, 2002). Therefore, software systems must be engineered with reliable protection mechanisms against potential attacks while still providing the expected quality of service to their customers within the budgeted time and cost. Software should be designed with the objective not only of implementing the quality functionalities required for their users but also of combating potential and unexpected threats. The principal obstacle in achieving the above two different but interdependent objectives is that current software engineering processes do not provide enough support for the software developers to achieve security goals.

Some of the principal software engineering objectives are usability, performance, timely completion, reliability, and flexibility in software applications (Finkelstein & Kramer, 2000; Pressman, 2001; IEEE, 1999). On the other hand, some of the major objectives of security engineering are customized access control and authentication based on the privilege levels of users, traceability and detection, accountability, non-repudiation, privacy, confidentiality, and integrity (Pfleeger & Pfleeger, 2003; Viega & McGraw, 2001). Having stated that, software security engineering objectives are to design a software system that meets both security objectives and application objectives. However, software security engineering is still considered a difficult task due to inherent difficulties associated with the addressing of the security issues in the core development and maintenance of software systems. Both software engineering and security engineering are ever evolving disciplines and software security engineering is still in its infancy. A precise and well-accepted understanding of software security engineering does not yet exist (ISSEA, 2003; Wolf, 2004).

The principal objectives of software security engineering need to be reinvestigated, and a methodology is required that can be employed for building secure software systems. Software security engineering is a practice to address software security issues in a systematic manner. We believe that the security issues must be addressed in all the stages of software system development and maintenance life cycle such as requirements specifications, design, testing, operation, and maintenance to provide secure software systems. This chapter identifies some possible ways to adapt readily the current practices of security engineering into a software engineering process model. In other words, this chapter suggests a unification of the process models of software engineering and security engineering. The unification is desirable between the two processes by removing the unnecessary differences in their corresponding steps that obscure the fundamental principles of the development and maintenance of secure software systems. This unification will help system designers to employ the techniques and tools of software engineering and security

engineering in a complementary fashion. It will also help to incorporate the advancement of the features of one engineering process into the other. In our attempt, we suggest to incorporate new, more intuitive but well-defined steps in the software security engineering process in order to build secure software systems. It may be noted here that a number of studies have already proved that "end-to-end integration" of security aspects in the software life cycle have significant benefits with respect to the quality of the end software products (Devanbu & Stubblebine, 2000; Viega & McGraw, 2001).

In this chapter, we describe a software security engineering process, which is primarily based on the famous waterfall software development process model (Royce, 1987). The major steps of the proposed software security engineering process model are described in detail. The rationale for choosing the waterfall model as a basis for the description is that it contains most of the fundamental steps present in all other software process models that currently exist in the literature. Therefore, our idea of a software security engineering process which incorporates security issues in all the steps of software life cycle will work fine in other software process models. For example, the incremental model is widely used in industry with a view to reducing the delay in delivering software products. It consists of several increments or builds, where each increment follows the waterfall model. Similarly, in an incremental model based software security engineering process, each increment may adopt the steps described in this chapter.

The rest of the chapter is organized as follows. Section 2 provides a brief overview of software engineering and security engineering, and presents a brief synopsis of the current state of the art of other related efforts towards software security engineering. Section 3 provides the details of the proposed software security engineering process model. The chapter concludes in Section 4 with a summary of current research and future recommendations.

BACKGROUND

A Glimpse of Software Engineering

In the IEEE Standard Glossary of Software Engineering Terminology (IEEE Std. 610.12-1990), software engineering is defined as follows (IEEE, 1999): "(1) Software engineering is the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software; that is, the application of engineering to software. (2) The study of approaches as in (1)". It primarily focuses on applying an engineering approach to the design, implementation and maintenance of software systems. Software engineering is an engineering discipline, which is concerned with all aspects of software production, from the early stages of system specification to maintenance of the system after it has been deployed for use (Finkelstein & Kramer, 2000). Software engineering is a subset of system engineering, which focuses on overall system (both software and hardware), while software engineering only focuses on the software aspects of the system development.

There are different software development life cycle models such as the waterfall, incremental, spiral, and rapid prototyping (Pressman, 2001). Among these models, the waterfall model (Royce, 1987) is the most widely used and discussed. Most models consist of steps for requirement gathering and analysis, software architecture, implementation, and testing. Stakeholders involved in a software engineering process influence software engineers to follow certain process models to address and solve different issues of the software in an effective way. The stakeholders include analysts, designers, programmers, testers, maintenance personnel, project managers, and end users or customers. The project manager

leads the whole software development group of analysts, designers, programmers, testers, and maintenance personnel. An analyst collects and analyses the requirements, and a designer forms the architecture with a view to leading the requirements towards the implementation. A programmer implements the architecture or design provided by the designer, and testers test the software for ensuring high quality end product. Maintenance personnel deploy and maintain the software so that the operators can use the software effectively.

Software engineering refers to techniques intended for making software development more orderly, systematic, and organized. It also helps to reduce time and cost for developing software in a scientific way. In summary, low cost, high quality, and rapid software development are the key goals of software engineering. The rapid development and expansion of the software are possible with effective use of a software engineering process; however, security issues have not yet been incorporated or addressed in the software development processes.

A Glimpse of Security Engineering

The IFIP (International Federation for Information Processing) working group WG10.4 on dependable computing and fault tolerance considers security as one of the attributes of software 'dependability', where dependability is defined as the "trustworthiness of a computer system such that reliance can be justifiably placed in the service it delivers" (Laprie, 1992). The other principal attributes of dependability are reliability, availability, and safety, while security professionals usually consider safety and reliability as attributes of security. The threats to security are identified as interception, interruption, modification, and fabrication of data (Pfleeger & Pfleeger, 2003). The threats are usually defined based on some security policy of the organizations, while the violations of any security policy are combated using different security mechanisms such as encryption, authentication, authorization, and auditing.

Security engineering is a discipline for "building systems to remain dependable in the face of malice, error, or mischance", where the discipline "emphasizes the tools, processes, and methods needed to design, implement, and test complete systems, and to adapt existing systems as their environment evolves" (Anderson, 2001). Security engineering deals with a number of issues such as intrusion protection and detection. It ensures a system to be secured from both software and hardware perspectives. System security is becoming increasingly more important due to the new trend of ubiquitous/pervasive computing that has evolved during the last few years; numerous mobile or embedded devices such as PDAs and cell phones are connected via internet, incurring enormous security vulnerabilities.

Security engineering addresses the complete lifecycle for building a secure system: requirements specification and analysis, design, development, integration, operation, maintenance and re-engineering (ISSEA, 2003). It requires expertise in inter-disciplinary areas such as computer system management and development, software and hardware security, networking and cryptography, applied psychology, organizational management, and law. Without incorporating the security engineering principles derived from the relevant cross-disciplinary areas to every level of a software development process, it is nearly impossible to deliver a secure software system in its first release.

Related Effort to Address Security Issues in Software Engineering Context

We begin this section with the following question that was asked in (Wolf, 2004): "Is security engineering really just good software engineering?" We also believe in their concluding ob-

servation that security engineering cannot be differentiated from software engineering if "the underlying mathematics and higher-level policy and human factor issues" are not considered. Our approach of software security engineering is along the line of the following research challenges outlined in (Finkelstein & Kramer, 2000; Devanbu & Stubblebine, 2000): integration of security requirements with software requirements into early development life cycle; design of adaptive software systems to handle new attacks and changing security policies of any organizations; testing security requirements of software systems; derivation of intelligent and responsive framework for operational stage monitoring and maintenance. A number of other related efforts towards incorporating security engineering principles into software development life cycles are discussed in the following paragraphs.

In (Viega & McGraw, 2001), a software risk management process is proposed for assessing, quantifying, and establishing an acceptable level of risk in an organization. The proposed process is inspired by Boehm's spiral software process model (Boehm, 1988). In this process, security aspects are considered when software requirements are derived. The most severe security risks are evaluated and strategies are planned for resolving those risks. The risks are addressed through prototyping, and validated that the risks of those security violations are eliminated. Then, the solution to the security risks is applied for the next version of the software requirements, design, or source code. Finally, the planning for the next phase is outlined.

In (Flechals, Sasse, & Hailes, 2003), a process for usable and secure software systems called 'Appropriate and Effective Guidance in Information Security (AEGIS)' is proposed. The AEGIS involves the context in which the system is going to be used, and analyzes the potential risks to help developers handle security related issues. Similar to the risk management process proposed in (Viega & McGraw, 2001), the AEGIS is also based on Boehm's spiral software process model. It requires communication among a system's stakeholders in the risk analysis and the selection of appropriate defense mechanisms so that the developers gain a better understanding of the security and usability requirements. The AEIGS employs Unified Modeling Language (UML) (Jacobson, Booch, & Rumbaugh, 1999) to describe a way to perform "risk-usability-design" simultaneously.

Software Security Assessment Instrument (SSAI) project (Gilliam, Wolfe, & Sherif, 2003) identifies five important entities with respect to software security engineering: software security checklist (SSC), vulnerability matrix (Vmatrix), flexible modeling framework (FMF) for verification of requirements, property-based tester (PBT) for testing vulnerabilities, and security assessment tools (SATs). Similar to our objective in this chapter, the SSC "provides instrument to integrate security as a formal approach to the software life cycle".

The System Security Engineering Capability Maturity Model (SSE-CMM) (ISSEA, 2003) proposes a unified process of practicing security engineering in the context of software development. In the systems security engineering process, the security engineering task is divided into three interrelated but separate basic process areas: risk process, engineering process, and assurance process. The risk process identifies and prioritizes the risks inherent to the product under development; the engineering process interfaces with the other engineering disciplines to provide solution to the identified risks; and the assurance process improves the level of confidence of the product developer as well as the customers with respect to the proposed security solutions. The SSE-CMM describes the characteristics of five capability levels, which are inspired by the CMM used to evaluate software engineering practices.

The Unified Modeling Language (UML) (Jacobson, Booch, & Rumbaugh, 1999) has cur-

rently become the de facto standard to specify, visualize, and document models of software systems including their structure and design. More specifically, it is suitable for object oriented analysis and design. The UML defines twelve types of diagrams of three categories. Nevertheless, the UML does not provide a framework that can address the issues with respect to developing secure software system. A number of efforts are taking place in order to enrich the UML based software development processes. Some of them are as follows: UMLSec (Jürjens, 2003), Misuse and Abuse cases (Sindre & Opdahl, 2000; Dermott & Fox, 1999), Secure UML (Lodderstedt, Basin, & Jurgen, 2002; Basin, Doser, & Lodderstedt, 2003), and Security Integrated Rational Unified Process (Oikinomopoulos & Giritzails, 2004).

To address security issues in the context of software development processes, some of the elements of UML such as use case, class, sequence, state chart, package and deployment diagrams are extended (Jürjens, 2003). This UML extension for secure software development is called UMLSec. The extensions included in the UMLSec are based on using stereotypes and tag values, which enrich the existing UML diagrams with security related information.

Standard use case diagrams are often useful for eliciting functional requirements, while they are not that suitable for describing security requirements (Jacobson, Booch, & Rumbaugh, 1999). The security requirements are usually related to prohibited activities. Therefore, an extension to standard UML use case notations is proposed in (Sindre & Opdahl, 2000) in order to include unwanted use case scenarios. A use case describes a sequence of actions that represents a service to the user. On the other hand, a misuse case in the context of security requirements is defined as a sequence of actions that results in security violations for the organization or some specific stakeholder. They also define "mis-actor" as just the opposite of an actor and it initiates the misuse cases. In (Dermott & Fox, 1999), a use case based object-oriented modeling technique is used to represent significant forms of abuses that need to be prevented. However, security issues are not addressed in every phase of the software engineering process.

Secure UML (Lodderstedt, Basin, & Doser, 2002; Basin, Doser, & Lodderstedt, 2003) describes a methodology for modeling access control policies and integrating it into a model-driven software development process. This work is inspired by the idea of using UML to model Role Based Access Control (RBAC) policies. The unique feature of the Secure UML is that it also includes elements to be used in behavioral models.

A number of above extensions of the UML for the purpose of security are compared and contrasted in (Oikinomopoulos & Giritzails, 2004). We agree to their view that most of those extensions are concerned with the presentation (notational) issues of security related information rather than a methodology, which emphasizes the activities to be performed for software security engineering. In most of the above work, there is very little or no guideline about how and in what phase of the development cycle the extended UML notations will be utilized. In (Oikinomopoulos & Giritzails, 2004), they incorporate security engineering to the Rational Unified Process (RUP). The RUP divides the software development effort in phases and major workflows. They extend each workflow with additional security related activities, and identify the artifacts that should be produced. To support these activities, they also introduce the role of a "security engineer" in their methodology.

SOFTWARE SECURITY ENGINEERING

Having discussed both software engineering and security engineering, it is important to note that

"while software engineering is about ensuring that certain things happen, security is about ensuring that they don't" (Anderson, 2001). Nevertheless, following the IEEE Standard 610.12-1990 (IEEE, 1999) definition of software engineering, software security engineering can be defined as "the application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of" secure software; i.e, "the application of engineering" to obtain secure software (Anderson, 2001). In the software security engineering process, the principles and specialties of other engineering disciplines with respect to software and security are integrated to achieve the "trustworthiness" in software systems. This process will help software development to proceed in a way where it will have less chance to expose itself to security related loopholes. It will endorse low cost, high quality, and a rapid software development process where the security issues will be addressed in every phase of the process. Software security engineering involves the stakeholders of software engineering while actively involving security engineers in most of its phases. Similar to both software engineering and security engineering, software security engineering incorporates expertise from various other cross-disciplinary areas such as computer system management and development, software and hardware security, computer networks, organizational management, psychology, and law.

We describe a software security engineering process, which is primarily based on the famous waterfall software development process model. The waterfall model contains most of the fundamental steps present in other software process models currently used in industries and academia. The major steps of the proposed model are as follows: system engineering, requirements specification, software design, program implementation, and system operation. The steps are presented schematically in Figure 1. While the following paragraphs provide a brief introduction to the steps, all of the steps are further detailed in the following subsections.

System Engineering. The software concerns of a system development are separated from its hardware concerns. Then both functionality issues and security issues are identified based on the users' or stakeholders' needs and in the context of other system elements such as hardware, software, people, database, documentation, and procedure.

Requirements Specification. The security requirements of a software system are specified, analyzed, and integrated along with the other functional and nonfunctional requirements of the software system. It is recommended that both security requirements and the other software requirements should be specified using the same formal language . The requirements are expressed as a set of scenarios.

Software Design. Both functionality and security issues should be considered when deciding where the application components are deployed and how they communicate with each other. A scenario based software architecture is designed based on functional scenarios from users' perspective and attack scenarios from intruders' perspective. The architecture should be compositional so that whenever a new attack is encountered, the system architecture can be easily adapted to defend against the attack.

Program Implementation. The system is implemented to meet the specified requirements, and the correctness and effectiveness of security mechanisms along with functional characteristics are verified with respect to the requirements specification. When the required functionalities are implemented, the source code is refactored (changed) to control any number of vulnerabilities against threats from attackers, while still meeting all of the functional acceptance tests.

System Operation. The software is monitored for security violation or conformance to its functional requirements based on the specification

Figure 1. A waterfall based software security engineering process model

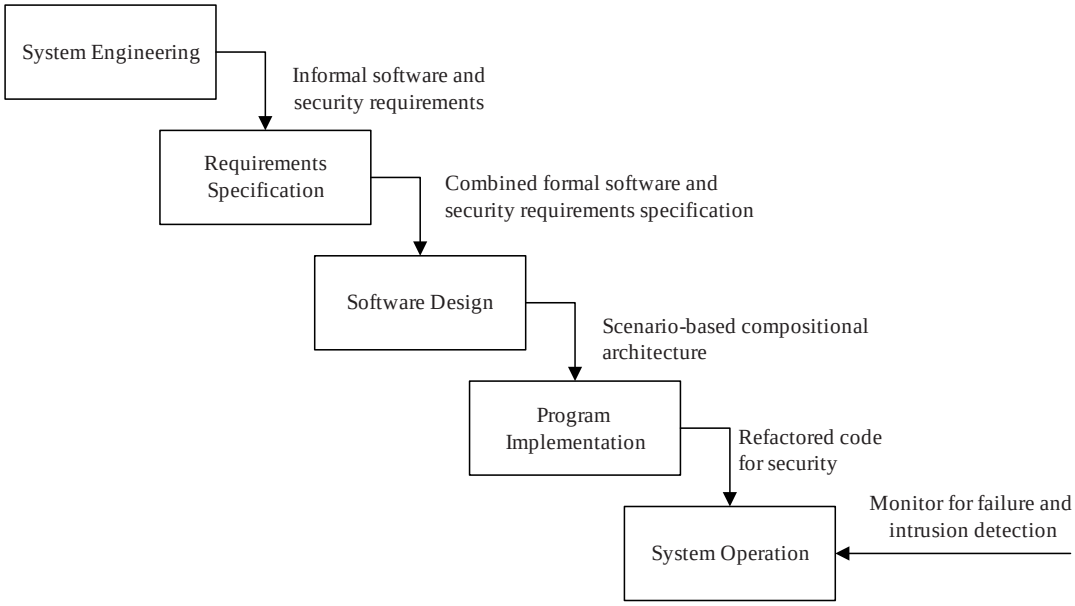

Figure 2. The system engineering phase of the software security engineering process

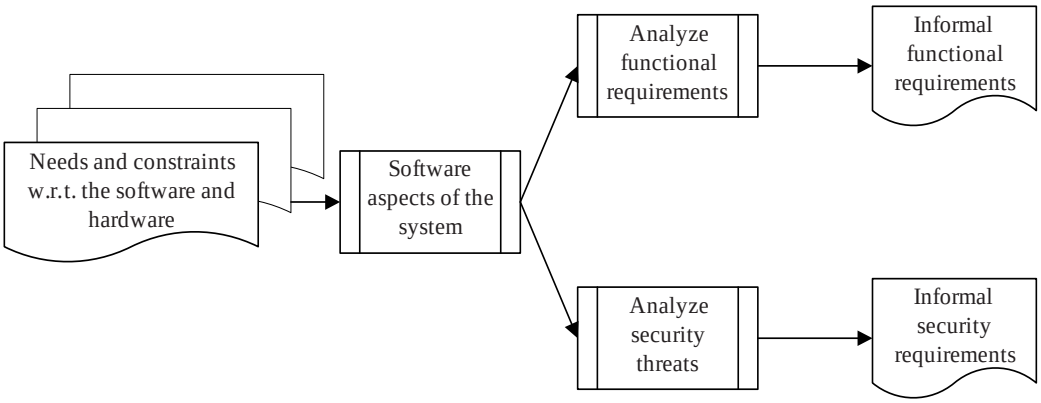


formalized in the requirements specification phase. In other words, the software monitor is equipped with different intrusion detection capabilities. The monitor also measures whether the operational impacts due to security vulnerabilities or residual software faults in a system are acceptable or not.

System Engineering

Software engineering deals with the software aspects of system engineering while security engineering focuses on the overall system engineering (both software and hardware). Similar to software engineering, the end product of the

software security engineering process is software. The system engineering phase of the software security engineering process identifies the software aspects of the system to be developed. Obviously, this phase equally focuses on both functionalities and security issues of the software system based on the users' or stakeholders' needs and in the context of other system elements such as hardware, software, people, database, documentation, and procedure. Both software engineers and security engineers closely work in this phase.

Similar to IEEE Standard 1220-1998 for system engineering (Thayer, 2002), this phase of the software security engineering process involves defining the system requirements that determine the needs and constraints of the software and hardware. This is accomplished through analyzing the functional requirements and all the aspects of security related threats (see Figure 2). The outcomes of this phase are the informal functional and security requirements. These informal requirements then become the input of the requirements specification phase.

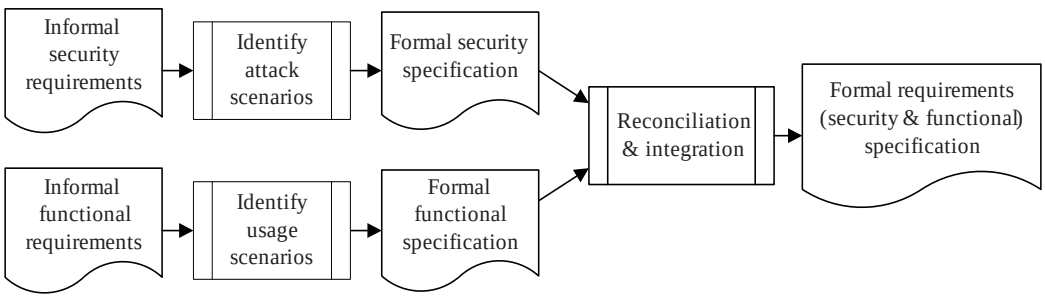
Requirements Specification

Software requirements are usually referred to as functional requirements that specify the behavior of the system, that is, the relationship between inputs and outputs. A nonfunctional software requirement describes not what the software will perform, but how effectively the software will perform. For example, usability, reliability, interoperability, scalability, and security are some of the nonfunctional properties of software systems. Like most other nonfunctional requirements, security is regarded as an important factor to the success of any software project, and it is usually incorporated in the system development in a subjective manner.

There are some inherent difficulties associated with security requirements specification: security requirements are often difficult to be specified in the early phases of the software development life cycle since the software model tends to be very abstract, and is usually presented in an informal manner. In addition, security risks are difficult to be estimated, and as the software development progresses, developers receive new information about the system security (Zhang & Zulkernine, 2004). Given that, it is often difficult to specify security measures and integrate them into the actual system from the very beginning of the software development process. In most cases, security requirements are not addressed at all during the early design phases.

In the software security engineering process, both security and functional requirements are specified in the requirements specification phase (see Figure 3). We believe that the weaknesses of

Figure 3. The requirements specification phase of the software security engineering process



software controlled systems with respect to the software security can be alleviated by specifying functional and security requirements using formal methods, and then by reconciling and integrating the two sets of formal specifications at an abstract level. As the software design evolves, the specifications are refined to reflect the progressive changes towards the end product. In this way, security requirements get closely involved in the later stages of software development.

Scenarios have been widely used as a technique for elicitation, analysis, and documentation of software requirements. A scenario is a sequence of a limited number of related events or actions that represents some meaningful high level operation in a system. The length of a scenario may vary from a single event to all the events of a system. However, all the events of a single scenario must occur during a particular run of the system. In this phase of the software security engineering process, two types of scenarios are identified based on the corresponding requirements: usage scenarios and attack scenarios. The usage scenarios are selected based on the operational profile of the intended software system. The attack scenarios can incorporate expert knowledge on security, and they may be ranked based on their importance in the system being implemented. For example, defending against denial of service attack in a client machine may not be as important as it is in a server machine.

A scenario can be represented in various forms: natural language, pseudo code, data flow diagrams, state machine based notations, communicating event based notations, etc. To avoid inconsistency and redundancy, it is highly recommended that both usage scenarios and attack scenarios should be defined using the same specification language. In the literature, we find a number of formal software specification languages and a relatively fewer number of attack languages to describe attack scenarios (Eckmann, 2001; Vigna, Eckmann, & Kemmerer, 2000). However, currently available software specification languages are not completely suitable for specifying the security related aspects of software systems, nor are attack specification languages suitable in specifying functional requirements. As an initial attempt, software specification languages can be translated to attack languages and vice versa. For example, in (Zhang & Zulkernine, 2004), a formal software requirements specification language of Microsoft called Abstract State Machine Language (AsmL) (Barnett, Grieskamp, Gurevich, Schulte, Tillman, & Veanes, 2003) are automatically transformed to a high level attack specification language called State Transition Analysis Technique Language (STATL) (Vigna, Eckmann, & Kemmerer, 2000), which can be preprogrammed and loaded into an intrusion detection system at runtime. The translation scheme will initially help to close the gap between security requirements and functional requirements with respect to their modeling and implementation.

Software Design

A software architecture or software design defines the software components of a system and the interactions among these components. The examples of application components include user interfaces, databases, and middleware (Kazman, Carriere, & Woods, 2000). Both functionality and security issues are interconnected to where the software components are deployed and how they communicate with each other. For example, the architecture and its protection mechanisms depend on whether the system will operate as a centralized or a distributed one. The software components should be deployed based on the trustworthiness and information flow among them following the principle: “what needs to be protected and from whom those things need to be protected, and for how long protection is needed” (Viega & McGraw, 2001).

In the software security engineering process, a software system should be designed based on the following two principles: compositional software architecture and scenario based software architecture. The following paragraphs discuss these two principles in the context of software security engineering.

New attacks are made to the software systems and security loopholes may be discovered at any point during the life of software. Flexible software architectures are desirable to make the design changes in those situations. A compositional software architecture is one in which the changes required for the whole system can be obtained by applying the changes to its components. As a result, whenever a new attack is encountered, the system architecture can be easily adapted to defend against the attack if a clear and clean notion of component is present. This is only possible if the principle of compositionality and the security concerns were taken into consideration in defining each software component in the software design phase. This adaptive architecture is very useful for rapidly evolving security policies in the post deployment system administration period, and to facilitate the re-engineering of security features into legacy systems. We define the concept of compositionality with respect to software security engineering following the definition of compositional specification and verification (de Roever, 1997). Assume that a system C is composed of the components C1, C2,..., and Cn by employing a set of composition operators. Let the security requirements of C1, C2,..., and Cn be S1, S2,..., and Sn respectively. A compositional design implies that the whole system C satisfies the complete specification S if each component Ci satisfies Si for i= 1,...,n. Therefore, any change of security requirements in any of the components can be addressed and verified without modifying the other components (in a true compositional case).

Scenarios are employed to build the software architecture of a system with a view to incorporating different features described by each scenario (Kazman, Carriere, Woods, 2000). Scenarios are very useful to compare design alternatives, and to understand a legacy system by analyzing the system responses in the context of different environments. Booch et al compared scenario-based design to "making a film" (Jacobson, Booch, & Rumbaugh, 1999). However, scenario-based design of a software system is more than making a single movie as scenarios may be composed in parallel, alternative, or iterative manner in order to build the desired composite system. Similarly, the potential attacks to a system can be specified using attack scenarios, which initially may be abstract, and are refined as the design evolves by considering all security relevant issues.

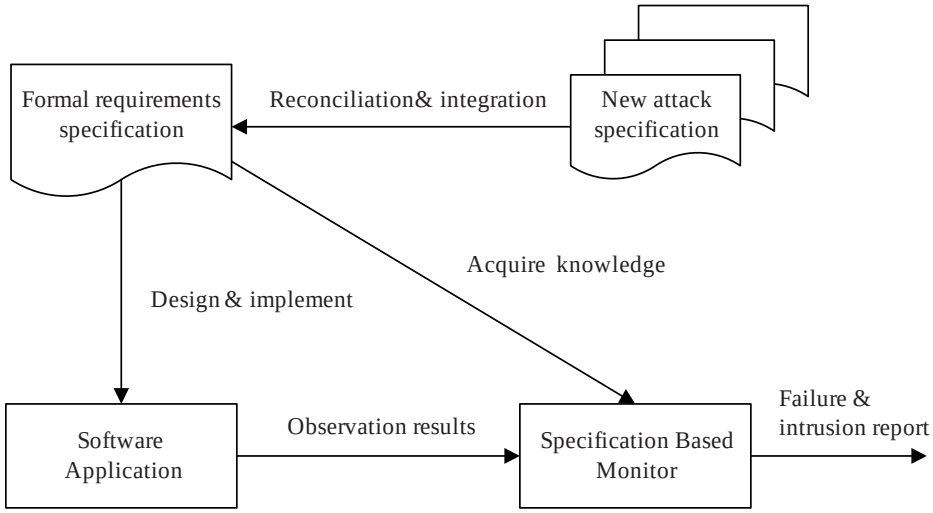
Implementation

Security requirements define the behavior of a system, which should not occur. A programmer working for a particular implementation or an intruder who somehow manages to gain access to the source code can initiate certain actions in the program that may cause target system behavior which should not be allowed. During programming, we should ensure that potential security flaws, identified as security requirements and avoided in the earlier phases of the software security engineering process are not re-introduced in the source code. Any unexpected behavior with respect to program security is called 'security flaw', while 'vulnerability' is considered as a special security flaw (Pfleeger & Pfleeger, 2003). In (Landwehr, Bull, McDermott, & Choi, 1994), the surveyed 'program security flaws' are divided into two categories: intentional and inadvertent. Intentional flaws are categorized as malicious and non-malicious, while inadvertent flaws are divided into the following six types: incomplete or inconsistent validation error, domain error, serialization or aliasing, insufficient identification or authentication, boundary condition violation, and other potential exploitable logic errors.

Given the varying and intricate nature of the above mentioned security flaws, security engineers should participate in coding or understand the code well enough to identify potential security flaws, and convey those to software developers. Security engineers may participate in formal code inspection and review processes to document any security relevant issues present in the source code. More specifically, in the software security engineering process, we propose to follow the principle of code refactoring successfully employed in the context of extreme programming (Beck, 1999). In extreme programming, code refactoring refers to the practice of restructuring the source code without changing the intended functionalities of the system such as removing any duplicate or unreachable code and re-organizing code for simplicity and flexibility. It is important to confirm that refactoring does not introduce any new faults or security flaws into the code. Therefore, individual refactoring steps should be small to address the above mentioned security flaws, and each change should be tested to ensure that the implementation is as functional and self-protected as it was before the refactoring. Note that refactoring is not intended to replace testing in the software security engineering process but rather to complement testing by increasing the confidence in the source code of security critical applications. Once the functionalities required for the system are implemented, refactoring is employed to change the program so that the software can control its vulnerabilities against attacks from intruders while still passing all of the functional requirements tests.

The software should be tested for both functional and security requirements. Based on these requirements along with other non-functional requirements such as performance and quality of service identified in the early phases of the software security engineering process, the test cases for the software system are derived. Vulnerability scenarios of the software that can be exploited for intrusions or security violations are tested. A "read teaming" approach may be used whereby a system is tested using simulated scenarios under which it may be attacked (Viega & McGraw, 2001). We have to ensure that the system is tested in the network environment in which the system will actually run. Keeping that in mind, the testing of

Figure 4. Monitoring an operational software application using a specification based monitor



the software can be divided into two steps: unit testing that tests a host for security; and integration testing that tests the whole system by deploying the system in the target network configuration guided by the applicable security policies.

System Operation

A number of studies have shown that professionally written programs may contain between one and ten faults per thousand lines of codes. Moreover, despite rigorous use of different 'protective shields', there exist security loopholes which elude those protection efforts, and unauthorized intrusions may occur when the network is operational. The difficulty in releasing correct and secure software has resulted in a growing interest in the usefulness of operational stage monitoring of software systems. However, existing intrusion detectors cannot monitor the behavior of software systems, while the current software monitors cannot detect security violations in the target systems.

In software security engineering, a software monitor should also have the capability of detecting intrusions (see Figure 4). The monitor passively observes some of the actual events occurring in a software application at runtime and reports the occurrences of intrusions or behavioral failure. To detect any intrusion or behavioral failure in a target system, the monitor must have the knowledge of what is the ideal or normal behavior of the monitored system. This knowledge can be obtained from the system's formal (behavioral and security) specification identified in the requirements specification phase. Note that this requirements specification was originally used to design and implement the software application as shown in Figure 4. During system operation, the behavior of the monitored system when it is under attack by the intrusions known later on can be specified. Similar to previously considered intrusions, it is also obvious that the newly discovered intrusions may change the behavioral profile of a host or a network. Therefore, new attack specifications are reconciled with the existing formal requirements specification. The monitor interprets the formal specification using the observed events of the monitored host or the network in order to generate a report on intrusive activities as well as unexpected behavior.

CONCLUSIONS AND RECOMMENDATIONS

In this chapter, we have presented a software security engineering process based on the waterfall software process model. The adaptation of the proposed process into other existing software engineering process models is straightforward. It is worth mentioning here that many new engineering disciplines such as software engineering and security engineering have incorporated many concepts and principles from other mature engineering disciplines. Similarly, the individual concepts and techniques suggested in the proposed process are not completely new. What is new in this chapter is their systematic integration and organization into a process that will lead to secure software systems.

It is very difficult to achieve two sets of desired objectives while they "trade off against one another" (Viega & McGraw, 2001). For example: an application software may require root level access privileges in a system to run the application while in some cases it may mean weakening the security of the target system. We believe that the trade off among these goals is very application dependent. The potential conflict between software characteristics and network defenses should be resolved early in the development phase, that is, in the requirements specification phase. In other words, security measures must not hamper the expected quality of service of a system, while at the same time any functionality should not be

achieved at the cost of weakening security. Given that, a software security engineering process should be employed, where functionalities of a system must be specified and defined by considering the security concerns or requirements with respect to the system.

Currently available specification languages are not completely suitable for defining security related aspects of software behavior. The standardized formal software specification languages used in industry should be investigated and extended (if needed) for expressing security related features of target systems. However, it may not be always feasible to formally specify all of the suspicious activities occurring in the target system. Therefore, the formal specification may be supplemented by the statistical components of the operational profiles of the system, users, or intruders. Statistical analysis may be performed to detect any additional intrusions.

History of well-established engineering disciplines shows the key role that automatic development tools played in their advancement. Automatic tools can play a similar role in the area of software security engineering to improve the productivity and quality of the software with respect to security. Existing Computer Aided Software Engineering (CASE) tools cannot be used for software security engineering since their focus is solely on software not security. Both security and software along with productivity and quality, need to be addressed in the CASE tools. The availability of such tools is likely to provide support to further the evolution of software security engineering.

Though we have described the proposed process independent of the current software development paradigms such as procedural, object oriented, or component based, it is worth mentioning here the issue of trustworthiness of software components. With the increase in component based software development, the security of components has become an important issue due to design of software systems composed of untrusted components from independent sources. It is still an open question as to the level of security one can achieve when integrating third party components of a software system (Lindqvist & Jonsson, 1998). In component based software development, components interact to accomplish the functionalities of software systems. In future, a metadata based approach can be used to address the security issues in component interactions since metadata describes the static and dynamic aspects of the components including the accessibility by their users (Orso, Harrold, & Rosenblum, 2001).

ENDNOTES

1 For brevity, functional software requirements are mentioned as software requirements or functional requirements.

2 IEEE definitions (IEEE, 1999) of 'fault' and 'failure' are defined from a different perspective. However, (Wolf, 2004) view "vulnerability" as a "fault" since an attack cannot cause a security failure if no vulnerability exists.

Chapter 7.8
Trusting Computers Through Trusting Humans:
Software Verification in a Safety–Critical Information System

Alison Adam
University of Salford, UK

Paul Spedding
University of Salford, UK

ABSTRACT

This article considers the question of how we may trust automatically generated program code. The code walkthroughs and inspections of software engineering mimic the ways that mathematicians go about assuring themselves that a mathematical proof is true. Mathematicians have difficulty accepting a computer generated proof because they cannot go through the social processes of trusting its construction. Similarly, those involved in accepting a proof of a computer system or computer generated code cannot go through their traditional processes of trust. The process of software verification is bound up in software quality assurance procedures, which are themselves subject to commercial pressures. Quality standards, including military standards, have procedures for human trust designed into them. An action research case study of an avionics system within a military aircraft company illustrates these points, where the software quality assurance (SQA) procedures were incommensurable with the use of automatically generated code.

INTRODUCTION

They have computers, and they may have other weapons of mass destruction. Janet Reno, former US Attorney General

In this article our aim is to develop a theoretical framework with which to analyse a case study where one of the authors was involved, acting as an action researcher in the quality as-

surance procedures of a safety-critical system. This involved the production of software for aeroplane flight systems. An interesting tension arose between the automatically generated code of the software system (i.e., 'auto-code'—produced automatically by a computer, using CASE [Computer Aided Software Engineering] tools from a high level design) and the requirement of the quality assurance process which had built into it the requirement for human understanding and trust of the code produced.

The developers of the system in the case study designed it around auto-code—computer generated software, free from 'human' error, although not proved correct in the mathematical sense, and cheaper and quicker to produce than traditional program code. They looked to means of verifying the correctness of their system through standard software quality assurance (SQA) procedures. However, ultimately, they were unable to bring themselves to reconcile their verification procedures with automatically generated code. Some of the reason for this was that trust in human verification was built into (or inscribed into [Akrich, 1992]) the standards and quality assurance procedures which they were obliged to follow in building the system. Despite their formally couched descriptions, the standards and verification procedures were completely reliant on human verification at every step. However these 'human trust' procedures were incompatible with the automated production of software in ways we show below. The end result was not failure in the traditional sense but a failure to resolve incommensurable procedures; one set relying on human trust, one set on computer trust.

Our research question is therefore: How may we understand what happens when software designers are asked to trust the design of a system, based on automatically generated program code, when the SQA procedures and military standards to which they must adhere demand walkthroughs and code inspections which are impossible to achieve with auto-code?

The theoretical framework we use to form our analysis of the case study is drawn from the links we make between the social nature of mathematical proof, the need to achieve trust in system verification, the ways in which we achieve trust in the online world, the methods of software engineering, and within that, the software quality movement and the related highly influential domain of military standards.

In the following section we briefly outline the social nature of mathematical proof. The next section discusses the debate over system verification which encapsulates many of the ideas of mathematical proof and how such proofs can be trusted by other mathematicians. The article proceeds to consider 'computer mediated' trust, briefly detailing how trust has been reified and represented in computer systems to date, mainly in relation to the commercial interests of e-commerce and information security. Trust is particularly pertinent in the world of safety-critical systems, where failure is not just inconvenient and financially damaging, although commercial pressures are still evident here, but where lives can be lost. The model of trust criticised by e-commerce critics is more similar to the type of trust we describe in relation to safety-critical systems, than one might, at first, expect. Understandably, we would like to put faith in a system which has been mathematically proved to be correct. However computer generated proofs, proofs about correctness of computer software, and automatically generated code are not necessarily understandable or amenable to inspection by people, even by experts. The question then arises of whether we can bring ourselves to trust computer generated proofs or code, when even a competent mathematician, logician,or expert programmer cannot readily understand them.

Following this, we describe the evolution of software development standards and the SQA movement. We argue that the development of quality assurance discourse involves processes of designing human ways of trusting mathematical evidence into standardisation and SQA. Military

standards are an important part of the SQA story, having consequences far beyond the military arena. Standards are political devices with particular views of work processes inscribed (Akrich, 1992) in their design. We note the way that military standards, historically, moved towards formal verification procedures only to move back to rely more on 'human' forms of verification such as code walkthroughs and inspections in the later 1990s. The story is shot through with a tension between finding ways to trust the production of information systems and finding ways to control them. Formal methods, based on mathematical proof offer the promise of control, but only if we can bring ourselves to trust a proof generated by a machine rather than a proof constructed by another person. We present the background to the case study in terms of a description of the complex 'post cold war' military and commercial environment. This is followed by a description of the action research methodology employed in the project, an outline of the case study and an analysis of the case study findings in terms of our theoretical framework. In the conclusion we briefly note that mathematicians and others are gradually finding ways of trusting computers.

THE SOCIAL NATURE OF MATHEMATICAL PROOF

At first sight, the concept of mathematical proof appears to be relatively simple. The idea of a logical and rigorous series of steps, leading from one or more starting positions (previous theorems or axioms) to the final conclusion of the theorem seems to be the basis of mathematics. The concept of mathematical proof leading inexorably to true and incontrovertible truths about the world is very compelling. It is not surprising that we would like to apply the apparent certainty and exactness of mathematical approaches to computer programming. However if we consider briefly how agreement on mathematical proof and scientific truth is achieved by communities of mathematicians, then the social and cultural dimension of proof, as an agreement amongst trusted expert witnesses, reveals itself.

With the epistemological and professional success of mathematical proof, many of the cultural processes which go into making a proof true sink from consciousness and are only rendered visible in times of dispute; for example as in claims to the proof of Kepler's conjecture or Fermat's last theorem (Davies, 2006; Kuhn, 1962; Singh, 1997). Only on the margins then do we call into question our ability to trust these people when a mathematical proof cannot be agreed to be true by an expert community of mathematicians, as sometimes happens.

The apparently pure and abstract nature of mathematical proof fairly quickly breaks down when we inspect it more closely. In particular, when there is disagreement about a proof, the nature of proof is revealed as a social and cultural phenomenon; the matter of persuading and convincing colleagues. DeMillo, Lipton, and Perlis (1977, p. 208) wrote

Mathematicians talk to each other. They give symposium and colloquium talks which attempt to convince doubting (sometimes hostile) audiences of their arguments, they burst into each others' offices with news of insights for current research, and they scribble on napkins in university cafeterias and expensive restaurants. All for the sake of convincing other mathematicians. The key is that other mathematicians are inclined to listen!

This traditional approach towards mathematical proof, which could be described as one of *persuasive rigorous argument between mathematicians leading to trust*, is not the only way to address the idea of proof. A quite different approach appeared in the 1950s and was based on the work on logic developed by Bertrand Russell and others in the 1930s and used the newly invented electronic computer. This new

logic-based approach was not dependent on the computer, but the computer's speed and accuracy had a major impact on its application to the proof of theorems in replacing the persuasive rational argument of competent mathematicians with a *formal* approach which sees any mathematical proof as a number of steps from initial axioms (using predicate logic), to the final proof statement (based purely on logical inference) without the requirement of a human being.

Many proofs can be completed by either method. For instance, many persuasive rigorous argument proofs can be converted to formal proofs (MacKenzie, 2004). It should be emphasised, however, that there is a real difference between the two types of proof. We are not simply talking about a machine taking on the role of a competent mathematician. Some proofs which are readily accepted by mathematicians rely on arguments of symmetry and equivalence, analogies, and leaps of imagination, which humans are very good at understanding but which a formal logic approach cannot replicate. Symmetry and analogy arguments of this type cannot be established by formal methods based on logical progression because symmetry relies on understanding semantics and cannot be gleaned from the syntax of a proof.

Whereas the persuasive rigorous argument, the 'human' approach, has been used for thousands of years, the formal or 'computer generated' approach has been in use for only about half a century. Clearly, the two methods are not treated in the same way by the expert community of mathematicians. With a rigorous argument type of proof, although one may expend much energy convincing one's colleagues of the validity of the proof, the *potential* for coming to agreement or trust of the proof is there. Essentially, in trusting that a mathematical proof is correct, mathematicians are demonstrating their trust in other competent mathematicians. However, expert mathematicians clearly have trouble bringing themselves to trust computer proofs, for good reason, as a computer cannot explain the steps in its reasoning (Chang, 2004).

COMPUTER SYSTEM VERIFICATION: TRUST AND THE SOCIAL

The preceding section contrasted the *use* of computer technology in a claimed proof: the formal method and the human 'rigorous argument' approach to proof. Although this is not the same thing as the proof or verification of a computer system *itself*, in other words the formal, computer generated proof that the computer system matches the specification, the question of whether we can trust the computer is exactly the same.

The idea of *proof* or *verification* of a program is quite different from simply testing the program. Typically, a large suite of programs might have thousands or millions of possible inputs, and so could be in many millions or even billions of states. Exhaustive testing cannot be possible. If a computer system is to be used in the well-funded and high-profile military field to control a space craft, aeroplane, or a nuclear power station, it is highly desirable if the system can be actually *proved* to be correct, secure, and reliable. Since testing, although vital, can never prove the system's correctness, more mathematical methods involving the notion of proof became of great interest in the late 1960s and have remained so ever since.

In fact the history of the verification of computer systems echoes that of mathematical proof, with basically the same two approaches: those who support the rigour of formal methods and those who believe that the purely formal, mechanised proof lacks the crucial element of human understanding (Tierney, 1993). In a paper to an ACM Symposium, DeMillo et al. (1977) argued that the two types of proof were completely different in nature, and that only the persuasive rigorous argument proof with its strong social aspect will

ultimately be believable and capable of earning *trust*

COMPUTER-MEDIATED TRUST

In ethical terms, trust is a complex phenomenon and is essentially a human relationship (Nissenbaum, 1999; Stahl, 2006). We think of trust in terms of a trustor who does the trusting and a trustee who is trusted. The trustee does not of course have to be human, but Nissenbaum (1999) suggests that the trustee should be a being to whom we ascribe human qualities such as intentions and reasons, what might be termed an 'agent.' Trust allows meaningful relationships and a vast range of intuitions to work. Nissenbaum (1999) argues that when we are guaranteed safety trust is not needed: 'What we have is certainty, security, safety – not trust. The evidence, the signs, the cues and clues that ground the formation of trust must always fall short of certainty; trust is an attitude without guarantees, without a complete warrant.' Intrusive regulation and surveillance are attempts at control and bad for building trust.

This generalised definition of trust clearly maps onto our description of mathematicians trusting proofs. They may not have complete certainty over the correctness of a mathematical proof, but they have good reason to trust a competent member of the community of expert mathematicians. Therefore they can trust the proof supplied by such a person.

Understandably, there has been much interest in trust in the online world, both in terms of online security and trust in e-commerce transactions. Nissenbaum (1999) suggests that excessive safety controls, say in e-commerce, may encourage participation but they limit experience: 'Through security we may create a safer world, inhospitable to trust not because there is distrust, but because trust cannot be nourished in environments where risk and vulnerability are, for practical purposes, eradicated.'

Stahl's (2006) take on trust in e-commerce shows another example of the intangible human nature of trust, which has become reified and commodified, so that it can be measured and exchanged in machine transactions. Like Nissenbaum (1999), Stahl points to the way that a trustor does not have complete control over a trustee; vulnerability and uncertainty must be accepted in a trusting relationship. This of course includes business transactions, and is especially important in e-commerce as many of the traditional ways of developing trust are absent from online transactions. Trust becomes a way of generating profit; small wonder that trust, including technological ways of creating trust and maintaining it, has been of so much interest in e-commerce. In the world of e-commerce research, trusts lose its relational aspects and becomes a form of social control. 'If trust is limited to calculations of utility maximisation in commercial exchange, then most of the moral underpinnings of the mechanisms of trust become redundant. Trust changes its nature and loses the binding moral quality that it has in face-to-face interaction.' (Stahl, 2006, p. 31)

Although, on the face of it, Nissenbaum's and Stahl's arguments on the problems of online trust in e-commerce are not the same as the issue of trust described in the body of this article, there are important congruencies which are very directly applicable to our characterisation of trust. Whether it is a human trusting another human or an expert mathematician trusting another expert mathematician to supply an accurate proof, the same relationship between trustor and trustee obtains.

For Nissenbaum and Stahl, the issue is what happens to trust when it is commodified within an online relationship. In other words, what happens when the human-trusting-human relationship is mediated by technology? In this article we also consider what happens when the human-trusting-human relationship—in terms of a human trusting another human's mathematical proof, or computer program—is replaced by a human

having to trust a machine. Of course, in this trustor-trustee relationship, the trustee, that is, the machine, cannot be understood in the way that another person can be.

The pressure to create computer-mediated trust is completely bound up with commercial pressures. The maximisation of profit drives the reification of trust in e-commerce. Similarly in the world of military avionics we describe, it is the commercial pressure of building systems more cheaply and faster which provides the impetus to turn over proofs, testing of programs, and automatic generation of code to a machine. A third aspect of similarity between Stahl's and Nissenbaum's view of computer-mediated trust and ours relates to the tension between trust and control. This is clearly present in the debate over trust in e-commerce. But it is also present in software quality discourse as we discuss below.

In the following section we briefly discuss some of the ways in which human trust has traditionally been built into procedures designed to verify program correctness, and how this can be seen to mirror an ideal group of mathematicians agreeing upon a mathematical proof.

BUILDING TRUST INTO A COMPUTER SYSTEM

We argue that, historically, much of the development of the software engineering discipline can be understood in terms of the development of procedures, through which we can convince ourselves to trust, and control, the development of information systems and the production of software. For instance, Myers' (1979) classic book on software testing explores the topic of human testing in detail, justifying methods such as formal *code inspections* and *code walkthroughs*. The differences between the two methods depend on different usages of the terms 'inspection' and 'walkthrough,' but the important point is that both involve a small group of professionals carefully reading through code together. We argue that this can be viewed as an imitation of the social (persuasive rigorous argument) form of proof described earlier where 'mathematicians talk to each other' in symposia and colloquia and so on (DeMillo et al., 1977). The original programmer should be in the group, analogous to the mathematician demonstrating a proof or principle to expert colleagues. The aim (as originally suggested by Weinberg [1971]—an 'egoless' approach) is to discover as many errors as possible rather than to try to demonstrate that there are none. So the team is to act as an idealised group of 'Popperian' scientists looking for 'refutations' (Popper, 1963). Under such an approach, one can never be entirely sure that the code is correct. But, as the walkthrough proceeds, the original programmer and the code inspection team can gradually come to trust the code as bugs are weeded out and fixed.

Myers claims positive advantages of code inspections and walkthroughs, including the value of the original programmer talking through the design (and thus spotting the errors). He also notes the ability of human testers to see the causes and likely importance of errors (where a machine might simply identify symptoms) and also the likelihood that a batch of errors will be identified simultaneously. Also the team is able to empathise with and understand the thought processes of the original programmer in a way which a machine arguably cannot. Importantly, the team can be *creative* in its approach. In working together they also, inevitably, form something of a sharing and trusting community (even if it is disbanded after a day or two).

The lesson gleaned from human verification techniques, such as walkthroughs and code inspections, is that these have been regarded, for some time, as reliable, if not exhaustive, ways of ensuring reliability of software.

SOFTWARE QUALITY ASSURANCE AND MILITARY STANDARDS FOR SOFTWARE

The software verification techniques of code walkthroughs and inspections are important parts of the armoury SQA. Effectively, we argue that SQA is a branch of software engineering which formalises and standardises the very human methods of trust, and ultimately control outlined above, which we need to build into software engineering procedures. The SQA movement is an important part of the story of the growth of software engineering because of its quest for rigour and control of potentially unruly programs and programmers.

First of all, SQA offers a promise of rational control over software, the software development process, and those who produce software. Software quality criteria include features for directing, controlling, and importantly, measuring the quality of software (Gillies, 1997). 'Qualification' is achieved when a piece of software can be demonstrated to meet the criteria specified in these quality procedures. An important aspect of SQA involves demonstrating that software meets certain defined independent standards.

The development and adherence to software standards is a very important part of the story of SQA. Generic industry standards are available, but also of much interest—particularly for the case study set out later in the article—are military standards. Indeed, the defence industry is so influential that Tierney (1993) argues that military standards influence software engineering far beyond applications in defence. Hence military standards are a very important part of SQA, and ultimately are important in formalising ways in which designers of computer systems can come to trust the systems and the production of correct software.

A number of military standards have been developed to regulate and control the use of software in defence applications. For instance, US standards DOD-STD-2167A (1988), MIL-STD-498 (1994), and ISO/IEC 12207 (1995) respectively established the requirements for software development and documentation in all equipment to be used by the US military (and effectively that of all Western armed forces), introduced object oriented development (OOD) and rapid application development (RAD), then broadened the scope of international standards to include acquisition and maintenance. (DSDM Consortium, 2006).

The relevant UK standard 00-55, (MoD, 1997) *Requirements for Safety Related Software in Defence Equipment*, was published in 1997 and echoes much of MIL-STD-498, but moves the discussion on provably correct software in a particular direction. At first sight, this seems highly significant to the current argument, because it clearly expressed a preference for *formal* methods, in other words mathematical procedures whereby the software is proved to be correct by a machine (MacKenzie, 2001).

Tierney (1993) argues that the release of UK Defence Standard 00-55 in draft in 1989 had the effect of intensifying the debate over formal methods in the UK software engineering community. It devoted as much space to regulating and managing software development labour processes as the techniques and practices to be used for formal designs. This reinforces our argument that SQA is concerned with control of work processes and those who perform them, the software developers. On the one hand, many argued that mathematical techniques for software development and verification could only ever be used sparingly, as there simply was not enough suitable mathematical expertise in most organisations and it increased software quality at the expense of programmer productivity. On the other side, those from a more mathematical camp argued that there was commercial advantage in proving software correctness as errors could be trapped earlier in the software development cycle (Tierney, 1993, p. 116).

Designed into the MoD (UK Ministry of Defence) standard was a view of safety-critical software as an important area of regulation and control. Some of the reason for this was a change in its own organisation from the 1980s. The UK government sought to open up work traditionally done in-house by the MoD in its own research establishments to private contractors (Tierney, 1993, p. 118). Given that it had to offer its software development to the private sector, it built in ways of controlling it within its defence standards (Tierney, 1993, p. 118). Further political impetus was offered by the introduction of consumer protection legislation in the UK in the late 1980s which required software developers to demonstrate that their software had not contributed, in the event of an accident enquiry, and that they had demonstrably attended to safety. Thus we can see that in Def Stan 00-55, politics, in the shape of the MoD's need to open up software development to the private sector and also to avoid being held responsible for inadequate software in the event of an accident, played an important role.

However, more significantly, this document has itself been superseded in 2004 by (draft) standard 00-56 (MoD, 2004). Def Stan 00-55 has now become obsolete. The changes involved in Def Stan 00-56 are of great interest, in that the preference for formal method is lessened. In the new standard, it is accepted that provably correct software is not possible in most cases and that we are inevitably involved in a human operation when we attempt to show that code is reliable in a safety-critical environment. Without a more detailed consideration of the history of formal methods in the UK over the last decade, which is beyond the scope of the present article, a strong claim that the move back to more human methods of verification might be difficult to sustain. Nevertheless it is interesting to note the way that Def Stan 00-5, with its emphasis on formal approaches and attendant onerous work practices, has been consigned to the history books with a clear move back to human verification.

CASE STUDY CONTEXT

The case study relates to a large European military aircraft company (MAC) with which one of the authors was engaged as a researcher in a joint research project, lasting around three years, during the mid to late 1990s. A high proportion of the senior management were men and its culture was masculine in style, particularly emphasising an interest in engineering and technical mastery (Faulkner, 2000). Indeed there was much interest, pleasure, and admiration for elegant products of engineering (Hacker, 1991). When one of their fighter planes flew over (an event difficult to ignore on account of the engine noise), offices would clear as employees went outside to admire the display of a beautiful machine. A certain amount of military terminology was used, sometimes ironically, in day-to-day work. A number of employees had links with the armed forces. MAC was exclusively involved in the defence industry, with the UK's MoD being its largest customer and other approved governments buying its products.

As a manufacturing company in an economy where manufacturing was in steep decline and with its ties to the defence industry, if a major defence contract went elsewhere, jobs would be on the line. Despite the 'hi-tech' nature of its work, MAC had a traditional feel to it. The company had existed, under one name or another, right from the beginning of the avionics industry. The defence industry, and within that the defence aerospace industry, faced uncertain times as the UK government was redefining its expectations of the defence industry in post-Cold War times. It quickly came to expect much clearer demonstrations of value for money (Trim, 2001). Therefore, the 'peace dividend' brought about by the end of the Cold War meant uncertain times for the defence aerospace industry as military spending was reduced significantly (Sillers & Kleiner, 1997). Yet, as an industry contributing huge amounts to the UK economy (around £5

billion per annum in export earnings Trim (2001, p. 227)), the defence industry is hugely important in terms of revenue and employment. Defence industries have civil wings (which was the case with MAC) and it was seen as important that the defence side of the business did not interfere with civil businesses. For instance, BAE Systems is a partner in a European consortium and was pledged £530 million as a government loan to develop the A3XXX aircraft to rival the USA's Boeing 747 (Trim, 2001, p. 228).

Although not strictly a public sector organisation itself, its location in the defence industry put MAC's business in the public sector. However, in the UK, views of public sector management were undergoing rapid change in the mid 1990s and it was seen as no longer acceptable that the taxpayer should underwrite investment (Trim, 2001). Such firms were required to be more competitive and to be held more accountable financially. Hence, quality management and value for money were becoming key concepts in the management repertoire of the UK defence industry from the mid 1990s onwards. As we discuss in the preceding section, this was at the height of the UK MoD's interest in formal approaches to the production of software. In a climate where post-Cold War defence projects were likely to demand a shorter lead time, there was considerable interest in speeding up the software development process.

Computer technology and related activity clearly played a central role in MAC. One division of MAC, the Technical Directorate (TD), developed most of the airborne software (much of it real-time). This software clearly has a central role in ensuring aircraft performance and safety. Around 100 people were involved in developing systems computing software. It was in this division that Software Development System (SDS), a safety-critical airborne software system for flying military aircraft, was developed.

Research Methodology

The methodological approach of the research was based on action research (Myers & Avison, 2002). As several successful participant observation studies in technology based organisations have been reported in the literature (Forsythe, 2001; Low & Woolgar, 1993; Latour & Woolgar, 1979), an ethnographic approach holds much appeal. However, a strict ethnographic approach was neither feasible nor desirable in this study. As someone with technical expertise, the researcher could not claim to be the sociologist or anthropologist, more typical of reported ethnographic studies of technological systems (Low & Woolgar, 1993; Forsythe, 2001). This also meant that he was not 'fobbed off' by being directed into areas that the participants thought he wanted to look at or where they thought he should be interested in as happened in the Low and Woolgar (1993) case study. Based in the Quality Assurance Division (QAD) in the SQA team, early in his research, the researcher proved his technical credentials by helping run a workshop on software metrics and this helped to gain him full inclusion in the technical work. Although as a technical researcher, rather than a social researcher, it was arguably difficult for him to maintain the 'anthropological strangeness' which ethnographers look for in explaining the common sense and every day logistics of working life. In any case, he had been invited, through this research, to make a contribution to the improvement of SQA procedures. Therefore the research can be characterised as a form of action research (Baskerville & Wood-Harper, 1996), where potential improvements to SQA were to be seen as the learning part of the action research cycle.

Although action research receives a mixed press from the IS research community (Baskerville & Wood-Harper, 1996; Lau, 1999), it is nevertheless seen as a way of coming to grips with complex social settings where interactions with information technologies must be understood

within the context of the whole organisation. Baskerville (1999) notes the growing interest in action research methods in information systems research. Two key assumptions are that complex social settings cannot be reduced for meaningful study and that action brings understanding (Baskerville, 1999). The culture of MAC was extremely complex, as we characterise above and discuss again in what follows. Arguably, key elements would be lost were the researcher to have adopted a more distant role, relying on interviews and questionnaires rather than becoming fully immersed and contributing to the detail of the project. The researcher adopted an interpretivist approach, looking to the interpretations of the other participants of the research. But by allowing for social intervention he became part of the study, producing shared subjective meanings between researcher and subjects as coparticipants in the research (Baskerville, 1999).

For a period of over one year out of the three that the whole project lasted, the researcher spent, on average, one day per week working with MAC staff with access to a variety of staff across the organisation, and was therefore able to participate in a range of meetings and workshops and to gain a familiarity with the individuals concerned. This could not easily have been gained from interviews or surveys. These events included meetings where software quality staff considered quality policy, such as the implication of international standards, to broader meetings where technical staff were considering development methods in detail. Free access was allowed to relevant policy and development documents. This permitted an overview of the detailed practices and culture of this large and complex organisation.

Analysis of Case Study Findings

The initial remit of the researcher was to work with staff to optimise the use of software quality assurance within the organisation. The use of cost benefit analysis was originally suggested by senior management. Given our characterisation of the UK defence industry's particular focus on management of quality and value for money, as described above, it is entirely in keeping with the industry's changing needs that the researcher was initially directed into these areas. The researcher viewed it as problematic to assign monetary cost to SQA activities, and even harder to assign monetary benefits. However, these concerns were never addressed directly in the project as it soon emerged that there was greater interest in a new approach to software development being pioneered by MAC.

Ince (1994, p. 2-3) tells the story of a junior programmer's first day in a new job. A senior programmer shows him around, advising him where to buy the best sandwiches at lunchtime, where to find the best beer after work, and other similarly important matters. Then the senior colleague points to a door. 'Whatever you do don't go through that door, the people there have been given the job of stifling our creativity.' The door, of course, led to the quality assurance department.

The staff of MAC's Quality Assurance Division expressed some similar feelings, albeit less dramatically. They wanted to act as consultants, offering a measure of creativity to the technical development process, although safely wrapped in appropriate quality assurance processes, but all too often they felt like the police. The strong awareness of the safety-critical nature of software development, and the related fairly advanced organisation of quality assurance in MAC, thanks in no small measure to the necessity to adhere to MoD standards, meant that SQA was never going to get quite the negative press that it attracted in Ince's (1994) anecdote. Nevertheless, there was still some feeling that the Quality Assurance Division could be brought on board in a project some time after the Technical Division had time to do the creative part.

Hence, TD had been prototyping the new SDS system for about a year when they decided to bring in Quality Assurance Division. As we explain below, the newness of the style of development in SDS made it unclear how it was to be quality assured. Unsure of how to proceed, the SQA manager turned to the researcher for suggestions. The researcher now became involved in investigating the use of the new software development approach, which would involve the inclusion of computer generated program code ('auto-code') in safety-critical airborne software systems, leading to the approval of the new approach and its incorporation into MAC's software quality assurance systems.

Although there has been a long tradition of using computers to aid the process of software engineering itself, such CASE tools (Pressman, 2005) have not generally been used to generate safety-critical code (this was always written by human programmers). The new MAC SDS was an ambitious system whose targets were principally to reduce avionics systems development time by 40% and the cost by 30%, whilst maintaining the very high quality standards necessary for computer-based system which fly—and therefore can crash—military aircraft.

A key aspect of SDS was process integration using an integrated modeling environment. There was consequentially a heavy reliance on automated methods. A specification was developed in a formal modeling language and this generated programming code automatically. In particular, automatic code generation was eventually to lead to aircraft flying 'auto-code' in safety-critical systems. Two aspects of SDS stand out in the climate of defence spending of the mid 1990s. First, there was pressure to reduce costs and show value for money. Second, the use of formal methods in computer programming received a huge boost in the mid-1990s through the Defence standard DEF Stan 00-55 which mandated the use of formal methods base approaches in safety-critical software. It is not surprising that there was considerable interest in a system which offered the promise of considerably reduced software production times.

MAC invested a great deal of money and time in SDS in the hope that the improved time-scales which SDS promised, together with reduced costs, could keep major current aircraft developments on course. This was particularly important in an environment of political intervention and considerable public interest and concern over escalating costs and delivery times in the public sector, including the defence industry. These benefits could only accrue to MAC if the quality, that is, correctness of the software, could be assured.

SDS was heavily dependent on software (CASE) tools. MAC had used these for many years, and had procedures in place for their qualification (i.e., acceptance) in certain circumstances. However, these applied to mission-critical rather than safety-critical systems. Furthermore, the movement towards auto-generated code led to a different environment than one where tools improved and speeded up the design process, but where failure would show up and be merely time-wasting. There was seen to be a need for a major improvement/update of these procedures, a quantum change, before they would be acceptable for safety-critical applications.

Some tools being used had major world-wide user communities, associated academic conferences, and came from supposedly secure and reliable suppliers. Others might not be so well supported, both intellectually and commercially. (For instance, it might be no use having an ideal tool if the supplier was small and unlikely to survive for many years.) Methods already existed for supplier qualification. These methods were undertaken by software quality staff. However, the qualification of these suppliers could be a crucial issue in the qualification of the tool and ultimately the integrity of the avionics system. The issue was not merely one of qualification, it was also one

of *demonstration* of qualification to customers. Ultimately, the need in some sense to *prove* the new methods became paramount. Hence we can see that quality procedures did not just involve procedures, such as code walkthroughs through which software teams could persuade themselves to trust program code, they also applied to the question of choosing and trusting suppliers.

A number of meetings took place with members of the SDS team. This discussion was very useful for an understanding of SDS and gave the researcher a richer understanding of the SQA needs. It soon became apparent that the necessary fundamental problems with SQA in SDS were going to be difficult to answer.

The difficulties were centred around two conflicting ideas. The first of these was that for the *persuasive rational argument* approach to be successful there would be a need for a group of professionals to participate in code walkthroughs, with consequent discussion and persuasion. On the face of it, this was simply not possible, since the computer which wrote the auto-code could not take part in such a discussion. Alternative approaches were considered. Clearly there would be a stage before the auto-code (at the requirements specification level) where human agents were involved, but this was found to be too high level to meet the relevant military standards (the US MIL-STD-498 [1994] and the UK standard 00-55 [MoD, 1997]). Both standards are very specific about the exact conduct of the necessary walkthrough. It had to be a *code* walkthrough.

On the other hand, for the *formal proof* approach method to work, there would first need to be such a formal proof. This did not seem within the capability of the QAD itself, despite the division being quite well resourced. MAC referred back to the auto-code tools suppliers, but once again there was no such proof and no realistic possibility of achieving such a proof. Although MAC was an important customer for the auto-code tool suppliers, they were not prepared to expend the necessary resources. Furthermore, a 'weakest link' argument demonstrates a fundamental flaw with the formal approach in computer systems. If the auto-code tool itself could be formally verified, it would then become necessary also to consider the operating system on which the tool would run and the hardware systems involved. Potentially this could involve a seemingly infinite regression of hardware and software systems having to be proved correct, where the system is only as good as its weakest link. Frustration grew as no solution was forthcoming and ultimately SDS was shelved indefinitely.

We have argued that mathematical proof is essentially a human achievement between members of the expert mathematical community who are persuaded of the correctness of mathematical proofs because they trust each other. These processes of trust are replicated in the procedures that have been developed in software engineering, and within that, software quality assurance. As part of the defence industry, developing safety-critical systems, MAC had highly developed SQA procedures which were obliged to follow international military standards. Their code walkthroughs, which are analogous to the ways mathematicians achieve trust in a proof, were an important part of such quality procedures. Formal methods offer the promise of an attractive certainty and control over software production and hence control over the work processes of human programmers. They also offer the promise of automatic verification of software systems which, potentially, could be much cheaper than traditional human based approaches to the verification of software through traditional SQA procedures.

SDS achieved very little despite the huge efforts put into it by the many people working for MAC. Although it was not, at the time, formulated in such stark terms, success was elusive because an attempt was being made to achieve the impossible: namely using auto-code whilst being held to quality assurance procedures which demanded

code walkthroughs which could not possibly be achieved in an auto-code system. Attempts were made to consider formally proving the correctness of the auto-code. In addition to supplier reluctance, this raised the spectre of the infinite regress. If one looks to proving the auto-code correct, then the operating system must be proved correct, the hardware platform and so on.

This was at the height of interest in formal methods for safety-critical systems for defence, a view embodied in Def Stan 00-55. The rise of formal methods is crucially linked to the defence industry. The interest in formal methods and automated approaches arrived as pressure mounted on Western governments to prove cost effectiveness due to the changing nature of defence developments after the end of the Cold War and the need to avoid litigation for software that might be implicated in an accident. Yet the difficulties of applying formal methods in systems of any level of complexity and the need to trust the program code acted as a spur to maintain complex human centred software quality assurance procedures.

CONCLUSION: TRUSTING COMPUTERS

There is much evidence that we already *do* trust computers in many walks of life without formal proof or other formal demonstration, even to the extent of trusting safety-critical systems such as the 'fly by wire' software in the Boeing 777 airliner, two million lines of code which have not been fully proved (Lytz, 1995). Expert mathematicians have begun to accept computer generated proofs, albeit in qualified ways (Chang, 2004). As MacKenzie (2001, p. 301) argues, 'moral entrepreneurs' of computerised risk ensure that warnings about computerised risk are heeded so that safety-critical software is avoided and, where it is unavoidable, much care is taken over its development. Military standards, so detailed about the use of formal methods in software design and attendant work processes in the 1990s, have moved a decade later to be much less prescriptive about the work methods of ensuring software quality, thereby allowing for the crucial element of human inspection in order that the software may be trusted. As Collins (1990) notes, we are remarkably accommodating to computers, making sense of them and involving them in our social networks, and will continue to find imaginative ways of doing so. This echoes Nissenbaum's (1999) view that we may trust computers if we can treat them as 'agents.' We may meaningfully ascribe intentions and reasons to them.

In this article we have sought to tell a story of trust, in particular how software may be trusted when it is not produced by a human programmer. This involves consideration of a complex set of discourses including the question of mathematical proof and how proof is achieved within mathematical communities. We see a similar need to replicate such human processes of trust in trusting computer systems. We have argued that the making of standards to be applied within software quality assurance procedures shows ways in which mechanisms of trust are inscribed in software standards. Our case study, an action research project in a military aircraft company, demonstrates the difficulties which occur when quality assurance procedures involving code walkthroughs—procedures with built-in human trust mechanisms—are incommensurable with a system which relies on auto-code. The climate of defence research and spending was a major influence, both on our case study and the wider development of standards. There is a continued tension between needing to trust and trying to control: trusting the software and controlling its production. The story which we tell here is one of continuing human ingenuity in finding ways of trusting computer software.

Chapter 7.9
Access Control Specification in UML

ABSTRACT

Security requirements have become an integral part of most modern soft¬ware systems. In order to produce secure systems, it is necessary to provide soft¬ware engineers with the appropriate systematic support. This chapter discusses a methodology to integrate the specification of access control policies into UML. The methodology, along with the graph-based formal semantics for the UML access control specification, allows to reason about the coherence of the access control spec¬ification. The chapter also presents a procedure to modify policy rules to guarantee the satisfaction of constraints, and shows how to generate access control requirements from UML diagrams. The main concepts in the UML access control specification are illustrated with an example access control model for distributed object systems.

INTRODUCTION

Security requirements are an important aspect in the development of software systems that are not used in completely trusted environments. In order to increase the overall system security and to better satisfy security constraints, security policies should be specified in terms of security models that are integrated with the general software engineering models. Modelling techniques that are well known to software engineers should be used, to prevent them from specifying mistakes in security

specifications due to inadequate expertise of the particular specification technique. The reasoning about and the verification of security properties require a formal semantics for the specification technique.

Since the UML is nowadays the de-facto standard modelling language, the usage of UML for the specification of security aspects is particularly attractive, since software engineers are used to the UML notation and the accompanying tools (Brose, Koch, & Lohr, 2002; Devanbu & Stubblebine, 2000; Epstein & Sandhu, 1999; Jurjens, 2001; Lodderstedt, Basin, & Doser, 2002). We identify in this chapter the parts necessary to specify an access control policy and propose a UML specification for these parts. In our framework, we use only existing UML model elements and extension mechanisms to ensure compatibility with UML tools that can then be directly used for the access control specification. The UML specification of an access control model makes use of UML class diagrams, object diagrams, some additional stereotypes and OCL constraints (OMG, 2003).

Access control constraints restrict an access control model and prevent the system from reaching unwanted protection states. The expression and specification of access control constraints is a difficult task and existing languages are often too complex for administrators to determine whether a set of constraints really satisfies the requirement. Therefore, access control languages have been proposed which have a manageable complexity and are understandable by administrators but still expressive enough to capture most practical access control constraints (Ahn & Sandhu, 2001; Jaeger & Tidswell, 2001; Koch, Mancini, & Parisi-Presicce, 2002c). We present in this chapter an approach to specify access control constraints in UML. We consider OCL constraints as a textual presentation of access control constraints, but present also visual constraint specification by UML object diagrams (Koch et al., 2002c; Ray, Li, France, & Kim, 2004).

In our approach, access control models are specified on several levels, depending on the added application domain information similar to the UML meta-modelling architecture (without the metametamodel). On the metamodel level, there is no application domain information and the access control specification shows only the policy rules and constraints. This is the level at which the generic access control model, such as Role-Based, Mandatory, Discretionary, are described. The model level is an instance of the meta access control model and refines it using application domain information. At this level, the specific roles used in RBAC or the clearance, and categories used to construct the labels in MAC are defined depending on the application. The last level is an instance of the access control model in a specific information domain. This is the level at which principals are assigned to roles or labels, or specific permissions are assigned to roles.

To verify that an access control policy satisfies all the access control constraints (i.e., the policy permits only system states that satisfy all the constraints) an appropriate formal semantics for the UML access control model is needed. We give a graph-based formal semantics (Rozenberg, 1997) to the UML access control specification by a transformation of UML class and object diagrams, respectively, into graphs and graph rules. The graph-based semantics enables us to use several verification concepts to verify the constraints with respect to the access control model (Koch, Mancini, & Parisi-Presicce, 2001; Koch, Mancini, & Parisi-Presicce, 2002b).

To know how to model access control requirements into UML is only part of the problem. Another essential part is to determine the access control requirements themselves. We present an approach to generate automatically access control requirements from UML use case, class, and sequence diagrams. The extracted access control information is the basis for the UML access control model.

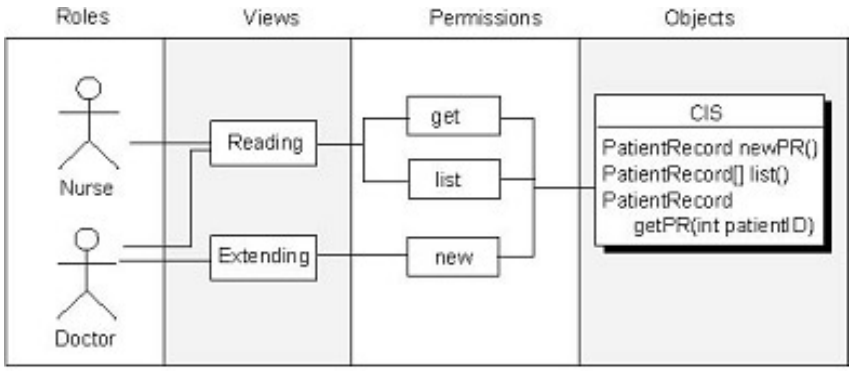
The remainder of the chapter is organized as follows: the next section briefly discusses access control policies and introduces View Based Access Control as the access control model used in this chapter as the running example. The following section gives an overview of our approach, introducing the three specification levels of access control models. The two subsequent sections present the UML specification of the access control metamodel and its refinement to an application domain specific access control model. Our example application domain is a small hospital information system. The model is then further refined with the specification of access control constraints in UML. The section on Verification briefly mentions graph transformations as an effective way to give a formal semantics for an UML access control specification. The next section illustrates the generation of access control requirements from UML diagrams, whereas the penultimate section provides a brief discussion of other approaches and of related work. The chapter closes with a summary of its contents and pointers and suggestions for open problems.

ACCESS CONTROL IN OBJECT-ORIENTED SYSTEMS

Access control is the typical approach to limit access to resources in general, and to objects in particular. The restrictions include preventing principals from reading the contents of a file to protect the confidentiality of the data, or from modifying entries in a database to maintain the integrity of the data and the trustworthiness of the information contained. Access control policies describe which states of the system are deemed acceptable (safe), in which authorized principals can access entities in the appropriate manner (e.g., in read mode for confidential data, in write mode for trusted data), and security mechanisms are designed to implement the security policies.

View-based access control (VBAC) is an access control model specifically defined to support the design and management of access control policies in object-oriented systems (Brose 2000; Brose 2001a). VBAC relies on roles as abstractions of callers and can be regarded as an extension of *role-based access control* (RBAC) (Sandhu, Coyne, & Feinstein, & Youman, 1996) to distributed object systems. Rolebased access control reduces the complexity and cost of security administration in large systems because roles serve as a link between access modes for

Figure 1. VBAC example



objects (e.g., read or write access if the object is a file, the print command for a printer, a method of a distributed object etc.) and subjects (users or processes that run on behalf of them). A subject can access an object if it has been authorized for, and has activated, a role that has been assigned the required permissions for the access.

The principal new feature of VBAC is that of a view for the description of fine-grained access rights, which are permissions for calling operations of objects. Views on objects are assigned to roles, and a subject can call an operation of an object if it has a view on the object with a permission for the operation. The subject has no access to the operation if the operation is not in a view assigned to one of the subject's roles.

Figure 1 illustrates a small access control example for CIS objects providing the operations newPR(), list() and getPR() (the meaning of these objects will be explained in more detail in a later section). The CIS represents a hospital central information system used to manage the records of patients.

The permissions get, list and new give the access right to call the operations *getPR()* (returns the patient record of a patient for a given ID), *list()* (lists all patient records) and *newPR()* (creates a new patient record). There are two views in this example: the view Reading contains the permissions get and list, and the view Extending has the permission new. The view Reading is assigned to both the role *Nurse* and the role *Doctor*, while the view Extending only to the role *Doctor*. Therefore, any user in the role *Doctor* can call any operation of CIS objects, while a user in the role *Nurse* has access to read the patient records, but cannot create a new one.

VBAC access policies are deployed (via descriptor files) together with applications in the target environments, as in approaches like EJB (Sun Microsystems, 2000) or the CORBA Component Model (OMG, 1999). These policies are initially designed by developers and subsequently used and possibly adapted by deployers and security managers. The deployment and management infrastructure designed for this approach is called Raccoon (Brose 2001a; Brose, 2001b). A deployment tool processes policy descriptors, and stores static view and role definitions in repositories that can be managed using graphical management tools. At runtime, role membership is represented by digital certificates, issued by a role server. Access decisions are made locally in the server processes that host application objects, based on policy information supplied by the policy servers, which rely on the deployed policy information. Policies can be managed in terms of roles and views using graphical management tools. A more detailed presentation of the policy enforcement infrastructure can be found in (Brose 2001a; Brose 2001b; Brose 2002).

OUTLINE OF OUR APPROACH

An access control policy consists of a set of policy rules that define the choices in the individual and collective behaviour of the entities in the system. To specify an access control policy, it is necessary to model the entities in the system, the policy rules for the behaviour of these entities and (possibly) additional constraints. We model all these parts of an access control policy using UML in order to integrate them easily into the UML software process. The entities on which the policy operates are specified in a UML class diagram, the policy rules are specified by specially annotated object diagrams, and the access control constraints are specified either textually by Object Constraint Language (OCL) constraints or visually by object diagrams. Therefore, a *UML access control specification* ACS = (*T, PRules, Constr*) consists of the following UML diagrams:

- T , called *type diagram*, is a class diagram that specifies the available entities,

- *PRules* is a set of object diagrams for the specification of the policy rules,
- *Constr* is a set of object diagrams or OCL constraints to model Access Control constraints.

In general, an access control model is independent of an application. For example, the RBAC model describes a general concept of how to manage access on resources that can be applied to many application domains. Therefore, we use a threelayer model structure consisting of an access control metamodel (ACMM), an access control model (ACM) and an access control instance model (ACIM). Each of these models (ACMM, ACM, and ACIM) consists of a type diagram and object diagrams for policy rules and constraints, but describes the access control policy on a different abstraction level. The access control metamodel defines the language for specifying access control models such as VBAC, RBAC, Discretionary or Mandatory Access Control models. The ACMM is independent of any information or application domain. The access control model is an instance of the access control metamodel and introduces the information and application domains. If the metamodel specifies an RBAC model, doctor and nurse would be roles specific to a medical information domain. The instance access control model is an instance of the access control model in a specific information or application domain. Examples would be orthopaedist, surgeon, internist, etc., as doctor role instance objects. The following table summarizes the three layers.

Figure 2 shows the relations between the access control diagrams on the different layers.

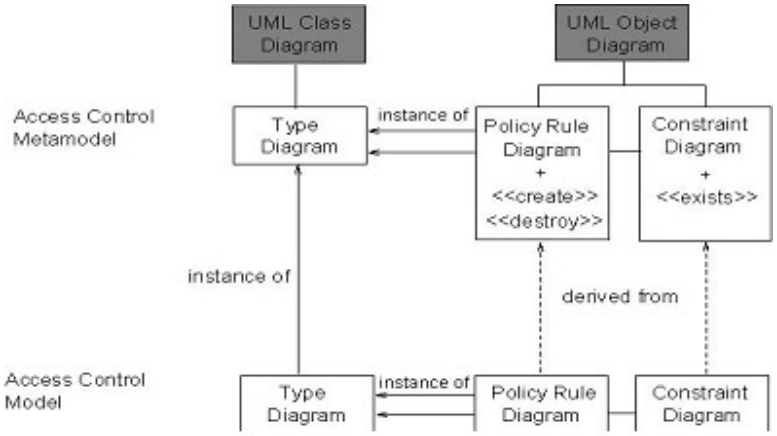
We focus here on the access control metamodel and the access control model and introduce, in the next sections, their specification for the example of the VBAC model described in the previous section. The application domain for the access control model is a medical information system.

The three-layer model structure gives a method to specify access control policies in UML, but it leaves open the question of what a system designer has to specify in a concrete access control policy while developing a concrete application since, so far, there is no support for access control requirement analysis. In the last section, we briefly present a model-driven approach to access control specification which supports a system designer in developing an access control model for a given application domain.

Table 1.

Layer	Description	Example
Access control metamodel (ACMM)	Access control model independent of an information/application domain	VBAC, RBAC, etc.
Access control model (ACM)	Access control model regarding an information/application domain	Nurses, Doctor, etc. for roles in RBAC
Access control instance model (ACIM)	Instance of the access control model in a specific information/application domain	surgeon, internist, etc. for role Doctor

Figure 2. Diagram overview



MODELLING ACCESS CONTROL ENTITIES

This section concerns the modelling of access control entities in UML on both the metamodel and the model layer. The access control entities are, for example, the objects on which access must be controlled, the subjects, which try to access the objects and the permissions that allow or deny access. In the Access Control List implementation, known from Unix operating systems, the entities are mainly users, groups, processes, and files/directories with their read, write and execute permissions. In a Role based access control model, the main entities are the roles and their assigned permissions, the users, the sessions and the objects. In the sequel, the VBAC model serves as the example for the access control model, a hospital application as the application domain for the application model.

Access Control Metamodel

The access control entities are modeled in a class diagram, which we call a type diagram. The associations between the class diagram elements specify the relations between the access control entities. Therefore, the class diagram constrains already all the access control relations, since a relation that does not occur in the type diagram is forbidden. Figure 3 shows the specification of the entities of the VBAC model by a type diagram. The intended meaning of the access control entities is given next.

In a concrete application, the classes in the type diagram are specialized to classes taken from the application class diagram. For example, the role class in the VBAC type diagram must be specialized to the concrete roles of the given application (e.g., to the roles Doctor or Nurse of Figure 1).

Application-Specific Access Control Model

The access control metamodel defines a language for specifying access control models and is independent of an information domain. The access control metamodel for VBAC defined above has, as metaobjects, Subject, Role, View, Permission, and Object. In an information domain, these metaobjects are mapped to application dependent objects.

The access control entities in the metamodel are specified in a class diagram. The access control

Table 2.

Object:	Used to represent the distributed objects in the system to which access must be controlled by a policy. Objects can be related (e.g., an object can be a sub-object of another object).
Subject:	Used to represent the system users and the processes that run on behalf of the users. Subjects may have references to objects to access them.
Permission:	A permission specifies a right to access an object, and is uniquely assigned to that object. An object, however, can be associated to several permissions.
View:	A view groups a number of permissions belonging to the same object (no view can contain permissions defined for different objects).
Role:	Used to represent the access control roles, which are assigned to subjects. A role can be played by several subjects, and a subject can play several roles. A view can be assigned to different roles and a role may have several views. Roles can be related by an inheritance relation, where the extended role inherits all the views of the base role.

Figure 3. The VBAC model

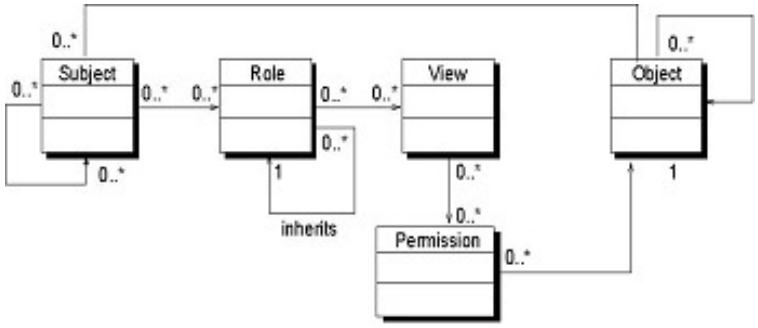


Figure 4. Class diagram for the application

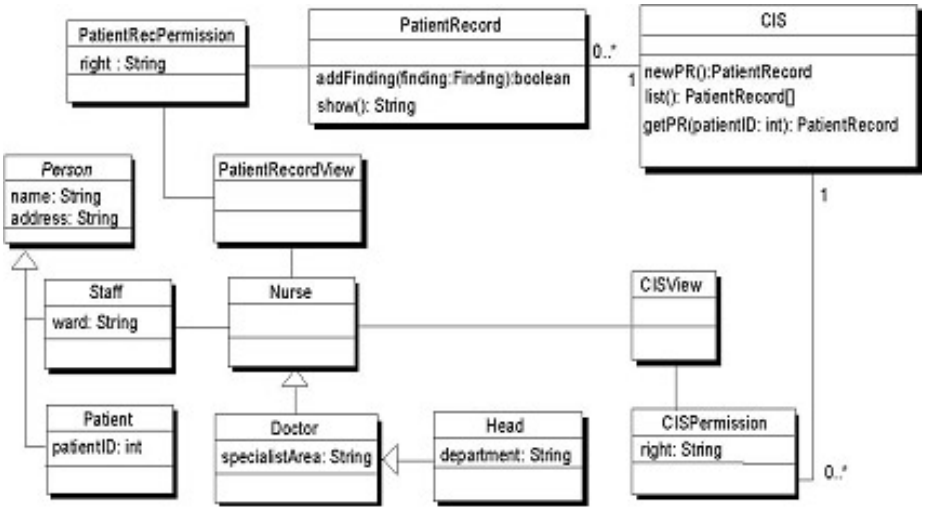

Table 3.

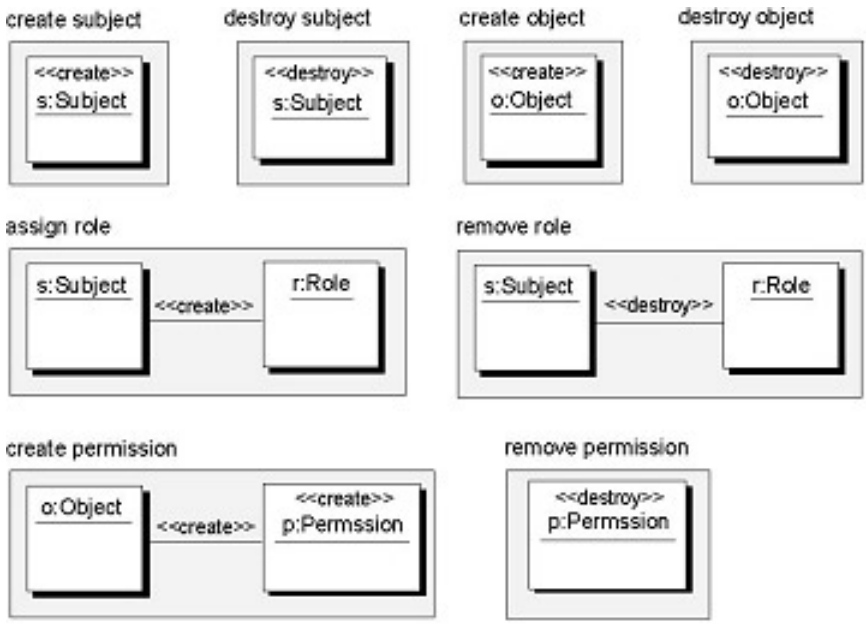
Metamodel	Model	Description
Subject	Person	A person has a name and an address. The class is abstract.
	Staff	Specialization of Person. Specifies the staff in the hospital. The attribute ward specifies on which ward the staff member is currently working.
	Patient	Specialization of Person. Patients are identified by a patient identifier patientID.
Role	Nurse	Role for nurses.
	Doctor	A specialization of the role nurse from which it inherits the permissions. The attribute specialistArea, e.g. surgery or orthopaedy, describes the doctor's specialization.
	Head	Specialization of the role Doctor, assigned to the department head of a ward.
Metamodel	**Model**	**Description**
View	CISView PatientRecord View	View for CIS permissions. Views for PatientRecord permissions.
Objects	CIS Patient-Record	The central information system (CIS) contains the electronic patient records. Patient records can be created by the operation newPR() if it is the patient's first visit in the hospital. The list of all the patient records can be requested by listPR(), a specific patient record is returned by getPR(). The (textual) contents of a patient record can be requested with the operation show(). Whenever findings for a patient are created due to new examinations, the findings are added to the patient record with the operation addFinding().
Permission	CIS-Permission Patient-Record Permission	Permissions for object CIS. The attribute right contains the name of the operation, to which the permissions grant access. Permissions for the object PatientRecord.

entities in the access control model are also specified in a class diagram, which is an instance of the metamodel class diagram and which contains information and application domain specific access control entities.

Figure 4 shows an instance of the VBAC metamodel applied to a medical information domain. We consider a small part of a hospital in which patients are medicated by doctors and nurses. Each ward has a department head. The following table shows the mapping of the metaobjects to the objects in the access control model with a brief description of their meaning. We keep the hospital application small, but detailed enough to demonstrate the specification of the VBAC model. A more detailed discussion to the hospital application can be found in Brose, Koch, and Lohr (2003).

Figure 5. VBAC policy rules



MODELLING ACCESS CONTROL POLICY RULES

An access control protection state is generally not fixed, but changes during the system lifetime. Possible causes for changes in the protection state are the addition or deletion of users or roles, the modification of permissions associated with roles, changes in access requirements of objects, etc. Access control policy rules define the permitted state changes and therefore Control the behavior of the system.

Access Control Metamodel

Policy rules are specified in object diagrams using the stereotypes <<create>> and <<destroy>>. The intended meaning of an object or link with a stereotype <<create>> is that the object or link is created by the system. The intended meaning of an object or link with stereotype <<destroy>> is that the object or link is removed from the system. Our approach in representing the actions of a policy rule is similar to the representation of post-conditions for actions in the Catalysis approach (D'Souza & Wills 1998). To visualize an action in Catalysis, one diagram is used to present the state before and after the action. Catalysis, however, uses a presentation of the "after" state by bold elements or different colors instead of stereotypes.

Figure 5 (role management) and Figure 6 (view management) show the policy rules for the VBAC model. Their intended meaning is described next.

Access Control Model Rules

The policy rules of the access control model are derived from the object diagrams for the policy rules of the metamodel. Metaobjects are instantiated with information domain specific objects specified in the type diagram of the access control model. The object diagram obtained by instantiating a policy rule must be an instance of the type diagram of the access control model.

Table 4.

create subject:	The object diagram for the policy rule create subject consists of one subject instance with the stereotype <<create>> which specifies that the subject instance is created by the rule. The creation of new subjects is unconditional and does not depend on the current system state (no context conditions)
destroy subject:	The object diagram for the rule destroy subject is similar to the create-subject but with stereotype <<destroy>>.
create object:	Object instances can be created with a rule similar to the one for subjects.
destroy object:	Object instances can be removed from the system with a rule similar to the one for subjects.
assign role:	The rule assign role specifies the assignment of a subject to a role, modeled by a link between the subject instance and the role instance. The link is created (carries stereotype <<create>>) while the subject and the role must already exist (no <<create>> stereotype).
remove role:	The rule remove role specifies the removal of the assignment of a subject to a role by deleting the link between the role and the subject. Both the subject and the role instance remain in the system, since they do not carry a <<destroy>> stereotype.
create permission:	The rule create permission creates a new permission instance which is immediately connected to an object, since a permission must always belong to a unique object.
remove permission	The rule remove permission specifies the removal of a permission
assign view:	The assignment of a view instance to a role instance is specified by a link created by the rule assign view between an existing role and an existing view
remove view:	The rule remove view specifies the removal of a view from a role by destroying the link between the role and the view
create view	View instances can be created analogously to subjects.
destroy view:	View instances can be removed analogously to subjects.
extend view:	The assignment of a permission to a view instance is specified by a link inserted by the rule extend view between the view and the permission instance
restrict view:	The rule restrict view removes a permission from a view by removing the connecting link

Figure 6. VBAC policy rules for view management

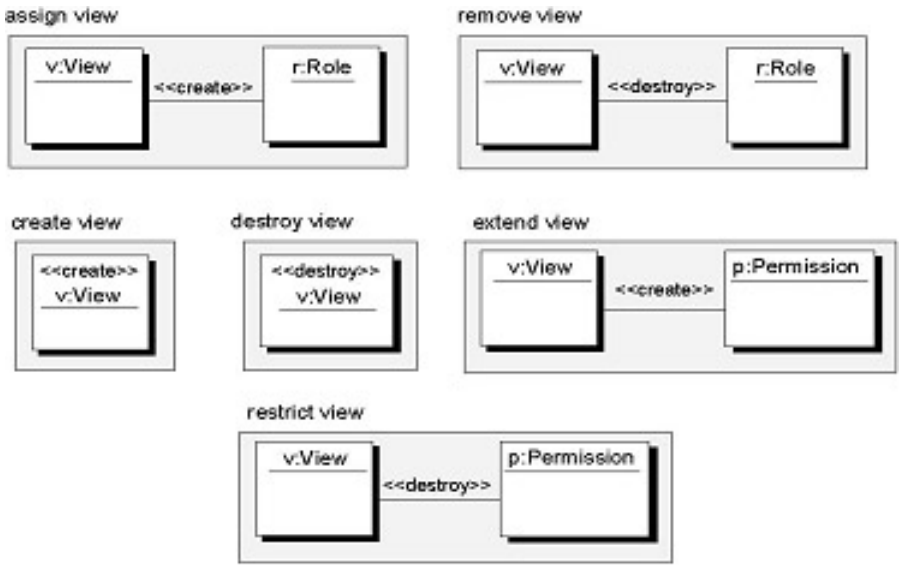


Figure 7. Policy rules in the access control model

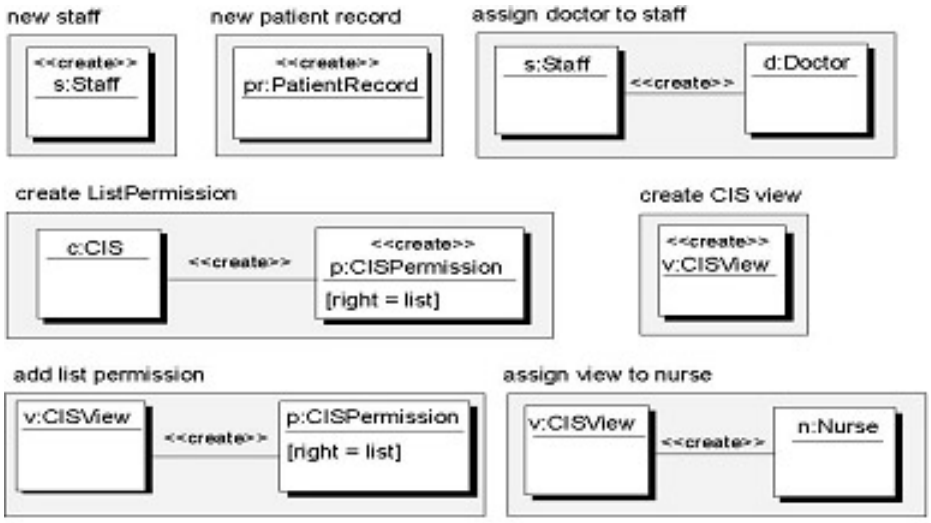


For example, the rule assign role in Figure 5 can be specialized to a rule in which the metaobject s:Subject is instantiated by the object s:Staff and the metaobject r:Role by d:Doctor. Another example is the metarule create permission. The metaobject o:Object can be instantiated by a CIS object, the permission object p:Permission by a CISPermission with a value list for the attribute right. Figure 7 shows this policy rule and other examples.

Not all instantiations are valid. The following are examples of invalid instantiations:

- The instantiation of the metaobject s:Subject to p:Person is not valid since the class Person is abstract (i.e., it has no instances).

- The instantiation of the metaobject s:Subject to p:Patient and the metaobject r:Role to d: Doctor in rule assign role is not acceptable since the type diagram of the access control model does not permit links between patient and doctor objects.

The policy rules of the access control model are given by all the object diagrams that can be derived from the policy rules of the metamodel, where the objects are taken from the access control model type diagram, which are instances of the type diagram.

MODELLING ACCESS CONTROL CONSTRAINTS

The access control policy rules determine the acceptable system states. In some situations, however, it is necessary to reduce the system states generated by the policy rules. For example, the policy rule assign role of the VBAC model can be used to assign any number of subjects to the same role (by repeated application to the same rule). In many applications, however, there are role cardinality constraints that limit the number of subjects in a role. Some cardinality constraints are already included in the access control type diagram of a UML AC specification (e.g., Figure 3 requires a unique object for each permission). But a requirement for at least one permission for a view assigned to a role is a prerequisite constraint not expressible by cardinalities. Therefore, it must be specified separately.

Possible representatives of constraints for our running example are:

1. In VBAC, if the view is assigned to a role, then this view must have at least one permission; otherwise permissionless views are allowed.
2. In the hospital application, there can be at most one department head for each ward.

The first constraint concerns the access control metamodel since it is a constraint that must be satisfied by all VBAC policies in any application domain. The second constraint concerns a special application domain (here a hospital domain) and is specified in the access control model. Therefore, access control constraints are specified on both the metamodel and the model levels. Before we consider the difference between these two levels, however, we discuss some ways to specify access control constraints in UML present in the literature, namely the Object Constraint Language (Ahn & Shin, 2001) as a representative of a textual constraint language and two different approaches based on object diagrams (Koch et al., 2002c; Ray et al., 2004) as representatives of visual constraint languages.

Textual Specification of Access Control Constraints by OCL

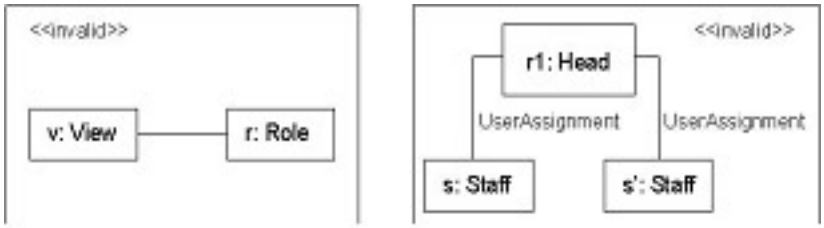
The object constraint language (OCL) (OMG 2003), a part of the UML specification, is a powerful specification language, based on first-order Logic, in which complex constraints can be textually expressed and attached to the graphical UML diagrams.

By using the OCL, the first of the two example constraints previously can be described with the following OCL expressions:

```
context View inv
(self.role->notEmpty) implies (self.permission-
>notEmpty)
```

This OCL constraint specifies that if a view is related to a role, then there is at least one permission related to this view. Note that the constraint does not place restrictions on views unrelated to roles. The second constraint is represented in OCL as:

Figure 8. Object diagram patterns



```
context Head inv self.staff->size() < 2
```

This OCL constraint forbids more than one person from the staff assigned to the application domain specific role Head.

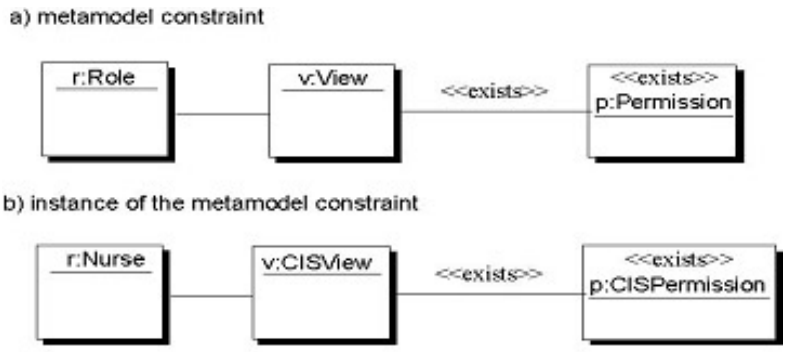
Visual Specification of Access Control Constraints

Visual specification languages to specify access control constraints in UML start from the observation that OCL is difficult to understand and does not integrate well with the remaining visual UML diagrams. Therefore, Ray et al. (2004) present a visualization of access control constraints using UML object diagrams. In their approach, object diagram templates describe object structure patterns that are violations of access control constraints. These patterns are used to check for violations of a constraint, as such an object diagram pattern represents a system structure which must not occur in the system state.

Figure 8 shows the object diagram for the two example constraints. On the left-hand side, the object diagram for the prerequisite constraint is specified. It shows the invalid state in which a view is assigned to a role, but there is no permission assigned to the view. On the right-hand side, the cardinality constraint is specified by the invalid state of two staff objects assigned to the role Head object.

The visualization of access control constraints presented in Koch et al. (2002c) also uses object diagrams. Similar to Ray et al. (2004) object diagrams are used to specify invalid system states which must not occur in a system state for the

Figure 9. A metamodel constraint and an instance of this metamodel constraint in the hospital access control model



constraint to be satisfied. The difference between the approach of Koch et al. (2002c) and that of Ray et al. (2004) are additional object diagrams for required states and a formal semantics based on graph transformations (Rozenberg, 1997) which can be used to apply verification concepts on access control constraints. The semantics will be explained in more detail in the next section.

An object diagram for a required state specifies an object structure that must occur in a system state. A system state satisfies such a constraint if the required object structure occurs as a substate. The existence of this object structure may be conditional, i.e., the object structure is required only in certain substates. The object diagrams for required states are called positive constraints and use the stereotype <<exists>> in the following way: all objects and links labeled with this stereotype must exist in a system state when the remaining (i.e., the non <<exists>>labeled) objects and links occur, as well.

Figure 9 shows the visual specification of the viewpermission requirement by a positive constraint. It shows the assignment of a permission p to a view v, which in turn is assigned to a role r. The permission object p and its link to the view v carry the <<exists>> stereotype. Both must exist whenever the view v is assigned to a role r. If no role is assigned to the view, the assigned permission need not exist. The object diagram for the invalid system state of two users in role Head is the same as the one shown in Figure 8.

Access Control Metamodel and Access Control Model

As previously mentioned, constraints may refer to, and be specified for, the metamodel level if they must be satisfied by all access control models independently of a specific application, or they may concern only a specific application and therefore must be valid only in a specific access control model.

Since metamodel constraints must be valid in any access control model, they must be part of a given access control model for a certain application, as well. Therefore, access control model constraints are derived from the access control constraints of the metamodel, as is the case for the policy rules: The metaobjects in the metamodel constraint are instantiated with objects given in the access control model type diagram, so that the resulting object diagram is a valid instance of the ACM type diagram. An example is the specialisation of the VBAC metamodel constraint in Figure 9 in which the metaobject role is specialized to a Nurse object, the metaobject view is specialized to a CISView object and the permission is a CIS-Permissiom. An invalid instantiation, according to the ACM type diagram, would be a CISView object for the view and a PatientRecPermission object for the permission, since it would be in conflict with the type diagram.

The access control constraints of an access control model, therefore, consist of a) all the object diagrams obtained by instantiating the metamodel constraint diagrams using objects specified in the access control model (ACM) type diagram, so that the resulting object diagrams are instances of the ACM type diagram and b) a set of object diagrams for information domain specific constraints.

VERIFICATION OF ACCESS CONTROL CONSTRAINTS

The access control constraints restrict the possible system states that can be produced by the policy rules. Whether a set of object diagrams for the policy rules of a UML access control specification satisfies all the access control constraints should be checked automatically as much as possible. To have an automatic verification, it is necessary to have a formal semantics for both the UML access control model and the UML constraints, on which an automatic verification support can be built.

Consider, as an example, the policy rules for the access control metamodel shown in Figure 5 and Figure 6. These object diagrams are specialized to application specific objects given in the access control model type diagram in Figure 4. One possible specialization is the instantiation of the policy rule assign role in Figure 5 with a Staff instance as subject and Head as role. Applying this rule several times to the same Head role but with different staff member instances, would produce several staffers who play the role Head for the same department. The negative constraint in Figure 8 on the right-hand side, however, forbids more than one subject in the role Head. Therefore, the UML access control specification is not correct since the policy rules can construct a system state that does not satisfy all the access control constraints.

We have developed (Koch et al., 2001) a graph-based, formal semantics for a UML access control specification which allows us to check statically if the set of object diagrams for the policy rules satisfy the constraints (Koch et al., 2002a; Koch et al., 2002c). To use these verification concepts we need to transform UML diagrams into graphs, UML object diagrams for policy rules into graph transformation rules and (visual) UML constraints into graphical constraints (for transformation details see (Koch & Parisi-Presicce 2002d). Due to the graphical notation of UML diagrams, the transformation of these diagrams into graphs is natural. Access control constraints are transformed into graphical constraints. The transformation of visually specified UML constraints can be done in a natural way. The transformation of OCL constraints is more difficult, but possible for a part of the OCL constraints. These are mainly those OCL constraints used to express properties on the object structure of the system state. In Bottoni, Koch, Parisi-Presicce, & Taentzer (2001), the interested reader can find a more detailed presentation on the visualization of (most) OCL constraints

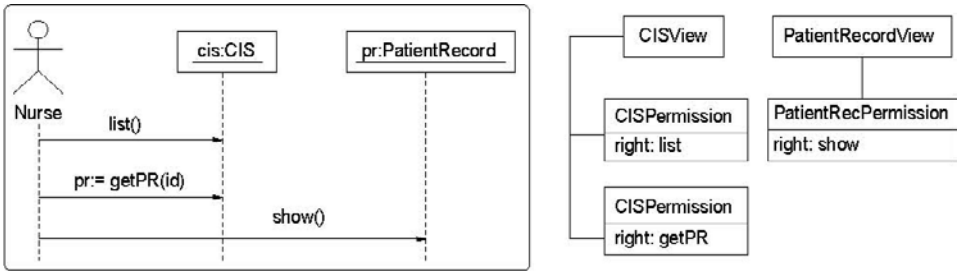
The checking algorithm (Koch et al., 2002c) determines, for each policy rule and access control constraint, whether the policy rule can construct a system state that violates the constraint. In this case, the algorithm modifies the rule by adding an additional condition to the rule, to ensures that the policy rule, whenever it is applied to a valid system state, will always construct a new system state which again satisfies the constraint. The policy rule condition forbids the application of the rule to system states that would lead to an invalid new system state. If we consider the example, mentioned above, of the policy rule assign role and the negative constraint which forbids two or more staffer in the role Head, then the checking algorithm adds a condition to the policy rule assign role to prevent its application to the Head role if there is already a staffer assigned to this role.

We have built a prototype of an RBAC administration tool, which implements the checking algorithm as well. The tool has been implemented according to the proposed NIST standard for RBAC (Ferraiolo, Sandhu, Gavrila, Kuhn, & Chandramouli, 2001) and is based on the general graph transformation engine AGG (Taentzer, Ermel, & Rudolf, 1999). It allows a security administrator to define graph-based policy rules and constraints, including several kinds of authorization constraints identified in the literature (Ahn & Sandhu, 2001) such as various types of separation of duty (SoD) properties (simple static SoD, simple dynamic SoD, sessionbased dynamic SoD, and objectbased static SoD), cardinality constraints, and prerequisite roles and permissions.

ACCESS CONTROL REQUIREMENT ANALYSIS

So far, we have described how to model an access control policy in UML. We use a metamodel for the access control model and refine this metamodel to a model that considers the application specific access control requirements. To determine the ac-

Figure 10. A sequence diagram



cess control requirements (i.e., what to model) is a difficult task, especially since system designer are usually not security experts. Therefore, the designer should be supported in the software development process to obtain the necessary access control requirements.

In Koch and Pauls (2005a) and Koch and Pauls (2005b), we have presented a model-driven approach to derive access control requirements from the UML diagrams for the functional system analysis and design. For example, access control roles are based on the actors in the use case diagrams, access rights are based on the class diagrams and the access control permissions are based on the operation calls in the sequence diagrams. The access control information can be automatically extracted from these UML diagrams and is presented in UML diagrams for access control as shown in the previous sections.

We present next the generation of views from UML sequence diagrams as an example of this generation process. For a more detailed presentation of the model-driven approach we refer to Koch et al. (2005a) and Koch and Pauls (2005b). Sequence diagrams contain inherent access information by specifying the access required of actors to call the operations. The sequence diagram in Figure 10 shows the accesses required of a nurse to read a patient record. The nurse role must be able to call the operations list() and getPR() on the class CIS to retrieve the list of all available patient records and a single patient record, respectively. To read the patient records, the nurse role needs the permission to call the operation show() on the class PatientRecord.

The algorithm for the generation of access control views from a sequence diagram considers all the objects in the sequence diagram on which operations are called: For each of these objects, a view on the class of the object is generated which contains the permissions to call the operations on the objects of this class. In our example sequence diagram in Figure 10 we generate two views: one on the class CIS with CISPermissions to call the operations list() and getPR() and one view on the class PatientRecord with PatientRecPermission to call the operation show(). The views for all the remaining sequence diagrams are generated in a similar way.

The generated views are usually incomplete in the sense that they do not give a complete access control specification. This is due to the fact that sequence diagrams show only scenarios the designer is interested in. On the other hand, the views may also be redundant in the sense that the same view may be generated from different sequence diagrams. Therefore, the designer uses the generated views as a starting point to be refined into the final access control specification.

RELATED WORK

A few authors have addressed the problem of integrating security requirements into UML.

Jurjens presents the integration of security into UML in Jurjens (2005), where he shows how to model several security aspects by UML model elements as, for example, stereotypes or tagged values. His approach is more general than ours since it is not restricted to access control but considers, for example, also security protocols. Furthermore, Jurjens considers a wider variety of UML diagrams (e.g., also deployment diagrams) since his concern is with the integration of security into the UML in general. Our approach is focused on access control, and the generation and enforcement of access control policies in distributed systems, and, therefore, we only use the UML diagrams necessary to meet our objective. In contrast to our approach and the one by Basin, Doser, and Lodderstedt (2004), Jurjens does not consider a model-driven approach and does not provide tool support or an infrastructure to generate security policies from UML models or to enforce security policies.

Moreover, Jurjens (2002) has extended UML for specifying aspects of multilevel secure systems and security protocols, where he proposes a tailored formal semantics to evaluate UML diagrams and to indicate possible weaknesses. Unlike our approach, there is no model-driven integration of security and the verification does not provide an automatic consistency construction to resolve unsatisfied security constraints.

Fernandez-Medina, Martinez, Medina, and Piattini (2002) extend UML to support the design of secure databases. They consider a multilevel database model in which all model elements have a security level and a security role, both modeled by tagged values. They extend the OCL to be able to represent multilevel system constraints. Unlike the approach in Fernandez-Medina et al. (2002) which is developed for multilevel databases, our approach is more general, dealing with any access control model and is not restricted to databases. In contrast to Fernandez-Medina et al. (2002), which extends the OCL by nonstandard features, we use standard OCL for the specification of constraints. The OCL extension has the advantage of a clearer and more legible specification in the particular context of multilevel databases, but does not ensure compatibility.

Epstein and Sandhu (1999) introduce a UML-based notion for RBAC, but this notion is not suitable for the verification of security properties and cannot easily be used for the generation of access control specifications.

An approach closely related to ours is SecureUML (Lodderstedt et al., 2002). SecureUML is a UML-based modelling language for the model-driven development of secure systems. It provides support for specifying constraints, as well. The security information integrated in the UML models is used to generate access control infrastructures. In contrast to our approach, SecureUML focuses on static design models, which are closely related to implementations. Therefore, there is no support for detecting security requirements (e.g., which roles are needed and which permissions they need). Unlike our approach, which is suitable for arbitrary access control models, SecureUML is based on RBAC, and does not have a formal semantics to verify security properties.

Work related to our model-driven development approach to security engineering is presented by Basin et al. (2004), to describe a model driven approach, called SecureUML, to develop role based access control policies for J2EE applications. A formal basis allows the designer to reason about access control properties, and tool support is given by an integration of SecureUML into the ArcStyler tool (Interactive-Objects, 2005). In contrast to our approach, however, the analysis stage of the software process is not considered and the process starts with the design models. The role based model in (Basin et al., 2004) is more coarse-grained compared with the view based access control model here, in which access rights are fine-grained on the level of operations and

operation parameters. Basin et al. use the J2EE infrastructure to enforce the generated policies, but their approach makes it difficult to modify a policy dynamically: the modified policy must be changed manually in the XML-based EJB descriptor files. Dynamic changes of the access control policy, however, are an integral part of our approach. On the one hand, the concept of schemas considers the changing of rights already in the model; on the other hand, our proposed infrastructure supports policy changes at runtime, immediately enforced without interrupting the application and the system.

CONCLUSION

This chapter has presented an approach to the specification of Access Control policies in UML by means of UML class and object diagrams that can be modelled with existing UML tools. It has been shown how the framework models the access control entities, the rules of the access control policy, and the access control constraints. By using a layered model structure, we have been able to model the different components at an abstract (metamodel) level that is application independent, and at a concrete (model) level that includes application specific information. A translation of the UML Access Control specification into a graph-based security framework permits the application of verification concepts from graph transformations to reason about the coherence of a UML Access Control specification. In particular, it allows the modification of the context of application of existing rules to ensure that the new state satisfies all the constraints (if the old one did). The chapter closes with an indication of how to extract access control requirements from UML diagrams.

The UML Access Control specification can be modelled using existing UML CASE tools. One possible direction of future work is the transformation of the XMI export (obtained from the CASE tool) into a XML format for graphs (Taentzer, 2001). Then, graph transformation tools (Ehrig, Engels, Kreowski, & Rozenberg, 1999) can be used for the automatic verification of Access Control requirements.

Chapter 7.10
Ethics in Software Engineering

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

As software becomes pervasive in our daily lives, its values from a purely human perspective are brought to light. Ethical conduct is one such human value.

There are various reasons for discussing the issue of ethics within a software engineering context. By participating in a software development process, software engineers can influence the final product, namely the software itself, in different ways including those that may be contrary to public interest. In other words, they could engage in an unethical behavior, inadvertently or deliberately. This could lead to personal harm, and potentially result in loss of confidence in software and loss of trust in organizations that own them. This can adversely affect the acceptance of software as a useful product, question the credibility of software engineering as a profession, lead to legal implications, and impact the bottom line of the software industry at-large.

This article is organized as follows. We first outline the background necessary for later discussion. This is followed by a proposal for a quality-based framework for addressing ethics, and software quality treatment of a software engineering code of ethics. Next, avenues and directions for future research are outlined, and finally, concluding remarks are given.

BACKGROUND

By viewing software engineering as a profession, we define ethics as a code of professional standards, containing aspects of fairness and duty to the profession and the general public.

Since a software can either be a benefit or a hazard to its potential users, the issue of ethics in

its engineering arises. Software failures (Sipior & Ward, 1998) that have led to loss of human life, rendered computer systems unusable, led to financial collapse, or caused major inconveniences are grim reminders of that.

In this article, we discuss the issue of ethics from the viewpoint of software product quality considerations in practice. There is an apparent symbiosis between ethics and quality. For example, the causes of the aforementioned failures were attributed to violations of one or more quality attributes such as reliability, safety, and so forth, and/or to lack of proper validation/verification of these.

Indeed, in the Software Engineering Body of Knowledge (SWEBOK) (Abran, Moore, Bourque, & Dupuis, 2001), ethics has been placed within the software quality "knowledge area." The issue of information technology in general, and the role of quality in software development in particular, have been addressed in (Reynolds, 2003; Tavani, 2004). Moreover, software quality is viewed as an ethical issue from a philosophical perspective (Peslak, 2004). However, these efforts are limited by one or more of the following issues: quality and ethics are often viewed as a tautology, treatment of software quality is at a very high level and often as a single entity, and there is lack of specific guidance for improvement of software quality within the domain of software ethics.

One way to enforce ethical standards in a software project is by explicitly documenting the ethical expectations from stakeholders such as via a *code of ethics*. The Software Engineering Code of Ethics and Professional Practice (SECEPP) is a recommendation of the ACM/IEEE-CS Joint Task Force on Software Engineering Ethics and Professional Practices. SECEPP puts forth eight categories of principles decomposed further into clauses that software engineers should adhere to in teaching and practicing software engineering. However, these principles and associated clauses suffer from several issues (expounded in the next section): lack of separation (of concerns), recency, precision, completeness, reachability (to certain audience), and specificity, which makes their realization difficult. The relevance of SECEPP for practical purposes has been questioned (Qureshi, 2001), however the view is largely managerial rather than oriented towards the software product.

ETHICS IN SOFTWARE ENGINEERING AND SOFTWARE PRODUCT QUALITY

For the purpose of this article, our understanding of the discussion on ethics in software engineering is based on the following interrelated hypothesis:

Hypothesis 1. Ethical behavior is dynamic, rather than static. Specifically, by appropriate means (such as code of ethics), ethical actions of software engineers could be regulated and with education even be instilled.

Hypothesis 2. Ethics is a "meta-concern" (Qureshi, 2001) leading us to adoption of steps for software quality assurance and evaluation. Specifically, ethics and software quality are related by direct proportionality, and so overall improvement in the quality of a software product leads to an improvement in ethical considerations related to that product.

A Theoretical Framework for Addressing Ethics from a Software Product Quality Perspective

In order to address the practicality of introducing the ethical dimension in software engineering, we first need a theoretical foundation. To do that, we separate the concerns involved as follows:

Table 1. A framework for ethics in a semiotic approach to software product quality

Ethical Concern	Software Product		
Semiotic Level	**Levels of Quality Attribute**	**Example(s) of Quality Attributes**	**Decision Support**
Social	External: Tier 1	Credibility, Trust	Feasibility
	External: Tier 2	Legality, Safety	
	External: Tier 3	Privacy, Security	
Pragmatic	External: Tier 1	Accessibility, Maintainability, Usability	
	External: Tier 2	Interoperability, Portability, Reliability	
Semantic	Internal	Completeness, Validity	
Syntactic	Internal	Correctness	
Empirical	Internal	Characters, Character Set	
Physical	Internal	Hardware Characteristics	

1. View ethics as a qualitative aspect and attempt to address it via quantitative means so as to minimize the potential for heuristics and to make the evaluation repeatable.
2. Select a theoretical basis for communication of information, and place ethics within its setting.
3. Address software product quality in a systematic and practical manner by means of adopting a quality model. In particular, select the quality model that separates internal and external quality attributes.

Using this as a basis, we propose a framework for ethics from the perspective of software product quality (see Table 1).

We now describe each of the components of the framework in detail.

Semiotic Levels

The first column of Table 1 states the semiotic levels. Semiotics (Stamper, 1992) is concerned with the use of symbols to convey knowledge. From a semiotics perspective, a representation can be viewed on six interrelated levels: physical, empirical, syntactic, semantic, pragmatic, and social, each depending on the previous one in that order.

The physical level is concerned with the physical representation of signs in hardware and is not of direct concern here. The empirical level is responsible for the communication properties of signs. The syntactic level is responsible for the formal or structural relations between signs. The semantic level is responsible for the relationship of signs to what they stand for. The pragmatic level is responsible for the relation of signs to interpreters. The social level is responsible for the manifestation of social interaction with respect to signs.

Software Product Quality Attributes and Examples

The second column of Table 1 draws the relationship between semiotic level and software product quality attributes.

The first level of quality attributes gives the *external attributes,* which on decomposition leads to second level of quality characteristics called *internal attributes* that are directly measurable via quality metrics. External attributes are extrinsic to the software product and are directly the user's

concern, while internal attributes are intrinsic to the software product and are directly the software engineer's concern.

Now, external attributes in the collection are *not* all at the same level. For example, security is a necessary condition for safety, which in turn is a necessary condition for credibility of a software product. Therefore, credibility of a software product is at a higher echelon than safety, which in turn is higher than security. So we extend the traditional software product quality models by introducing a further decomposition of external attributes into different tiers.

The third column of Table 1 includes examples of quality attributes at different semiotic levels based upon our experience from past software projects in different domains, observations from several software product quality models (Lindland, Sindre, & Sølvberg, 1994; Fenton & Pfleeger, 1997), and most importantly, those that have a direct impact on stakeholders. Their purpose is only to make the argument concrete, not to mandate a required list (that could be shortened or lengthened based on the application domain anyway).

Decision Support

The practice of software engineering must take into account organizational constraints (personnel, infrastructure, schedule, budget, and so on). These, along with external forces (market value or competitors), force us to make software-related decisions that could cross over on either side of the ethical boundaries. Therefore, the practice of ethics (say, enforcement via code of ethics) must also be feasible and is acknowledged in the last column of Table 1. There are well-known techniques for carrying out feasibility analysis, but further discussion of this aspect is beyond the scope of this article.

Ethics and Software Product Quality: Making SECEPP Practical

The following issues inherent to principles and associated clauses SECEPP make their realization difficult:

- **Separation:** The concerns are not separated clearly, and there are apparent overlaps across principles. For example, cost estimation is addressed in both Principle 3: PRODUCT and Principle 5: MANAGEMENT.
- **Recency:** The last version of SECEPP was announced in 1999 and is seemingly not constantly maintained.
- **Precision:** The clauses often include terminology that is either vague or open to broad interpretation, and many of the terms therein lack links/references to standard definitions. For example, Principle 3: PRODUCT states that "software engineers shall ensure that their products and related modifications meet the highest professional standards possible." However, it is unclear what "highest" means in this context and by whose measure, the reason for the distinction between "products and related modifications," and which "professional standards" are being implied.
- **Completeness:** SECEPP does not address certain classical practices such as (ethics in the light of) software reuse, reengineering, or reverse engineering, or current practices such as software modeling, and therefore needs to be extended. In retrospective, SECEPP does point out that the list of principles and clauses in it are not exhaustive.
- **Reachability:** The principles and/or clauses are often at a high level of abstraction that can make them prohibitive for novices such as beginning software engineering students

that need to start on the right foot. In this sense, SECEPP resembles the problems inherent in the use of guidelines per se.

- **Specificity:** In order to be applicable to the field of software engineering, SECEPP had to be both abstract and general. It does not include concrete examples for or against ethical conduct for development scenarios for specific software such as Web applications.

One of the main purposes of the article is to tackle some of these issues, particularly as they relate to the software product.

The commentary on SECEPP is structured as follows. Each principle and associated clause (and any sub-statements) in SECEPP that is seen within the scope of non-trivial quality considerations is listed verbatim in *italics*. This is followed by corresponding [Issues] and [Resolutions] for every case. The resolutions vary in their coverage where some address the issues better and in a more complete manner than others. We do not claim that the resolutions as being absolute, and their limitations are pointed out where necessary.

Principle 1: PUBLIC. Software engineers shall act consistently with the public interest. In particular, software engineers shall, as appropriate

1.07. Consider issues of physical disabilities…that can diminish access to the benefits of software.

[Issues] It is unclear why only *physical disabilities* are being addressed when software is also used by people with other forms of disabilities (such as visual, auditory, and cognitive/neurological) as well. Also, there are no details on means for addressing accessibility concerns.

[Resolutions] For the Web applications domain, the Web Content Accessibility Guidelines (WCAG) and its ancillary specifications or the Section 508 mandate of the U.S. Government Federal Access Board provide detailed guidelines and examples/non-examples of assuring accessibility. There are tools available that can automatically test for conformance to these guidelines.

3.02. Ensure proper and achievable goals and objectives for any project on which they work or propose.

[Issues] In absence of further details, it is unclear what are considered as *achievable goals*, how to define and achieve them, and when they are considered having been achieved.

[Resolutions] A goal-oriented software project is seen as a set {goals, means} to be satisfied. Indeed, one view of goal-oriented software engineering in general and measurement in particular is given by the Goal-Question-Metrics (GQM) approach (Van Solingen & Berghout, 1999). In GQM, a set of measurement goals are stated, corresponding to each of one or more questions asked, followed by one or more metrics to tackle each question. One of the limitations of GQM, however, is that it does not explicitly address the issue of feasibility.

3.07. Strive to fully understand the specifications for software on which they work.

[Issues] The term *fully understand* is not defined. If it means each software engineer must comprehend all aspects of a given specification at all times, then this goal is unrealistic.

[Resolutions] For our purpose, a working definition of comprehension is the acquisition of the explicit knowledge inherent in a specification. For a non-trivial specification, it is not realistic that each stakeholder will be able to comprehend each statement made by the specification in its entirety at all times. A comprehension is *feasible* (Lindland et al., 1994) if the cost of reducing the incomprehensible statements in a specification does not exceed the drawbacks of retaining them.

3.11. Ensure adequate documentation, including significant problems discovered and solutions adopted, for any project on which they work.

[Issues] It is unclear what *adequate* or *significant* means here. There is also no suggestion as to what kind of documentation is being addressed, and how and where such documentation should appear.

[Resolutions] All documentation should be minimal in the sense that if there is some documentation, then that must correspond to a problem/solution, and vice versa, and it should not be redundant (never appear in more than one place). This can be addressed via the "single source approach." All documentation should be modular in the sense that semantically similar aspects should be cohesive, and clearly separated from others. For example, all design decisions, including the ones not included, corresponding to each software requirement must be uniquely identified and rationalized, and appear in the software design description document. All documentation should be "globally" (anybody, anywhere, any device, any time) reachable. This could, for example, be done by representing software process documentation in the Extensible Markup Language (XML). The guidance for structuring and presenting technical documents has been given (Houp, Pearsall, Tebeaux, and Dragga, 2005).

3.12. Work to develop software and related documents that respect the privacy of those who will be affected by that software.

[Issues] In absence of details, it is non-trivial to address privacy concerns.

[Resolutions] One of the main privacy concerns that the users have is not knowing how or by whom the personal information that they have voluntarily or involuntarily released will be used. The Platform for Privacy Preferences Project (P3P) enables providers to express their privacy practices in a format that can be retrieved automatically and interpreted easily by user agents. This ensures that users are informed about privacy policies before they release personal information. A P3P Preference Exchange Language (APPEL) complements P3P and allows a user to express his or her preferences in a set of preference-rules that are placed in a profile document. This can then be used by the user agent to make decisions regarding the acceptability of machine-readable privacy policies from P3P-enabled applications.

Challenges to a Software Quality Approach to Addressing Ethics in Software Engineering

Open Source Software (OSS) suffers from various quality issues (Michlmayr, Hunt, & Probert, 2005), including that of usability and maintainability. Since there are modest opportunities, if any, for enforcing ethical regulations in the OSS realm, this brings into question the ways in which OSS can be used.

Due to constraints not imposed by choice but by technical considerations in practice of software engineering, quality attributes in technical and social tiers compete. For example, the pairs of usability–security or maintainability–efficiency are often in competition.

Finally, we note that there are ethical predicaments in software development that are irreconcilable from a software quality perspective. For example, a software engineer working for a company producing defense software could, when asked to make a decision on including a certain feature in software that will lead to striking improvement in a certain weapon capability, find his or her ethical commitments to the organization in conflict with his or her ethical obligations to society at-large. Therefore, alternative means of tackling such scenarios are desirable.

FUTURE TRENDS

Since project and process quality is not mutually exclusive from the product quality, it would be worth examining them in general and within the SECEPP framework. For example, according to the Capability Maturity Model (CMM), the organizations below Level 3 do not have formal quality evaluation practices, such as inspections, in place.

In a similar spirit of organizational quality management, it would of interest to study the interplay between ethics and the Total Quality Management (TQM) that focuses on the optimization of industrial processes under economic considerations in such a way as to achieve customer satisfaction.

Finally, it would be of interest to closely investigate the ethical concerns in specific software domains such as mobile or Web applications (Johnson, 1997). The issue of ethics is also important to these applications as they are increasingly being used as technological means for persuading consumers (Fogg, 2003). To that regard, a recast of SECEPP applicable to Web engineering is also highly desirable.

CONCLUSION

Software engineers are expected to share a commitment to software quality as part of their culture (Wiegers, 1996). There needs to be a regulatory and/or educational shift to accommodate making ethics a first-class member of this culture as well.

The improvement of software quality is technical as well as an ethical imperative. By addressing software product quality in a systematic manner, ethical concerns can be largely attended to.

Organizations that are engaged in software production from an engineering standpoint need to adhere to a code of ethics and monitor its practice. Institutions that have software engineering as part of their curriculum must include the role of ethics on the forefront. A code of ethics such as SECEPP can be helpful in that regard, but it needs to evolve to be more effective in such practical situations.

KEY TERMS

Code of Ethics: A resource that describes the ethical and professional obligations with respect to which the public, colleagues, and legal entities can measure the behavior of and decisions made by a professional.

Quality: The totality of features and characteristics of a product or a service that bear on its ability to satisfy stated or implied needs.

Quality Model: A set of characteristics and the relationships between them that provide the basis for specifying quality requirements and evaluating quality of an entity.

Semiotics: The field of study of signs and their representations.

Software Engineering: A discipline that advocates a systematic approach of developing high-quality software on a large scale while taking into account the factors of sustainability and longevity, as well as organizational constraints of time and resources.

Software Failure: A departure from the software system's required behavior from a user's perspective.

Software Fault: A human error in performing some software activity from a software engineer's perspective. A fault is not a sufficient condition for a software failure.

Chapter 7.11
Free Access to Law and Open Source Software

Daniel Poulin
Université de Montréal, Canada

Andrew Mowbray
University of Technology, Sydney, Australia

Pierre-Paul Lemyre
Université de Montréal, Canada

ABSTRACT

Law consists of legislation, judicial decisions, and interpretative material. Public legal information means legal information produced by public bodies that have a duty to produce law and make it public. Such information includes the law itself (so-called primary materials) as well as various secondary (interpretative) public sources such as reports on preparatory work and law reform and resulting from boards of inquiry and available scholarly writing. The free access to law movement is a set of international projects that share a common vision to promote and facilitate open access to public legal information. The objectives of this chapter are to outline the free access to law movement, to set out the philosophies and principles behind this, and to discuss the role that open source software has played both in terms of its use and development.

INTRODUCTION

The *free access to law movement* is a set of international projects that share a common vision to promote and facilitate open access to public legal information. There are direct synergies between the notion of "freeing the law" by providing an alternative to commercial systems and the ideals that underpin *open source software*. In addition, open source software has been an essential foundation for the work that has been done and new open source code has been developed.

The objectives of this chapter are to outline the *free access to law movement*, to set out the philosophies and principles behind this, and to discuss the role that open source software has played both in terms of its use and development. It concludes with an assessment of what has been achieved and of the similarities between the free access to law and open source software movements.

BACKGROUND

Law consists of legislation, judicial decisions and interpretative material. *Public legal information* means legal information produced by public bodies that have a duty to produce law and make it public. This includes the law itself (so-called *primary materials*) as well as various *secondary* (interpretative) public sources such as reports on preparatory work and law reform and resulting from boards of inquiry and available scholarly writing. It also includes legal documents created as a result of public funding.

Lawyers have been interested in the electronic publication of legal materials and associated information retrieval systems for a very long time. The earliest reported experiment is generally said to have been done by John Horty at the University of Pittsburgh in the late 1950s (Bing, 2004). The first major commercial system appeared in 1973 with the launch of *Lexis* (now *LexisNexis*). This was based on an earlier system developed by the Ohio Bar (OBAR) which had been established in 1969. OBAR was acquired by Mead Data Central and redesigned to become Lexis. LexisNexis is now one of the largest commercial text databases in the world. It is currently owned by the Reid publishing group. Lexis was followed by *Westlaw* in 1976. Westlaw is now owned by Thomson Publishing and is the major business competitor to Lexis. Several other commercial and government based systems also appeared about this time, but were largely ultimately unsuccessful such as the now defunct European system *EUROLEX* and the Australian system *SCALE* (Greenleaf, Mowbray, & Lewis, 1988).

In the 1980s and 1990s, Lexis and WestLaw expanded the scope of their services to include international collections and in their original jurisdiction (the United States) established a near duopoly (McKnight, 1997; Arewa, 2006). Attempts were made in various other places such as Australia and Canada to create either government or government sanctioned commercial monopolies (Greenleaf et al., 1988).

The resulting environment was, and to some extent still is one that is characterised by limited access to basic legal materials. Whilst the commercial systems provide a very sophisticated set of services they are for the most part targeted at the legal profession, they require significant training in order to use them. The services are very expensive and generally are not available for casual use. Non-lawyers seldom access the commercial systems and even lawyers can often not afford to use them.

Why is Free Access to Legal Information Important?

At the most fundamental level, access to public legal information supports the rule of law. Citizens are governed by laws and so have a need and right for effective access to these laws. Businesses also generally operate in a regulated environment and have similar needs. Effective access to basic legal information is essential both from a social perspective and also to facilitate the proper operation of business and commerce.

Apart from being able to access domestic laws, there is also increasingly a need to access law from other jurisdictions. Business operates on an international basis. Corporations need to be aware of international regulatory requirements and countries need to make their legal systems

transparent to encourage international investment and trade. Particularly in the case of developing countries, there is a major need for access to international laws to assist with law reform and development (Poulin, 2004).

The Free Access to Law Movement

The *free access to law movement* has grown out of a set of projects that have attempted to address these issues and to provide alternatives to the commercial legal publishers' systems. Most of these projects are called *legal information institutes* (or *LII*s for short).

The earliest initiatives were in the United States and Canada. In 1992, Tom Bruce and Peter Martin established the Cornell *Legal Information Institute* (Bruce, 2000). This service was initially based on *Gopher* and provided free access to decisions of the United States Supreme Court and the United States code. It moved to the Web in 1994. In Canada, Daniel Poulin and his team at *LexUM* started publishing the full text of decisions of the Canadian Supreme Court in 1993 (Poulin, 1995).

Both systems helped to identify a strong demand for free public access to primary legal materials. In Australia, Graham Greenleaf and Andrew Mowbray founded *AustLII* (the *Australasian Legal Information Institute*) in 1995 (Greenleaf, Mowbray, King, & van Dijk, 1995). By the end of the year, AustLII was publishing some 16 databases including the decisions of most of the major Australian federal courts as well as federal and state legislation and by 1998 became the first LII to achieve national coverage. It now includes over 200 databases covering virtually all courts and tribunals in the country.

Other systems adopting a similar approach followed. These included the *British and Irish Legal Information Institute* (*BAILII*) in 1999, the *Pacific Islands Legal Information Institute* (*PACLII*) and the *Canadian Legal Information Institute* in 2000, and the *Hong Kong Legal Information Institute* (*HKLII*) in 2003. Various *meta-systems* were also built that drew upon the information contained in the other LIIs (*WorldLII, Droit francophone* and *CommonLII*).

The *free access to law movement* was proclaimed at the annual *Law via the Internet* conference in Montreal in 2002. The current terms of the *Montreal Declaration* (as amended in Sydney, November 29, 2005 and Paris November 5, 2004) are (in part):

Legal information institutes of the world, meeting in Montreal, declare that:

- *Public legal information from all countries and international institutions is part of the common heritage of humanity maximising access to this information promotes justice and the rule of law;*
- *Public legal information is digital common property and should be accessible to all on a non-profit basis and free of charge;*
- *Independent non-profit organisations have the right to publish public legal information and the government bodies that create or control that information should provide access to it so that it can be published.*

...

Legal information institutes:

- *Publish via the internet public legal information originating from more than one public body;*
- *Provide free, full and anonymous public access to that information;*
- *Do not impede others from publishing public legal information; and*
- *Support the objectives set out in this Declaration.*

Each LII is responsible for publishing legal materials for a particular country or geographical region. AustLII, for example, publishes materials for Australasia (i.e., Australia and New Zealand).

Apart from providing access to the full-text decisions of all major courts (such as the High Court, Federal Court, and State Supreme Courts), as has been said, AustLII also publishes decisions of nearly all Australian tribunals. Access to consolidated (and in some cases, *point in time*) legislation and regulations from all nine jurisdictions is also available. Other content includes: Law Reform Commission reports from most States; access to most Australian law journals; and a database of all bilateral and multi-party treaties.

Like most of the other LIIs, AustLII uses automated processes to add rich hypertext markup to its materials. In all, the system currently includes around 40 million internal hypertext links. Free text searching is available over the entire system or selected databases. AustLII is the major source of legal information in Australia and accounts for 25-30% of all legally related traffic in the country.

At the time of writing, the various LIIs together publish around 663 databases containing legal materials from 86 countries as well as 21 international collections. The total number of individual documents exceeds 3 million. Total usage is estimated to be in the vicinity of 3.5 million direct hits (or page accesses) per day.

The content of these databases consists mainly of *primary materials*—that is, court decisions, legislation and treaties, but increasingly secondary materials such as law journals, law reform commission reports, and the like are being added.

The LIIs have changed the way that law is made available to the public. Whereas in the past, there was exclusive reliance upon commercial publishers as conduits for the dissemination of this information, primary legal information now flows directly from courts and governments to consumers. The LIIs freely offer a level of value adding that establishes a new baseline for commercial publishers. Examples of this value adding include hypertext markup and search capabilities. The citator created by LexUM for CanLII (Reflex) provides a further example (Poulin, Paré, & Mokanov, 2005).

Each LII concentrates on making available domestic laws, but beyond these local endeavors all LIIs collaborate to expand the freely accessible law space internationally. This collaboration takes many forms. First of all, they all participate in promoting and supporting free access to the law by lobbying data providers such as courts, governments, and other bodies. They also provide, within their means, technical assistance and advice and training to other organizations. They hold annual conferences in order to exchange information and share knowledge. These conferences are public and all those interested can register to take part. Since many LIIs are based in universities, a significant part of those conferences is set aside for academic exchange of research results.

This cooperative spirit can be easily illustrated by the collaboration between the University of the South Pacific and AustLII to establish PacLII. Robynne Blake had worked for a number of years to build a substantial collection of South Pacific legal materials. AustLII assisted by provision of technical know-how and their software. In 2006, after many years of progress PacLII obtained a large grant from New Zealand Aid to expand its reach towards making the laws of the various states of the area freely accessible on the Internet. PacLII is now (in terms of the number of staff) one of the largest of the LIIs.

Similarly, LexUM collaborated with many interested parties in Burkina Faso to establish Juriburkina. Today, Juriburkina is operated from Ouagadougou by the local bar association and with the support of the higher courts, government general secretariat and a local Internet startup called ZCP informatique. A similar approach is being followed in Senegal and the project has reached implementation stage.

MAIN FOCUS OF THE CHAPTER

Development of Interest in Open Source Software

The LII promoters and developers were not always early adopters of open source software. Although most of the LIIs were Unix based, the significance of open source software only started to become more evident towards the end of the 1990s. Today, not only is most of the software used by LIIs open source, but the LIIs have themselves started to offer elements of their own production software under open source licences.

Many reasons may be put forward to explain the initial caution. First of all, in the early 1990s, open source was not as developed and mature as it is today. At the time, the LIIs rightly set "making the law accessible for free" as their principal agenda item. To achieve this, the most effective software, proprietary or otherwise was deployed. The reluctance towards more generally embracing open source by the LIIs, was partly based on the lack of maturity of the available open source software and partly attributable to the dominant prevailing prejudice towards conventional corporate approaches.

There was a major reappraisal of the initial attitude towards open source software from around 1998. At the time, for example, the operating system of choice for the LexUM's servers was Solaris from Sun Microsystems (this was also in use at AustLII and the Cornell LII). However, LexUM's programmers were mostly undergraduates and some of them had Linux installed on their home computers. These programmers were aware of the value of open source and argued strongly for the adoption of GNU/Linux. In the course of this campaign, they had even installed for demonstration purposes another open source flagship of the time, the already well respected—Apache Web server to replace the Netscape Enterprise server that was then in use. But despite the apparent functioning of Apache, LexUM, was reluctant to abandon the safety of using a proprietary solution for what appeared to be a more risky free alternative.

Then as today, LexUM was working with the Supreme Court of Canada (SCC) to make its decisions available for free in a timely manner. A long-awaited SCC judgment was expected on August 20, 1998 when the court's decision on the legality of a unilateral secession of Quebec from Canada was to be published. The morning the decision became available, the LexUM Netscape Enterprise based server went down at the moment the decision became available. The server was unable to cope with the rise in demand. After over an hour of rebooting the server, LexUM's student programmers brought up the Apache based sever. The move saved the day, and Apache kept running without failure for many weeks. From then on, LexUM used Apache as its Web server. In the following years, LexUM switched all of its servers to Linux and Apache.

The other LIIs had similar experiences. Most either had already or were soon to adopt Apache. Many moved to Linux and to generally adopt open source software as the basis of their production systems.

Current Use of Open Source Software

Although the commitment to open source has never been a religious one, most of the LIIs are nevertheless strongly reliant upon open source software. Although this is partly a matter of simple economics, this is not of itself sufficient to drive the adoption of open source as even free bad software is still obviously a poor choice. The open source orientation leads to a twofold benefit: savings in licence costs, but more importantly it led to the provision of reliable tools and powerful products to achieve the vision of freely accessible law. The current approaches used by the LIIs

closely match open source trends. Open source developers develop many tools targeted for the Web that closely meet the needs of LIIs.

As has been said above, most of the LIIs use GNU/Linux and Apache. In addition some commonly used open source programs include database and indexing programs such as PostgreSQL, Open LDAP, Apache Lucene, and Nutch; programming languages and tools that include: perl, python, gcc, Eclipse, mod_perl, and Mason; and various other tools such as FastCGI and Mason.

Proprietary software is still used but only where a suitable open source solution cannot be identified. For example, most LIIs still rely upon proprietary software for a significant part of basic document preparation and conversion (such as Microsoft Word) and for some aspects of network security (for example, AustLII uses Check Point and Tripwire).

FUTURE TRENDS

Development of Open Source Software by LIIs

Prior to the World Wide Web, the publishing of databases of legal information was essentially the work of commercial publishers who used specialised software that had often been developed in-house. The Web brought with it a number of generic publishing tools such as conversion tools, search tools and Web servers. However, tools to support more specialised legal publishing needs remained rare. This led a number of the LIIs to develop the tools they needed.

One of the first of these was *Sino* (short for "size is no object"). Sino is a high performance free text search engine. It was originally written in 1995 and has been mainly used to provide production level search facilities for most of the Legal Information Institutes that form part of the free access to law movement. Sino went to a major rewrite in 2006 that makes it even faster and adds new functionality. Sino from its initial release has always been a very fast search engine and its indexing and searching time have been kept at the level of the fastest proprietary products.

Sino is designed to be easy to interface with via a simple C/Perl API as well as a ready written interactive interface for testing or for actual use on Unix sockets. The tool is relatively small and easy to understand at about 12K lines of ANSI/POSIX.1 compliant C code. Sino concordances (indexes) are portable across platforms with different architectures. Sino has been in use on a number of major Web sites answering many millions of requests for the past 10 years and so is robust and reliable.

Sino is a tool aimed at improving the access to the law. It was at the heart of AUSTLII from the very beginning and has been subsequently adopted by BAILII, PacLII and HKLII. LexUM used it for CanLII for many years. From 1995 until 2006, Sino and its source code were made available for free to anybody wanting to publish the law openly and for free. With its last rewrite, Sino became open source and it is now licensed under the GNU General Public Licence (GPL).

LexUM has also developed a number of pieces of open source software. *LexEDO* is a legal publishing platform aimed at providing a ready-made and easy to use solution for small-scale publication projects particularly in the developing world. LexEDO provides a means to manage legislation, caselaw, and legal periodicals as simple databases, to automatically convert documents to PDF and HTML and to generate a Website accordingly. All of these tasks can be accomplished by lawyers or law students acting as editors through Web-based management interfaces.

LexEDO has been distributed to such organisations as the Bar of Burkina Faso, the government general secretariat of Burkina Faso and the Bar of Senegal. In the context of these projects, the

availability of the source code was critical for capacity building purposes. In Burkina Faso for instance, LexEDO has been maintained locally for a period of over two years by a private host called ZCP Informatique. To some extent, the fact that LexEDO source code is available allows ZCP to develop local solutions to local problems without requiring LexUM's assistance. It also provides them with the means to control the evolution of their project, or even to replicate it elsewhere thus spreading free access to law. As is the case for Sino, LexEDO is distributed under the GPL.

LexUM has also developed a program called NOME to assist with the anonymisation of judicial decisions. In many jurisdictions some or all judgments must not contain the names of parties or accused. For instance, anonymisation of judicial decisions involving young offenders is mandatory in Canada. To efficiently achieve this result, LexUM worked with the Computer Science Department at the University of Montreal (Plamondon, Lapalme, & Pelletier, 2004). The result was a small program which is capable of guessing and initialising proper names in Word documents. NOME is now distributed for free with its source code.

In respect to software developed in LIIs, Sino is certainly the most mature. Sino, LexEDO, and NOME are distributed under the GPL. Various other software tools have been developed and are distributed by the LIIs to various partner organisations. As other tools become of more general application, they will become candidates to become new open source offerings.

CONCLUSION

The use of open source software by the LIIs reflects the fact that both movements are well aligned and in many senses similar. The most evident of these similarities can be listed as follows:

Avoiding Monopolistic Control over the Information

Legal information, similarly to source code, *wants to be free* (Williams, 2002). Both the free access to law and the open source software movements were conceived in reaction to the seizure of information by entities (state or commercial) not willing to share it freely with others.

Promote the Reuse of Information by Third Parties

As is the case for source code, legal information is useful only if it can be reused for various purposes. Users need the possibility to save legal documents in different formats, to send them to colleagues and to present them in courts. Some users might even need the right to reuse documents in a commercial context (for the publication of a paper based law report, e.g.).

Promote the Development of Standards

As for software development, the dissemination of legal information is improved by the adoption of standards by the players involved. These standards can take the form of uniform citation mechanisms, drafting practices or workflow models. Historically, LIIs are at the center of such initiatives.

Need to Share Tools

Organizations involved in free access to law all face the same difficulties. They constitute a community tied together by the need to edit and convert large volume of legal documents, to publish them on the Web and to provide information retrieval tools to their users. Similarly to every open source software community, LIIs have in-

centives to share their efforts in the achievement of common goals.

Proponents do not Derive Revenue from Selling Information as a Product

The source of revenue of LIIs and open source software developers is the same. It flows not from the information they publish but from the expertise they developed doing so.

Considering all these similarities, the use of open source software can easily be seen as a complementary strategy to strengthen free access to law. It allows the LIIs to achieve near complete transparency by opening-up not only the legal information, but also their publication process. By doing so, the LIIs achieve several goals at once: they guarantee (to a certain degree) the integrity of their data; they facilitate interactions with the other players in the field; and finally, they help foster the emergence of additional free access to law projects.

For people or organisations that would like to pursue free access to law projects in their own country or region, the required software is now available. There are many high quality resources available from the open source community that can be used to establish Web services. The major distributions of Linux (and other open source operating systems) and the Apache Web server are of world-class quality. There are a number of suitable search engines available. The Web and the availability of open source software means that it is now relatively straight forward to disseminate information.

For the more specialized requirements involved in publishing the law such as the conversion of data, hypertext markup, metadata extraction, and the like, the LIIs are able to make a contribution. As a result, it is increasingly the case that for those who wish to make the law more accessible, there are available tools.

KEY TERMS

Jurisdiction: The geopolitical region in which the laws of a certain governing body are recognized as legitimate and can be enforced.

Law: A body of knowledge consisting of legislation, judicial decisions, and interpretative material.

License: Permission needed to use or modify materials in a way that is recognized as legitimate by the owner of such materials and by an overall community familiar that recognized a similar understanding of legitimate use.

Primary Materials: Court decisions, legislation, and treaties.

Public Access: Making materials available for all members of the general public to read and review.

Public Legal Information: Legal information produced by public bodies that have a duty to produce law and make it public.

Secondary Materials: Public sources, such as reports on preparatory work, that report on and often interpret legal developments.

Chapter 7.12
Ethical, Cultural and Socio-Economic Factors of Software Piracy Determinants in a Developing Country:
Comparative Analysis of Pakistani and Canadian University Students

Arsalan Butt
Simon Fraser University, Canada

Adeel I. Butt
Simon Fraser University, Canada

ABSTRACT

Consumer software piracy is widespread in many parts of the world. P2P based websites have made it easier to access pirated software, which has resulted in an increased emphasis on the issue of software piracy in both the software industry and research community. Some factors that determine piracy include poverty, cultural values, ethical attitudes, and education. Earlier empirical studies have looked at software piracy as an intentional behaviour. This study explores the demographic, ethical and socio-economical factors that can represent software piracy as a social norm among a developing country's university students. The authors have conducted a comparative analysis of university students from Pakistan and Canada, two countries that differ economically, socially, and culturally. The results of the study indicate that software piracy behaviour is different in both groups of students, but that there are also some similarities. Future research directions and implications are also presented.

If nature has made any one thing less susceptible than all others of exclusive property, it is the action of the thinking power called an idea, which an individual may exclusively posses as long as he keeps it to himself; but the moment it is divulged, it forces itself into the possession of everyone, and the receiver cannot dispossess himself of it. Its peculiar character, too, is that no one possesses the less, because every other possesses the whole of it. He who receives an idea from me, receives instruction himself without lessening mine; as he who lights his taper at mine, receives light without darkening me. That ideas should freely spread from one to another over the globe, for the moral and mutual instruction of man, and improvement of his condition, seems to have been peculiarly and benevolently designed by nature, when she made them, like fire, expansible over all space, without lessening their density at any point, and like the air in which we breathe, move, and have our physical being, incapable of confinement or exclusive appropriation. Invention then cannot, in nature, be a subject of property.

-Thomas Jefferson

Congress shall have power … to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries.

-The Constitution of the United States, Article 1, Section 8, 1788

INTRODUCTION

Ethicist Richard Mason (1986) identified four main ethical issues of the information age: privacy, accuracy, property and accessibility. It has been suggested that Mason's work was very significant in the field of Management Information Systems ethics (Freeman & Peace, 2005). Mason (1986) considered intellectual property (IP) "as one of the most complex issues we face as a society" (p. 9). Mason identified *bandwidth* as the real threat in the digital world and viewed it as a scarce and fixed commodity at the time. However, with the rapid progress of hardware and software technology, bandwidth has increased immensely and has therefore made peer-to-peer (P2P) technology possible making e-file sharing a matter of few mouse clicks.

According to Husted (2000), knowledge and information are now more important factors in a national economy than the traditional physical assets that used to indicate economic well-being. Therefore, the protection of intellectual property (IP) has received increased attention in the recent past. Intellectual property refers to "the results of intellectual activity in the industrial, scientific, literary or artistic fields" (Forester & Morrison, 1990, p. 31). A government plays its role to protect the rights of owners by preventing unauthorised use of this intellectual property for a limited period of time (Seyoum, 1996) by using different measures such as copyrights, trade agreements and patents. Legality aside, there are ethical and moral issues that have risen from the use of software and its unauthorised copying both at the consumer and commercial level. The concept of ***Techno-ethics***[1] deals with such aspects of technology. "It designates that portion of ethics which deals with questions arising from technological development and activities. More precisely, technoethics deals with moral questions governing or resulting from the conception, production, distribution and the use of artifacts or technological systems" (Findeli, 1994, p. 50). In our chapter's context technoethics or ethics refers to the moralities and ethical values presumed or perceived with the use and copying of commercial software.

Software is a form of intellectual property and its unauthorized duplication is a crime. However, the practice of making illegal copies of software amounts to high rates in various parts of the world and in environments such as universities,

businesses, and government, the behaviour has become socially acceptable (Sims, Cheng, and Teegen 1996; Cheng, Sims, and Teegen 1997; Hinduja 2001; Christensen and Eining 1991).

Cheng et al (1996) and Husted (2000) suggested that economics play a vital role in determining software piracy. Other studies have however shown that low national income and low personal incomes are not the only reasons for which software is pirated. Swinyard, Rinne, and Kau (1990) observed that attitudes towards software piracy are affected by cultural standards and customs. Hence, "the neglect of culture as an explanation of software piracy seems odd given the fact that cultural values have such a significant impact on a wide array of business practices in different countries" (Husted, 2000, p. 200). Thus, this chapter will not only look into the relationship between economic factors and software piracy, but will also reflect on the cultural and ethical values and social norms that affect the trends of software piracy amongst students.

RESEARCH QUESTION

This study focuses on software piracy amongst university students – specifically with regard to its occurrence over the Internet, sharing (copying or borrowing) software on physical media such as floppy disks and CD-ROMs and buying pirated software from retail outlets[2]. This research explores the question whether software piracy behaviour among university students of a developing country can be conceptualized in terms of social and cultural norms rather than in terms of intentions as has been described (for piracy amongst university students) in most of the literature (e.g. Kwong & Lee, 2002; Rahim, Seyal & Rahman, 2001; Limayem, Khalifa & Chin, 1999; Tang & Farn, 2005; Gopal, Sanders & Bhattacharjee, 2004).

RESEARCH JUSTIFICATION

Empirical studies have been done on the subject of software piracy in different countries such as Saudi Arabia (Al-Jabri & Abdul-Gader, 1997), Thailand (Kini, Ramakrishna & VijayaRama, 2003; Leurkittikul, 1994), People's Republic of China (Wang, Zhang, Zang & Ouyang, 2005) and India (Gopal & Sanders, 1998). Other empirical studies include those done by Gan & Koh (2006); Ki, Chang & Khang (2006); and Mishra, Akman & Yazici (2006). Although Husted (2000) and Proserpio, Salvemini & Ghiringhelli (2004) included Pakistan as one of the countries in their respective analytical studies, empirical studies on software piracy issues of Pakistan do not exist in the literature. A comparative study can provide a means of highlighting differences and possible similarities of software piracy determinants between a developed and a developing country. Therefore Canada was chosen for this purpose as it is culturally and economically in contrast with Pakistan. Moreover, there hasn't been any recent Canadian scholarly literature[3] in this context. This research can therefore help fill a part of that void and the results can provide a better understanding of a developing country's software piracy issues that can help the policy makers to address the problem more effectively.

LITERATURE REVIEW

Intellectual Property and its Protection

According to Merriam-Webster's Dictionary of Law, intellectual property (IP) is a "property that derives from the work of the mind or intellect". Basically IP "refers to a legal entitlement which sometimes attaches to the expressed form of an idea, or to some other intangible subject matter"

(Wikipedia, 2006, para. 1). Moreover, IP law "regulates the ownership and use of creative works, including patent, copyright and trademark law" (Nolo, 2006). Simply put, intellectual property is a realization of someone's idea or thought. Composed music, lyrics, paintings, published written work, and software are the intellectual property of the artists or the professionals that produced or developed them.

Several authors, however, still debate the justifiability of the intellectual property laws (Siponen, 2004; Hettinger, 1989; Ladd, 1997; Stallman, 1995; Weckert, 1997). Although detailed discussion on their arguments is out of the scope of this research, it is important to have a broad view of some of the important concepts.

There are several IP protection organizations across the world, such as Business Software Alliance (BSA), Canadian Alliance Against Software Theft (CAAST), International Intellectual Property Alliance (IIPA), Software & Information Industry Association (SIIA), and World Intellectual Property Organization (WIPO). Many countries have their own intellectual property laws protecting the rights of individuals and organizations alike. The Copyright Act of Canada (Department of Justice Canada, 2006) provides protection to intellectual property in Canada. It considers computer programmes (or software) to be literary work and therefore has several laws controlling their unauthorized copying and distribution. Similarly, computer programmes are considered literary work under the Copyright Ordinance, 1962 of Pakistan. A significant amendment was made to this ordinance in 1992 called the Copyright (Amendment) Act, 1992. This amendment addressed the copyright issues of computer software in more detail than the original Copyright Ordinance. However, some laws are also considered debatable. For example, the Digital Millennium Copyright Act (DMCA) is usually seen as a controversial law approved by the U.S. Congress in 1998[4] (SearchCIO.com, 2006).

With society's transition to a digital world, copyright protection has become an important area of IP law (Blanke, 2004). It is evident from the discussion above that intellectual property rights hold immense importance in today's world but justification of IP rights and laws continues to be a debate among the subject experts. "On one hand are those who believe that anything they conjure up, anything that transforms an idea into form, is intellectual property. On the other are the individuals who believe just as passionately that the entire notion of intellectual property is at best a farce, at worst just another way to suck profits out of the ether" (Gantz & Rochester, 2004, p. xxiii). For example, Hettinger (1989), Ladd (1997), Stallman (1995) and Weckert (1997) view software as an intangible commodity and therefore favour its copying. Weckert reflected on intellectual property rights concerning software as unjustifiable. Hettinger holds similar views on IP rights and their protection. Hettinger suggested that patents and trade secrets are more difficult to justify than copyrights which "restrict only copying an expression of an idea" (Hettinger, 1989, p. 52). Siponen however argues that "it is fair and just for people to claim financial rewards for their creations" (Siponen, 2004, "Concluding remarks" section) and that respecting IP laws and rights is necessary for the society to live in harmony.

Software Piracy

Sims et al (1996) define software piracy as "the illegal copying of computer software" (p. 839). Copying software is easy and can be carried out in many forms. Moores (2003) identified common forms of software piracy as counterfeiting, Internet piracy, and softlifting. He further noted, that "counterfeiting and Internet piracy both involve creating bootlegged copies of licensed software for sale or distribution. Internet piracy makes use of the Internet to distribute the software, and has become a particular concern for vendor organizations" (Moores, 2003, p. 208). Softlifting

is also a very common type of software piracy among businesses that install single-user licensed software on multiple machines (Rahim, Seyal, & Abdul-Rahman, 2001; Simpson, Banerjee, & Simpson, 1994). Another kind of software piracy involves software installation by retailers onto the hard disk drives of customers' personal computers (PCs) in order to encourage the sale of hardware.

Can Software Piracy be Justified?

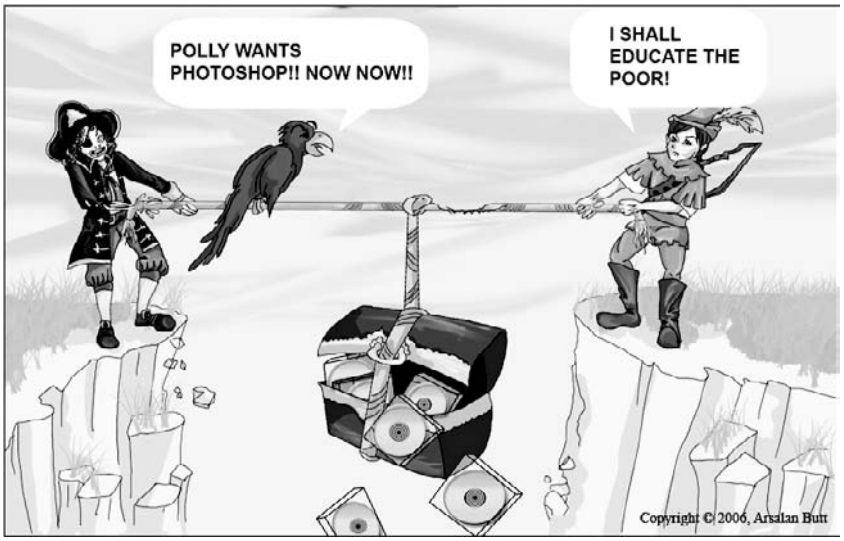
As is the case with intellectual property, issues surrounding software piracy are debated as well. For example, worldwide software piracy figures reported by BSA are cited by almost every published article on software piracy.[5] However, many authors consider BSA's methodology for calculating the levels of software piracy and the amount of reported monetary losses incurred as highly controversial (Locklear, 2004; The Economist, 2005). Even IDC (www.idc.com), an organization which has worked for BSA on the latter's several world software piracy reports, has commented that the conclusions presented in the 2004 BSA study were exaggerated (Locklear, 2004). Some authors, however, have argued that software piracy increases the popularity of the product itself as suggested by Slive and Bernhardt (1998) that "a software manufacturer may permit limited piracy of its software. Piracy can be viewed as a form of price discrimination in which the manufacturer sells some of the software at a price of zero" (p. 886).

A similar opinion was voiced by Microsoft Founder, Chairman, and Chief Software Architect Bill Gates in 1998. Gates reportedly said, "Although about three million computers get sold every year in China, people don't pay for the software. Someday they will, though. And as long as they're going to steal it, we want them to steal ours. They'll get sort of addicted, and then we'll somehow figure out how to collect sometime in the next decade" (CNN.com, 2001). This may also suggest that software manufacturers can allow initial piracy of their product as a strategy to enter or monopolize the market by making consumers attached to a particular software only (as could be the case for Microsoft's operating system Windows), since the purchasing power of the average consumer does not allow him/her to purchase the legal product at full price. Bill Gates faced a lot of criticism for his comments as Microsoft itself is probably the strongest advocate of the anti-software piracy campaign, the company's products being widely pirated all around the world.

Givon, Mahajan and Muller (1995) stated that "software piracy permits the shadow diffusion of a software parallel to its legal diffusion in the marketplace, increasing its user base over time. Because of this software shadow diffusion, a software firm loses potential profits, access to a significant proportion of the software user base, opportunities for cross-selling, and marketing its other products and new generations of the software. However, shadow diffusion may influence the legal diffusion of the software. Software pirates may influence potential software users to adopt the software, and some of these adopters may become buyers" (p. 1). LaRue (1985) also suggested that software publishers could eventually benefit by adopting a shareware marketing strategy of their software. This strategy is currently adopted by many software manufacturers and as Karon (1986) noted, the idea of such marketing strategies has also been supported by the president of an education software firm who believes that some pirates may eventually buy their products due to value-added benefits. Slive and Bernhardt (1998) also stated that piracy of software by home users can be viewed as a price discrimination strategy by the manufacturer (selling software for free) which will eventually increase the demand for the software by business users.

According to The Linux Information Project [LINFO] (2006), the critics of the concept of software piracy argue that the terminology associated

Figure 1. Can software piracy be justified?



with this concept is deliberately manipulated by the major commercial software developers. "That is, use of the term piracy itself is also highly controversial in a software context" (The Linux Information Project [LINFO], 2006, "Inappropriate Terminology" section, para. 1). And "this is also because it implies that people or organizations that create or use copies of programs in violation of their [end user licensing agreement] EULAs are similar to *pirates.* Pirates are violent gangs that raid ships at sea in order to steal their cargoes and rob their crews; they also frequently injure or kill the crews and sink their ships. Critics of this terminology claim that it was chosen for its dramatic public relations value rather than because of any relationship to the traditional use of the word" (LINFO, 2006, "Inappropriate Terminology" section, para. 2).

Another factor that has been shown to associate directly with computer abuse is called the Robin Hood Syndrome (Forester & Morrison, 1990; Perrolle, 1987; U.S. Department of Justice, National Institute of Justice, 1989a, 1989b). Harrington (2002) describes the Robin Hood syndrome as "the belief that harming a large organization to the benefit of an individual is the right behavior" (p. 180). In her study of software piracy, Harrington found that people high in Robin Hood Syndrome are more likely to pirate software as this syndrome allows an "individual to neutralize ethical judgments about software piracy and copy software offered for sale by large organizations" (p.181). The Robin Hood Syndrome could be applied in the context of developing countries as well, where software piracy is justified on the grounds "that it is unfair to charge prices in low income countries that are comparable to those in the higher income countries, and thus virtually unaffordable by most citizens and many businesses in such countries" (LINFO, 2006, "Reasons and Justifications For" section, point 4).

The purpose of this research is not to justify software piracy in a developing country such as Pakistan or any other part of the world. The authors believe that software piracy in any form is illegal and an unethical behaviour. However, it is equally important to stress the fact that depending upon the circumstances, individuals either inevitably *have to* indulge in this behaviour, reasons for which will be discussed later; or they have the option of pirating software, that is to say they do it because they *can*. Another important clarification

that needs to be established at this point is that this research mainly focuses on individual piracy rather than commercial piracy (organizations producing pirated software on a large scale for selling purposes) which is purely done for profit. Commercial piracy however is a crucial element that creates a piracy facilitating environment in a society and will therefore be discussed where relevant. However as stated earlier, the focal point of this research is individual piracy by university students.

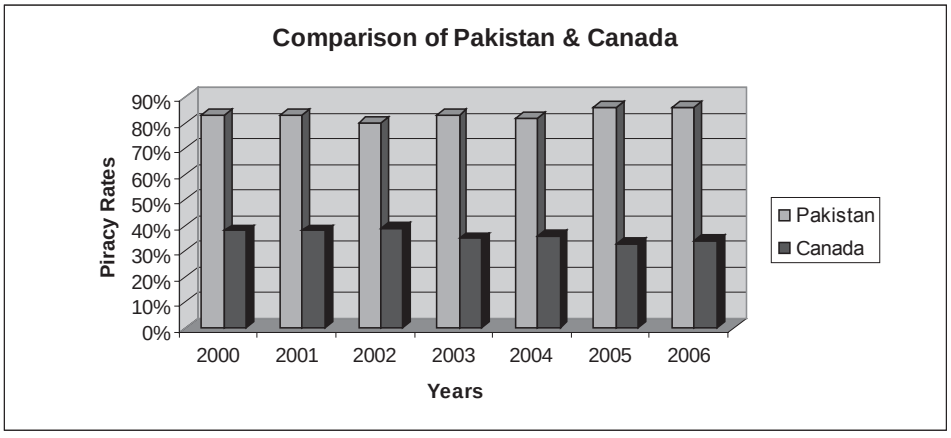
Software Piracy in Pakistan and Canada

Developed nations such as U.S. or Canada have anti-piracy policies and organizations to control unauthorized publishing or copying of software. However, "developing countries are passive in addressing computer ethics in general and intellectual property rights in particular" (Al-Jabri et al., 1997, p. 335). Al-Jabri et al. also suggested that developing countries lack interest groups that combat software piracy. However, it has also been observed that even the presence of these organizations and the existing copyright laws of the country cannot make a significant difference in developing countries (IIPA, 2004). According to IIPA A (2006) Canada also falls short in meeting the objectives laid down in the WIPO Copyright Treaty (WCT) and the WIPO Performances and Phonograms Treaty (WPPT). IIPA notes that the Canadian government introduced Bill C-60 in order to comply with these treaties but the bill eventually died as a result of a call for federal elections in November 2005. IIPA further points out that "Canada remains far behind virtually all of its peers in the industrialized world with respect to its efforts to bring its copyright laws up to date with the realities of the global digital networked environment. Indeed, most of the major developing countries have progressed further and faster than Canada in meeting this challenge" (IIPA, 2006, p. 2). As per the IIPA recommendation, Canada remains on the Watch List of countries. As indicated in Figure 2, the software piracy rates have remained nearly constant over the past few years in Pakistan and Canada.

RESEARCH MODEL

Theory of reasoned action (TRA) suggested by Fishbein & Ajzen (1975) and theory of planned behaviour (TPB) later developed by Ajzen (1991) have been used extensively in the literature to

Figure 2. Software piracy levels in Pakistan & Canada (Source: BSA 2005, 2007)



explain software piracy behaviour and intentions. Both of these theories look at behaviour as an intentional act. While it is true that the literature on software piracy (significant portion of which is based on TRA and TPB) has helped in understanding various aspects of the matter, there have been no empirical studies to prove that software piracy can be conceptualized as an *unintentional behaviour* or *as a behaviour that is the product of the social and cultural environment within which the behaviour is carried out.*

The model developed for this research[6] is shown in Figure 3. It includes social norms as one of the variables. The basic structure of this model has been adopted and modified from a model that was used by Proserpio et al. (2004). Their model was based on a multi-causality approach to determine software piracy factors in 76 countries (including Pakistan and Canada) and is therefore appropriate for this research.

RESEARCH HYPOTHESES

Economic Development

According to Marron and Steel (2000), intellectual property rights encourage novelty and economic growth. In a study on the relationship between national economy and piracy levels, they concluded that a strong inverse correlation existed between piracy rates and the income level of the country. Bezmen & Depken (2006) also found a negative relationship between software piracy and income, tax burdens, and economic freedom. Therefore, it is hypothesized that:

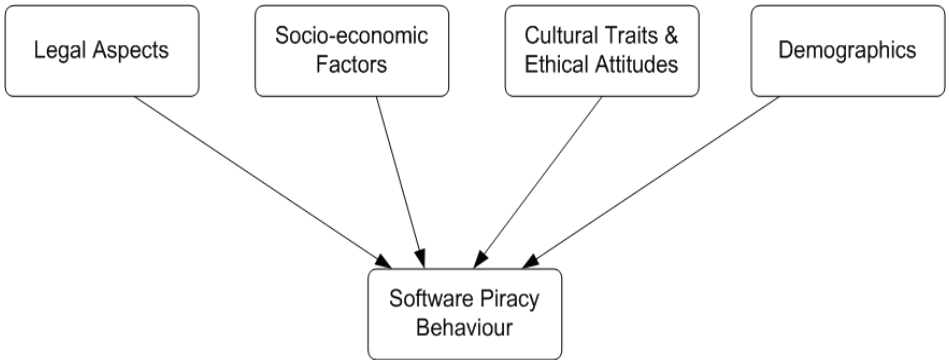
H1: Income will have an inverse influence on piracy intention of subjects.

H2: High price of original software will have a direct influence on the piracy intention of subjects.

Culture

Culture has been defined as "the collective programming of the mind which distinguishes the members of one group or category of people from another" (Hofstede, 1997, p.260); yet culture is a very broad concept, and has little power if it is used as a residual category (Child, 1981). Marron & Steel (2000) and Shin et al. (2004) concluded that the collectivistic culture is to blame for the high software piracy rates. Therefore, social norms and culture will be taken into consideration and the following is hypothesized.

Figure 3. Software piracy behavior model (Source: Butt, 2006)



H3: Social/Cultural norms will have a direct influence on the piracy behaviour of subjects.

Other Piracy Facilitating Factors

Besides the effects of social and cultural norms and poor economy on software piracy, the availability of pirated products is a very important factor that could be significantly related to higher piracy rates. For instance, Rainbow Market in Karachi, and Hafeez Centre in Lahore are two of the biggest and best-known hardware and software malls in Pakistan. Each of these malls comprises hundreds of retailers selling pirated software. The Canadian software market's situation is totally different from the one described above. There are few, if any retailers openly selling pirated software. However, according to a CAAST news release (CAAST, 2005), forty seven percent of the surveyed students admitted to pirating software.

Moores & Dhaliwal (2004) suggested that *high availability of illegal software, absence of legal punishments and high cost of legal software* reflect the high piracy rates of the regions being studied. Simpson et al. (1994) also included the element of legal factors in the piracy model they proposed, and found that these factors have an effect on the ethical decision process, which leads to the actual piracy behaviour. The following is therefore hypothesized in regards to the availability and legal factors.

H4: There will be a positive influence of the availability of pirated software on the intent of subjects.

H5: Legal enforcement will have a negative influence on the piracy intent of the subjects.

H6: Legal enforcement will have a positive influence on the social norms.

Previous studies have also suggested that gender is an important demographic factor that affects one's intention to pirate software. In a survey of moral intentions towards software piracy, Kini et al. (2003) found that males were more inclined towards pirating software, and similar results were proposed by Higgins and Makin (2004). Therefore, the following is considered as the null hypothesis for gender.

H7: There will be no difference between males and females regarding their software piracy behaviour.

"People's perceptions of a particular behaviour are shaped by the existing value system of the society" (Lau, 2003, p. 234). The decision-making model proposed by Jones (1991) suggested that an individual's attitude toward ethical issues will affect the individual's ethical judgement and then their ethical behaviour. It is therefore hypothesized that:

H8: There will be a direct relationship between attitudes towards piracy and the piracy behaviour of subjects.

The discussion that has been presented so far in this research elaborates on the fact that current literature regards piracy behaviour as intentional. To conform to the current literature, the following final hypothesis is made.

H9: Intention to pirate software will have a positive influence on the actual piracy behaviour of subjects.

RESEARCH METHODOLOGY

Site Selection

As is the case with many research projects, this study also had limited resources in terms of time and money. The sites for the study were therefore chosen with these factors taken into consideration.

For the Canadian part of the study, the authors' home university was chosen. For the Pakistani study, the city of Lahore was chosen since it has one of the biggest pirated software markets in Pakistan and also has several IT institutions. Five universities were chosen in Lahore.

Sampling Characteristics

Students were chosen as the target population in order to conform to the existing research, most of which is based on samples of college and university students. Students at both undergraduate and graduate levels from information technology and computer science departments were included in this study.

Pilot & Actual Studies

A self-administered survey instrument/questionnaire was developed. This questionnaire consisted of closed-ended questions that were used to collect demographic details about the research participants. The questionnaire also consisted of, 31 items, each rated on a 5-point Likert scale to assess respondents' attitude towards ethical, economical and demographic implications of software piracy. Negatively worded items were included to detect response patterns. Various items in the questionnaire were adopted from current literature including Moores & Dhaliwal (2004), Siegfried (2005) and Al-Jabri et al. (1997). Based on the feedback of pilot study (conducted in Canada), minor changes were made to the format and content of the questionnaire, and it was also modified to make it adaptable in Pakistan.

While conducting the study in Pakistan, hard copies of the questionnaire were physically distributed at the same time in four classrooms and one computer laboratory at each of the five universities. The questionnaire at the university in Canada was administered through the Internet with the use of a secure program written in PHP/CGI to capture responses.

DATA ANALYSIS

Descriptive Statistics

The online survey conducted at the university in Canada returned 208 responses out of which 196 were usable. Most of the Canadian respondents were under the age of 26 (n=172, 88%).[7] There were 122 (62%) males and 74 (38%) female respondents. The survey in five Pakistani universities returned 365 responses out of which 339 (n=339) were usable. As was the case in Canadian data, most of the respondents were under the age of 26 (n = 325, 96%). There were 221 (65%) males and 118 (35%) female respondents.

Hypotheses Testing

For testing hypothesis, the questionnaire items in both Pakistani and Canadian questionnaire were grouped together to make the statistical tests feasible. The groupings (Table 1) were made based on (1) the face validity, i.e. interpretability; (2) factor loadings; and (3) reliability aka Cronbach's alpha.

Structural Equation Modelling (SEM) with LISREL was used to test the relationships between the above groups/variables. Based on composite scores, the *'Norm-attd'* group in the Pakistani data was further split into '*socnorm*' for *'social norms*' and '*attit*' for *'attitude'*. In the SEM for the Pakistani group, a latent variable called ***'sociomor'*** was created which was composed of '*socnorm*' and '*attit*'**.**

Fitting Data on Structural Models

In addition to fit statistics, structural equation modelling (SEM) produces estimates for partial regression coefficients (referred to as path coefficients), standardized regression coefficients and estimates of squared multiple correlations" (Wagner & Sanders, 2001, p. 165). LISREL was used to fit the data on a structural equation model.

Table 1. Composite variables in the study[8]

Pakistani Study – Variable (Group) Names	Canadian Study – Variable (Group) Names
Availability	Availability
Legal	Legal
Intent	Intent
Norm-attd (i.e. Norms and socially or culturally mediated attitudes grouped together)	Ethical beliefs and Attitudes
Price	Price
Piracy Behaviour	Piracy Behaviour
-	Norms

The resulting path coefficients for Pakistan and Canada are shown in Figure 4.[9] The structural models developed in this research represent the direction and strength of independent variables' relationship with dependent variables.

In the Pakistani model, the price factor (price → piracy behaviour, 0.03) does not seem to have any effect at all on the piracy behaviour, therefore rejecting hypothesis 2. Price also has a fairly strong negative relationship (-.047) with the intent variable, thus contradicting hypothesis 1. In the Canadian model, price has very weak relationships with intent (.01) and piracy behaviour (.02), therefore rejecting hypotheses 1 and 2 for Canadian students. Legal issues have a fairly strong influence on intent (0.54) and not so strong (although it is in the right direction) on the *sociomor* variable (0.40) in the Pakistani model. Hypothesis 5 and hypothesis 6 are accepted and rejected respectively. The Canadian legal construct has a weak relationship with intent (0.07) and a fairly strong relationship with ethical beliefs and attitudes (0.46), thus rejecting hypothesis 5 but accepting hypothesis 6. The gender →piracy behaviour paths in both models have very weak coefficients indicating no difference in piracy behaviour between males and females, thus accepting hypothesis 7.

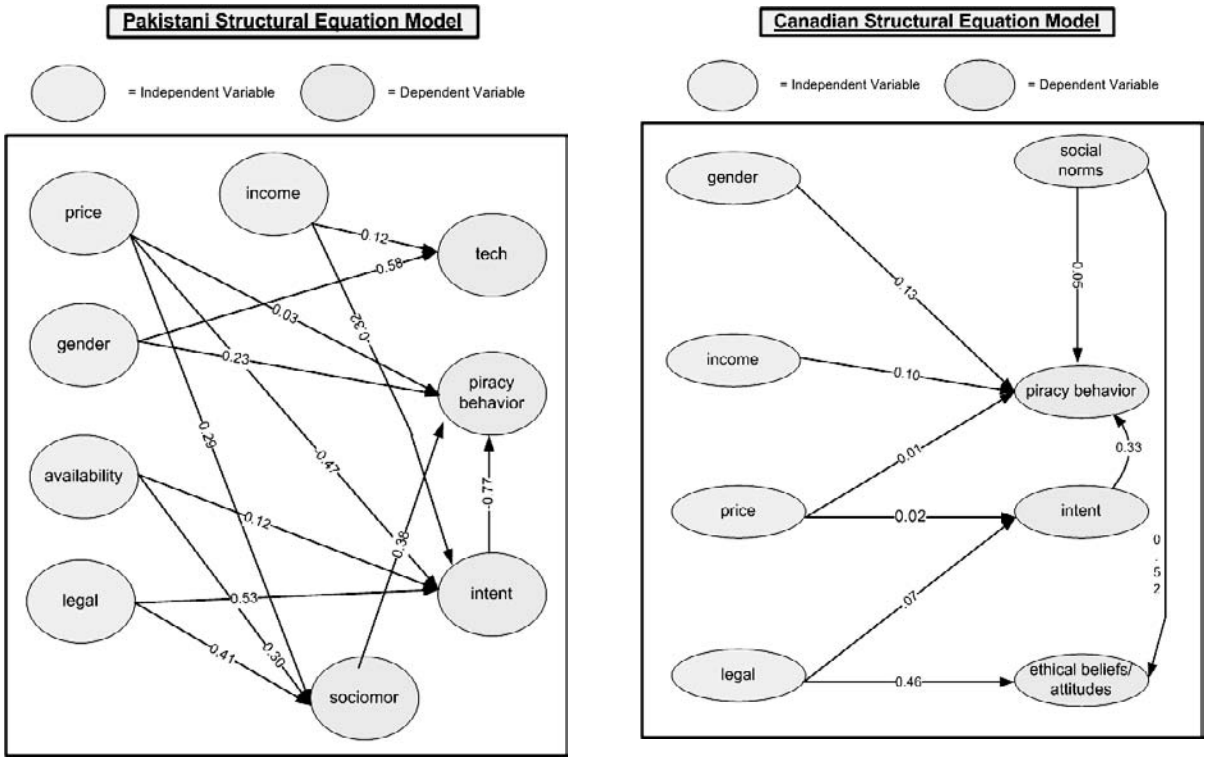
The availability of pirated software has a very small effect on the intent of Pakistani (0.13) and Canadian (0.23) students rejecting hypothesis 4. Intentions in the Pakistani model have a very high negative relationship (-0.76) with the piracy behaviour. Hypothesis 9 is therefore rejected. The *sociomor* construct, despite having a positive relationship (0.39) with the piracy behaviour, is not strong enough to accept hypotheses 3 and 8 in the Pakistani model. As far as the Canadian model is concerned, the *norms* variable has a strong influence (0.52) on ethics and attitudes toward piracy but negligible effect on piracy behaviour with a path coefficient of 0.05. Intent on the other hand shows a relationship in the correct direction (though not very strong) with a path coefficient of 0.34 with the piracy behaviour of the students.

DISCUSSION

This research has focused on the cultural dimension of software piracy and its effect on the behaviour of university students. Two structural models that incorporate social and cultural norms, economic conditions, ethical attitudes towards piracy and the availability of software piracy have been developed and tested. Since Canada and Pakistan are culturally and economically different, they were chosen to provide a contrasting view of the software piracy phenomenon.

The IT industry in Pakistan is progressing, though not at a rapid pace. Still in its infancy, it began in Pakistan with the introduction of

Figure 4. Pakistani and Canadian SEMs



the Internet in 1996. The analysis of economic factors (high price of legal software and low income) in this study provides a rationale for the reluctance of Pakistani government in enforcing intellectual property rights. Despite being aware of the rampant software piracy, governments of countries such as Pakistan are aware of the economic conditions of the mass population. People (students, in the context of this research) in the developing countries need to have cheap access to resources (software) in order to keep up with the rapid pace of technological advancement in the developed world. It can therefore be assumed that governments of developing countries are aware of this and therefore are always reluctant to enact and enforce strict IP protection laws.

The empirical evaluation provides support that social norms and positive attitudes towards piracy are correlated with the actual piracy behaviour of Pakistani students.[10] This finding is similar to that of Proserpio et al., (2004), Seale et al., (1998) and Al-Jabri, I. & Abdul-Gader (1997). Intentions proved to be stronger predictors of piracy behaviour of Canadian students and this finding conforms to the literature which regards piracy behaviour as intentional. The achieved results indicate that software piracy behaviour in Pakistan cannot be regarded as purely intentional. It should rather be conceptualized as a consequential behaviour resulting from various elements, with customs or social norms being the strongest of them all. This also indicates that in two culturally different countries, the conditions that are responsible for creating a piracy-favouring environment are essentially different. Due to a lack of IP related awareness (unlike the developed world), this culture of copyright infringement is deeply rooted in the Pakistani society in such a way that students buy or share pirated software without even realizing that their action might

be considered illegal and/or unethical. It is an established norm: a custom; the way an act is supposed to be normally carried by a member of the society.

Gopal and Sanders (1998) correctly identified the need for a behavioural model for software piracy activity that would help software publishers gain insight into the behavioural dynamics of software pirates. However, as they also found that their economical model was appropriate for the U.S. and not for India, caution should be practiced in all future research that attempts to study piracy behaviour. This study was an exploratory, cross-cultural investigation of piracy in two very different cultures. The applicability of Western constructs such as *'attitudes'* and *'intentions'* to collectivist societies must always be critically examined. Future research should look at the questions left unanswered by this study. Subjects from more countries should be included in future cross-country studies of software piracy behaviour so that the results of this study could not only be generalized for the general student population but also to the population at large.

Authors of this chapter feel necessary to reflect upon the fact that a discovery or invention of a new technology cannot be blamed for its eventual uses. Albert Einstein reportedly said, "My name is linked to the atomic bomb in two different ways. Almost fifty years ago I discovered the equivalence of mass and energy, a relationship which served as the guiding principle in the work leading to the release of atomic energy. Secondly, I signed a letter to President Roosevelt, stressing the need for work in the field of the atomic bomb. I felt this was necessary because of the dreadful danger that the Nazi regime might be the first to come into possession of the atomic bomb" (Nathan & Norden, 1960, p. 569). Einstein however considered signing the letter a "great mistake" (Tobar-Arbulu, 1984). Technology itself can therefore not be blamed for its eventual uses.

FUTURE TRENDS

Findeli (1994) correctly argued that technoethical issues have been continuously rising from the unparalleled developments in technology. One could argue that such issues can act as catalysts to invoke other socio-political and ethical dilemmas. It is not only in software or computer technology that further development will raise ethical questions, but other walks of life such as medicine, engineering, journalism, etc. can have equally grave issues: human cloning, embryonic stem cells research, and inappropriate use of media to shape public opinion during conflicts (e.g. in a war), are only a handful of examples. It is a matter of time before such conflicts will give birth to new unforeseen technoethical issues.

CONCLUSION

This study has found that there are more ways than one of understanding piracy behaviour across different countries. Although poor national economy plays a substantial role in software piracy rates, culture is also part of the equation. This study has also suggested that software piracy behaviour in a developing country such as Pakistan should not be conceptualized in terms of intentions alone. Caution should be practiced in all future research that attempts to study piracy behaviour as the applicability of Western constructs such as *'attitudes'* and *'intentions'* to collectivist societies must always be critically examined. Subjects from more countries should be included in future cross-country studies of software piracy behaviour so that the results of this study could not only be generalized for the general student population but also for the population at large. There is also a lack of longitudinal research and also of other forms of electronic piracy, such as the availability of pirated e-books on the Internet.

Future research could therefore attempt to study both of these domains as well.

KEY TERMS

Culture: Source: Hofstede (1997): "The collective programming of the mind which distinguishes the members of one group or category of people from another."

Individualism and Collectivism: Source: www.Geert-Hofstede.com, An individualistic society is one in which the ties between individuals are loose: everyone is expected to look after him/herself and his/her immediate family. On the collectivist side, we find societies in which people from birth onwards are integrated into strong, cohesive in-groups, often extended families (with uncles, aunts and grandparents) which continue protecting them in exchange for unquestioning loyalty. The word 'collectivism' in this sense has no political meaning: it refers to the group, not to the state. Again, the issue addressed by this dimension is an extremely fundamental one, regarding all societies in the world.

Intellectual Property: Source Forester & Morrison (1990): Results of intellectual activity in the industrial, scientific, literary or artistic fields.

P2P: Source (www.tech-faq.com): Peer-to-peer (P2P) file sharing is a system of sharing files

directly between network users, without the assistance or the interference of a central server.

Software Piracy: Unauthorized duplication of computer for personal and/or commercial purposes. Types of software piracy addresses in this chapter (Source: www.siia.net):

a. **Softlifting:** It occurs when a person purchases a single licensed copy of a software program and loads it on several machines, in violation of the terms of the license agreement. Typical examples of softlifting include, "sharing" software with friends and co-workers and installing software on home/laptop computers if not allowed to do so by the license. In the corporate environment, softlifting is the most prevalent type of software piracy - and perhaps, the easiest to catch.
b. **Hard-Disk Loading:** It occurs when an individual or company sells computers preloaded with illegal copies of software. Often this is done by the vendor as an incentive to buy certain hardware.
c. **CD-R Piracy:** It is the illegal copying of software using CD-R recording technology. This form of piracy occurs when a person obtains a copy of a software program and makes a copy or copies and re-distributes them to friends or for re-sale. Although there is some overlap between CD-R piracy and counterfeiting, with CD-R piracy there may be no attempt to try to pass off the illegal copy as a legitimate copy - it may have hand-written labels and no documentation at all.
d. **Internet Piracy:** It is the uploading of commercial software (i.e., software that is not freeware or public domain) on to the Internet for anyone to copy or copying commercial software from any of these services. Internet piracy also includes making available or offering for sale pirated software over the Internet. Examples of this include the offering of software through an auction site, IM, IRC or a warez site. Incidences of Internet piracy have risen exponentially over the last few years.

ENDNOTES

1 For a detailed discussion on technoethics, see Tobar-Arbulu (n.d.) and Findeli (1994).
2 These types of software piracy are defined at the end of this chapter.
3 There was only one Canadian empirical (scholarly) study found in the literature (see Limayem et al., 1999). This study however relied on 98 research participants only and therefore cannot be considered very extensive.
4 For more discussion on the controversial aspects of DMCA, see http://www.eff.org/IP/DMCA/20020503_dmca_consequences.pdf; http://chronicle.com/free/v48/i47/47b00701.htm
5 This chapter also cites BSA figures but does not rely on any one of them as a major argument.
6 It is important to emphasize here that the model shown in Figure 1 presents a very basic structure which represents the theoretical base of this research.
7 All percentages are rounded off.
8 Factors with Cronbach's alpha >= .70 were only retained.
9 The positive paths between two variables indicate a positive relationship between them and vice versa. The closer the coefficient is to 1, the stronger the relationship. Authors feel the need to emphasize that the structural models were modified until an acceptable fit was achieved. The model was modified because (1) some of the independent variables had significantly non-normal distributions and (2) the relatively small sample size in the

Canadian case made parameter estimation in more complex models more difficult. This is due to the under-identification problems that often arise when the number of degrees of freedom—a function of sample size and number of free parameters—is small. In SEM, structural coefficients between observed variables and latent variables and between latent variables and other variables are parameters to be estimated. For these reasons as well as for parsimony, a less complex SEM model was adopted.

[10] Absence of very strong relationships in SEMs can be attributed to small sample sizes in both studies. Nonetheless, the direction of relationships supported the underlying hypothesis: intentional vs. un-intentional piracy behaviour.

Chapter 7.13
Legal and Economic Justification for Software Protection

Bruno de Vuyst
Vrije Universiteit Brussel, Belgium

Alea Fairchild
Vrije Universiteit Brussel, Belgium

ABSTRACT

This chapter discusses legal and economic rationale in regards to open source software protection. Software programs are, under TRIPS[1], protected by copyright (reference is made to the Berne Convention[2]). The issue with this protection is that, due to the dichotomy idea/expression that is typical for copyright protection, reverse engineering of software is not excluded, and copyright is hence found to be an insufficient protection. Hence, in the U.S., software makers have increasingly turned to patent protection. In Europe, there is an exclusion of computer programs in Article 52 (2) c) EPC (EPO, 1973), but this exclusion is increasingly narrowed and some call for abandoning the exclusion altogether. A proposal by the European Commission, made in 2002, called for a directive to allow national patent authorities to patent software in a broader way, so as to ensure further against reverse engineering; this proposal, however, was shelved in 2005 over active opposition within and outside the European parliament. In summary, open source software does not fit in any proprietary model; rather, it creates a freedom to operate. Ultimately, there is a need to rethink approaches to property law so as to allow for viable software packaging in both models.

INTRODUCTION

Copyright Protection of Software

A software program is foremost a sequence of orders and mathematical algorithms emerging from the mind of the innovator, hence creating

a link with copyright law as a prime source of intellectual property protection.

According to Article 10 TRIPS, computer programs, whether in source or object code, shall be protected as literary works under the Berne Convention provided that they are (1) original and (2) tangible. In light of Article 9 TRIPS, which states that copyright protection shall extend to expressions, but not to ideas, procedures, methods of operation or mathematical concepts as such, copyright protects the actual code of the computer program itself, and the way the instructions have been drawn up, but not the underlying idea thereof (Overdijk, 1999).

Hence, an author can protect his original work against unauthorized copying. Consequently, an independent creation from another person would not automatically be seen as a copyright infringement (Kirsch, 2000a; Leijnse, 2003). With respect to software programs this could have as consequence that a person disassembles and decompiles an existing software program to determine the underlying idea and uses this idea to build his own program (reverse engineering). As he only uses the idea, which is not copyrightable, no infringement will result.

BACKGROUND

Patent Law Protection of Software

Software is a novel form in the technology world, and may make a claim to patent protection from that angle. The conditions to be met to enjoy patent protection are more stringent than those to enjoy copyright protection. In Europe[3], for example, an invention will enjoy protection from patent law provided that the invention (1) is new (i.e., never been produced before), (2) is based on inventor activity (i.e., not have been before part of prior art), and (3) makes a technical contribution (i.e., contribute to the state of the art). In the U.S., the patent requirements to be met are (1) novelty, (2) non-obviousness, and (3) the innovations must fall within the statutory class of patentable inventions.

Pursuant to patent law, a patent holder can invoke the protection of his patent to exclude others from making, using or selling the patented invention. As opposed to copyright protection, the inventor's patent is protected regardless whether the software code of the patented program was copied or not.

The Evolution of the Legal Protection of Software

Prior to the 1980s, U.S. courts unanimously held that software was not patentable and that its only protection could be found in copyright. Indeed, the U.S. Supreme Court ruled in two landmark decisions, Gottschalk vs. Benson (1972) and Parker vs. Flook (1978), that software was similar to mathematics and laws of nature (both excluded from being patented) and, therefore, was unpatentable.

In Diamond vs. Diehr (1981), however, the court reversed course, deciding that an invention was not necessarily unpatentable simply because it utilized software. Since this decision, U.S. courts as well as the US Patent Office gradually broadened the scope of protection available for software-related inventions (Kirsch, 2000). The situation evolved to the current status in which it is expected to obtain a patent for software-related inventions. Since the State Street Bank and Trust Co. vs. Signature Financial Group Inc. (1996) case even mathematical algorithms and business methods have been found to be patentable (see also the Amazon One-click case IPXL Holding, plc vs. Amazon.com, Inc., 2005; Bakels , 2003). As from this decision, the U.S. focus, for patentability, is "utility based," which is defined as "the essential characteristics of the subject matter" and the key to patentability is the production of a "useful, concrete and tangible result" (Hart, Holmes, & Reid, 1999). The evolution resulted in

a rush of patent applications for software-related inventions and business methodologies.

Contrary to the U.S., Europe has been unwilling to grant patents for ideas, business processes and software programs. The most important reasons are their (in-) direct exclusion from patent protection, as stated in Article 52 (2)(c) European Patent Convention (EPC)[4]. Nevertheless, the European Patent Office (EPO) also reversed course. Its view on patentability of software programs and, more particularly, the interpretation of the "as such" limitation as described below, has been under revision, especially driven by the context of computer programs (the so-called computer-implemented inventions).

Following three landmark cases, Vicom/Computer Related Invention (1987), Koch & Sterzel/X-ray apparatus (1988), and SOHEI/General purpose management system (1995), the European Patent Office concluded:

a claim directed to a technical process is carried out under the control of a program (whether implemented in hardware or software) cannot be regarded as relating to a computer program as such *within the meaning of Article 52 EPC,* (emphasis added)

and

an invention must be assessed as a whole. If it makes use of both technical and non-technical means, the use of non-technical means does not detract from the technical character of the overall teaching.

Notwithstanding this enlargement in European patent law, patens have, contrary to the U.S., never been granted for software programs "as such," the main reason being that in Europe an invention has to be technical in nature. This requirement of technicality is not explicitly stated in the EPC, but can be deduced from Article 52 (2) EPC. Indeed, this provision contains a list of subject matters that are not patentable "as such" (among them programs for computers). The list is not meant to be exclusive, as it only gives examples of materials that are non-technical and abstract in nature and, thus, cannot be patented (Sarvas & Soininen, 2002).

In the U.S. on the other hand, a patentable invention must simply be within the technological arts. No specific technical contribution is required. The mere fact that an invention uses a computer or software makes it become part of the technological arts if it also provides a "useful, concrete and tangible result" (Hart et al., 1999; Meijboom, 2002).

In Europe, a number of software developers desire patent protection to be enlarged in such a way that software programs become eligible. One of the arguments of supporters of the patentability of software is that patent law provides inventors with an exclusive right to a new technology in return for publication of the technology. Thus, patent law rewards innovators for the investment and encourages continued investment of time and money. Opponents of patent protection argue that such protection is not needed, indeed appropriate in an industry such as software development, in which innovations occur rapidly, can be made without a substantial capital investment and tend to be creative combinations of previously-known techniques (Pilsch, 2005).

The opponents of software patents also indicate practical problems in administering the patent system, as software is voluminous and incremental. Indeed, an invention can only enjoy patent protection provided that it is not part of the prior art. To verify whether this condition is met or not, it is required to know the prior art. However, knowledge about software is widespread and unbundled (very often either tacit or embedded) and may thus be insufficiently explicit for the patent system to work well. In other words, there is too much software, not enough information about it, and what there is, is hard to find (Kahin, 2003). As transaction costs are high, a

patent system will favor those with enough resources to verify whether their software can be patented and, afterwards, to search for and deal with possible infringers.

Next to these financial impediments, there are some theoretical issues that concern the installing of a system of software patents. These have to do, first, with the basic, global instrument for intellectual property protection, in other words, TRIPS, and second with the specific legislation in Europe and the U.S.

Although according to Article 10 TRIPS, computer programs are protected by copyright, it is the intention of TRIPS not to exclude from patentability any inventions, whether products or processes, in all fields of technology, provided that they are new, involve an inventive step, and are capable of industrial application (Article 27 TRIPS) (Janssens, 1998). Consequently, TRIPS states, implicitly, that computer programs may also be the subjects of patent protection.

From what is stated previously, it is clear that the U.S. legislation allows patentability of software. In Europe, however, Article 52 (2) EPC remains an obstacle for such a protection, however regretted by even EPO. Indeed, in its decision of February 4, 1999, the Board of Appeals of EPO (hereafter the "Board") stated[5]:

The fact that Article 10 is the only provision in TRIPS which expressly mentions programs for computers and that copyright is the means of protection provided for by said provisions, does not give rise to any conflict between Articles 10 and 27 TRIPS. Copyright and protection by patents constitute two different means of legal protection, which may, however, also cover the same subject matter (e.g., programs for computers), since each of them serves its own purpose. (…) The Board has taken due notice of the developments in the U.S. (and Japanese) patent offices, but wishes to emphasize, that the situation under these two legal systems differs greatly form that under the EPC in that it is only the EPC which contains an exclusion as the one in Article 52 (2) and (3). Nevertheless, these developments represent a useful indication of modern trends. In the Board's opinion they may contribute to the further highly desirable (world-wide) harmonization of patent law.

This decision makes it clear that if software "as such" must be protected on the basis of patents, the exclusion under Article 52 (2)c EPC shall have to be deleted. Which brings one to the question of whether one should want this to happen and whether one perceives its consequences favorably.

Supporters of software patents would like to win a first battle in the race for software patentability by endorsing the proposal for a directive on the protection by patents of computer-implemented inventions currently being discussed within the European Union. They are aware that approving this directive will not immediately result in patentability of software "as such," however, it will form "a new development that may contribute to the further highly desirable (world-wide) harmonization of patent law," which can end up in a deletion of the exclusion now stated in Article 52 EPC. Obviously, opponents will do anything to avoid this evolution, however oblique, from taking place.

Currently the latter have the wining hand: a proposal to allow patents for computer-implemented inventions was rejected on July 6, 2005 by the European Parliament, and any new proposal will take time to develop, if ever again (Perens, 2005)[6].

MAIN FOCUS OF THE CHAPTER

Economic Justifications for Software Protection as Part of Intellectual Property (IP) Protection?

If the European Union may want to strike a balance, it must on the one hand take into account

societal needs, and on the other hand the reward of the inventor.

The theoretical foundations of intellectual property rights are debatable, to say the least. Classical philosophy has attempted to explain why intellectual property rights exist, but neither Hegel—the Germanic, idealistic school—nor Locke—the English, empirical school—has been able to provide a coherent, suitable philosophical basis for intellectual property rights—not for lack of trying by themselves or their more recent adherents (Radin, 1982; Schnably, 1993; Hettinger, 1989; Gordon, 1993). The explanation may ultimately occur, not out of law, which is in any event but a mechanic's framework, and not out philosophical theory, but out of the theory of economic pragmatism. Indeed, it may be argued that intellectual property rights, among them software protection, are what they are because they are based on, and fundamentally about, incentives to create and invest.

The United States Supreme Court summed it up in Marer vs. Stein (1954):

"The copyright law, like the patent statutes, makes reward to the owner a secondary consideration." United States v. Paramount Pictures, 334 U.S. 131, 158 . However, it is "intended definitely to grant valuable, enforceable rights to authors, publishers, etc., without burden-some requirements; 'to afford greater encouragement to the production of literary [or artistic] works of lasting benefit to the world.'" Washingtonian Co. v. Pearson, 306 U.S. 30, 36 .

The economic philosophy behind the clause empowering Congress to grant patents and copyrights is the conviction that encouragement of individual effort by personal gain is the best way to advance public welfare through the talents of authors and inventors in "Science and useful Arts." ***Sacrificial days devoted to such creative activities deserve rewards commensurate with the services rendered.*** (emphasis added)

Hence, it appears that the utilitarian, economic incentive perspective is the key driver in the granting of intellectual property laws. But are these incentives really necessary to ensure and sustain creation and invention? In the 1970s, professor (and later justice) Stephen Breyer argued that lead time advantages and the threat of retaliation reduced the cost advantages of copiers, hence obviating if not eliminating the need for copyright protection of books (Breyer, 1970, 1972; Tyerman, 1971). Advances in technology may not have strengthened Breyer's argument. George Priest argued that economic analysis (in his case of patent law) is "one of the least productive lines of inquiry in all of economic thought" because of the lack of adequate empirical bases for the assessment of theoretical models of innovation (Priest, 1986). Still, this view does not undo the fact that the pragmatic utilitarian/economic incentive perspective may remain if not the only, then at least the most useful underpinning for IP rights. These rights inescapably clash with a libertarian view that "information wants to be free" (Barlow, 1994) while those arguing against such freedom cry insist that creation and incentive will be hampered by the diminishing of intellectual property rights. Extremism has polarized views on both sides of the argument, while in the end balanced IP laws may be what are being sought (Lessig, 2004).

Enter Open Source Software

The open source software approach differs radically from the IP protection approach stated above in that it, in the words of Richard Stallman, flips it over to serve the opposite of its usual purpose: instead of a means of "privatizing" software—as Stallman puts it—through IP (copyright or patent) protection, it becomes a means of keeping software free (Stallman, 1999).

In effect, it is meant to create, at least initially, what in patent terms would be deemed a freedom to operate. In other words, open source creates an at least initial space that is open for users. Whether

this is a public domain space or another, similar form may be debated. If it is a public domain space, such an approach does not necessarily keeps open all that it touches (Friedman & Kreft, 2000). Open source software as such does not, as it does with a General Public License (GPL), have this "viral" effect.

If open source may mean the creation of a space to all users, the effect of the different licenses granted to users limits the grant of freedom to operate. There may be free software under a GPL. There may also be Open Source Initiative (OSI) licenses, which require nine elements to qualify for approval as an OSI certified license:

1. Free redistribution (no royalties or fees)
2. Access for any party to a source code
3. The license must allow modifications and derived works.
4. The license may restrict a source code, however, from being distributed in modified form but only if certain conditions are fulfilled.
5. There may be no discrimination against groups or persons.
6. Or against fields of endeavour
7. It is prohibited to require any additional licenses from users to whom a program is redistributed.
8. The license must not be specific to a product.
9. The license must not restrict other software.

Next to OSI licenses, there are others that may be copying features of such licenses, but differ, for example, as to treatment of derivative work[7]. In effect, there appear to be over 50 different open source licenses, and no clear guide (Gormulkiewicz, 1999, 2002, 2004). This is a first challenge—one that has not yet been overcome by any centralized system or standardisation.

This first challenge leads to a second one, as the licensing of open source software poses a number of legal challenges that are not necessary resolved at present. First, there is the issue of validity—a classical one that is also known in the proprietary would and goes back to the use of shrink wrap and click wrap agreements to use—assuming acceptance of the user when she/he opens the software. If this constitutes sufficient an agreement remains a question (Trompenaars, 2000).

Coupled with validity is the issue of enforceability, which is more pregnant in a open source model, because the end user may not have, or even be aware, of any license agreements unless he downloads the source code and starts using the software.

Open source software moral rights—rights related to the inventor's personality—include in patent law the right to attribution (also known as a paternity right) and in copyright include in addition at least the right to resist deformation and defamation (de Vuyst & Steuts, 2005; Metger & Jaeger, 2001). Moral rights being inalienable (i.e., non transferable) they may never be put to a user. If a user were to apply a software package for a use that the author/inventor did not like, the latter could, particularly on the European continent, where the notion of moral rights remains strongest, enforce an injunction for such use (e.g., in violent games or pornographic displays).

A third issue that is particular to an open source software approach, from a legal viewpoint, is that of representations and warranties. In a proprietary, particularly a patented would, it is inherent that the invention has been reduced to practice—that is works—before patent publication. No such warranty can necessarily be given in an open source model. In effect, the GPL does not state explicitly that the GPL code can be run—paradoxically, it does state that one may modify and redistribute. As liability is inherent in a proprietary atmosphere, it is not so inherent in an open source model (Kennedy, 2001) where limitations of liability and disclaimers of warranties may be more rightfully expected—but many limit attractiveness to users.

However, open source licensing on the basis of the principle of "no liability" is paramount to the success of open source software development. The fact that a developer of open source code has the ability to distribute work accompanied by little or no warranties effectively shifts the risk from the licensor of the code to the recipient of the code.

This is important:

Valid reasons underlie this risk-shifting strategy … . Individual hackers are unwilling to assume the risk of a multi-million dollar class action law suit as the consequences of pursuing their passion for hacking code. "Low Risk" also means low barriers to entry; anyone can contribute code to the process, not just those that can afford insurance or lawyers … . (Gormulkiewicz, 2002)

If open source software developers were not able to disclaim liability on their code, it might substantially increase development costs on account of legal risks and greatly discourage open source development.

It is however questionable whether disclaimers and limitations of liability work in all jurisdictions. Choice of jurisdiction in business open source software licenses is therefore essential, but remains problematic in a consumer atmosphere and certainly in cross-border licensing.

Last but not least, the issue of derivative work is, in all cases but in the GPL, an issue. The GPL's "viral effect," in which any modification to the source code must also be under the GPL is unique—and hard to enforce: who can find out but a disgruntled customer faced with a violation? The explanations given by the Free Software Foundation[8] refer to the judiciary for an answer to the question as to what constitutes a contribution of two parts into another program. But the courts may not be the best, certainly not the most efficient means of interpreting open source model licenses (Costello, 2002). In effect, a single German case giving effect to the GPL may not yet be an end to the relative quiet for GPL infringers (Shankland 2004). The lack of clarity in GPL licensing (not to speak of other forms, e.g., BSD or LGPL licensing) makes for uncertainty in derivative work's proprietary or non-proprietary status.

In a proprietary model, the answer, under patent law, is forthright: any derivative work is an infringement of the patent owner's rights. In the open source model, the question is the reverse: can derivative work, including interoperable work as decompiled from the source code, become proprietary in nature? In other words, can reverse engineering lead to proprietary software as it is based only on the idea encompassed in open source software?

If one reverses this risk, one should acknowledge that open source software may have the ability to expose software developers to risk if they use open source licenses improperly. This may be a disincentive to use open source software as a base platform for future development.

FUTURE TRENDS

Discussion: Open Source and the Balance of IP Rights

Free distribution and an open source code propel the open source software movement. It is a fact that software patents are expensive to prosecute and take time to publish, hampering development effort—even being bypassed by events in a quickly developing world.

The benefits of open source software also provide it its soft legal underbelly. The plethora of open source licenses, the lack of clarity and a dependence on court interpretation are a disincentive to users, but more importantly, to developers.

The solution may be in a more formal description—a restatement or standardisation, if one wants—of open source software terms of use

and licenses. But this appears not to occur yet or in the near future, although efforts to state best practices are in the make (Kennedy, 2005).

More fundamentally to the discussion of open source versus proprietary rights, a restatement of the debate as one on excessive rent seeking and a consequent imbalance of rights may point to a way to set the stage for a meaningful discussion which may lead to long-term policy framing, likely at the level of a WTO's TRIPS—a new one, with a more globally accepted balance of interest. If one addresses, in this mindset, software protection and IP rights in general, in terms of its value as an economic good to society, one is bound to find a balanced view. As Judge Posner put it:

granting property rights in intellectual property increases the incentive to create such property, but the downside is that those rights can interfere with the creation of subsequent intellectual property (because of the tracing problem and because the principal input into most intellectual property rights is previously created intellectual property). Property rights can limit the distribution of intellectual property and can draw excessive resources into the creation of intellectual property, and away from other socially valuable activities, by the phenomenon of rent seeking.

Striking the right balance, which is to say determining the optimal scope of intellectual property rights, requires a comparison of these benefits and costs—and really, it seems to me, nothing more:

The problems are not conceptual; the concepts are straightforward. The problems are entirely empirical. They are problems of measurement. In addition, we do not know how much intellectual property is in fact socially useful, and therefore we do not know how extensive a set of intellectual property rights we should create. For all we know, too many resources are being sucked into the creation of new biotechnology, computer software, films, pharmaceuticals, and business methods because the rights of these different forms of intellectual property have been too broadly defined. (Posner, 2002)

The socio-economic measurements, in empirical studies to be undertaken, set a daunting task in terms of methodology as well as in terms of execution. But they point to the way forward: a need to measure the impact of IP rights to determine the optimally needed scope vis-à-vis society.

For software protection, a know-nothing attitude that denies all rights to inventors will be a disincentive to valorise. As became clear to the first author during his tenure at the Common Fund for Commodities, what is put in the public domain is most often left there, as it is difficult to invest the time and energy to shape a competitive advantage from an invention known to and ready to use by all.

That appears to be the case at present: open source would not exist if it was not out of dissatisfaction with an excessively proprietary business model that ignores societal needs. The balance is indeed one between rights and societal needs. Unbalancing in one way or another risks, the wrong investment, or disinvestments, in software development or any other form of IP.

It is open source software that pushes towards this balance by its very existence on alternative to a proprietary business model.

Indeed, it may in three ways contribute to this balancing act already: first, though the so-called Open Patent Review it may involve the citizen in making sure patents represent progress over prior art. This is being accomplished by an alerting system that activates from the USPTO Web site (front of the AppFT database). It will enhance a public view, and review, of applications and assists in preserving safeguards against flooding strategies by would-be patent holders.

Second, open source software Prior Art, an initiative by IBM, Novell, Red Hat and SourceForce aims at developing a system that stores

source code in an electronically searchable format, exposing open source software—millions of lines of publicly available computer source code—as prior art to examiners and the public, so as to assist in ensuring that patents are issued only for actual software inventions and not for appropriations—expropriations, if one wants—of existing open source software (Noveck, 2004).

Finally, a patent quality index, in other words, a numeric index in respect of the quality of patents and patent applications, as a resource for the patent system[9], may be of interest if it proves an objective and data-driven tool. Patent rights, if put to the test, might show their true worth—and there may be a readiness to re-evaluate European and U.S. patent law—if there is a tool which assists citizens and examiners in finding the necessary balance between property rights and innovative freedom to operate, through the application of economic tools, such as a rent-seeking methodology.

CONCLUSION

While it may not be a panacea, open source software is clearly a sufficient counterweight to excessive IP creation, which in the words of professor Jeremy Phillips, does to the public domain—and to innovation—what men do to the Amazon forest (Phillips, 1996).

KEY TERMS

Copyright: A set of exclusive rights regulating the use of a particular expression of intellectual property.

EPC: Convention on the grant of European patents (European Patent Convention) of October 5, 1973.

EPO: European Patent Office (München) established by the EPC.

Patent: A grant made by a government that confers upon the creator of an invention the sole right to make, use, and sell that invention for a set period of time, through letters patent which protect an invention by such a grant.

TRIPS: The Agreement on Trade-Related Aspects of International Property, Annex 1C of the Marrakech Agreement of April 15, 1994 establishing the World Trade Organization ("WTO").

USPTO: United States Patent and Trademark Office.

WTO: World Trade Organization, established on April 15, 1994.

ENDNOTES

1 The Agreement on Trade-Related Aspects of International Property, Annex 1C of the Marrakech Agreement of April 15, 1994 establishing the World Trade Organization ("WTO").

2 The Berne Convention for the Protection of Literary and Artistic Works (1971).

3 By Europe, we mean the European national patent and the system pursuant to the European Patent Convention so that patents can be applied centrally for all contracting states of the European Patent Office (EPO).

4 Article 52 (2) (c) EPC states that programs for computers shall not be regarded as inventions within the meaning of Article 52 (1) EPC and are, therefore, excluded from patentability. Article 52 (3) EPC establishes, however, an important limitation to the scope of this exclusion. According to this provision, the exclusion applies only to the extent to which a European patent application or a European patent relates to programs for computers "as such."

Chapter 7.14
How Can We Trust Agents in Multi-Agent Environments? Techniques and Challenges

Kostas Kolomvatsos

National and Kapodistrian University of Athens, Greece

ABSTRACT

The field of Multi-agent systems (MAS) has been an active area for many years due to the importance that agents have to many disciplines of research in computer science. MAS are open and dynamic systems where a number of autonomous software components, called agents, communicate and cooperate in order to achieve their goals. In such systems, trust plays an important role. There must be a way for an agent to make sure that it can trust another entity, which is a potential partner. Without trust, agents cannot cooperate effectively and without cooperation they cannot fulfill their goals. Many times, trust is based on reputation. It is an indication that we may trust someone. This important research area is investigated in this book chapter. We discuss main issues concerning reputation and trust in MAS. We present research efforts and give formalizations useful for understanding the two concepts.

INTRODUCTION

The technology of Multi-agent systems (MAS) offers a lot of advantages in computer science and more specifically in the domain of cooperative problem solving. **MAS** are systems that host a number of autonomous software programs that are called agents. **Agents** act on behalf of their owners giving them access to information resources easily and efficiently. Users state their requirements and agents are responsible to fulfill them. Hence, MAS include many entities trying to solve their problems that are beyond of their capabilities. For this reason, in many cases, agents must cooperate with others in order to find the

appropriate information and services to achieve their goals.

It is obvious that **MAS** are dynamic and distributed environments where agents may co-operate and communicate with others in order to complete their tasks. A key challenge arises from this nature of MAS. In such open systems, entities change their behavior dynamically. Thus, there is a requirement for trust between agents when they must exchange information Therefore, the basic question in such cases is: How and when can we trust an agent? Agents, in the majority of cases are selfish and their intentions and beliefs change continually.

We try to address this dilemma throughout this chapter. Specifically, we cover the fields of reputation and trust in MAS. This is an active research area, which is very important due to the fact that these two concepts are used in commercial applications. However, open issues exist in many cases, as it is difficult to characterize an agent as reliable or not.

In our work, we try to provide a detailed overview of reputation and trust models highlighting their importance to open environments. Due to the abundance of the relevant models, only the basic characteristics of models are discussed. We discuss basic concepts concerning MAS, reputation and trust. Accordingly, we present efforts, formalizations, and models related to the mentioned concepts. Finally, we discuss about trust engineering issues and we present future challenges and our conclusions.

BACKGROUND

Multi-Agent Systems (MAS)

Software agents and agency have been active research areas for many years due to their importance in various domains. The Web and the recently emerged Semantic Web are the most appropriate examples of such systems. In this section, basic characteristics of MAS are described. Our goal is to provide necessary knowledge about these systems and their requirements for security.

With the rapid evolution of the Internet, Software agents are a very important research area in Computer Science. **Software agents** are components of software or hardware which are capable of acting on behalf of a user in order to accomplish tasks (Nwana, 1996). The owner of an agent may be a human or another computational entity. Tasks are requested by the owners of agents in order to fulfill their needs. There are different kinds of agents. One can meet information agents that search for information sources, mobile agents that move from an environment to another, intelligent agents that can learn from their owners and the environment and so forth. For an extensive discussion of the different types of agents one can refer to Nwana (1996).

In the most cases, agents must deal with complicated tasks that demand cooperation with others. A **Multi-agent system (MAS)** can be defined as a loosely coupled network of problem solvers that interact to solve problems that are beyond the individual capabilities or knowledge of each problem solver (Durfee & Lesser, 1989). In such systems agents can cooperate or compete with others to complete their tasks. We must note that such systems are open. An open system is one in which the structure of the system is capable of dynamically changing (Sycara, 1998). In open MAS, the basic components may change over time such as information sources or agents' behaviors. From this point of view, it can be assumed that in open MAS (Huynh, Jennings, & Shadbolt, 2006):

- Agents have different owners and for this reason they are selfish and may be unreliable;
- There is no knowledge about the environment in which agents must interact with each other; and

- There is no central authority that controls the agents.

The last point is important for the cooperation among agents. Cooperation is often presented as one of the key concepts which differentiates MAS from other systems (Doran, Franklin, Jennings, & Norman, 1997). Through cooperation agents are able to obtain the necessary information needed for their tasks. Of course, interactions are the key issue for the cooperation.

It is obvious that there is an increasing need for the definition of trustworthy entities. In an open environment like MAS, agents change their intentions, goals and behaviors continually thus rendering imperative the need to define methods based on which each agent can be enabled to recognize nontrustworthy entities. The most important thing in such cases is to find ways to acquire information related to others' behavior. For example, an agent must communicate with the candidate partner or with others, in order to infer its trustworthiness. We describe methods to achieve this goal, and we give their basic characteristics.

Reputation in MAS

Reputation is an important factor in many research fields. Especially in computer science, reputation mechanisms are used either in research efforts or in commercial applications. In MAS, agents have to interact with others in order to fulfil their owners' needs for information. In such cases, reputation plays an important role.

According to a dictionary "**reputation is the state for a person of being held in high esteem and honour.**" From a social point of view "**reputation is the general estimation that the public has for a person**" (Wordnet, http://wordnet.princeton.edu).

In MAS, reputation refers to a perception that an agent has of the intentions and norms of another (Mui, Halberstadt, & Mohtashemi, 2002). This is critical for the cooperation among autonomous components in open environments, where the knowledge about the plans of others is limited.

One can find a categorisation of reputation in Wang and Vassileva (2003). Authors distinguish reputation models as centralised or decentralised, according to who has the responsibility to derive a reputation value. It should be noted that authors consider that trust is elicited through reputation. Therefore, their categorisation concerns both reputation and trust models.

- **Centralised.** In centralised reputation and trust models, the system is responsible to collect ratings for agents and publish them. Through this procedure, all ratings are evident to all members of the community and there is little need for communication among agents. Also, an aggregation procedure is performed by the system. The aggregation procedure aims to combine the different opinions in a final reputation level. Centralised models are characterised by simplicity and are mainly encountered in the area of e-commerce, where the main transactions are between sellers and buyers.
- **Decentralized or Distributed.** In decentralised systems there is not a central responsible authority and for this reason each agent develops its own reputation level for other community members. This means that there is an increased need for interactions between agents. Through them, agents form a subjective trust in their potential partners.

Mui et al. (2002) discern reputation based on which experiences and ratings are taken into consideration, and through what procedure information for the opponents is extracted. According to authors, reputation models can be divided into the following:

- **Individual Reputation.** Individual reputation is the description of the reputation level of a simple entity by another. This level is computed based on actions and information related to an agent and not a group of agents.
- **Group Reputation.** Group reputation depicts the social dimension of reputation. In these models, reputation is a function of the aggregated ratings taken from a group of entities. Entities rate others having their own experiences. These ratings may be utilised to provide information to an agent, when it needs to cooperate with others.
- **Direct Reputation.** Direct reputation is based on straight experiences with an entity. Usually, these observations are taken by interactions held between two entities. Direct reputation may be *observed* or *encounter-derived*. We have observed reputation when feedbacks through direct experiences of others consists a reference of the reputation of an agent. On the other hand, entities' ratings, after an interaction with others, may affect the reputation level of an agent. In this case, we have encounter-derived reputation.
- **Indirect Reputation.** With the lack of direct experiences for an entity, reputation can be derived from information gathered indirectly. There are three basic models for indirect reputation. The first model uses prior beliefs that agents carry about their interactions with strangers while the second model takes into consideration the group that an agent belongs to. Finally, the third model uses the information taken about an agent from the entities in the environment.

Trust in MAS

Trust is a common theme in computer science research, and refers to a range of different issues. It has important impact on domains such as security, e-commerce and Semantic Web. Trust is also an important concept for MAS. While in general trust refers to an aspect of the relationship of individuals, the concept has a completely different meaning depending on the context is used (Deriaz, 2006). Hence, trust has different meaning when we use it to characterize that humans' actions are trusted or when an agent decides to rely on another in order to obtain some resources.

Trust can be seen as the extent to which one entity intends to depend on somebody in a given situation (McKnight & Chervany, 1996). Trust can be defined as the belief that one can rely on someone else to accomplish a task. There is, however, a possibility that unfavourable issues can arise from interactions with a trusted person.

In this point, we describe a list of trust categories found in the literature.

According to Ramchourn, Huynh, and Jennings (2004) trust may be categorised, based on the part which decides the grade of trust, into the following:

- **Individual Level Trust:** Each agent decides which entity can be trusted based on its beliefs. These beliefs derive from interactions held between agents. Individual level trust can be further divided into:
  a. **Learning based.** Agents may interact with each other many times before deciding to trust someone. From this procedure, useful conclusions can be derived for the potential partners. Through repeated games, agents are able to analyze their opponents' moves in order to reach a conclusion. There are different kinds of metrics used in such models, as bi-stable values (good or bad) or fuzzy mechanisms with which one can decide to trust someone else for various acts.
  b. **Reputation based.** Reputation-based models use ratings from the members of a community in order to derive a trust level. Important issues concern-

ing this type of trust are the collection of ratings, their aggregation and the diffusion of members' opinions. First of all, an agent must collect ratings from the members of the community through the use of *referrals*. Referrals are the opinions of community members about a certain entity. After that, he must use an aggregation method in order to extract a result. In this point, there are issues that can complicate the whole procedure, as the lying witnesses or the absence of ratings. Finally, an important issue is the propagation of reputation in a community based on reputation scores that agents have for a set of other entities.

c. **Socio-cognitive based.** Contrary to previous types, where trust is computed taking into consideration the results and the components of interactions between agents, socio-cognitive-based trust is computed based on beliefs that an agent has for their opponents. These beliefs are: competence, willingness, persistence, and motivation belief.

- **System Level Trust:** Agents are selfish components which want to obtain as much profit as possible. For this reason, it is imperative to force them to follow some rules when interacting in the context of a system. This is the system level trust. In consequence, they will be trustworthy, thus minimizing the danger to interact with liars. System level trust can be further divided into:
  a. **Truth-eliciting protocols.** These protocols may be used to elicit trustworthy behaviour of an agent. Agents must conform to certain protocols' steps in order to complete transactions in the system.
  b. **Reputation mechanisms development.** Reputation may be used in system level trust. There are rules posed by the system concerning the three key elements of reputation models (collection of ratings, aggregation and propagation). In such systems, the entities responsible to store ratings may be centralised or decentralised. All agents working in the system have access to these entities either to read ratings or to publish their own.
  c. **Security mechanisms development.** In these model types, a number of features are taken into consideration in order to provide a reliable security mechanism that ensures trust in system entities. The essential elements that make an agent trustworthy can be identity proof, access permissions, content integrity and content privacy (Poslad, Calisti, & Charlton, 2002). Additionally, certificates may be used to provide a higher level of security. The system forces members to give the necessary information as for the aforementioned elements in order to have an acceptable degree of safety.

Artz and Gil (2006) note that there are two methods to derive trust:

- **Based on credentials.** Credentials are elements that can be used to elicit information for an entity. A credential may be simple as a signature or complex relationships between elements in an open environment as the Semantic Web. For example, an agent may have an identifier with which may interact with others. This identifier may be used in a system to provide to an agent permissions or rights to work with specific information sources. An extensive review of systems that use credentials-based trust models is presented in Artz and Gil (2006).
- **Based on Reputation.** This model uses reputation to assign trust to members of

a community. An agent utilizes personal experiences taken from interactions held between potential partners, and ratings from other members of the system. There are two ways to extract the trust level for an entity. One can rely on a central authority to have access in reputation ratings or on himself. Few efforts in literature use the first method. The second one describes the decentralised model where each entity must develop methods for the aggregation of ratings taken from the community.

In Osman (2006), authors specify the difference between trusting an agent, and trusting an interaction. They provide a categorization and a specific connection with the categories presented in Ramchourn et al. (2004). Two new categories are presented:

- **Local Deontic Level.** It concerns the constraints and permissions that an agent must follow when interacting in a multi-agent system. Agents are dynamic components and their goals, intentions and plans change continually. This means that when they work in an open environment, they have obligations, permissions and prohibitions, posed by the system. Through this, the system defines a security level concerning the transactions held among the potential partners.
- **Global Interaction Level.** Apart from the internal deontic model of each agent, there is another interaction model that specifies the rules based on which interactions are held. Every agent must conform to these rules in order to gain access to interactions with others, useful for the completion of its goals. Specifically, the interaction model is a protocol that determines steps to carry out interactions.

Grandison and Sloman (2000) presented a set of trust classes which are:

- **Provision Trust**. It describes the trust that an entity may have to a service provider.
- **Access Trust.** It describes the trust that an entity may have for the purposes of accessing resources.
- **Delegation Trust.** It describes the trust that an entity may have to an agent that works on its behalf.
- **Identity Trust.** It describes the belief that an identity is as claimed.
- **Context Trust.** It describes that the relying entity has confidence in a system in which transactions are held. Moreover, each entity can rely on system, when problems may arise in transactions.

Finally, another categorisation found in Wang and Vassileva (2003) has already been presented, where trust quantification may be held either by a central authority or by each agent individually.

A significant amount of work on trust has been performed in the area of Normative MAS (NMAS). NMAS is an extension of classical MAS which combines traditional MAS with normative systems where concepts such as obligations, commitments, permissions and rights are used to describe the behaviour of an entity (Boella, Van Der Torre, & Verhagen, 2006). Thus, every agent acting in a community has some obligations and commitments that should be fulfilled. In such systems, norms are defined to describe when the behaviour of an agent is acceptable. While the agent follows these norms its trust level increases in the community. In reverse, the agent's trust level decreases when its actions do not conform to the specified rules of normal behaviour. These rules aim to force agents to do the right thing cooperating with others in the broader environ-

ment. However, norms can be violated for various reasons and thus there is a dynamic trust valuation (Boella & Van Der Torre, 2005).

ISSUES CONCERNING REPUTATION

Reputation level can be derived based on three elements: the experiences of the evaluator, the referrals of others and the combination of the experiences and the referrals (Josang et al., 2006). There are methods that deal with all these three issues. Generally speaking, in MAS a set of agents $A=\{a_1, a_2, \ldots, a_n\}$ want to interact with others in order to complete their goals. For each potential partner, every agent must calculate its reputation degree which is extracted through a reputation function:

$$Reputation\_value=f(R, E, S) \quad (1)$$

where R represents ratings from other members of the community, E are the individual experiences taken from direct interactions with the target entities, and S represents ratings retrieved from the system.

The factor R is computed based on aggregation of ratings. Namely, there is an aggregation function which derives a final value from a set of witness agents $WA=\{wa_1, wa_2, \ldots, wa_m\}$.

$$R=g(r_1, r_2, \ldots, r_m) \quad (2)$$

where r_i denotes the referrals of the i_{th} witness agent. In literature, there are models that use only one of the above mentioned elements or a combination of them. As discussed below, every reputation model uses a function in order to calculate the final result, which follows the general form depicted in (1). For example, an agent may be based only on direct experiences with the target agent, without paying attention to the ratings of others. In order to define efficiently final reputation value, a model must be based on a combination of the above mentioned features (e.g., referrals, the system's ratings and direct interactions). The majority of systems in the literature follow this direction. Their difference is located to the form of the referred functions and the type of the computed values. Hence, in all models we can find a reputation function that produces a value that can be either discrete (e.g., "Confident," "Non-Confident") or continuous (represented through a real number).

A short description of reputation models follows. Furthermore, we present our point of view related to their advantages and disadvantages.

Simple Mathematical Models

They are the simplest models. In these models simple calculations are used in order to compute reputation values. For example, the system may store the number of positive and negative opinions for agents and compute the final score. If the positive opinions are $P=\{p_1, p_2, \ldots, p_k\}$ and the negative are $N=\{n_1, n_2, \ldots, n_m\}$ then the final score is:

$$Score = |P| - |N| \quad (3)$$

where |x| denotes the cardinality of set x. The higher the value of *Score* is the more reliable the agent is considered. For example, if an agent has received 10 positive and 2 negative referrals, it has a reputation degree of 8. This agent is more reliable than another that has a reputation degree of 5. However, these models do not take into consideration the initial numbers from which the final result is computed. Let us examine an agent that may have received 100 positive and 90 negatives opinions. This means that the agent has approximately 47% negative opinions in the community. Nevertheless, this agent is more reliable than another with 10 positives and 1 negative referral (approximately 9% negative opinions).

In order to cover these disadvantages, advanced mechanisms use a weighted sum to compute an average which shows the reputation level. These mechanisms use the information related to the ratings such as the age of each rating, the distance between rating and current reputation value, and so forth (Josang, Roslam, & Colin, 2006).

It should be noted that such systems do not take into consideration critical issues concerning the selfish and dynamic nature of agents. It is possible that agents may form coalitions in order to exchange positive marks thus achieving better reputation scores. Furthermore, the simple mathematical models do not examine in depth the referrals retrieved from the community members in order to extract useful information about the behaviour of an agent.

Bayesian Reputation Systems

Bayesian systems are based on statistics. They compute reputation using the Beta probability density function. This function can be used to describe probability distributions of binary events. For simplicity, we give only a short description of such systems.

A Bayesian reputation system takes binary ratings and uses the *a priori* reputation score and the current ratings to compute the *a posteriori* result (Josang & Ismail, 2002; Mui, Mohtashemi, Ang, Szolovtis, & Halberstadt, 2001; Whitby, Josang, & Indulska, 2004). In agent systems, we can describe the behaviour of an agent as "Honest" vs "Dishonest," or as "Reliable" vs "Unreliable" which constitute binary events. If, for one agent, there are x positive and y negative observations, then the reputation score can be computed as follows:

$$\alpha = x+1,\ \beta = y+1 \text{ with } x,y \geq 0 \qquad (4)$$

the probability expectation value is:

$$E(p) = \frac{\alpha}{\alpha + \beta} \qquad (5)$$

for the Beta distribution, which can be expressed as:

$$B(p|\alpha,\beta) = \frac{\Gamma(\alpha + \beta)}{\Gamma(\alpha) \cdot \Gamma(\beta)} p^{\alpha-1} \cdot (1-p)^{\beta-1} \qquad (6)$$

where $p \in [0..1]$, $\alpha,\beta>0$, $p \neq 1$ when $b<1$ and $p \neq 0$ when $a<1$.

When the a priori probability does not exist, then we consider $\alpha=1$ and $\beta=1$. From this function, each agent can compute the possibility that a potential partner is reliable based on previous values of reputation. For example, if the expectation value E(p) has a score of 0.9 means that the most likely value of positive outcomes in the future is 0.9, but the actual outcomes are uncertain.

Bayesian models give a computational theoretical framework for the reputation score good for autonomous computational entities as agents are. It is an efficient mechanism to combine evidences. An entity must keep track of the outcomes of others and compute the reliability possibility through the above referred functions. A full description of a system representative of this kind of model can be found in Josang and Ismail (2002). However, these models are complicated due to the calculations that must be performed in order to derive a final reputation value. Also, the definition of a priori probability used for the calculations is necessary. The probability value is important for these models and must be derived by a subjective method.

Social Networks

Social networks are originated in sociology. Social networks can be represented as graphs that depict relations between members of a community. Social networks analysis emerged as a set of methods for the analysis of social structures (Sabater & Sierra, 2002). In MAS, agents must retrieve data

concerning the relation among the members of the system in order to decide the reputation level of a potential partner. However, it is difficult to use methods taken from sociology in order to poll information for the network architecture. For example, sociologists use methods as the opinion poll or interviews. In cases where autonomous computational components are the nodes of a social network, more "computational" ways must be found to extract the necessary information.

The procedure that agents adopt for building the network is critical for the success of such systems. They must describe as much relational data as they can in order to have a significant view of the system. We must also note, that these networks change dynamically due to the open nature of MAS. Agents may enter or leave at every time and, moreover, may alter their goals, behaviours and intentions.

Generally speaking, in systems based on social networks there is a set $A=\{a_1, a_2, a_3, \ldots, a_n\}$ of agents that want to obtain information from others in order to complete their goals. Each agent builds a social network $G=\{d_1, d_2, \ldots, d_n\}$, with nodes d_i representing the members of the system. Edges that connect nodes show a relation between them. For example, edge $e_{i,j}$ denotes that there is a relation among nodes i and j. Next, it finds its potential partners and tries to collect information about them. It may be based on referrals or on the system or on a combination of them. Referrals are taken from other members that have interaction history with the target agents, and after a careful selection. These referrals must be aggregated in order to extract a final value through which reputation is computed.

Three critical factors must be taken into account: the possibility that agents may tell lies, the possibility that agents may conceal information about others and the careful selection of referral agents. In these cases, social networks may be constructed based on false values as for the reputation degree of each member. Also, there are cases in which agents ally with others and for this reason may hide the bad reputation that an examined agent acquired. A method to alleviate the problem of lying in MAS is presented in Schillo, Funk, and Rovatsos (2000).

As mentioned above, in MAS social networks agents appear as nodes and their relationships as edges. Each edge has a value which represents the weight of the relationship between the two connected agents. After the graph creation, the construction of the network and the computation of reputation follow. Such computation is based on the weights assigned to edges. An extensive survey on reputation mechanisms based on social networks can be found in Ramchourn et al. (2004).

In this point, we present two simple examples of social networks models. A first example of such model is presented in Pujol and Sanguesa (2002). Authors describe an algorithm which is named *NodeRanking* and is used to extract a reputation value for members in a community. Its main idea is that every node and, respectively, agents have an authority degree which is an importance measure. For example, the authority of a node x is computed as a function of the total measure of authority presented in the network and the authority of the nodes pointing in x. The main rationale is that if a node has a lot of edges pointing to it, this means that the node is important in the community because this means that it cooperates with many other members. Another critical issue is that every authority value is propagated through the out-edges. The reputation value is computed based on the authority value of each node, taking into consideration the importance and hence the number of agents that are related to the examined entity.

Another system that uses social information in order to compute reputation is REGRET (Sabater & Sierra, 2002). Reputation in REGRET has three dimensions, the *individual*, the *social*—according to the source of the information used to extract a

reputation value—and the *ontological* dimension, which helps to transfer the reputation between related contexts. While the individual dimension takes into consideration the results of direct interactions between potential partners, the social dimension utilizes information taken from the other members of the community. In the second dimension of reputation, agents may use witnesses from others or consider neighbourhood reputation. Furthermore, the system assigns a reputation level to every role defined in it. Hence, agents that have a specific role in the system inherit the reputation level assigned to the role.

System reputation is the easiest to compute but is dangerous because a role held by an agent does not convey information about its intentions. In the REGRET system, reputation is combined with a domain and calculated using a table in which rows are the potential roles and columns are the reputation types. More complicated are the remaining two methods. Witnesses reputation uses the referrals of others in order to establish a reputation level. REGRET gives the opportunity to an agent to define a set of witnesses and aggregate their referrals based on fuzzy rules. Of course, witnesses are entities that have interacted in the past with the target agent and they are taken into account based on the same event, if it is possible. Neighbourhood reputation is not related to the physical location of the agents but to the links created by interactions. These interactions and the relations between agents are very useful to compute reputation level for a target agent. Fuzzy rules are also used in this case.

Belief Theory Models

Belief theory characterizes the remaining of the subtraction between 1 and the summary of the possibilities of the all possible outcomes, as uncertainty. In these models, agents use their beliefs about the behaviour of another entity. In Yu and Singh (2002), authors propose the use of Dempster-Shafer theory (Dempster, 1968; Shafer, 1976) for the computation of reputation degree. There are two kinds of belief in their model: *Local* and *Total*. Local belief is obtained from direct interactions with the target agent and Total belief is extracted from the opinions of others combined with local belief. Witnesses from others are necessary when interactions are not available. Each agent models the information from others using belief functions. There are two outcomes related to the reliability of an agent: *Trustworthy* or *Not Trustworthy*, each of them has a belief value m(T) and m($\neg$ T) respectively, taken from the correspondent belief function. The reputation score for an agent A is:

$$\Gamma(A)=\beta_A(\{T_A\})-\beta_A(\{\neg T_A\}) \qquad (7)$$

where β_A is the cumulative belief result computed using the testimonies from a set of L neighborhoods. When no testimonies are available, then the reputation score is 0. Also, authors present the reputation value of a set of K agents, which is:

$$\text{Group\_Reputation} = \frac{1}{K}\sum_{i\in[1..K]}\Gamma(A_i) \qquad (8)$$

These models are able to exhibit the beliefs of agents, accumulated from past experiences or others, in functions that combine them and produce the final result. However, the definition of a threshold value is critical. This threshold defines when an agent may be characterized as trustworthy or not. Moreover, the assumption of only two possible outcomes limits the model.

Fuzzy Models

Fuzzy models try to catch the subjective point of view of an agent related to another member of a community. In these models, reputation is presented through linguistic fuzzy values in contrast to other models in which common reputation levels are defined by means of real numbers. For

example an agent may be characterised as "reliable" or "not reliable." Fuzzy logic (Zadeh, 1989) is very important because it provides reasoning techniques for the extraction procedure. Rules may have the next form:

IF andecent THEN consequent

where *andecent* is represented with fuzzy sets.

Fuzzy logic techniques depend on subjective criteria that may lead an agent to cooperate based on its thoughts about others. This means that if an agent has very optimistic views of the community he may rely on others that have bad intentions.

In Rubiera, Molina Lopez, and Muro (2001) a method for the computation of reputation based on a fuzzy model is presented. Each agent retrieves opinions only from entities that are highly appreciated. Based on their answers it computes a value that is extracted from a fuzzy set according to its point of view. The result is the weight of an agent's opinion. Furthemore, there is interest on combination of the new and the old reputation values. The old reputation score of the candidate partner is taken into consideration and, hence, the final result is the average of two fuzzy values: the old and the new one. The agent is responsible to decide on defection. Usually, if a threshold is reached, cooperation is held.

Another system that relies on fuzzy rules is REGRET, which was briefly described in the previous section.

Role-Based Reputation

In some models, reputation can be seen as a value of a role fulfilment. A role is a set of obligations and actions that an entity has in the community. If an agent acts and behaves as a role dictates, then it has the reputation level that this role offers. In Carter and Ghorbani (2004) a framework for the role fulfilment measurement is presented. Three roles are investigated: The Assistant, the Provider and the Citizen. A general overview of how measurements take place in each role is given by the authors. In order to compute the final value of reputation, authors examine the satisfaction degree of each role for a specific entity and combine these partial results. The reputation is a weighted sum of each value that reflects the fulfilment of each role.

The main problem with these models is that they do not examine in depth the intentions that agents have. Meeting the requirements of a role by an agent does not mean that the agent will not change its behaviour.

Unfair Ratings: Deception

As mentioned above in distributed reputation models, when a central authority is absent each agent that wants to cooperate with others must collect ratings from the environment in order to decide the reputation degree of an entity. In these cases important issues are:

- The possibility that some agents provide unfair ratings for others. These ratings may be unfairly positive or unfairly negative (Dellarocas, 2000).
- The possibility that an agent deludes others.

According to Whitby et al. (2004), methods of avoiding unfair ratings are divided into *endogenous* and *exogenous.*

Endogenous methods are based on the statistical analysis of the rating values. They can give or exclude ratings that are possible to be unfair. Classical examples of this kind of systems are Bayesian reputation systems. Authors describe an algorithm that filters unfair ratings in a Bayesian model. Exogenous methods are based on factors that are related to external elements such as the reputation of the witness. The main idea is that an entity with low reputation is likely to give unfair

ratings and vice versa. In the relevant literature, one can find a lot of works falling in the aforementioned categories.

Another algorithm for the detection of deceptive agents is proposed in Yu and Singh (2003). This method uses exogenous characteristics of the witnesses as we presented above. The algorithm assigns weights to witnesses and makes a prediction based on the weighted sum of their ratings. The second idea is to tune these weights when a prediction fails. In this case, the weight of successful witnesses is increased and the weight for the unsuccessful is decreased. We must note that the ratings that an agent takes are belief functions and for this reason the algorithm maps belief functions to probabilities in order to be able to compute and update the weights of each witness. Moreover, authors study the number of witnesses and its effect to the system's prediction values.

ISSUES CONCERNING TRUST

Trust is usually researched in the security domain. The main reason is that these two concepts are related, but they have different orientations. However, trust and security provide protection against malicious components. In this sense, trust can be considered as a *soft security* mechanism. This term first appeared in Rasmusson and Jansson (1996). Authors discern *hard* and *soft* security mechanisms. Hard tools are authentication, cryptography, and so forth, and soft tools are those that take into consideration social control issues, as they are trust and reputation.

In MAS, trust plays an important role because agents need to cooperate with other members of the community. The importance of trust in MAS is shown in Castelfranchi and Falcone (1998). Critical questions arise such as: When can I trust another entity? Which entity is trustworthy? What are the elements that can be used in order to conclude a trust level? What methods should be used to conclude trust level? Such questions are addressed in the fourth section of our chapter.

Discussion

The main differences between trust and reputation are:

a. Usually, trust is a score that reflects the subjective view of an entity from another, whereas reputation is a score that reflects the view of the community.
b. In trust systems, transitivity is considered explicitly while in reputation systems is seen implicitly (Wang, Hori, & Sakurai, 2006).

The common element between the two concepts is that both of them try to help someone that wants to find trustworthy partners to achieve its goals through cooperation. However, trust is more complicated concept that involves many parameters. For this reason, it is very difficult to assign a strict definition to trust.

As mentioned above, trust is a subjective view of an entity. It is based on some beliefs that an entity has for another, but it is not clear where such beliefs originated. This means that an agent may be reliable only for a set of other agents and not for all of them. The level of trust is also depended on the context in which it is being studied. For example, an agent may be trustworthy when providing information but it is nontrustworthy when selling products. These two factors are basic to open systems and must be taken into consideration. Moreover, trust is dynamic. An agent may consider another entity as reliable in a specific time but its opinion may change accordingly based on the behaviour of the target entity.

The simplest form of trust is centralized. In such systems, there is a central authority that keeps the trust level of entities who rate each other after every transaction. Soft mathematical

calculations are held to provide the final result. It is a scheme that must take into account issues concerning lying entities or unfair ratings. Also, there must be a high security level to prevent violations in central database where ratings are kept. On the other hand, decentralized trust models are complex and require effort from the side of each entity that tries to find partners. In such systems, critical issues are the storage of trust values, the location of witnesses and the inference procedure.

In general, a trust function has the following parameters: the beliefs of the examiner (B), the reputation of the examinee (R), previous trust values (P) and the context (C).

$$\text{Trust\_value}=f(B, R, P, C) \quad (9)$$

An interesting value is B. B may be extracted from direct experiences through communication or past experiences with the target entity. It may be a positive or a negative belief. Relation (9) concerns a general function form. As we discuss in the following paragraphs all the described models use a function that follows this general form and takes into consideration one or more values from B, R, P or C.

The result of the referred function may be discrete or continuous values. For example, in discrete models, as fuzzy models are, a trustworthy behaviour may be characterized as "Very Trustworthy," "Trustworthy," "Untrustworthy," or "Very untrustworthy," for direct trust between two entities, or "Very good," "Good," "Bad," or "Very bad" for recommender trust (Abdul-Rahman & Hailes, 2000). Either discrete or continuous, the final trust value reflects a confidence over the knowledge we have about an entity.

Trust mechanisms vary from these that use simple computations to those that use more complicated characteristics of the entities involved in such situations. However, the common procedure among them is that they map a set of features to trust information. In the following paragraphs, we give a description of some important categories of trust and examples of each one.

A key issue concerning trust is its dynamic nature. Trust evolves over time as entities cooperate with others. For this reason, it is critical to define a trust update procedure. Especially in open environments like MAS, where goals, intentions and beliefs of each agent change continually, there is a need for dynamic adaptation of the trust level. This means that in every model that is used to compute trust, developers must take into consideration how trust levels evolve over time and transactions. The evolution of trust may be based on the experiences of the trustor or on new information taken from other members of the community.

In conclusion, in the computing trust procedure, the phases that an agent may handle are:

a. Trust Discovery Phase (TDP);
b. Trust Aggregation Phase (TAP); and
c. Trust Evolution Phase (TEP).

In TDP, each agent tries to find the appropriate sources for referrals and may communicate with the target agents in order to elicit useful information about their behaviour. In this phase it is important to have mechanisms to identify if a group of agents have formed a coalition and share good referrals among them. In TAP, the most important issue is to use an appropriate aggregation function in order to derive the final value of trust. This function may take into consideration the results of direct experiences and of course the referrals of peers. Finally, the TEP is a continuous procedure through which an initial trust level is evolving over time based on observations. Its great importance relies on the dynamic nature of MAS. If an agent is trusted in a specific time this does not mean it is to be trusted forever. Agents are selfish and may change their behaviour without warning or may ally with others.

Trust Propagation

MAS can be viewed as graphs where their agents are represented by nodes. Edges consist of their relationship in the community and weights represent the trust value between the two connected nodes. Graphs may be used to transfer trust information among members. Every agent trusts some others in the network. *Estimated trust belief* is derived through the trust network based on inferences while *expected trust belief* is the ideal target (Ding, Kolari, Ganjugante, Finin, & Joshi, 2004). It is very difficult to achieve the expected trust belief due to the lack of global knowledge of the community and its members. As the trust network evolves over time and more information is gathered from the agents, the ultimate goal is gradually approached.

Propagation of trust is very important in such networks because it gives the opportunity to derive beliefs about agents through the combination of values taken from multiple sources. The most common method for trust propagation is referrals. Referrals have been investigated in reputation mechanisms (see Section "Issues Concerning Reputation"). An agent, having collected opinions from a set of peers, needs an aggregation method in order to define the final estimated value of trust. Through this procedure, trust information can be propagated over the network. Additionally, we must take into consideration that agents may ally with others and give positive recommendations for their allies. However, when an agent establishes trust based on recommendations from others, this trust value cannot be greater than the trust value between the agent and the recommender, and neither the trust value between the recommender and the target agent (Lindsay, Yu, Han, & Ray Liu, 2006). Another effort on trust propagation is discussed in Guha, Kumar, Raghavan, and Tomkins (2004).

Simple Trust Models

Simple trust models try to determine relations that depict the behaviour of an entity as a function of positive and negative opinions. The simplest form, found in Deriaz (2006), is:

$$\text{Trust\_score} = \frac{|\,Positive\ Ratings\,|}{|\,Positive\ Ratings\,| + |\,Negative\ Ratings\,|} \tag{10}$$

where |Positive Ratings| and |Negative Ratings| represent the number of positive and negative ratings, respectively.

Whenever an certain agent has only positive ratings and no negatives, then the trust score is equal to 1. Therefore, *Trust_score* can take values ranging from 0 to 1. An extension to this model that take into consideration the time in which these ratings are provided gives more efficient trust computation because it can exclude obsolete ratings. Furthermore, trust can be computed if we scale recent events. Accordingly, if in Deriaz's model we set a=b=c=1, which are the default values of parameters a, b, c, then the following holds:

$$Trust\_score = \frac{|\,PosRatings\,|\cdot(1+\delta_p) + A}{|\,PosRatings\,|\cdot(1+\delta_p) + |\,NegRatings\,|\cdot(1+\delta_n) + B} \tag{11}$$

where

$$A = \frac{1}{T}\sum_{i\in[1..|PosRatings|]} t(po_i) \tag{12}$$

$$B = \frac{1}{T}\left(\sum_{i\in[1..|PosRatings|]} t(po_i) + \sum_{i\in[1..|NegRatings|]} t(pn_i)\right) \tag{13}$$

and δ_p, δ_n are the statistical variance of the positive and negative outcomes, T is the current time, po_i, pn_i are positive and negative rating received at time i, |PosRatings| and |NegRatings| are the cardinality of positive and negative ratings, respectively.

The disadvantage of this mechanism is that it does not take into account the context in which these ratings were made. The above forms deal with the positive and the negative opinions without separating them into the context fields for which ratings are formulated. Furthermore, the model does not notice cases where entities may ally with others in order to elicit positive outcomes or the case that an entity is neutral to another.

Entropy-Based & Probability-Based Trust Model

In this section, we present two models of trust based on the work reported in Lindsay et al. (2006). Authors, influenced by information theory, present *Entropy-based* and *probability-based* trust. The trust relationship between two entities is represented by T(S,A,AC), where S is the subject which examines the trust level of the agent A for an action AC. Similarly, the probability that and agent A will perform the action AC in the subject's S point of view is represented by P(S,A,AC). The entropy based value of trust is calculated as follows:

$$T(S,A,AC) = \begin{cases} 1 + p \cdot \log_2(p) + (1-p) \cdot \log_2(1-p) & 0.5 \le p \le 1 \\ -p \cdot \log_2(p) - (1-p) \cdot \log_2(1-p) + 1 & 0 \le p < 0.5 \end{cases} \quad (14)$$

where

$$p = P(S,A,AC) \quad (15)$$

The final trust value is a real number in the interval [-1,1]. Some important examples that show the trust level of an agent are:

$$C = \begin{cases} \textit{Subject trusts the agent} & p = 1 \textit{ and } T = 1 \\ \textit{Subject distrusts the agent the most} & p = 0 \textit{ and } T = -1 \\ \textit{Subject has no trust} & p = 0.5 \textit{ and } T = 0 \end{cases} \quad (16)$$

In general, the following holds:

$$T(S,A,AC) = \begin{cases} < 0 & \textit{when } p \in [0..0,5) \\ > 0 & \textit{when } p \in (0,5..1] \\ = 0 & \textit{when } p = 0,5 \end{cases} \quad (17)$$

We should note that the probability P(S,A,AC) represents the view of a specific subject which means that different agents have different opinions about a target agent.

The entropy-based model depends on the trust value described above. Especially for the propagation of trust, a simple product is used where the two factors are the recommendation value of another agent multiplied by the trust value of the recommender. For multipath recommendations, the final result is the weighted sum of each recommendation. In the probability-based model, the probability that an agent will perform the specific tasks combined with the probability that a recommender make correct recommendations is adjusted.

Reputation-Based Trust Models

Reputation based trust models are used in distributed systems where there is little information on the overall network. If an entity has a high reputation level in a community then others may trust it more easily than another that has lower reputation value. For the computation of trust, an agent depends on opinions of a set of community members. Important issues in these cases are the collection method of ratings and the aggregation procedure. It should be reminded that trust is a concept derived from direct interactions between two entities, while reputation is the view of a member from the community side.

Reputation-based models rely on methods that give the opportunity to an entity to gather referrals from other members and apply an aggregation function in order to calculate the final value of trust. It is wiser to combine these results with values obtained from direct experiences. In Ramchourn et al. (2004), authors give an extensive review describing methods for the retrieval of ratings and the aggregation procedure from a social network point of view.

Reputation models are discussed in previous section.

Bayesian Network Trust Models

A Bayesian network is a network where probability relationships of some entities are presented (Ben-Gal, 2007). The final trust value is represented by the root of the network and leafs are the sources in which the beliefs of the examiner are based. A formalization of Bayesian trust networks is given in Melaye and Demazeau (2005). Each agent forms its basic beliefs investigating a number of belief sources. We have:

$$\text{Basic\_Belief}_i = f(B_{i1}, B_{i2}, \ldots, B_{iN}) \quad (18)$$

where $i \in [1..\text{number\_of\_basic\_beliefs}]$ and N are the number of belief sources. An important point is that the function f is depended on conditional probabilities, which means that a tree node may be more influential than another. Each trust component is associated with a probability of satisfaction. Accordingly, the final trust value is calculated as follows:

$$\text{Trust\_value} = g(BB_1, BB_2, \ldots, BB_N) \quad (19)$$

where BB_i is the i-th basic belief taken from (18). It is obvious that in such cases a bottom-up approach is adopted, starting from the belief sources and concluding with the final result.

Another representative example is shown in Wang and Vassileva (2003). Each agent builds a Bayesian network for every potential partner. Each network has a root with two values. The first represents the satisfaction level while the second the nonsatisfaction degree. The satisfaction level is derived from the number of the successful interactions divided by the total number of interactions. The leaf nodes in the network represent the different capabilities that potential partners have. In this model, the recommendations of other agents are taken into consideration.

Belief and Fuzzy Models

In belief models, we meet methods that use the beliefs of an agent that another entity is trustworthy or not. In belief theory, each opinion may be represented as a triplet (belief, disbelief, uncertainty). The sum of probabilities of these three values is 1:

$$\text{belief} + \text{disbelief} + \text{uncertainty} = 1 \quad (20)$$

Agents use their and others' beliefs in order to extract the final score. This score is computed through the use of belief theory and consists of a subjective certainty of the pertinent beliefs. An example of a belief trust model one can be found in Josang (1999, 2001). Josang names his trust model "subjective logic" and combines belief theory with Bayesian probabilities. The forms used for this purpose are:

$$\text{belief} = \frac{p}{p+n+2} \quad (21)$$

$$\text{disbelief} = \frac{n}{p+n+2} \quad (22)$$

$$\text{uncertainty} = \frac{2}{p+n+2} \quad (23)$$

where p and n are the positive and negative ratings, respectively. These two parameters are also used in the beta probability density function (see Section titled "Bayesian Reputation Systems"). For the combination of beliefs, external or internal, an aggregation function is used. "Majority consensus"

functions are well-known for handling beliefs with discrete values while numerical functions are more appropriate for handing beliefs with continuous values (Ding et al., 2004). The authors in Josang (1999, 2001) use operators for the combination of opinions that are not based on Dempster-Shaffer theory as Yu and Singh do (2002).

In fuzzy models trust and reputation are described with linguistic fuzzy values. Reasoning is used in order to achieve the definition of a trust level. The most important and completed example is the system REGRET, which is described in the "Social Networks" section.

Role-Based Trust

These models are based on the notion of role and its assigned permissions to operate in a system. Hence, credentials are used to define access to a system such as identity, authentication, and so forth. Thus, an entity can be uniquely identified by the system and can obtain a specific role. Roles are used to give information about an entity. The key is the trust management mechanism that employs different languages and engines for reasoning on rules for trust establishment. It is a model used in access control systems and tries to determine the trust level of an entity based on credentials and security policies. A framework based on roles is presented in Li and Mitchell (2003).

REPUTATION AND TRUST ENGINEERING

Modeling trust requirements is the most important issue in developing efficient systems. Especially in cases where open systems are examined (e.g., MAS), this feature receives more attention. This section of our work aims to show the basic elements in which a requirements engineering procedure must be based.

As mentioned, MAS are open systems with members that change their behaviours continually. They are characterized by openness, heterogeneity, and dynamic character. Selfish agents try to locate partners in order to achieve their goals. Main issues that must be taken into consideration in MAS are:

- **Agents' identity.** Each autonomous component that interacts in a system should have a unique name and should be able to prove its identity. Identity is a requirement when agents communicate with others, because it shows to the potential partner that the component is a registered user of the system. Of course, a critical issue is the administration of the names. For example, an agent having bad reputation in a community may change its name in order to avoid the consequences.
- **Agents' communication.** Agents' communication is also important. Developers of MAS should introduce standards for communication. A security policy is necessary in order to avoid problems in the exchange of messages. Corrupted messages should be recognised by the recipients. Mechanisms that can be use for safe communication are authentication, cryptography, and so forth.
- **Agents' context.** The context in which each agent is activated should be defined. Mechanisms that take the context into consideration should be developed. This could provide efficiency in the cooperation procedure.
- **Agents' behaviour.** Agents' behaviour should be observed by the interested members and from the system. It is imperative to have the opportunity to observe and recognize bad or good behaviours in the system. Based on behaviour, trust is developed and members obtain a high reputation value in the community. Constructive trust must be promoted through the observation of interactions of an agent in the society. Also, from the systems' point of view, mechanisms

that "punish" bad behaviours should be developed.

In Wong and Sycara (1999), the authors present a number of possible threats in MAS and their potential solutions. The basic threats that MAS may meet are related to corrupted naming of agents, insecure communication channels, insecure delegation and lack of accountability. Synoptically, the proposed solutions are:

- The use of trusted agent name servers and matchmakers.
- The provision of methods for the unique identification of each agent and proofs for their identifications.
- Secure the communication channels through the authentication of messages.
- Force agents to prove their owners.
- The provision of methods through which owners of the agents may be liable for their actions.

Authors give a full description of these solutions and explain the mechanisms with which these goals will be achievable.

A methodology for agent-based software development is described in Giorgini, Massacci, and Zannone (2005) and Giorgini, Mouratidis, and Zannone (2007). In TROPOS there are phases through which the trust establishment is feasible. The first phase is the requirement phase. In this stage, the functional and the nonfunctional requirements are determined in two subphases: the *early requirements phase* and the *late requirements phase*. The key concepts in secure TROPOS are:

- **Actor.** It is an entity that represents a physical or software agent as well as a role or position, having its goals and intentions.
- **Goal.** Represents actors' interests that they wish to accomplish.
- **Plan.** It concerns a number of steps targeting to achieve a goal.
- **Resource.** It is a physical or an information entity.
- **Dependency.** Indicates that an actor depends on some other entity in order to complete their goals.

Accordingly, in TROPOS four new relationships are defined, which are: **Ownership** which indicates that an actor has a goal, **provisioning** which is the capability of an actor to achieve a goal or to have a plan or to provide some information, **trust** which indicates the belief of an actor that another entity will perform some task according to their goals and plans and **delegation** which shows that an actor delegates to some other to achieve its goals.

In TROPOS methodology, basic operations are:

- The definition of the actor's model and the dependency model. The essential actors should be recognised as well as the dependencies among them from the point of view of achieving their goals.
- The trust and delegation models. They determine the relationships between actors.
- The goal and plan models. Such models identify, from the viewpoint of actors, goals and plans that are necessary to achieve (sub)goals. Moreover, the resources needed to this procedure are recognised.

An extension to classic TROPOS is the security constraint modeling, which involves security constraints posed by the actors and the system. The architectural design development process for this extension relies on the following:

1. Secure Architectural style model.
2. Actor model, Goal/plan model, and security constraint model.

3. Capability and secure capability model.
4. Agent model.

In this chapter, due to the space constraints, we have presented only a short description of the TROPOS methodology. For a full discussion the interested reader should refer to the Giorgini et al. (2005, 2007).

FUTURE DIRECTIONS

Reputation and trust are important concepts in today's dynamic systems. However, there are some open issues that must be addressed in order to develop efficient methods for adoption in MAS.

First of all, for the construction of a theoretical framework that covers all the aspects of reputation and trust generation, manipulation and propagation is necessary. This model will set basic specifications in which developers may be based on, in order to construct efficient and productive systems. Such a framework will set the essentials that will allow the comparison of existing models. Today, this comparison is very difficult to accomplish, because the existing models come from specific domains and they are not based on a common theoretical framework.

The social network dimension in MAS presents new opportunities in reputation and trust management. However, it must be validated in real applications in order to discover its advantages and disadvantages. In social networks, there is an extensive need to deal with problems related to strategic lying and strategic coalition formation. This domain must be further studied in order to produce effective methods to deal with. Moreover, there is a need to define basic mechanisms through which opinions of members can be stored and secured in order to provide a higher security level.

Interactions of agents are held in a system under specific context. Context must be taken into consideration when defining the trust and reputation level of an entity. To the best of our knowledge, only a few works deal with this issue. Additionally, concern should be posed in trust propagation in specific contexts. Propagation allows the building of relations between all the agents communicating in a system. New methods for propagation should be developed with regard to the combination of the aforementioned models such as statistical functions, belief and fuzzy theory.

CONCLUSION

This chapter introduces the reader to the domain of reputation and trust in Multi-agent systems. It presents the existing reputation and trust quantification methods that are used in commercial and research applications. We show the importance of these two concepts especially in open systems where control over the actions of agents is limited. Also, the environment, where agents act, may change at any time due to the nature of the involved entities, which are autonomous components trying to serve their owners. For this reason, they are selfish and change their behavior subject to new conditions. A lot of models have been proposed for reputation and trust extraction in specific domains. We shortly present the most important of them, giving their basic characteristics. Certain models are very simple, while others are more sophisticated and utilize statistical functions, belief or fuzzy theory. Finally, we discuss key contribution in the domain of trust and reputation engineering. It is a critical field that leads to more efficient and productive systems. The engineering process must drive developers to construct systems that pay special attention to issues that ensure secure communication and fair ratings for all.

Reputation and trust will play an important role in future systems. Such concepts will be

extensively adopted and used for gaining access to information sources in open environments like MAS and the Semantic Web.

Chapter 7.15
Improving Credibility of Machine Learner Models in Software Engineering

Gary D. Boetticher
University of Houston – Clear Lake, USA

ABSTRACT

Given a choice, software project managers frequently prefer traditional methods of making decisions rather than relying on empirical software engineering (empirical/machine learning-based models). One reason for this choice is the perceived lack of credibility associated with these models. To promote better empirical software engineering, a series of experiments are conducted on various NASA datasets to demonstrate the importance of assessing the ease/difficulty of a modeling situation. Each dataset is divided into three groups, a training set, and "nice/nasty" neighbor test sets. Using a nearest neighbor approach, "nice neighbors" align closest to same class training instances. "Nasty neighbors" align to the opposite class training instances. The "nice", "nasty" experiments average 94% and 20% accuracy, respectively. Another set of experiments show how a ten-fold cross-validation is not sufficient in characterizing a dataset. Finally, a set of metric equations is proposed for improving the credibility assessment of empirical/machine learning models.

INTRODUCTION

Software Project Management: State-of-Practice

Software project management has improved over the years. For example, the Standish Group, a consulting company, which has been studying IT management since 1994 noted in their latest release of the *Chaos Chronicles* (The Standish Group, 2003) that, "2003 Project success rates improved by more than 100 percent over the 16 percent rate from 1994." Furthermore, "Project

failures in 2003 declined to 15 percent of all projects. This is a decrease of more than half of the 31 percent in 1994."

Even with these successes, there are still significant opportunities for improvement in software project management. Table 1 shows several "state-of-practice" surveys collected in 2003 from IT companies in the United States (The Standish Group, 2003); South Africa (Sonnekus & Labuschagne, 2003); and the United Kingdom (Sauer & Cuthbertson, 2003).

According to the *Chaos Chronicles* (The Standish Group, 2003), *successful projects* refers to projects that are completed on time and within budget with all features fully implemented; *project challenged* means that the projects are completed, but exceed budget, go over time, and/or are lacking some/all of the features and functions from the original specifications; and *project failures* are those projects which are abandoned and/or cancelled at some point.

Applying a weighted average to Table 1 results in 34% of the projects identified as successful, 50% are challenged, and 16% end up in failure. Thus, about one-third of the surveyed projects end up as a complete success, half the projects fail to some extent, and one sixth end up as complete failures. Considering the role of computers in various industries, such as the airlines and banking, these are alarming numbers.

From a financial perspective,[1] the lost dollar value for U.S. projects in 2002 is estimated at $38 billion with another $17 billion in cost overruns for a total project waste of $55 billion against $255 billion in project spending (The Standish Group, 2003). Dalcher and Genus (2003) estimate the cost for low success rates at $150 billion per year attributable to wastage arising from IT project failures in the Unites States, with an additional $140 billion in the European Union. Irrespective of which estimate is adopted, it is evident that software project mismanagement results in an annual waste of billions of dollars.

Empirical Software Engineering

One of the keys for improving the chances of project development success is the application of empirical-based software engineering. **Empirical-based software engineering** is the process of collecting software metrics and using these metrics as a basis for constructing a model to help in the decision-making process.

Two common types of software metrics are project and product metrics. **Project metrics** refer to the estimated time, money, or resource effort needed in completing a software project. The Standish Group (2003) perceives software cost estimating as the *most effective way to avoid cost and schedule*. Furthermore, several studies (Jones, 1998; The Standish Group, 2003) have shown that by using software cost-estimation techniques, the probability of completing a project successfully doubles. Thus, estimating the schedule, cost, and resources needed for the project is paramount for project success.

Product metrics are metrics extracted from software code and are frequently used for soft-

Table 1. State-of-practice surveys

Year	Successful	Challenged	Failure	Projects Surveyed
United States (Chaos Chronicles III)	34%	51%	15%	13,522
South Africa	43%	35%	22%	1,633
United Kingdom	16%	75%	9%	421

ware defect prediction. Defect prediction is a very important area in the software development process. The reason is that a software defect dramatically escalates in cost over the software life cycle. During the coding phase, finding and correcting defects costs $977 per defect (Boehm & Basili, 2001). In the system-testing phase, the cost jumps to $7,136 per defect (Boehm et al., 2001). If a defect survives to the maintenance phase, then the cost to find and remove increases to $14,102 (Boehm et al., 2001).

From an industry perspective, Tassey (2002) estimates that the annual cost of software defects in the United States is $59.5 billion and that "feasible" improvements to testing infrastructures could reduce the annual cost of software defects in the United States by $22.2 billion. The Sustainable Computing Consortium (SCC), an academic, government, and business initiative to drive IT improvements, estimates that from a global perspective, defective computer systems cost companies $175 billion annually. Thus, there are major financial incentives for building models capable of predicting software defects.

There are primarily two methods for constructing models in empirical software engineering. The first adopts an **empirical approach** which emphasizes direct observation in the modeling process and results in one or more mathematical equations. Common examples of this approach include COCOMO I (Boehm, 1981), COCOMO II (Boehm et al., 2000), function points (Albrecht, 1979; Albrecht & Gaffney, 1983), and SLIM (Putnam, 1978) for effort estimation. The second method automates the observation process by using a **machine learning** approach to characterize relationships. Examples of machine learners include Bayesian belief networks (BBN), case-based reasoners (CBR), decision tree learners, genetic programs, and neural networks. The by-product of applying these learners include mathematical equations, decision trees, decision rules, and a set of weights as in the case of a neural network. For the purpose of this chapter, a cursory description will suffice; further details regarding the application of machine learners in software engineering may be found at Khoshgoftaar (2003), Pedrycz (2002), and Zhang and Tsai (2005).

Although the financial incentives are huge, empirical software engineering has received modest acceptance by software practitioners. A project manager may estimate a project by using a human-based approach, an empirical approach, or a machine learning approach. Even though popular models, such as COCOMO or function points, have existed for 25 or more years their application is rather low. In 2004, Jørgensen (2004) compiled a series of studies regarding the frequency of human-based estimation and found it is used 83% (Hihn & Habib-Agahi, 1991), 62% (Heemstra & Kusters, 1991), 86% (Paynter, 1996), 84% (Jørgensen, 1997), and 72% (Kitchenham, Pfleeger, McColl, & Eagan, 2002). It is evident that human-based estimation is the dominant choice relative to empirical or machine learning-based estimation. Furthermore, Jørgensen (2004) states the empirical-based estimation ranges from about 7 to 26% and machine learning-based estimation is only about 4 to 12%.

A key question is *"Why haven't empirical-based models and particularly machine learner models gained greater acceptance by software practitioners?"*

One possible answer to this question is the difficulty in assessing the credibility of these models. A model may boast accurate results, but these results may not be realistic. Thus, the lack of perceived credibility makes it difficult for software practitioners to adopt a new technology within their software development process.

It may be argued that "credibility processes" exist in the form of *n*-fold cross validation and accuracy measures. Unfortunately, none of these approaches address the issue of a dataset's difficulty (how easy or hard it is to model). An empirical model that produces spectacular results may be the consequence of a test set that closely resembles a training set rather than the capabil-

ity of empirical learner. The outcome is a set of unrealistic models that is unlikely to be adopted by industry. Without a mechanism for assessing a dataset's difficulty, empirical/machine learning models lose credibility.

This chapter introduces several credibility metrics which may be incorporated into the model formulation process with the goal of giving greater credibility. Before introducing these metrics, a series of experiments are conducted to demonstrate some of the difficulties in using a dependent variable for making sampling decisions. The **dependent variable**, also known as the **class variable**, is the attribute we are trying to predict from a set of independent (non-class) variables. The initial set of experiments demonstrates the importance of sampling on non-class attributes. These experiments examine the "best case" versus "worst case" for a NASA-based defect repository dataset.

Next, a second set of experiments demonstrates that a *ten*-fold cross validation may not be sufficient in building realistic models.

After demonstrating some of the inadequacies of current validation processes, several credibility metrics are introduced. These metrics measure the *difficulty* of a dataset. Adoption of these metric equations will lead to more realistic models, greater credibility to models, and an increased likelihood that software practitioners will embrace empirical software engineering.

RELATED RESEARCH

This section provides a general overview of different sampling/resampling techniques, a description of the K-nearest neighbor (KNN) algorithm, and an overview of assessing models for accuracy.

Traditional sampling typically adopts a **random**, **stratified**, **systematic**, or **clustered** approach. The randomized approach, which is the simplest, randomly selects tuples to be in the test set. One way to improve estimates obtained from random sampling is by arranging the population into strata or groups. A non-class attribute (e.g., age, gender, or income) is used to stratify samples. Systematic sampling orders data by an attribute, then selects every i^{th} element on the list afterwards. Cluster sampling is a method of selecting sampling units in which the unit contains a cluster of elements (Kish, 1965). Examples of cluster samples may include all students of one major from all university students or residents from a particular state.

When extracting samples for a test set, systematic and cluster sampling focus on the class (or dependent) variable. Stratified sampling may use a non-class variable, but typically this is limited to at most one of the non-class variables and does not consider the non-class attribute in light of the class attribute. The problem is that non-class (independent) variables contain a lot of vital information which needs to be considered when partitioning tuples into training and test sets.

An ***n*-fold cross validation** is a resampling method for validating a model. For this technique, data is partitioned into *n*-classes, and *n* models are constructed with each of the *n*-classes rotated into the test set. *N*-fold cross validation addresses the issue of data distribution between training and test sets, but does not consider difficulty in modeling the training data.

The **K-nearest neighbor** (**KNN**) algorithm is a supervised learning algorithm which classifies a new instance based upon some distance formula (e.g., Euclidean). The new instance is classified to a category relative to some majority of K-nearest neighbors. Traditionally, the KNN algorithm is viewed as a machine learner, rather than a method for dividing training and test data.

Regarding approaches for measuring accuracy, Shepperd, Cartwright, and Kadoda (2000) discuss the merits of various methods for measuring accuracy including *TotalError*, *TotalAbsoluteError*, *TotalRelativeError*, *BalancedMMRE*, *MMRE*, *Pred(X)*, *Mean Squared Error*, and R^2. There is validity in using one or more of these accuracy

methods. However, they do not provide any information regarding the difficulty in modeling a dataset.

A SIMPLE EXAMPLE

To illustrate why it is important to consider the relationship between non-class attributes over a training and test set, consider the dataset in Table 2. It consists of three attributes: source lines of code (SLOC); v(g), also known as cyclomatic complexity, which equals the number of decision points within a program plus one; and *defects*. For this example, defects refer to the number of software defects present in a software component. If a software component has zero defects, then it is classified as an *A*, otherwise it is classified as a *B*.

Figure 1 plots these points. The points form 4 clusters of *A*s and *B*s, respectively.

If the goal is to build a model for predicting software defects, a systematic sampling approach may be applied, which generates the training and test sets in Tables 3a and 3b.

Applying a nearest neighbor approach to the non-class attributes, it is clear that the *A*s in the test set match the *A*s in the training set. This is depicted as arrows between Tables 3a and 3b. The same is true for those defects in the *B* class. It is expected that such an experiment would produce very good results irrespective of the machine learner selected. Figure 2 highlights training samples with gray boxes.

Suppose a second experiment is conducted using stratified sampling and produces the training and test sets in Tables 4a and 4b.

Applying a nearest neighbor approach to the non-class attributes, it is clear that the *A*s in the test set match a *B* instance in the training set. Also, the *B*s in the test set match an *A* instance in the training set. It is expected that such an experiment would generate very poor results irrespective of the machine learner selected. Figure 3 highlights training samples with gray boxes.

By ignoring nearest neighbors when building models, success/failure may be a function of the nearest neighbor distribution rather than the capability of the algorithm/machine-learner.

To illustrate the importance of considering nearest neighbor in training/test distribution, a series of experiments are conducted using NASA-based defect data. Although the focus is on defect data, the idea easily extends to other types of software engineering data (e.g., effort estimation data).

NASA DATASETS

To demonstrate how non-class attributes dramatically impact the modeling process, a series of experiments are conducted against five NASA defect datasets. These experiments fall into two categories. The "nice" experiments use a test set where the non-class attributes of the test data have nearest-neighbors in the training set and are the same class value. The "nasty" experiments use a test set where the non-class attributes of the test data have nearest-neighbors in the training set with an opposite class value.

All experiments use five public domain defect datasets from the NASA Metrics Data Program (MDP) and the PROMISE repository (Shirabad & Menzies, 2005). These five datasets, referred to as CM1, JM1, KC1, KC2, and PC1, contain static code measures (e.g., Halstead, McCabe, LOC) along with defect rates. Table 5 provides a project description for each of these datasets.

Each dataset contains 21 software product metrics based on the product's size, complexity, and vocabulary. The size metrics include *total lines of code, executable lines of code, lines of comments, blank lines, number of lines containing both code and comments,* and *branch count.* Another three metrics are based on the product's complexity. These include *cyclomatic complexity, essential complexity,* and *module design*

Table 2. Simple dataset

87	13	A
193	32	A
53	10	B
140	30	B

complexity. The other 12 metrics are vocabulary metrics. The vocabulary metrics include *Halstead length, Halstead volume, Halstead level, Halstead difficulty, Halstead intelligent content, Halstead programming effort, Halstead error estimate, Halstead programming time, number of unique operators, number of unique operands, total operators,* and *total operands.*

The class attribute for each dataset refers to the propensity for defects. The original MDP dataset contains numeric values for the defects, while the PROMISE datasets convert the numeric

58	10	B

values to Boolean values where *TRUE* means a component has one or more defects and *FALSE* equates to zero defects. The reason for the conversion is that the numeric distribution displayed signs of an implicitly data-starved domain (many data instances, but few of interest) where less than 1% of the data has more than five defects (Menzies, 2005a).

DATA PRE-PROCESSING

Data pre-processing removes all duplicate tuples from each dataset along with those tuples that have questionable values (e.g., LOC equal to 1.1). Table 6 shows the general demographics of each of the datasets after pre-processing.

NEAREST NEIGHBOR EXPERIMENTS

Training and Test Set Formulation

To assess the impact of nearest-neighbor sampling upon the experimental process, 20 experiments are conducted on each of the five datasets.

For each experiment, a training set is constructed by extracting 40% of data from a given dataset. Using stratified sampling to select 40% of the data maintains the ratio between defect/non-defect data. As an example, JM1 has 8,911 records, 2,007 (22.5%) of which have one or more defects. A corresponding training set for the JM1 project contains 3,564 records, 803 (22.5%) of which are classified as having one or more defects (TRUE).

Figure 3. Plot of training and test sets (Square boxes are training samples)

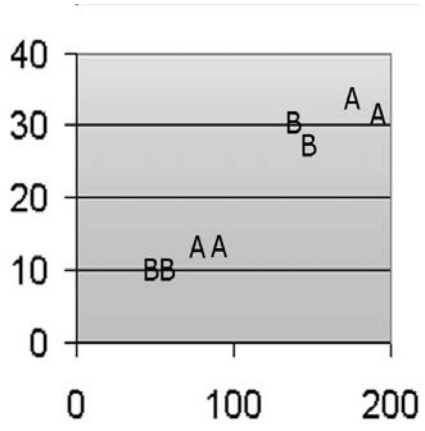

Table 5. Project description for each dataset

Project	Source Code	Description
CM1	C	NASA spacecraft instrument
KC1	C++	Storage management for receiving/processing ground data
KC2	C++	Science data processing. No software overlap with KC1.
JM1	C	Real-time predictive ground system
PC1	C	Flight software for earth orbiting satellite

It could be argued that a greater percentage (more than 40%) of the data could be committed to the training set. There are several reasons for choosing only 40%. First, Menzies claims that only a small portion of the data is needed to build a model (Menzies, Raffo, Setamanit, DiStefano, & Chapman, 2005b). Second, since the data is essentially a two-class problem, there was no concern about whether each class would receive sufficient representation. Finally, it is necessary to insure that there is a sufficient amount of test data for assessing the results.

Once a training set is established, the remaining 60% of the data is partitioned into two test groups. Prior to splitting the test data, all of the non-class attributes are normalized by dividing each value by the *Difference* ($Maximum_k - Minimum_k$ for each column k). This guarantees that each column receives equal weighting. The next step loops through all the test records. Each test record is compared with every training record to determine the minimum *Euclidean Distance* for all of the non-class attributes. If the training and test tuples with the smallest Euclidean Distance share the same class values (TRUE/TRUE or FALSE/FALSE), then the test record is added to the "nice neighbor" test set, otherwise add it to the "nasty neighbor" test set. Figure 4 shows the corresponding algorithm.

Essentially, this is the K-nearest neighbor algorithm that determines a test tuple's closest match in the training set. Nearest neighbors from the same class are considered "nice", otherwise they are classified as "nasty."

Table 6. Data pre-processing demographics

Project	Original Size	Size w/ No Bad, No Dups	0 Defects	1+ Defects	% Defects
CM1	498	441	393	48	10.9%
JM1	10,885	8911	6904	2007	22.5%
KC1	2109	1211	896	315	26.0%
KC2	522	374	269	105	28.1%
PC1	1109	953	883	70	7.3%

Figure 4. Nice/nasty neighbor algorithm

```
For j=1 to test.record_count
  minimumDistance = 9999999
  For i=1 to train.record_count
    Dist = 0
    For k=1 to train.column_count - 1
      Dist = Dist + (train_ik - test_jk)^2
    end k
    if (abs(Dist) < abs(minimumDistance))
     then if Train_i.defect = Test_j.defect
       then minimumDistance = Dist
       else minimumDistance = -Dist
  end i;
  if minimumDistance > 0
    then Add_To_Nice_Neighbors
  if minimumDistance < 0
    else Add_To_Nasty_Neighbors
  if minimumDistance = 0
    then if Train_i.defect = Test_j.defect
     then Add_To_Nice_Neighbors
     else Add_To_Nasty_Neighbors
end j;
```

All experiments use the training data to build a model between the non-class attributes (e.g., *size*, *complexity*, or *vocabulary*) and the class attribute *defect* (which is either *True* or *False*).

After constructing 300 datasets (one training set and two tests sets; 20 trials per software project; five software projects), attention focuses on data mining tool selection.

Data Mining Tool Selection

Since the data contains 20-plus attributes and only two class values (TRUE/FALSE), the most reasonable data mining tool in this situation is a decision tree learner. A decision tree selects an attribute which best divides the data into two homogenous groups (based on class value).

The split selection recursively continues on the two or more subtrees until all children of a split are totally homogenous (or the bin dips below a prescribed threshold). Decision tree learners are described as greedy in that they do not look ahead (two or more subtree levels) due to the associated computational complexity.

One of the most popular public domain data mining tools is the Waikato environment for knowledge analysis (Weka) tool (Witten & Franks, 2000). Weka is an open-source machine learning workbench. Implemented in Java, Weka incorporates many popular machine learners and is widely used for practical work in machine learning. According to a recent KDD poll (KDD Nuggets Web site, 2005), Weka was rated number two in terms of preferred usage as compared to other commercial and public domain tools.

Within Weka, there are many learners available. The experiments specifically use the naïve Bayes and J48 learners for analysis. There are reasons for adopting these tools. First, these tools performed very well in more than 1,000 data mining experiments conducted by the author. Second, success in using these particular learners was noted by Menzies et al. (2005b) in their analysis of the NASA defect repositories.

A naïve Bayes classifier uses a probabilistic approach to assign the most likely class for a particular instance. For a given instance *x*, a naïve Bayes classifier computes the conditional probability

$$P\,(C = c_i \mid x) = P(C = c_i \mid A_1 = a_{i1},\ldots A_n = a_{in}) \quad (1)$$

for all classes c_i and tries to predict the class which has the highest probability. The classifier is considered naïve (Rish, 2001) since it assumes that the frequencies of the different attributes are independent.

A second learner, J48, is based on Quinlan's C4.5 (Quinlan, 1992).

Assessment Criteria

The assessment criterion uses four metrics in all experiments to describe the results. They are:

- **PD**, which is the probability of detection. This is the probability of identifying a module with a fault divided by the total number of modules with faults.
- **PF**, which is the probability of a false alarm. This is defined as the probability of incorrectly identifying a module with a fault divided by the total number of modules with no faults.
- **NF**, which is the probability of missing an alarm. This is defined as the probability of incorrectly identifying a module where the fault was missed divided by the total number of modules with faults.
- **Acc**, which is the accuracy. This is the probability of correctly identifying faulty and non-faulty modules divided by the total number of modules under consideration.

Each of these metrics is based on simple equations constructed from Weka's **confusion matrix** as illustrate by Table 7.

PD is defined as:

$$PD = A / (A+B) \quad (2)$$

PF is defined as:

$$PF = C / (C + D) \quad (3)$$

NF is defined as:

$$NF = A / (A + B) \quad (4)$$

and *Acc* is defined as:

$$Acc = (A + D) / (A + B + C + D) \quad (5)$$

Based on the example in Table 7, the corresponding values would be:

$$PD = 50 / (50 + 200) = 20\% \quad (6)$$

$$PF = 100 / (100 + 900) = 10\% \quad (7)$$

$$NF = 200 / (200 + 50) = 80\% \quad (8)$$

$$Acc = (50 + 900) / (50 + 100 + 200 + 900) = 76\% \quad (9)$$

Results

Table 8 shows the accuracy results of the 20 experiments per project. As might be expected, the "nice" test set did very well for all five projects for both machine learners averaging about 94% accuracy. Its counterpart, the "nasty" test set, did not fare very well, averaging about 20% accuracy.

It is interesting to note that the JM1 dataset, with 7 to 20 times more tuples than any of the other projects, is above the overall average for the "nice" datasets, and below the overall average on the "nasty" datasets. Considering the large number of tuples in this dataset and how much of the solution space is covered by the JM1 dataset, it would seem that a tuple in the test set would have difficulty aligning to a specific tuple in the training set.

Regarding *PD*, the results as expressed in Table 9 for the "nice" test set are superior to the "nasty" test set for the learners. An overall weighted average is preferred over a regular average in order not to bias the results towards those experiments with very few defect samples.

The results in Table 9 can be misleading. Seventy-six of the 100 "nice" test sets contained zero defect tuples. Of the remaining 24 "nice" test sets, only 2 of these 24 had 20 or more samples with defects.

The "nice" test set did very well at handling false alarms as depicted in Table 10. The "nasty" test set triggered alarms about 18 to 37% of the time depending upon learner. Overall, the sample size is small for the "nasty" test sets. Ninety percent (from the 100 experiments) of the "nasty" test sets contain zero instances of non-defective data. For the remaining 10 "nasty" datasets, only three contain 10 or more instances of non-defective modules.

To better understand these results, consider Tables 11 and 12. These tables show the weighted averages (rounded) of all confusion matrices for all 100 experiments (20 per test group). In the "nice" test data, 99.6% are defined as having no defects (FALSE). Less than 1% of the tuples actually contain defects. Although the "nice" test sets fared better than the "nasty" test sets regarding defect detection, the relatively few samples having one or more defects in the "nice" test sets discount the results.

Analyzing the "nasty" datasets in Tables 11 and 12 reveal that 97.2% (e.g., (50+249)/(50+249+2+7)) of the data contains one or more defects.

NNP	110	0	25	28
NNN	None	None	NA	NA

Referring back to the right-most column of Table 6, the percentage of defects to the total number of modules ranged from 7.3 to 28.1%. Considering that all training sets maintained their respective project ratio of defects to total components, it is quite surprising that the "nice" and "nasty" datasets would average such high proportions of non-defective and defective components, respectively.

To better understand these results, two additional experiments are conducted using the KC1 dataset. The first experiment randomly allocates 60% of the data to the training set, while the second allocates 50% of the data. Both experiments maintain a defect/non-defective ratio of 26% (see Table 6). For both experiments, the test data is divided into eight groups using a three-nearest neighbor approach. For each test vector, its three closest neighbors from the training set are determined. These neighbors are ranked based on first, second, to third closest neighbor. A "P" means that there is a positive match (same class), and an "N" means there is a negative match (opposite class). Thus, a "PPN" means that the first and second closest matches are from the same class and the third closest match is from the opposite

Table 14. KC1 data, KNN=3, 50% of training data

JM1	79.68%	76.56%
KC1	84.29%	74.03%
KC2	81.65%	76.22%
PC1	93.43%	91.65%

class. Thus, the best case would be a "PPP" where the three closest training vectors are all from the same class.

Tables 13 and 14 show the results from these experiments. It is interesting to note that all eight bins contain homogenous (all TRUEs, or all FALSEs) data. There is a general trend for the bin configuration to change from all non-defective tuples (all FALSEs) to all defective tuples (TRUEs) as the neighbor status changes from all positives (PPP) to all negatives (NNN). Also, the accuracy seems positively correlated to the nearest neighbor classifications.

These last two sub-experiments confirm the results achieved in Tables 11 and 12.

Ten-Fold/Duplicates Experiment

The next experiment demonstrates that a *ten*-fold cross validation does not provide a total perspective regarding the validation of a dataset.

This experiment uses the five NASA datasets described in the earlier sections. For each dataset, two types of experiments are conducted: the first uses the original dataset (less bad data) with duplicates, and a second where duplicates are removed. Note that each original dataset had only one bad data sample. Each experiment uses a *ten*-fold cross validation for each of the 20 trials. A defect prediction model is constructed based on the C4.5 learner from Weka (J48) using the default settings.

Table 15 shows the results from these experiments. For all five NASA datasets, the learner produces a better model with the inclusion of duplicates. A t-test shows that these differences are statistically significant for all five NASA datasets.

In these experiments, the duplicates are the "nice neighbors" described in the previous set of experiments. Performing a *ten*-fold cross validation insures that datasets with duplicates will have a distinct advantage over datasets without duplicates.

DISCUSSION

In general, project managers are reluctant to embrace empirical-based models in their decision-making process. Jørgensen (2004) estimates more than 80% of all effort estimation is human-based and only about 4% is machine learning-based. If empirical software engineering is going to have any hope of gaining favor with project managers, then it is critical that the modeling process be understood very well.

The first set of experiments shows the extreme range of answers in corresponding best case/worst case scenarios. These experiments clearly indicate how significantly nearest-neighbor sampling influences the results despite the fact that no dataset had any duplicates.

The second set of experiments reflects a more realistic situation where an empirical software engineer may (or may not) include duplicates in the modeling process. The difference in results is statistically significant. For some learners, the issue of duplicates is not a problem. However, as seen with the C4.5 learner, it is a problem.

In order to avoid building artificial models, perhaps the best approach would be to not allow duplicates within datasets. Another attribute could be added to the dataset, *Number of Duplicates*, so that information regarding duplicates is not lost.

This solves the issue of duplicates within datasets, however it does not address the issue regarding the synergy between testing and training datasets ("nice" versus "nasty" test sets). The next section addresses this issue.

BETTER CREDIBILITY THROUGH NEAREST NEIGHBOR-BASED SAMPLING

As demonstrated in the first set of experiments, it is evident that nearest-neighbor test data distribution dramatically impacts experimental results. The question is *How may nearest-neighbor sampling be incorporated into the project development process in order to generate realistic models?*

There are at least two possible solutions: one of which adapts to an organization's current software engineering processes; the second solution offers an alternative process.

In the first approach, a software engineer determines the nearest neighbor for each of the tuples in the test set (based on non-class attributes), relative to the training set. If the test tuple's nearest neighbor in the training set shares the same class instance value, then add *1* to a variable called *Matches*. *Matches* will be used to define a metric called *Experimental Difficulty* (*Exp_Difficulty*) as follows:

$$Exp\_Difficulty = 1 - Matches / Total\_Test\_Instances \quad (10)$$

The *Experimental Difficulty* provides a qualitative assessment of the ease/difficulty for modeling a given dataset. Combining this metric with an accuracy metric would offer a more realistic assessment of the results. For example, a "*Exp_Difficulty * Accuracy"* would give a more complete picture regarding the goodness of a model leading to better model selection and more credible models. For an *n*-fold cross validation,

the *Experimental Difficulty* could be calculated for each fold, then averaged over the *n* folds.

A second approach starts with the whole dataset prior to partitioning into training and test sets. For each tuple in the dataset, its nearest neighbor (with respect to the non-class attributes) is determined. Add 1 to the *Match* variable if a tuple's nearest neighbor is from the same class. Modifying Equation 10 results in the following equation:

$$Overall\_Difficulty = 1 - Matches / Total\_Data\_Instances \quad (11)$$

This gives an idea of the overall difficulty of the dataset. A software engineer may partition the data in order to increase (or decrease) *Experimental_Difficulty*. In the context of industrial-based benchmarks, the *Experimental_Difficulty* may be adjusted to coincide to a value adopted by another researcher. This lends greater credibility to comparing experimental results.

Considering an estimated 99% of the world's datasets are proprietary, this approach provides an additional benchmark for those models constructed on private datasets. Furthermore, these metric equations provide a means for assessing the robustness of the results.

CONCLUSIONS

Most datasets are proprietary in nature, making it impossible to replicate results in this situation. As demonstrated by the NASA experiments, not all data distributions result in similar results. This work extends previous research in defect prediction (Khoshgoftaar, 2003; Porter & Selby, 1990; Srinivasan & Fisher, 1995; Tian & Zelkowitz, 1995) by conducting nearest-neighbor analysis for gaining a deeper understanding of how datasets relate to each other, and thus the need for developing more realistic empirical/machine learning-based models. In the first set of NASA experiments, the "nice" dataset experiments (easy datasets to model) resulted in an average accuracy of 94.0% and the "nasty" dataset experiments (difficult datasets to model) produced an average accuracy of 19.5%. These results suggest that success in modeling a training dataset may be attributable to the ease/difficulty of the dataset, rather than the capability of the machine learner.

Including duplicates within a dataset reduces the difficulty of a dataset since similar tuples may appear in both the training and test sets. This research proposes removing duplicates in order to eliminate any bias.

Finally, this work proposes a set of metric equations for measuring the difficulty of a dataset. Benefits of using these metric equations include:

- **The creation of more realistic models.** These metrics will help the software engineering community better gauge the robustness of a model.
- **Greater credibility for models based on private datasets.** Since most datasets are proprietary, it is difficult to assess the quality of a model built in this context. Using the proposed metrics will make it easier to compare experiment results when the replication is impossible.
- **Greater chances of adoption by the industrial community.** As mentioned earlier, human-based estimation is still the method of choice. By providing a difficulty metric with a set of results, project managers will be able to assess the goodness of an empirical model. This will make it easier for a project manager to trust an empirical/machine learning-based model. Thus making it easier for the industrial community to more readily adopt empirical software engineering approaches.

FUTURE DIRECTIONS

This work could be extended from a two-class to an *n*-class problem. For example, the NASA datasets could be divided into four classes, (0, 1, 2, 3+ defects).

Another common type of software engineering dataset estimates programming effort. Thus, a likely future direction would examine these types of datasets.

Finally, it would be interesting to see whether accuracy results could be scaled by the "dataset difficulty metrics" in order to make better comparisons over datasets of varying difficulty.

Chapter 7.16
Morality and Pragmatism in Free Software and Open Source

Dave Yeats
Auburn University, USA

ABSTRACT

This chapter analyzes the differences between the philosophy of the Free Software Foundation (FSF) as described by Richard Stallman and the open source movement as described in the writings of Eric Raymond. It argues that free software bases its activity on the argument that sharing code is a moral obligation and open source bases its activity on a pragmatic argument that sharing code produces better software. By examining the differences between these two related software movements, this chapter enables readers to consider the implications of these differences and make more informed decisions about software use and involvement in various software development efforts.

INTRODUCTION

As governments around the world search for an alternative to Microsoft software, the open source operating system Linux finds itself in a perfect position to take market share from Microsoft Windows. Governments in France, Germany, The Netherlands, Italy, Spain, and the United Kingdom use Linux to encourage open standards, promote decentralized software development, provide improved security, and reduce software costs (Bloor, 2003). The Chinese government strongly supports Linux as its operating system of choice because Chinese experts have complete access to the source code and can examine it for security flaws (Andrews, 2003). In Brazil, leftist activists gathered to promote the use of open source software (OSS) (Clendenning, 2005).

There is a connection between the technological reasons for choosing open source software and the political ones. Many governments see open source as a way to promote a socialistic agenda in their choices of technology. Open source advocates, however, do not necessarily make these connections between the software development methods involved in open source and political movements of governments. There is evidence,

however, that leaders in the open source movement have expressed their rationale for advocating opening the source code of software.

The open source movement can trace its roots back to an alternate, still very active, software movement known as free software. While open source and free software can (and do) coexist in many ways, there are some essential differences that distinguish the two groups from one another. Perhaps most notably, the free software movement is based on a belief in a moral or ethical approach to software development, while open source takes a much more pragmatic view. While both groups argue for the open sharing of source code, each has its own reason for doing so. Understanding the differences between open source and free software can help open source researchers use more precise terminology and preserve the intent of each of these groups rather than assuming that they are interchangeable.

The following chapter begins with a brief historical overview of the free software and open source movements and highlights some of the main beliefs of each. The chapter then offers an examination of both the moral and pragmatic aspects of open source software. The conclusion invites readers to consider the implications of the differences between the two viewpoints and suggests ways for readers to apply this information when making choices about software.

BACKGROUND

The open source movement grew out of the software development practices in academic settings during the 1970s. During those early years of software development, computer scientists at colleges and universities worked on corporate-sponsored projects. The software developed for these projects was freely shared between universities, fostering an open, collaborative environment in which many developers were involved in creating, maintaining, and evaluating code (Raymond, 1999).

In his *A Brief History of Open Source* article, Charlie Lowe (2001) describes the end of open and collaborative methods of developing computer software in the 1980s when the corporate sponsors of academic software projects began to copyright the code developed for them. Corporations claimed that the university-run projects created valuable intellectual property that should be protected under law. This, of course, was just one of the signs of the shift from the commodity-based economy in the U.S. to a knowledge-based one. The wave of copyrights threatened to end the collaboration between computer scientists and slow the evolution of important projects. It looked as if the computer scientists would be required to work in smaller groups on proprietary projects.

Richard Stallman (1999) reports that he created the GNU General Public License (GPL) to maintain the ability to collaborate with other computer scientists on software projects, without restriction. The name GNU is a self-reflexive acronym meaning "GNU's Not UNIX," a play on words that pays homage to and differentiates itself from the UNIX legacy.[1] Stallman was concerned that the UNIX operating system, created during the collaborative era of the 1970s, would no longer be supported by new programs that used its stable and robust architecture when access to the source code was cut off. Stallman started the GNU initiative (which enabled the establishment of the Free Software Foundation [FSF]) to ensure that new software would be freely available.

The GNU GPL gave programmers the freedom to create new applications and license them to be freely distributable. Specifically, the GNU GPL gives anyone the right to modify, copy, and redistribute source code with one important restriction: Any new version or copy must also be published under the GNU GPL to insure that the improved code continues to be freely available. Many programmers (both those accustomed to the academic practices of the 1970s and new computer enthusiasts) adopted the GNU GPL and continued to work in open, collaborative systems.

Arguably the most important piece of software developed under the GNU GPL is the Linux operating system. Linus Torvalds, while still a student at the University of Helsinki in 1991, created a new operating system based on the ideas found in the UNIX operating system. This new piece of software, Linux, not only proved the success of GNU GPL, but it also represented a further shift toward a widely cooperative effort in software development. According to Eric Raymond, Linux debunked the myth that there were software projects with an inherent "critical complexity" that necessitated a "centralized, *a priori* approach" (Raymond, 2001, p. 21). With wide adoption among software developers and computer scientists, Linux proved to be a stable and powerful system despite its complexity and rapid development schedule.

In 1998, when Netscape decided to make its source code public as part of the Mozilla project, Eric Raymond and Bruce Perens suggested the use of the term "open source" in response to confusion over the term "free." Stallman, in many cases, found himself explaining that he was using the term "free" in the sense of "freedom" or "liberty" rather than "without monetary cost." Raymond and Perens founded the Open Source Initiative (OSI) to differentiate the new group from the FSF.

While there are many other active voices in the free software and open source movements such as Linus Torvalds (originator of the Linux operating system) and Robert Young (co-founder and CEO of Red Hat), Richard Stallman and Eric Raymond continue to be the most influential and widely cited. While Stallman and Raymond do agree at some level that software development benefits from the free distribution of source code, they see this free distribution in two completely different ways.

THE DEBATE

Many people have written about the debate between Eric Raymond and Richard Stallman. It is widely reported (Williams, 2002) that Stallman disagrees with Raymond's pragmatic reasons for promoting the term "open source" over "free software." In fact, Raymond's *Shut Up and Show Them the Code* and Stallman's *Why "Free Software" is Better Than "Open Source"* are two examples of the heated exchange between the two writers, each defending his own position on the issue of freely available source code. Bruce Perens reports that it is "popular to type-case the two as adversaries" (Perens, 1999, p. 174). While most studies emphasize that the term "open source" was adopted simply to avoid confusing the word "free" in "software" (DiBona, Ockman, & Stone, 1999; Feller & Fitzgerald, 2002; Fink, 2003), others are careful to point out that the shift in terminology really signaled a shift in strategy for open source advocates.

Perhaps the best work done on the differences between these groups is David M. Berry's (2004) work, *The Contestation of Code: A Preliminary Investigation into the Discourse of the Free/Libre and Open Source Movements.* By analyzing the discourse of the two movements (in the words of Stallman and Raymond), Berry concludes that the discourse of the free software movement more closely identifies with the user, is more utopian, and advocates a communal, socialist approach. The discourse of the open source movement, on the other hand, advocates a more individualistic approach that identifies with the "owners" or creators of software, resulting in a more libertarian emphasis.

In any case, the rift between those who choose to use the term free software and those who choose to use the term open source has resulted in some scholars choosing sides on the issue. Lawrence

Lessig (2004), an important scholar in the area of intellectual property law, discusses open source at great length in his work, *Free Culture*. However, he quotes only Stallman's writings, not Raymond's. To Lessig, at least, the open source movement is more about Stallman's rhetoric of freedom than Raymond's pragmatism. Understanding the rationale behind such choices is important in understanding the impact of open source software outside of the software industry.

OPEN SOURCE AND FREE SOFTWARE

In *The GNU Operating System and the Free Software Movement*, Stallman suggests that the two terms "describe the same category of software … but say different things about the software, and about values" (Stallman, 1999, p. 70). The following sections examine the work of Richard Stallman and Eric Raymond to investigate the different philosophical approaches to software development espoused by each.

Free Software: The Works of Richard Stallman

Stallman's (Stallman, 2002c) theorizing about software rests on what he identifies as the four main "freedoms" of his "Free Software Definition." According to Stallman (2002c, p. 18), these freedoms are:

- **Freedom 0:** The freedom to run the program, for any purpose
- **Freedom 1:** The freedom to study how the program works, and adapt it to your needs (access to the source code is a precondition to this)
- **Freedom 2:** The freedom to redistribute copies so you can help your neighbor
- **Freedom 3:** The freedom to improve the program, and release your improvements to the public, so that the whole community benefits (access to the source code is a precondition to this)

In other words, Stallman directly relates his views about software development to a set of freedoms for users of that software. In the rhetoric of these main "freedoms," at least, Stallman is concerned more with the users of a software program than with the program itself.

In *The GNU Manifesto*, Richard Stallman makes impassioned arguments about his stance toward software development. "I consider that the golden rule requires that if I like a program I must share it with other people who like it" (Stallman, 2002a, p. 32), he writes. "So that I can continue to use computers without dishonor, I have decided to put together a sufficient body of free software so that I will be able to get along without any software that is not free" (Stallman, 2002a, p. 32). He constructs his call for radical change in the way software development occurs with several ideological claims. Specifically, Stallman claims that sharing is fundamental and that free software offers the only ethical alternative for software programmers.

Stallman's rationale for calling programmers to work on an alternative to proprietary software is based on what he calls the "fundamental act of friendship of programmers": the "sharing of programs" (Stallman, 2002a, p. 33). Stallman suggests that "[m]any programmers are unhappy about the commercialization of system software. It may enable them to make more money, but it requires them to feel in conflict with other programmers in general rather than feel as comrades" (Stallman, 2002a, p. 32-33). More than simply suggesting that the sharing of programs is ideal or simply important, Stallman argues that it is a fundamental imperative and a source of conflict. He goes so far as to suggest that programmers "must choose between friendship and obeying the law" (Stallman, 2002a, p. 33), implying that the law, on the issue of software availability, is in error.

The metaphors Stallman uses to expand on the idea of the centrality of sharing among developers makes it sound as if restricting software use is against nature itself. He writes: "Copying … is as natural to a programmer as breathing, and as productive. It ought to be as free" (Stallman, 2002a, p. 34). He goes on to equate software with air itself: "Once GNU is written, everyone will be able to obtain good system software free, just like air" (Stallman, 2002a, p. 34). Denying people the right to free software, in other words, would be like trying to regulate and restrict breathing itself. According to Stallman, restricting software use results in a kind of "police state" employing "cumbersome mechanisms" (Stallman, 2002a, p. 34) in the enforcement of copyright law.

While Stallman characterizes a software development community that shares all of its resources as a utopian society, he harshly criticizes proprietary software. He claims that restricting use of a program through intellectual property law constitutes "deliberate destruction" (Stallman, 2002a, p. 36) and a failure to be a good citizen. Stallman's rhetoric sets a scene with only two alternatives: free software based on the ideas of camaraderie, friendship, freedom, good citizenship, community spirit, and sharing of proprietary software based on the ideas of restriction, destruction, commercialization, and materialism. Clearly, Stallman's purpose is to set up a binary in which the only good is free software and the only evil is proprietary software. Any programmer who chooses to develop software in the capitalist proprietary software environment is choosing to be less moral than his or her free software counterparts.

Open Source Software: Raymond's Cathedral and Bazaar

Eric Raymond's *The Cathedral and the Bazaar* (2001), promotes open source software using two pragmatic claims that compliment each other: the promotion of the individual and the conscription of others. Unlike Stallman's emphasis on sharing and morality, Raymond emphasizes the practical aspects of open source that leads to its technical superiority. Specifically, Raymond describes the importance of the lead developers of projects while at the same time emphasizing the necessity of using others to complete work on projects. In neither case does Raymond express a belief in the moral superiority of open source development. Instead, all of the benefits of open source are described in terms of the development of a superior technological artifact.

Throughout *The Cathedral and the Bazaar*, Raymond (2001) promotes an egocentric view of technological development that emphasizes the role of the individual in the process. This egoistic approach is revealed in many ways—from Raymond's own self-congratulation, to his description of how developers find incentive to volunteer to participate in projects. Raymond's tendency to promote individuals over the group begins with his own tendency to describe himself as a gifted individual. While some of his claims may be true, it is unusual for a person to sing their own praises quite as blatantly as Raymond does. Usually, modesty does not allow for such open self-congratulation. In describing the personality traits common to good leaders for open source software projects, Raymond points to his own abilities. "It's no coincidence that I'm an energetic extrovert who enjoys working a crowd and has some of the delivery and instincts of a stand-up comic" (Raymond, 2001, p. 49). His infatuation with his own charming personality illustrates how much he values the individual over the group. More than once, Raymond cites instances where his superior programming skills enabled him to make extraordinarily wise decisions that a lesser programmer might miss. For his programming and writing skills, Raymond mentions that he got "fan mail" (Raymond, 2001, p. 38) and "help[ed] make history" (Raymond, 2001, p. 61). Clearly, Raymond's focus on the individual begins with himself.

Raymond goes beyond his own egoism, however, when he generalizes about what constitutes a good open source software project. According to Raymond, "every good software project starts by scratching a developer's personal itch" (Raymond, 2001, p. 23). This aphorism is the first of the 19 rules of open source software development. It is interesting that Raymond recognizes that the motivation behind good software comes not from a need in the community but rather from a personal interest or desire. Raymond reiterates this emphasis on the individual developer's primacy in starting a project in tenet 18: "To solve an interesting problem, start by finding a problem that is interesting to you."(Raymond, 2001, p. 49) Again, nowhere in Raymond's writing does he refer to moral behavior or developers and a need to share. Instead, he believes that the curiosity of an individual developer is enough to justify work in the open source model.

The natural conclusion to a system that encourages individuals to involve themselves in only those projects which they find personally interesting is a hierarchical system that promotes these individuals. Open source developers who choose to take on a particular software problem promote themselves to the role that Raymond calls the "core developer" (Raymond, 2001, p. 34). This role bestows the leadership upon a single individual who is, in turn, supported by a "halo of beta-testers" who exist to serve the needs of the leader (Raymond, 2001, p. 34). Naturally, this leader wields considerable power over his or her user community. And, according to Raymond, not every developer possesses the skills to be a good project leader. Raymond presupposes that any good project leader has superior technical abilities that are generally recognized in the open source community. Further, he suggests that the core developers have skills "not normally associated with software development"—people skills (Raymond, 2001, p. 48).

What Raymond calls people skills is actually an ability to provide incentive to other developers to enlist their help with a project. Raymond posits that the success of the Linux project came largely from core developer Linus Torvalds' ability to keep his volunteer developers "stimulated and rewarded" by giving them "an ego-satisfying piece of the action" (Raymond, 2001, p. 30). In his own fetchmail project, Raymond says he made a habit of "stroking [users] whenever they sent in patches and feedback" (Raymond, 2001, p. 38). In his analysis of how to encourage participation in members of the open source community, Raymond asserts that hackers find rewards in "the intangible of their own ego satisfaction and reputation among other hackers" (Raymond, 2001, p. 53). A project leader must "connect the selfishness of individual hackers as firmly as possible to the difficult ends" involved in software development (Raymond, 2001, p. 53). Rather than provide monetary incentive, then, Raymond encourages an approach that enables project leaders to conscript users' assistance through a coercive appeal to their egoistic, selfish desire for glory. This approach simultaneously reinforces the leader's domination over other developers and de-emphasizes any development practice based on goals related to benefit to the community.

Raymond discusses how the paradigm of encouraging egoistic behavior of volunteer developers affects the individual reputation in the leader in the following passage:

Interestingly enough, you will quickly find that if you are completely and self-deprecatingly truthful about how much you owe other people, the world at large will treat you as though you did every bit of the invention yourself and are just being becomingly modest about your innate genius. (Raymond, 2001, p. 40)

It is difficult to believe that Raymond would ever be mistaken as "becomingly modest." Even when he encourages leaders to give credit to those that assist with the project, he reveals the underly-

ing motive of additional glory and recognition in the open source community.

The dominating force that goes hand-in-hand with Raymond's suggestion that project leaders should appeal to a volunteers' selfishness is the idea that these users must be recruited and conscripted in order to create a successful open source project. Raymond quotes Linus Torvalds as saying, "I'm basically a very lazy person who likes to take credit for things that other people actually do" (Raymond, 2001, p. 27). While Torvalds is obviously speaking tongue-in-cheek here, it reveals a common theme that Raymond continues to espouse. Two of the 19 development practices include, "If you treat your beta-testers as if they're your most valuable resource, they will respond by becoming your most valuable resource" (Raymond, 2001, p. 38), and "The next best thing to having good ideas is recognizing good ideas from your users" (Raymond, 2001, p. 40). Both of these statements imply that the volunteer developers belong to and work for the project leader. In addition, the project leader can use these volunteers for his or her own purposes like a natural resource.

The idea of individual ownership extends beyond the volunteers on a particular project to the software itself. Despite the fact that projects are "co-developed" by many individual developers, the lead project coordinator actually "owns" the technology. This idea is present in another one of Raymond's main tenets: "When you lose interest in a program, your last duty to it is to hand it off to a competent successor" (Raymond, 2001, p. 26). Therefore, the technology can be bequeathed and inherited much like a traditional patriarchal succession of ownership. And when a software project is passed down to the next generation of leadership, the volunteer user base comes with it.

Speaking of this volunteer user base, Raymond suggests that "[p]roperly cultivated, they can become co-developers" (Raymond, 2001, p. 26). In addition to cultivating, Raymond suggests that users can be "harnessed" (Raymond, 2001, p. 50) to do work for the lead developer. Essentially, Raymond espouses conscripting volunteers to do the work of the lead developer. Tenet 6 summarizes his position: "Treating your users as co-developers is your least-hassle route to rapid code improvement and effective debugging" (Raymond, 2001, p. 27). The implication of that statement is not that users *really are* co-developers but rather that users should be treated *as if they were* co-developers in order to ensure that they will do work for the improvement of the system. Raymond seems to believe that core developers could build open source software projects on their own, but enlisting the help of users provides a less difficult way to achieve the goal of creating a powerful system. Conspicuously absent in this method of project management is the idea that these volunteer users are better served by participating in the development process. Instead, Raymond's main concern is with the system itself.

According to Raymond, the true benefit of this conscription model of development comes from the advantages of using a large body of volunteers to detect and fix bugs in the system. Tenet 7 is, "Release early. Release often. And listen to your customers" (Raymond, 2001, p. 29). However, Raymond's description of the value of this rule does not include a plea for technology that is sensitive to users' needs. Instead, he asserts that this innovation is simply an effective way to test the software for technological bugs, not usability problems. The goal is to "maximize the number of person-hours thrown at debugging and development, even at the possible cost of instability in the code" (Raymond, 2001, p. 30). Raymond suggests that a "program doesn't have to work particularly well. It can be crude, buggy, incomplete, and poorly documented" (p. 47). Therefore, he promotes systems exposed to "a thousand eager co-developers pounding on every single new release. Accordingly you release often in order to get more corrections, and as a beneficial side effect you have less to lose if an

occasional botch gets out the door" (Raymond, 2001, p. 31).

His suggestion that less-than-usable software can be released shows that his interest is not in the value of the software to users. His interest is in the value of the users to the software.

MORALITY AND PRAGMATISM

While Stallman's emphasis in advocating for the free software movement is clearly one of moral behavior and obligation, Raymond's characterization of the open source movement emphasizes the technological superiority of a decentralized development process. Stallman's argument sets up free software as a superior and more ethical alternative to proprietary software development that focuses on the rights and freedoms of users and developers. Nowhere in Raymond's writings does he suggest that proprietary software is less ethical. That is not to say Raymond isn't critical of proprietary software. However, his main concern is always the technological implications of software rather than the moral.

Table 1 outlines a few of the more important differences between the two movements:

Faced with two very different value systems surrounding these related movements, open source software users should pay careful attention to the software they choose to use or the software communities in which they participate. While the two approaches to software development adopt similar practices, they represent two different viewpoints that are often at odds with one another. If a user is making a choice to use open source software because of a belief that it is more moral to support open intellectual property policies, they may want to seek out like-minded projects that use the Stallman approach. If a user is more concerned about the technological superiority of open source software even if that superiority comes at the cost of an emphasis on equality among users, then they may want to seek out projects that are run by maintainers that use the Raymond style.

In either case, users should be aware that the choices they make in their affiliations also signal to others that they adopt the worldview represented in those choices. While there may be many instances of individual developers and software projects that blend the ideas and beliefs of both Raymond and Stallman, it is still important to understand that these philosophies often result in development approaches at odds with each other. Though the practices are admittedly similar, a difference in *why* one would choose to develop open source software can affect *how* one carries out that choice.

Perhaps the most important thing to realize, however, is that neither the Raymond nor the Stallman approach is inherently superior for all users. Instead, the choice to adopt one of the approaches over the other rests entirely upon the needs and situation of the individual user. While the rhetoric of both Stallman and Raymond suggest that their understanding of software development represents a truly enlightened and superior approach, neither one can be said to offer the final word.

FUTURE TRENDS

The most inclusive and technically accurate description of software with freely available source code is free/libre open source software (F/LOSS or FLOSS) because it accurately maintains portions of each of the various movements in the software community. However, the term *open source* has proven to be the most popular, partly because of the deliberate attempt by open source advocates to make the licensing structures more business-friendly. Apart from its popularity, many choose the term open source almost exclusively due to its influence on the broader culture; open source has been used as a descriptor for everything from yoga to t-shirt designs.[2] When these non-technological instances of open source are used, the suggestion is that the development of these particular creative

Table 1. The morality and pragmatism of the free software and open source movements

Morality ***Free Software/Stallman***	**Pragmatism** ***Open Source/Raymond***
Defines the benefit of free software as a superior moral choice.	Defines the benefit of open source as a pragmatic way to develop superior software.
Emphasizes developers' moral obligation to share with others.	Emphasizes satisfying developers' personal and individual desires.
Understands the development process as a shared, communal, group effort based on socialistic principles.	Understands the development process as one driven by one or a small group of leaders who conscript volunteers to assist with the project.

endeavors is open to many. More than FLOSS, open source represents both a software development phenomenon and a cultural one.

However, when popular culture adopts open source to mean an open, sharing community of creative invention, it misses the main emphasis of the movement. According to Raymond, the movement is less about the moral imperative to share with others and more about the benefit of harnessing the creative energy of individuals who are free to choose their own work. Rather than seeing open source as good for the public, Raymond emphasizes the benefit of the process for the technology. In other words, Raymond is more interested in product than people.

Unfortunately, it is likely too late to correct the trend in popular culture to equate the term open source with "sharing intellectual property" even though open source refers to a process and value system much more complicated than simply sharing. While the term open source government" certainly carries with it a grandiose image of participatory, shared government in which each member of a community has a voice, but it is unclear how open source government is different from a healthy democracy.

Members of the open source community can contribute to the increased use of the term open source by helping others understand where new uses of the term open source resonate with similarities in the software movement and where they miss the mark. Very few creative endeavors have anything akin to the source code found in software development, so making the source code freely available, the essential meaning of the phrase open source, cannot be replicated in other fields. However, the idea that creative work should be shared and that sharing can be protected with creative licensing is a contribution from the open source movement that can be adopted by others. Rather than adopting open source, other communities may benefit by using more precise and applicable language such as Creative Commons to refer to the sharing of intellectual property.

CONCLUSION

While many researchers and developers of open source software (myself included) typically lump free software and open source software together, both Stallman and Raymond adamantly insist that there are fundamental differences between the two groups. In his essay *Why "Free Software" is Better than "Open Source,"* Stallman explains that the two groups "disagree on the basic principles, but agree more or less on the practical recommendations" (Stallman, 2002b, p. 55). In other words, free software and open source software are essentially the same in *practice*, but not in *principle.*

Because open source and free software appear to operate the same way to outside observers, there is very little insight into when a piece of software

should be labeled open source and when it should be labeled free software. Often, both use the same licensing structures. The essential difference is not a technological one; it is one of philosophies. Only the developers themselves can attest to the reasons they choose to develop software with freely available source code. However, it is useful for outside observers to be more precise in their allegiances. It could mean the difference between freedom and pragmatism.

KEY TERMS

Free/Libre and Open Source Software (FLOSS): A more inclusive term for all software with freely available source code.

Free Software (FS): Software with freely available source code developed in the tradition of the Free Software Foundation and influenced by the writings of Richard Stallman.

Morality: An appeal to the fundamental goodness of an act; primary rationale behind the free software movement.

Open Source Software (OSS): Software with freely available source code developed in the tradition of the Open Source Initiative (OSI) and influenced by the ideas of Eric Raymond and Bruce Perens.

Proprietary Software (PS): Software without publicly available source code, commonly seen as the opposite of free and open source software.

Pragmatism: An appeal to the usefulness of an act; primary rationale behind the open source movement.

ENDNOTES

1 It is common for developers to use reflexive acronyms, partly as a tongue-in-cheek recognition of the overuse of acronyms in technology. Other examples include PHP (PHP hypertext protocol) and WINE (WINE Is Not an Emulator).

ABSTRACT

Testing the correctness of services assures the functional quality of service-oriented applications. A service-oriented application may bind dynamically to its supportive services. For the same service interface, the supportive services may behave differently. A service may also need to realize a business strategy, like best pricing, relative to the behavior of its counterparts and the dynamic market situations. Many existing works ignore these issues to address the problem of identifying failures from test results. This article proposes a metamorphic approach for online services testing. The off-line testing determines a set of successful test cases to construct their corresponding follow-up test cases for the online testing. These test cases will be executed by metamorphic services that encapsulate the services under test as well as the implementations of metamorphic relations. Thus, any failure revealed by the metamorphic testing approach

will be due to the failures in the online testing mode. An experiment is included.

INTRODUCTION

The service-oriented architecture (SOA) is an architectural reference model (Bass et al., 2003) for a kind of distributed computing such as the Web services (W3C, 2002). It promises to alleviate the problems related to the integration of heterogeneous applications (Kreger et al., 2003; Mukhi et al., 2004). In this reference model, a SOA application is denoted by a collection of self-contained communicating components, known as *services*. The model also emphasizes that each service should make little or no assumption about its collaborating services. This setting advocates the dynamic composition of a service by using different configurations of supportive services, creating behavioral differences amongst different invocations of a service. Typical end-users of a SOA application, such as bank customers using an online foreign exchange trading service, may expect consistent outcomes each time they use the service. The customers may further compare the online foreign exchange service of a bank to similar services of other banks to judge whether the service is of good quality. If a B2B service provider is driven by a predefined business strategy to, for example, maintain its market share, then the criteria to define functional correctness of the service may vary according to its environment. In other words, testers need to integrate the environment of a service to check test results.

Services may be subject to both the off-line testing and the online testing. Unlike the testing of conventional programs, services bind dynamically to other peer services when it is tested online. While the off-line testing of services is analogous to the testing of conventional programs, the online testing of services needs to address new issues and difficulties.

Testers may generally apply certain static analyses or testing techniques to assure the correctness of a software application. The evaluation criteria of the functional correctness, on the other hand, must be predefined. For a unit testing, testers also want to address the test case selection problem and the test oracle problem (Beizer, 1990). We restrict our attention to the latter problem in this article.

A test oracle is a mechanism that reliably decides whether a test succeeds. For services, as we will discuss, formal test oracle may be unavailable. The expected behavior of a service that represents business goods and services changes according to the environment. Such an expected behavior is relative to the behaviors of competing services or other services. Intuitively, it is hard to define the expected behavior explicitly in the first place. Tsai et al., (2004) for example, suggest using a progressive ranking of similar implementations of a service description to alleviate the test oracle problem. The behaviors of different implementations of the same service vary in general. Test results of a particular group of implementations cannot reliably be served as the expected behavior of a particular implementation of the same service on the same test case. Also, a typical SOA application may comprise collaborative services of multiple organizations, knowing all the implementations are impractical (Ye et al., 2006). For example, a travel package consultant may wrap up services of various hotels, airlines, and entertainment centers to personalize tour packages for a particular client. Without the implementation details, static analysis appears infeasible to assure the implementation quality. The black box approach for test results checking remains viable and popular to assure the correctness of a software application.

Metamorphic testing is a promising approach to the test oracle problem in the testing of conventional scientific programs (Chan et al., 1998; Chen et al., 1998, 2002). Instead of relating an

output to its input, metamorphic testing relates multiple input-output pairs via well-defined relations, called metamorphic relations.

This article extends the preliminary version (Chan et al., 2005a) to propose an online testing approach for testing services. The main contributions of the preliminary version (Chan et al., 2005a) include:

1. It proposes to apply the notion of metamorphic testing to services computing to alleviate the test oracle problem. It constructs more test cases to reveal faults than those ordinarily required when test oracles are known.
2. It proposes to realize the metamorphic testing mechanism as a metamorphic service in services computing that encapsulates a service under test, executes test cases and cross-validates their test results. Such realization seamlessly integrates the existing SOA framework. It automates the construction of follow-up test cases and their test results checking.

The main extended contributions of this article include:

3. It devises the use of the successful test cases for off-line testing as the original test cases for online testing. Since, in an off-line testing, the environment of services can be controlled by testers, test oracle could be defined. Thus, any failure revealed by our metamorphic testing approach will be due to the failures in the online testing mode.
4. It refines the testing approach presented in the preliminary version of this article to take the successful test cases from the off-line testing phase into account.
5. It evaluates the revised proposal against a control experiment having no prior confirmation of test results through an experiment. The experimental result indicates that our proposal is superior to the control experiment. The control approach suffers from an extra 16% effort to check test results and a 13% reduction of failure detection.

The rest of the article is organized as follows. The next section introduces the concepts of services, metamorphic testing and other preliminaries. After that, we describe our testing proposal. Our approach will be illustrated by a sample scenario, followed by an experiment on the feasibility of applying the proposal in a SOA application. Based on the experimental results, we compare our approach to related work, and discuss our experience. Finally, we conclude the article and outline the future work.

PRELIMINARIES

In this section, we briefly introduce the notion of service, metamorphic relation, and metamorphic testing. We also discuss how a metamorphic relation can be aligned with the notion of service and discuss our assumptions. Finally, we clarify our terminologies on online testing and off-line testing.

Service

A *service* in SOA is a self-contained application function, packaged as a reusable component, for the use in a business process (Colan, 2004). It can describe itself so that other services may discover and locate the service. Services also use simple and self-contained messages with well-defined interfaces for communications. Those interfaces are neutral to different hardware or software platforms to support the execution of a service. Meta-models, such as XML Schema (W3C, 2001), are often used to govern the syntactic validity of the messages.

For example, the Web services (Curbera et al., 2002; W3C, 2002) use the *Web service defini-*

tion language or WSDL (W3C, 2005) to let each service of an application define the syntactic and interoperability requirements. It also uses the *universal description, discovery and integration* or UDDI (OASIS, 2005) to offer applications a unified and systematic way to locate services from common registries. The *simple object access protocol* or SOAP (W3C, 2003) is then used to support XML[2]-based messaging between peer services.

In general, there are two types of services, namely *stateless* and *stateful*. They are analogues to conventional programs and object-oriented programs, respectively. Both types are popular in these days.[3] Intuitively, in terms of modeling, one may use a stateless service with self-addressing stateful messages to simulate a stateful service. We thus restrict ourselves to consider stateless services in this article.

Metamorphic Relation (MR)

As a service is a self-contained and function-oriented component, some functional properties of the service should be identifiable; otherwise, it would be difficult for collaborating services to identify the usefulness of the service. One way to display the functional properties of a service is to show the connection of multiple invocations of the service.

A metamorphic relation, or MR, is an existing or expected relation over a set of distinct inputs and their corresponding outputs for multiple executions of the target function (Chen et al., 1998, 2002, 2003). For example, consider a sorting program *Sort*( ) that sorts the input list of integers into a list of integers in ascending order. The expected result of *Sort*(⟨*1,4,3*⟩) is ⟨*1,3,4*⟩, which is same as that of *Sort*(⟨*1,3,4*⟩). Generalizing the scenario would lead to the formulation of the relation: *Sort*(*X*) = *Sort*(*Sort*(*Y*)) *if X = Y.*

Readers can easily observe that in the above example, the expected output of the input ⟨*1,4,3*⟩ is only induced implicitly. This relieves testers to predetermine the expected behavior of a test case in an absolute term. It is particularly important when a tester is conducting the online testing of a service, for the reason that the concrete expected behavior of a service may depend on other peer services, which may not be under the control of the software developers or testers of the service under test.

A metamorphic relation can be formally described as follows:

> Suppose that *f* is an implemented function under test. Given a relation *r* over *n* distinct inputs $x_1, x_2, \ldots, x_n$, the corresponding *n* computation outputs $f(x_1)$, $f(x_2)$, …, $f(x_n)$ must induce a necessary property r_f.

A metamorphic relation MR_f of *f* over *n* inputs and *n* outputs can be defined as follows:

$$MR_f = \{(x_1, x_2, \ldots, x_n, f(x_1), f(x_2), \ldots, f(x_n)) \mid r(x_1, x_2, \ldots, x_n) \Rightarrow r_f(x_1, x_2, \ldots, x_n, f(x_1), f(x_2), \ldots, f(x_n))\}$$

We observe that, when a service is seen to be a function, and all input and output messages are self-contained, the notion of metamorphic relation readily applies to services. We will give an example after the introduction of metamorphic testing in the following section.

Metamorphic Testing (MT)

Metamorphic testing or MT (Chen et al., 1998, 2002, 2004) is a program testing technique that employs the mathematical relations, namely metamorphic relations, to conduct testing. It has been applied to numerical applications (Chan et al., 1998) and context-aware applications (Chan et al., 2005c).

It uses *successful test cases* to alleviate the test oracle problem when a test oracle is unavailable or expensive. Given a program *P* of target function *f* with input domain *D.* A set of test cases *T,*

$\{t_1,\ldots,t_k\}$ ($\subset D$), can be selected according to any test case selection strategy. Executing the program P on T produces outputs $P(t_1), \ldots, P(t_k)$. When they reveal any failure, testing stops and debugging begins. On the other hand, when no failure is revealed, these test cases will be termed as *successful*. A set of successful test cases is called a successful test set.

Testers may apply the metamorphic testing approach to continue to verify whenever some necessary property of the target function f is satisfied by the implementation P. The metamorphic testing approach constructs the *follow-up* test set T', $\{t'_1,\ldots,t'_m\}$ ($\subset D$), automatically from the initial successful test set T, with the reference to some given metamorphic relation.

Let us cast an example in the services computing setting. Suppose that S is an expected USD−HKD exchange service, accepting deal orders in USD and returning deal orders in HKD; x and y are two deal orders; $g(\ )$ is a function that accepts a deal order and returns its deal order amount. Further suppose that the following metamorphic relation sample is given, meaning that doubling the deal order in USD, doubling the resultant amount in HKD:

$MR_a(x, y, S(x), S(y))$:
$2g(S(y)) = g(S(x))$ if $g(x) = 2g(y)$

Consider a successful test case x_1 = "a deal order of US$20,000." The metamorphic testing approach constructs automatically another test case y_1 = "a deal order of US$10,000" based on the condition $g(x) = 2g(y)$ of MR_a. Suppose P is an implementation of S. If the comparison $2g(P(y_1)) = g(P(x_1))$ fails, the MT approach reveals a failure due to the pair of failure-causing inputs x_1 and y_1. As x_1 is successful in the first place, the identified failure should be due to the test case y_1.

In the MT terminology, x_1 is termed as the *original test case*, and y_1 is termed as the *follow-up test case*. By checking the results amongst multiple input-output pairs, metamorphic testing bypasses the need to define the expected result explicitly to alleviate the test oracle problem. We refer readers to (Chan et al., 2005c; Chen et al, 2002, 2003, 2004; Tse et al., 2004) for more details about metamorphic testing.

In this article, we assume that MRs are provided by testers. Verification is generally undecidable, thus, we further assume that the provided MRs describe some necessary conditions of the expected behavior of the program under test. In practice, we recommend testers to define their MRs in a style so that they are directly coded in certain executable specification languages such as Prolog. As such, the implementation of MRs is a non-issue when testers use our methodology. In the next section, we further describe a few major assumptions of our proposal.

Assumptions and Terminologies

In this section, we list out a few major assumptions to establish our model for the online testing of services. These assumptions facilitate us to propose an infrastructure, namely metamorphic service, to be discussed in the metamorphic service section. We also clarify our terminologies on off-line testing and online testing.

We make the following assumptions: A service could be wrapped up by another (wrapper) service. It is based on the understanding that services are loosely coupled amongst themselves and they recognize one another through the common service registries. We assume that in the common service registries, the entries of the former service are replaced by those of the latter service for the testing purpose. This allows the latter service to query and catch messages for the former one. In our model, we use a message as a *test case* or *test result* of a service. This kind of treatment is also adapted by other researchers (Tsai et al., 2004; Offutt & Xu, 2004). It enables the wrapper service to construct test cases and evaluate their test results.

Furthermore, we agree with other researchers that a service is self-contained and independent to the contexts of other services. It also outputs results on every input.

We refer the term *online testing* to the testing of a service under the SOA environment, and the term *off-line testing* to the testing of a service without interaction with other services relevant to the service under test. We also term *off-line testing* and *testing in the off-line mode* interchangeably, and *online testing* and *testing in the online mode* interchangeably. Moreover, for the off-line testing, we refer a *stub service* as a service, since it is obvious in the context that the service under test does not interact with any other peer services of the SOA application when it is subject to an off-line testing. In the next section, we will present our testing proposal.

AN ONLINE TESTING APPROACH

In this section, an online testing methodology will be presented. We propose to test a service in two distinct modes, namely off-line mode and online mode. Informally, we propose to use the test oracle available to the off-line testing and make it also available to the online testing via metamorphic relations. In the overview section, we first introduce the two modes of testing. Next, in the metamorphic service section, we propose a core design artifact of our approach, the metamorphic service, which serves as a surrogate of the services under test to relay messages. At the same time, it constructs follow-up test cases and evaluates results accordingly. It then summarizes the methodology in the testing in the online mode section.

Overview

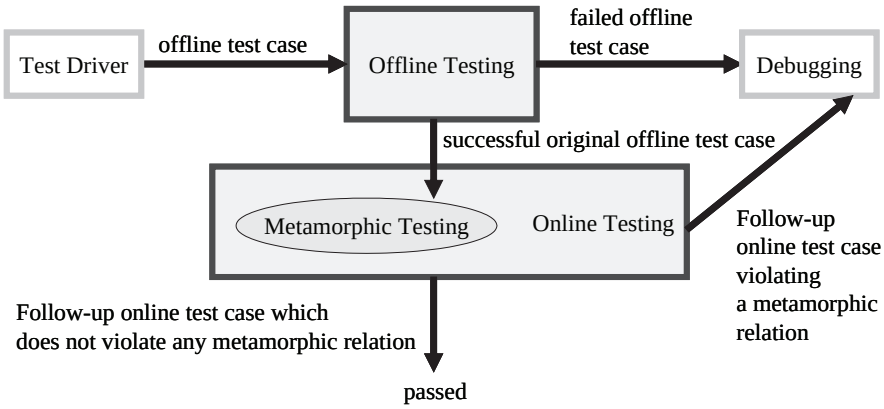
The off-line mode tests a service in the absence of interacting services. We view that it strongly resembles the convention techniques for the unit test of a conventional program. Many test data selection strategies (such as dataflow testing (Beizer, 1990; Zhu et al., 1997)) and test oracle construction for the unit test of conventional programs have been researched for years. As testers could control the off-line environment (such as providing test drivers and stub services, and messages), it is relatively easier to define test sets to test a service and validate the test results in such a mode. Thus, whether a test case reveals a failure or not, for off-line testing, can be determined through the checking of their test results against certain test oracle.

The above observation motivates us to apply the successful test cases of an off-line testing as the original test cases for the online testing mode. In the sequel, we restrict ourselves to discuss the online testing mode. We presume that a set of successful test cases for the off-line testing is available.

For online testing, as these original test cases are determined to be successful in advance, any violation of a corresponding metamorphic relation should be due to the failures of the follow-up test cases. Thus, when their corresponding follow-up test cases are for online testing, our approach pinpoints the online failure-causing inputs automatically even if the test oracle for online testing is not available. Figure 1 depicts the relation between off-line testing and our proposal for online testing.

Interested readers may compare the above strategy and the strategy that an original test case is unknown to be successful. In the latter strategy, when a violation of a metamorphic relation is detected, testers still need to further evaluate whether the violation is due to the original test case (no matter if it is in the off-line or online testing mode) or the follow-up (online) test case. Therefore, this alternative strategy may incur more overheads than our proposal. We will further study this issue in our empirical experiment in the experiment section.

Figure 1. The Integration between off-line and online testing



We will introduce a fundamental building box of our approach in the metamporphic services section, and then elaborate our online testing approach in the rest of this section. To ease our discussion, in the sequel, we use a metamorphic relation with two input-output pairs. The extension of the approach to more than one input-output pair is not hard.

Metamorphic Service (MS)

We formulate a metamorphic service as a service that has the characteristics of being an access wrapper (Mecella & Pernici, 2001; Umar, 1997) and being an agent to conduct metamorphic testing. A metamorphic service imitates all the data and application access paths of the service being encapsulated. It also embodies the program logics, which is the implementation of metamorphic relations, to compute follow-up test cases based on an incoming (or outgoing) message, and evaluates test results according to the implemented metamorphic relations.[4]

Since a metamorphic service is a service, which dynamically discovers a service implementation to receive a follow-up test case. The result of the follow-up test case will be sent to the metamorphic service for the detection of failures. The metamorphic service checks the test results against other test cases by using its metamorphic relations. Any violation of an implemented metamorphic relation reveals a failure.

Testing in the Online Mode

The testing in the online mode validates whether a service can interact correctly with other services. The following shows the self-explanatory methodological steps for this mode.

(ON-1). For a service under test S, collect the set of service descriptions D_S that represents the services interacting with S.
(ON-2). Design a metamorphic relations MR_i applicable to test S in the online mode.
(ON-3). Implement MR_i in the metamorphic service MS of the service S.
(ON-4). Repeat Steps (ON-2) to (ON-3) until no additional metamorphic relation is required for online testing.
(ON-5). For each available successful off-line test case t_o, do
  i. MS uses applicable MR_i to construct the following-up test case t_f of t_o.
  ii. MS invokes S to execute t_f.
  iii. MS obtains the corresponding results t_f

iv. If *MS* detect a failure by using MR_i, then report the failure and go to Step (ON-7).
v. Repeat Steps (On-5-i) to (On-5-iv) until no more applicable MR_i.

(ON-6). Report that no failure is found.
(ON-7). Exit

Step (ON-1) collects the service description that the service under test intends to collaborate. They facilitate testers to define and implement relevant metamorphic relations[5] in Steps (ON-2) and (ON-3) respectively.

If a tester does not identify any further metamorphic relation, Step ON-4 naturally stops, because there is no additional metamorphic relation in the tester's context. On the other hand, if a tester knows a metamorphic relation, but is incompetent to implement such a relation, it is obvious that the tester cannot use such a metamorphic relation according to our methodology; unless the tester seeks helps to implement the metamorphic relation.

Step (ON-5) uses an original test case to construct a follow-up test case. It also invokes the service under test to execute the follow-up test case, and collects the test result of the follow-up test case. Next, it evaluates the results until no more implemented and applicable metamorphic relation is available. When it detects a violation of any metamorphic relation, in Step (On-5-iv), it reports the failure and stops the testing. Otherwise, the process iterates, using another original test case until no more original test case is available. If no failure could be detected by any test case, the process will report such a case in Step (ON-6) and stop at Step (ON-7).

After presenting our approach in this section, the next section will demonstrate a way to use metamorphic testing to reveal failures related to the relative correctness for the testing of a service. We will then present an empirical experiment of our proposal in the experiment section.

AN ILLUSTRATION SCENARIO

In this section, our proposal for online testing will be further illustrated by an example. We first describe an application and its faults. Then, we illustrate how these faults can be revealed.

Figure 2 shows a foreign exchange dealing service application with five services, namely FXDS1 to FXDS5. In particular, FXDS2 is embraced by a metamorphic service. We denote the metamorphic service as *MS*. It has three metamorphic relations, namely MR1, MR2 and MR3. To ease our discussion, we restrict ourselves to discuss the exchange of US dollars to Renminbi.

A bank normally offers cross-currency rates inquiry services. A sample USD−RMB exchange rate is a pair of values such as 8.2796/8.2797. The first value and the second value in the pair refer to the *bid rate* and the *ask rate*, respectively. The difference between the two values in such a pair is known as the spread. We will use this rate for the following illustration, and assume these rates to be provided by the service FXDS4.

Suppose the expected behaviors of FXDS2 include:

1. A uniform exchange rate for any deal order.
2. A better, or at least the same, exchange rate to its clients than its rivals (e.g., the service FXDS3).
3. Checks on the exchange rates from central banks dynamically (e.g., the service FXDS4 for Central Bank of China, or FXDS5 for European Central Bank).

Also suppose that the implementation FXDS2 contains the following two faults (see (Table 2):

a. It uses the bid rate or the ask rate to process a deal order non-deterministically.
b. The rate provider logic has faults to cause it to use the minimum (that is, the worst rate)

instead of the maximum (that is, the best rate) for its rate calculations.

To test the service FXDS2, testers can apply our testing proposal, which is illustrated as follows.

Testers first formulate metamorphic relations. For the requirement (i), testers can check whether the output amount of service FXSD2 for a deal order is proportional to the deal order size. It forms the first metamorphic relation:

MR1: nFXDS2(x) = FXDS2(nx).

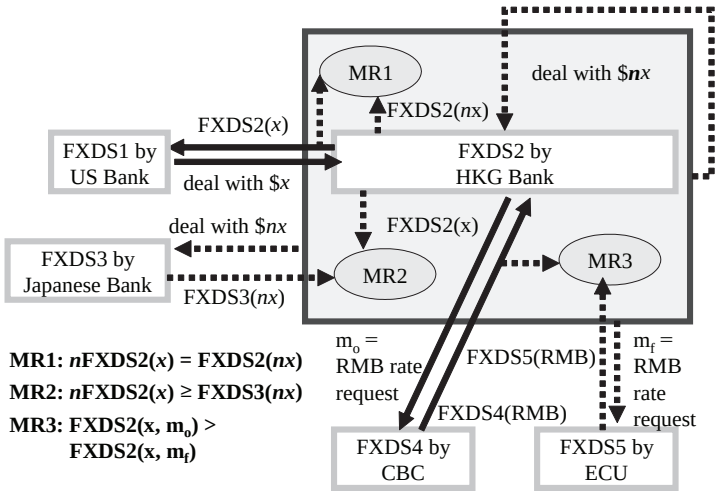
Consider an original test message t_o: a deal order of x (= US$100). FXDS2 correctly uses the above bid rate to output a message FXDS2(US$100) = 827.96 = 8.2796 × 100 in the off-line testing mode by using stubs. The metamorphic service *MS* constructs a follow-up test case t_f: a deal order of US$200 = 2 × x. It then passes this message to FXDS2 to execute in the online testing mode. (This is shown as the top-right dotted arrow in Figure 2).

Suppose, unfortunately, FXDS2 incorrectly uses the above ask rate and outputs FXDS2(US$200) = 1655.94 = 2× 827.97. Since both messages FXDS2(US$100) and FXDS2(US$200) can be checked by *MS* via MR1, we have, 2 × FXDS2(US$100) = 1655.92 ≠ 1655.94 = FXDS2(US$200). It violates the equation MR1. Hence, a failure related to the fault (*a*) is revealed and reported by the metamorphic service.

Readers may be interested to know the results of other combinations of using bid and ask rates for either the original or the follow-up test cases. When the original test case and the follow-up test cases use the bid rate or the ask rate, the equation MR1 will be ineffective to reveal the fault. However, when the original test case incorrectly uses the ask rate and the follow-up test case correctly uses the bid rate, MR1 would reveal the fault.

Let us continue to describe the scenarios to reveal the fault (*b*). We also begin with the formulations of two metamorphic relations. For the requirement (ii), testers may enlarge or shrink a deal order size by a multiplier. (In practice, a deal order size applicable to a global bank may not be applicable to a small foreign exchange shop at a street corner.) Such a follow-up deal order will be forwarded to a competing service (e.g., FXDS3). Next, one can determine whether the output of

Figure 2. A foreign exchange services system.



FXDS2 of the same order size is better than or equal to that provided by a rival service. This formulates the metamorphic relation:

MR2: nFXDS2(x) ≥ FXDS3(n x).

For the requirement (iii), testers may formulate the metamorphic relation:

MR3: value(FXDS2(x)) > value(FXDS2(y)) if centralbank(FXDS2(x)) = m_o and centralbank(FXDS2(y)) = m_f

Alternatively, in a shorthand notation:

MR3: FXDS2(x, m_o) > FXDS2(x, m_f)

MR3 means that if the target exchange is between USD and RMB, then the rate, provided by the Central Bank of China via the rate request m_o, should be strictly better than that due to any other rate request m_f from other central banks. We note that we choose to show the outgoing messages that interact with other services as parameters in the metamorphic relation in the shorthand notation to ease our discussion. We also deliberately use a different notation (that is, m_o and m_f , instead of t_o and t_f) for outgoing messages that serve as test cases for the metamorphic testing being illustrated.

According to MR2, a follow-up test case m_f can be formulated: Deal order of US$60 = 0.3 × 200. Suppose that an implementation of the service FXDS3 is discovered dynamically, and the latter correctly receives m_f and returns a message FXDS3(US$60) = 60 × 8.2796 = 496.776 to *MS*. Both messages FXDS2(US$200) and FXDS3(US$60) are verified by the metamorphic service via MR2. We have, 0.3 × FXDS2(US$200) = 496.782 > 496.776 = FXDS3(US$60). It satisfies MR2. Hence, no failure will be reported by *MS* for this particular follow-up test case.

On the other hand, for online testing, in the execution of a deal order as the input, FXDS2 needs to communicate with services of central banks to collect relevant exchange rates. Thus, the original test case t_o will trigger an outgoing message m_o, a USD−RMB rate request, for such a purpose. Suppose that FXDS2 discovers both FXDS4 and FXDS5 to provide the quotes of exchange rates for USD−RMB. For the illustration purpose, further suppose that the exchange rate provided by the European Central Bank via FXDS5 for USD−RMB is 8.2795/8.2798. This spread is wider than that provided by FXDS4, and thus is poorer.

MS uses the metamorphic relation MR3 to produce the follow-up test case m_f of m_o. Owing to the faults (*a*) and (*b*), FSDS2 incorrectly selects the ask rate of the service FXDS4 to process the deal order. FSDS2 will output a message FXDS2(US$100) = 827.98 = 8.2798 × 100. We have, in the shorthand notation, FXDS2(US$100, m_o) = 827.96 < 827.98 = FXDS2(US$100, m_f). It violates MR3, and *MS* reports a failure due to the combination of faults (*a*) and (*b*).

We have illustrated the usefulness of using a metamorphic service for the testing of services. In reality, there are domain-specific rounding practices compliant to the international accounting practice. Since rounding rules are a part of the application domain, it is natural for the designed metamorphic relations to take this type of rounding rules into account. This type of domain-specific rounding does not affect the metamorphic approach for services testing. It is worth mentioning that there could be implementation-specific rounding errors also. We refer readers to a previous work on metamorphic testing (Chen et al., 2003) for using a metamorphic approach to identify failures in the presence of the implementation-specific rounding errors. In the next section, we report an experiment that applies our proposal and discuss observations.

EXPERIMENT

In this section, we examine two issues in our proposal through an empirical experiment. We would like to study the testing overhead when some of the original test cases have failed. This is to validate our proposal to use successful test cases applicable to off-line testing as the original test cases for online testing. Our rationale is that if the overhead, on the contrary, is marginal; it is unnecessary to predetermine the successfulness of original test cases. This also helps reduce the testing effort for the online testing of services.

The Subject Program

The subject service implements a service-oriented calculator of arithmetic expressions. It is developed in C++ on Microsoft Visual Studio for .NET 2003 as a Web services. It consists of 16 classes with 2,480 lines of code.

Functionally, the calculator accepts an arithmetic expression consisting of constants of designated data type and arithmetic operators. The set of supported operators are {+,–,×,÷} in which each operator is overloaded to enable every operand belonging to different data types. Five data types of operands are supported: integer, long integer, decimal, floating-point number, and floating-point number with double precision. Each operator is implemented as a supportive service of the subject service.

The subject service parses the inputted arithmetic expressions, locates other services, and composes the results from the results returned by its individual supportive services. In the case where different data types are associated with an operator in a sub-expression, the subject service is responsible to resolve the appropriate data types and to pass the sub-expression to an applicable supportive service. In the design of the application, we choose to allow at most three concurrent instances of the above logic in the subject service. They, together with an expression dispatcher instance, compose our subject service. The expression dispatcher discovers the above supportive services of the subject service, and sends outgoing and receives incoming messages for the latter services. The metamorphic service for the subject service is composed of the dispatcher and a program unit that implements a set of metamorphic relations, which will be explained in the next section.

All the above services are developed by a team of five developers. They have completed certain formal software engineering training. Before doing the experiment, they have gained at least one year of research-oriented and application software development to develop location-based systems, mobile positioning systems and common business applications.

Experimental Setup

In this section, we describe the setup configuration for the testing of the subject service. Specifically, we present the selection of the original test cases, the metamorphic relations, and our experience in finding and implementing the metamorphic relations for the experiment.

As described previously, every instance of services is executed on a designated machine. In total, 14 personal computers are used. All the machines to collect our data are located in the Compuware Software Testing Laboratory of the Hong Kong Institute of Vocational Education (Tsing Yi).

The selection of the set of the original test cases is a black-box combinatorial testing approach. This allows the test cases to serve as the original test cases for both the off-line testing mode and online mode. Consider an arithmetic expression of length 3, which we mean to have an expression having three values and two operators (e.g., 13 + 0.45 – 7). In our experiment, there are five types of data type and four types of operator. In total, there are 2,000 (that is, $5^3 \times 4^2$) combinations, not counting the possible choices of value to initialize

each variable. Since the length of an arithmetic expression could be ranged from zero to a huge figure, we choose to fix the length to three in this experiment. This minimizes the potential problem of using a very long expression to compare with a very short expression in our subsequent analysis. We also initialize test cases that do not cause integer value overflow, and the overflow of other data types alike. We are aware that we have implemented some design decisions in the test case selection process. We minimize these highlighted threats by designing our metamorphic relations *neutral* to these design decisions.

In ideal cases, a user would perceive every calculation as if it is derived analytically using mathematics. However, some expressions would incur rounding errors due to the limitation of programming or system configuration. Different orders of evaluations of an expression could thus produce inconsistent results. A good calculator would provide consistent results to its users. For example, the arithmetic expression "(1 ÷ 3) × 3" would be evaluated as "(1 × 3) ÷ 3" by a good calculator.

We follow the above general guideline to formulate our metamorphic relations. We first describe how we determine and implement metamorphic relations. Next, we will describe the chosen metamorphic relations.

The arithmetic operators for the calculator application domain naturally define associative and commutative properties amongst arithmetic operators. We use these properties as the basis to design our metamorphic relations. This aligns with our objective to design such relations neutral to the selection of the original test cases. Since these properties naturally occur in the domain application, we experience a marginal effort to design associative and commutative relations and convert them into their corresponding formats in the sense of metamorphic relation. Furthermore, since the .NET framework for C++ directly supports the chosen operators, the effort to implement the metamorphic relations in our experiment is also marginal.

The types of metamorphic relation used in the experiment are as follows. Suppose *A, B* and *C* are operands of some data type in the set {integer, long integer, floating point number, floating point number with double precision}, and θ_1 and θ_2 are overloaded operators in the set {+, –, ×, ÷}. Consider the expression "(A θ_1 B) θ_2 C." A commutative-property rule to generate the follow-up test cases is: "(A θ_1 B) θ_2 C" ⇒ "C θ_2 (A θ_1 B)". It derives the follow-up test case "C θ_2 (A θ_1 B)" based on the original test case "(A θ_1 B) θ_2 C."

Let us denote our subject service by *S*. The corresponding metamorphic relation of the above commutative rule would be: *S*("(A θ_1 B) θ_2 C") = *S*("C θ_2 (A θ_1 B)"). A metamorphic relation derived from an associative rule is *S* ("(A θ_1 B) θ_2 C") = *S*("A θ_1 (B θ_2 C)"). We also design variants of the follow-up test case derivation rules to deal with the division operator: "(A × B) ÷ C)" ⇒ "(1 ÷ C) × (A × B)," and other similar rules alike. The generation of test cases is implemented as logic in our program.

Let us continue the discussion on the execution of test cases. Even a program is ideal; messages could still be lost or corrupt in a distributed environment. Our subject application does not implement a sophisticated fail-and-retry strategy to handle these anticipated scenarios. To compensate the lacking of this kind of strategy, we choose to abort the execution of a test case when a service returns no output after a timing threshold. After some trials-and-errors in our laboratory environment, we choose the threshold to be 50 seconds per execution of a pair of (original and follow-up) test cases. A typical test case will yield the result with three seconds.

Based on the implementation of the subject application, we create additionally six consecutive faulty versions of the set of supportive services. Each version injects one additional mutation fault to its immediate ancestor. The six consecutive

faults are created in the following order: changing a "+" operator to the operator "–"; changing a "–" operator to the "+" operator'; changing a "×" operator to a "–" operator; swapping the operand of a "÷" operator; changing a "–" operator to the "×" operator; and changing a "×" operator to a "+" operator. These faults support operands of the following data types respectively: floating-point number with double precision, integer, decimal, floating-point number with single precision, long integer, and floating-pointer number with single precision.

The following configurations were deployed for off-line testing and online testing.

- The subject application (the subject service with the original version of the supportive services) simulates an off-line testing environment. The original non-faulty versions of the supportive services serve as stub services for the off-line testing, in the sense of conventional testing. Inexperienced developers implement the subject service and, thus, it naturally contains real faults. Some random test cases do reveal failures from the subject service. We however have reviewed that a set of test cases for the subject service for off-line testing are successful. This set of test cases could be used as the original test cases for online testing according to our approach. We refer this set of test cases to as the set of original test cases in the experiment.
- A faulty application (the subject service with a faulty version of the supportive services) simulates an online testing environment. A faulty version of the supportive services is not identical in behavior to its original counterpart (the test stub used in the off-line testing). The six faulty versions therefore facilitate us to re-use the above set of original test cases yet provide failed test results for some of the elements. This allows us to compare the effect of failed original test cases. In order to avoid biases towards a particular faulty implementation, we put all original test cases and their results of the faulty versions in the same pool for analysis and treat them homogenously.

In total, we executed 22,503 follow-up test cases and also 22,503 original test cases. These two figures are the same because we use metamorphic relations with two input-output pairs in this experiment. For the original version, we execute 3,987 pairs of test cases, and for each faulty version, we execute 3,086 pairs of test cases. To facilitate us to evaluate the effectiveness of test cases, we also mark every test case to be successful or failed, according to the expected result of the arithmetic expression. The result is shown in the next section.

Empirical Results

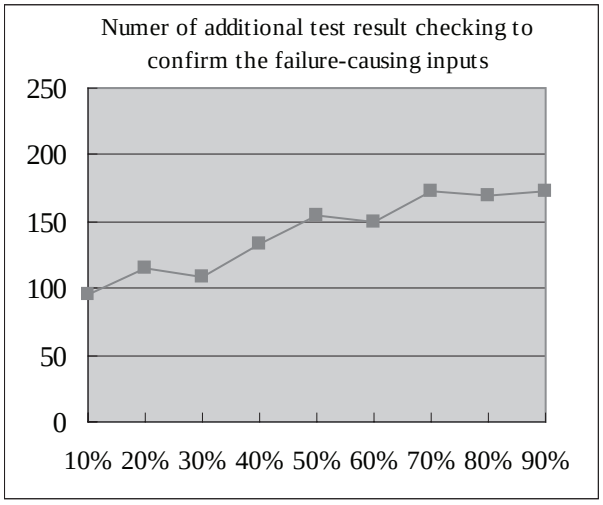
In this section, we will present the empirical results of the experiment and discuss our observations from the results. In summary, our experimental result shows that our approach uses 16% less in terms of effort to detect 13% more in terms of failures, compared to the control experiment having no prior confirmation of test results of original test cases.

We first analyze the overhead, including failed original test cases for online testing. According to the previously mentioned experimental setup, we have collected a pool of 18,516 (= 3,086 × 6) pairs of test cases from the six faulty versions. Some of the pairs contain failed original test cases. We evenly partition the pool into 18 groups so that each group consists of around 1,000 test cases. For the i-th group (for i = 1 to 18), we use database queries to help us randomly draw around 5i percent of its elements having failed original test cases and all elements having successful original test cases to calculate the overhead in terms of test result checking. The total number of elements drawn from each group is shown in Table 1.

Table 1. No. of elements drawn from selected groups

Group	2	4	6	8	10	12	14	16	18	Total
Percentages of failed test cases drawn	10%	20%	30%	40%	50%	60%	70%	80%	90%	-
No. of elements drawn	767	791	809	839	885	904	945	973	997	7,910

Figure 3. The overheads for different percentages of failed original test cases



The calculation of the *overhead* of a test pair is as follows.

- If no violation of the associated metamorphic relation is detected, then the overhead value is zero. It is because the test pair cannot reveal any failure.
- If a violation of the associated metamorphic relation is detected, then the overhead value is equal to the number of actual failure-causing test case(s) in the test pair. In other words, if both test cases are failure-causing inputs, the overhead value will be two; otherwise, it will be one.

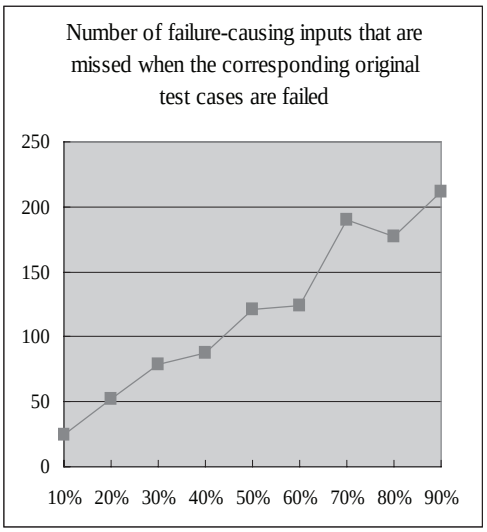
We further define that the number of additional test result checking to confirm the failure-causing inputs for a set of test pairs, denoted by Ω, is the sum of the overhead of every test pair in the set.

Figure 3 shows the value of Ω for 10%, 20% and up to 90% of total number of the failed original test cases of a group for the calculation. The mean value is 141 and the standard derivation is 29.4. (We are aware that there are inadequate numbers of data to calculate a good standard derivation statistically. We show the value just to give readers an impression about the skewness of data set.)

As expected, the value of Ω increases when the percentage increases. When more failed original test cases are added to a set for the calculation of Ω, the chance to detect a failure increases.

However, as we increase the number of test cases from 762 (for group 2) to 997 (for group 18), the change in Ω is moderate and is equal

Figure 4. The number of missed detection of failure-causing inputs



to 77 (= 173 – 96). When around 10% of failed original test cases are included, the value of Ω is 96. This initial value, 96, is even larger than the cumulated change, 77, increasing the percentages from 10% to 90%.

It confirms our assertion that the inclusion of small percentages of failed original test cases for the online testing of a service accounts for a major source of overhead in terms of additional test result checking. This substantiates our recommendation of using successful original test cases only for online testing to alleviate the test oracle problem.

We also observe that the overall percentage is not high. The mean is 15.9%. It suggests that even testers had to include inevitably some failed original test cases; measures should be taken to minimize such an inclusion.

We further examine the chance that we would miss to detect a failure if some failed original test cases are used for online testing. In our experiment, we use simple equations (instead of inequality) as metamorphic relations deliberately. We recall that, in our methodology, an original test case is known to be successful. It follows that any failure detected by the metamorphic testing approach would be due to the failure of the follow-up test case. On the other hand, when no violation of a metamorphic relation (in the form of equation) could be detected, the follow-up test case will be regarded as successful in the experiment.

For a set of test pairs, we define ω as the number of test pairs that each pair consists of one failed original test case and one follow-up test case, and at the same time, the associated metamorphic relation cannot detect the failure. The ω thus measures the missed opportunities to detect failures for online testing.

We also use the data sets reported in Table 1 to calculate ω for each group. The results are shown in Figure 4. The mean value is 118.7, that is, 13% of all failure-causing cases. The corresponding standard derivation is 64.2. The minimum is 25 for Group 2 (that is, the 10% group) and the maximum is 212 for Group 18 (that is, the 90% group).

The trend of missed detection of failures ω is increasing as the percentage of failed original test cases included in a group increases. Moreover, the number of missed detection appears proportional to the percentages of failed original test cases in the data set. This observation looks interesting and warrants further investigations.

RELATED WORK

Literatures on function testing research for SOA applications or Web services are not plenty. Bloomberg (2002) overviews a few major types of testing activity for testing Web services. We refer interested readers to the work of Bloomberg (Bloomberg, 2002) for the overview. In the rest of the section, we review selected related work on providing tools for testing, exception handling testing, generation of test cases and test result evaluation for service-oriented programs.

The use of the testing tool is an indispensable part to automate testing activities. Dustar and Haslinger (2004) propose to develop an experimental testing tool prototype to conduct batch mode and online mode testing. Their tool is reported to expect to handle several types of testing such as functional test and reliability test. Deng et al., (2004) extend AGENDA, a database application testing tool that populates database instances as a part of a test case, to test Web-based database applications. Rather than populating test database instances, SOATest (Parasoft, 2005) also reads data from different data sources to conduct testing. On the Internet, there are quite a few tools to conduct load and stress tests for Web services. Their discussions are not within the scope of this article.

To generate test cases, Offutt and Xu (2004) propose a set of mutation operators to perturb messages of Web services. They also suggest three types of rules to develop test cases based on the XML schema of messages. Their initial result on a sample application shows that 78% of seeded faults can be revealed. These faults include communication faults in SOAP, faults in statements for database query languages and conventional faults. The mutated messages could be considered as a method to construct follow-up test cases in the sense of metamorphic testing. Their empirical study of their approach is valuable. Rather than injecting faults to messages, Looker and Xu (2003) inject faults in SOAP-based programs to test the programs for robustness.

Chen et al., (2004a) also aim at testing for robustness. They focus on testing the exception handling of Java Web services through a data flow coverage approach. They propose to inject faults to system calls to trigger exception throws and require test cases to cover the exception-oriented def-use relations. Through their subject programs are Java-based Web service program; their techniques are not specialized to services testing.

Tsai et al., (2004, 2005) propose an approach to testing Web services that each service has multiple implementations with the same intended functionality. They apply test cases to a set of implementations of the same intended functionality progressively. Their test results are ranked by a majority voting strategy to assign a winner as the test oracle. A small set of winning implementations is selected for the integration testing purpose. At an integration testing level, they follow the same approach except using a weighted version of the majority voting strategy instead. To deal with the test case selection problem, their research group (Tsai et al., 2002a) proposes to generate test cases based on WSDL. Although WSDL-based testing has been proposed for a few years and implemented in testing tools such as SOATest (Parasoft, 2005), their version of WSDL (Tsai et al., 2002b) extends the standardized WSDL (W3C, 2001) to include features to express semantics. It is not difficult to use other voting strategies instead of the majority voting strategy in their approach.

The advantages of semantics checking are also observed by other researchers. An immediate example is our adaptation of metamorphic relation in this article. Keckel and Lohmann (2005), on the other hand, propose to apply the notion of design by contract to conduct testing for Web services. They suggest defining formal contracts to describe the behavior of functions and interactions of Web services. Based on the

contracts, combinatorial testing is suggested to apply to conduct conformance testing against the contracts of intended services.

Our approach uses metamorphic relations to construct follow-up test cases. It is not a fault-based approach; whereas Looker and Xu (2003) suggest a fault-based approach to testing for program robustness. In addition, unlike the work of Offutt and Xu (2004), these follow-up test cases in our approach are intentional to allow automated test result evaluations. A follow-up test case triggers a service to produce an output. The output of a follow-up test case is allowed to be different from the output of the original test case. Hence, it can be applied to configurations when multiple implementations of the same functionality are too expensive to be used. This distinguishes our work from Tsai et al., (2005). Our approach checks test results amongst themselves; whereas the work of Keckel and Lohmann (2005) checks the test results against some formal contract specifications. Chen et al., (2004a) is a white-box-centric approach; whereas ours is a black-box-centric approach. The tools (Dustar & Haslinger, 2004; Parasoft, 2005) appear to be developed as an integrated testing tool that includes a number of different testing modules. Their architectures are unclear to us at this moment. Our metamorphic service is an access wrapper to facilitate off-line and online testing of a service. We aim at reducing the amount of non-core elements from our metamorphic service. In this way, when exposing the function to other services, we would like to develop the approach further so that it enjoys a good scalability.

DISCUSSION

We have presented an approach to online testing and an experiment on a simple application to study metamorphic testing for services testing in the previous sections. The approach is useful for the online testing of a service if testers have difficulties to obtain the expected results of a test case in a cost-effective manner. The test oracle problem has been identified for many years (see also (Beizer, 1990)). In practice, many testers validate their software without a formal test oracle. Metamorphic testing is an approach towards the problem when a metamorphic relation exists and could be identified. We believe that this trend will continue for services testing.

In the rest of this section, we discuss the threat to validity of the experiment. The evaluation of using the metamorphic testing approach for services testing in the online mode is conducted in a small application. The application domain of the subject application is generic that it uses the basic computing functionality, namely a fundamental set of arithmetic operations and basic (communicative and associative) properties to define metamorphic relations. It is unknown about the impact on the results when certain domain-specific knowledge is taken into account to both define metamorphic relations and selections of test cases. We merely use a small number of faulty versions to conduct the experiment to discuss our findings. The statistics may be different if other faulty versions are used. Our subject program does contain real faults and hence some metamorphic relation instances are violated even if the original version is used. We believe that it is common for a typical testing of a newly-coded software program. However, the assumption is not valid if other rigorous quality assurance techniques such as rigorous regressions, code inspections or formal methods have been applied to a software development project. We have evaluated our approach on the Microsoft .NET 2003 platform only. The present implementation of the subject program is not portable to other platforms. There is a threat to interpret the empirical results in other configurations. We have reviewed the set test cases and the set follow-up test cases, and use a commercial spreadsheet to help us to check whether the target relation is maintained in the reviewed samples.

CONCLUSIONS AND FUTURE WORK

Testing services in a services-computing environment needs to deal with a number of issues. They include: (i) The unknown communication partners until the service discovery; (ii) the imprecise black-box information of software components; (iii) the potential existence of non-identical implementations of the same service; and (iv) the expected behavior of a service potentially depending on the behavior of competing services. In this article, we treat a service as a reusable software module with a well-defined function. A service can introduce itself so that other services can discover and use the service. Services communicate amongst themselves through well-defined messages and interfaces. A message is an input or an output of a service.

We have presented a testing approach to the online testing support of service-oriented applications. We formulate the notion of metamorphic service; the service that has the characteristics of being an access wrapper, the wrapper encapsulates the access for the service under test and implements the metamorphic testing approach. We also propose to use the successful test case for off-line testing as the original test case for online testing, as test oracle is much more likely to be available for off-line testing. Using our online testing methodology, testers builds a bridge between the test oracle available in the off-line testing mode and the test oracle problem encountered in the online testing mode. The services approach to conducting an online test alleviates the problem (i). It delays the binding of communication partners of the follow-up test cases after service discovery. Our realization of the metamorphic testing approach alleviates the problems (ii), (iii) and (iv).

We have also conducted an experiment to evaluate the feasibility of our proposal. The experimental results encouragingly indicate that, on average, when the set of original test cases are unknown to be successful, an extra 16% effort to check test results and a 13% reduction of failure detection are observed. This supports our proposal that original test cases should be (much) better to be successful, particularly when the checking is (much) less costly when it can be conducted in the off-line testing mode.

There are quite a number of future directions of research. We have not evaluated our proposal extensively. We plan to conduct more experiments. The way to control the chain reaction of the follow-up test cases generations due to interferences of multiple metamorphic services warrants more researches. We also plan to measure the degree of code coverage or fault coverage of our approach.

ACKNOWLEDGMENT

We would like to thank the program co-chairs of The First International Workshop on Services Engineering (SEIW 2005) for inviting us to extend the preliminary version (Chan et al., 2005a) to contribute to the special issue. We would also like to thank anonymous reviewer of the article. Special thanks should be given to Mr. Kwong–Tim Chan, Mr. Hoi-Shun Tam, Mr. Kwun-Ting Lee, Mr. Yuk-Ching Lam and Mr. King–Lun Yiu of the Hong Kong Institute of Vocational Education (Tsang Yi) who do the experiments presented in this article. Part of the research was done when Chan was with The University of Hong Kong. This research is supported by grants of the Research Grants Council of Hong Kong (Project Nos. HKUST 6170/04E and CITYU1195/03E).

Chapter 7.18
Deductive Semantics of RTPA

Yingxu Wang
University of Calgary, Canada

ABSTRACT

Deductive semantics is a novel software semantic theory that deduces the semantics of a program in a given programming language from a unique abstract semantic function to the concrete semantics embodied by the changes of status of a finite set of variables constituting the semantic environment of the program. There is a lack of a generic semantic function and its unified mathematical model in conventional semantics, which may be used to explain a comprehensive set of programming statements and computing behaviors. This article presents a complete paradigm of formal semantics that explains how deductive semantics is applied to specify the semantics of real-time process algebra (RTPA) and how RTPA challenges conventional formal semantic theories. Deductive semantics can be applied to define abstract and concrete semantics of programming languages, formal notation systems, and large-scale software systems, to facilitate software comprehension and recognition, to support tool development, to enable semantics-based software testing and verification, and to explore the semantic complexity of software systems. Deductive semantics may greatly simplify the description and analysis of the semantics of complicated software systems specified in formal notations and implemented in programming languages.

INTRODUCTION

Semantics in linguistics is a domain that studies the interpretation of words and sentences, and analysis of their meanings. Semantics deals with how the meaning of a sentence in a language is obtained, hence the sentence is comprehended. Studies on semantics explore mechanisms in the understanding of languages and their meanings on the basis of syntactic structures (Chomsky, 1956,

1957, 1959, 1962, 1965, 1982; Tarski, 1944).

Software semantics in computing and computational linguistics have been recognized as one of the key areas in the development of fundamental theories for computer science and software engineering (Bjoner, 2000; Gries, 1981; Hoare, 1969; McDermid, 1991; Slonneg & Kurts, 1995; Wang, 2006b, 2007c). The semantics of a programming language is the behavioral meaning that constitute what a syntactically correct instructional statement in the language is supposed to do during run time. The development of formal semantic theories of programming is one of the pinnacles of computing and software engineering (Gunter, 1992; Meyer, 1990; Louden, 1993; Bjoner, 2000; Pagan, 1981).

Definition 1. *The semantics of a program in a given programming language is the logical consequences of an execution of the program that results in the changes of values of a finite set of variables and/or the embodiment of computing behaviors in the underpinning computing environment.*

A number of formal semantics, such as the *operational* (Marcotty & Ledgard, 1986; Ollongren, 1974; Wegner, 1972; Wikstrom, 1987), *denotational* (Bjorner and Jones, 1982; Jones, 1980; Schmidt, 1988, 1994, 1996; Scott, 1982; Scott & Strachey, 1971), *axiomatic* (Dijktra, 1975, 1976; Gries, 1981; Hoare, 1969), and *algebraic* (Goguen, Thatcher, Wagner, & Wright, 1977; Gougen & Malcolm, 1996; Guttag & Horning, 1978), have been proposed in the last three decades for defining and interpreting the meanings of programs and programming languages. The classic software semantics are oriented on a certain set of software behaviors that are limited at the level of language statements rather than that of programs and software systems. There is a lack of a generic semantic function and its unified mathematical model in conventional semantics, which may be used to explain a comprehensive set of programming statements and computing behaviors. The mathematical models of the target machines and the semantic environments in conventional semantics seem to be inadequate to deal with the semantics of complex programming requirements, and to express some important instructions, complex control structures, and the real-time environments at run time. For supporting systematical and machine enabled semantic analysis and code generation in software engineering, the *deductive semantics* is developed that provides a systematic semantic analysis methodology.

Deduction is a reasoning process that discovers new knowledge or derives a specific conclusion based on generic premises such as abstract rules or principles (Wang, 2006b, 2007a, 2007c). The nature of semantics of a given programming language is its computational meanings or embodied behaviors expressed by an instruction in the language. Because the carriers of software semantics are a finite set of variables declared in a given program, program semantics can be reduced onto the changes of values of these variables over time. In order to provide a rigorous mathematical treatment of both the abstract and concrete semantics of software, a new type of formal semantics known as the deductive semantics is presented.

Definition 2. *Deductive semantics is a formal semantics that deduces the semantics of a program in a given programming language from a generic abstract semantic function to the concrete semantics, which are embodied onto the changes of status of a finite set of variables constituting the semantic environment of computing.*

This article presents a comprehensive theory of deductive semantics of software systems. The mathematical models of deductive semantics and the fundamental properties are described. The deductive models of semantics, semantic function, and semantic environment at various composing levels of programs are introduced. Properties of software semantics and relationships between

the software behavioral space and the semantic environment are studied. New methods such as the semantic differential and semantic matrix are developed to facilitate deductive semantic analyses from a generic semantic function to a specific semantic matrix, and from semantics of statements to those of processes and programs. The establishment of the deductive semantic rules of RTPA (Wang, 2002, 2003, 2006a, 2006b, 2007a, 2007b, 2008a, 2008b) is described, where the semantics of a comprehensive set of processes is systematically modeled.

THE THEORY OF DEDUCTIVE SEMANTICS

This section presents the theory of deductive semantics (Wang, 2006b, 2007c). A generic mathematical model of deductive semantics of software is developed, and the concepts of semantic environment and semantic function are rigorously defined. Based on them, deductive semantics of programs at different composition levels are rigorously modeled. Then, common properties of software semantics are analyzed.

The Semantic Environment and Semantic Function

Definition 3. *A semantic environment* Θ *of a programming language is a logical model of a set of identifiers I and their values V bound in pairs, i.e.:*

$$\begin{aligned}\Theta &\triangleq f: I \to V, V \subseteq \mathbb{R} \\ &= \{\mathop{R}_{k=1}^{\#I}(i_k, v_k)\} \\ &= \{(i_1, v_1), (i_2, v_2), ..., (i_{\#I}, v_{\#I})\}\end{aligned} \quad (1)$$

where $\mathbb{R}$ is the set of real numbers, $i_k \in I$, $v_k \in V \subseteq \mathbb{R}$, and *#I* the number of elements in *I*.

Note the big-R notation is adopted to denote a set of recurring structures or repetitive behaviors (Wang, 2002, 2007c, 2008a). The semantic environment constituting the behaviors of software is inherently a three dimensional structure known as those of operations, memory space, and time.

Definition 4. *The behavioral space* Ω *of a program executed on a certain machine is a finite set of variables operated in a 3-D state space determined by a triple, i.e.:*

$$\Omega \triangleq (OP, T, S) \quad (2)$$

where *OP* is a finite set of *operations*, *T* is a finite set of discrete *time* points of program execution, and *S* is a finite set of *memory locations* or their logical representations by *identifiers* of variables.

According to Definitions 3 and 4, the set of *variables* of a program, *S*, plays an important role in semantic modeling and analysis, because they are the objects of software behavioral operations and the carriers of program semantics. Variables can be classified as *free* and *system* variables. The former are user defined and the latter are language provided. From a functional point of view, variables can be classified into *object representatives*, *control variables*, *result containers*, and *address locaters*. The life spans or scopes of variables can be categorized as *persistent*, *global*, *local*, and *temporal*. The persistent variables are those that their lifespan are longer than the program that generates them, such as data in a database or files in a distributed network.

A new calculus introduced in deductive semantics is the *partial differential of sets* (Wang, 2006b, 2007c), which is used to facilitate the instantiation of abstract semantics by concrete ones, as described below.

Definition 5. *Given two sets X and U,* $X \subseteq \wp U$*, a partial differential of X on U with elements x,* $x \in$

X, denoted by ∂U/∂x, is an elicitation of interested elements from U as specified in X, i.e.:

$$\frac{\partial U}{\partial x} \triangleq X \cap U, \ x \in X$$
$$= X, \ X \subseteq \text{Þ}U \tag{3}$$

where Þ*U* denotes a power set of *U*.

The partial differential of sets can be easily extended to double, triple, or more generally, multiple partial differentials as defined below.

Definition 6. *A multiple partial differential of X_1, X_2, …, and X_n on ÞU with elements $x_1 \in X_1$, $x_2 \in X_2$, ..., and $x_n \in X_n$, denoted by*

$$\frac{\partial^n}{\partial x_1 \, \partial x_2 \ldots \partial x_n} U,$$

is a Cartesian product of all partial differentials that select interested elements from U as specified in X_1, X_2, …, and X_n, respectively, i.e.:

$$\frac{\partial^n}{\partial x_1 \, \partial x_2 \ldots \partial x_n} U \triangleq X_1 \times X_2 \times \ldots \times X_n \tag{4}$$

where $X_1, X_2, \ldots, X_n \subseteq \text{þ}U$ and $\forall i \neq j$, $l \leq i, j \leq n$, $X_i \cap X_j = \varnothing$.

For example,

$$\frac{\partial^2}{\partial \text{x} \, \partial \text{y}} U = X \times Y, \ x \in X, y \in Y, \text{and } X, Y \subseteq \text{þ}U$$

and

$$\frac{\partial^3}{\partial \text{x} \, \partial \text{y} \, \partial z} U = X \times Y \times Z, x \in X, y \in Y, x \in X, \text{and } X, Y, Z \subseteq \text{þ}U.$$

On the basis of the definitions of software behavioral space and partial differential of sets, the semantic environment of software can be formally described.

Definition 7. *The semantic environment Θ of a program on a certain target machine is its run-time behavioral space Ω projected onto the Cartesian plane determined by T and S, i.e.:*

$$\Theta = \frac{\partial^2 \Omega}{\partial t \, \partial s}, \ t \in T \wedge s \in S$$
$$= \frac{\partial^2 \Omega}{\partial t \, \partial s}(OP, T, S)$$
$$= T \times S \tag{5}$$

As indicated in Definition 7, the semantic environment of a program is a dynamic space over time, because following each execution of a statement in the program, the semantic environment Θ, particularly the sets of variables *S* and their values *V*, may be changed.

In semantic analysis, the changed part of the semantic environment Θ is particularly interested, which is the embodiment of software semantics. A generic semantic function is developed below, which can be used to derive a specific and concrete semantic function for a given statement, process, or program by mathematical deduction.

Definition 8. *A semantic function of a program ℘, $f_\theta(\wp)$, is a function that maps the semantic environment Θ into a finite set of values V determining by a Cartesian product on a finite set of executing steps T and a finite set of variables S, i.e.:*

$$f_\theta(\wp) \triangleq f : T \times S \to V =$$
$$\begin{pmatrix} & \mathbf{s_1} & \mathbf{s_2} & \cdots & \mathbf{s_m} \\ \mathbf{t_0} & \perp & \perp & \cdots & \perp \\ \mathbf{t_1} & v_{11} & v_{12} & & v_{1m} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{t_n} & v_{n1} & v_{n1} & \cdots & v_{nm} \end{pmatrix} \tag{6}$$

where $T = \{t_0, t_1, \ldots, t_n\}$, $S = \{s_1, s_2, \ldots, s_m\}$, and V is a finite set of values $v(t_i, s_j)$, $0 \leq i \leq n$, and $1 \leq j \leq m$.

In Equation 6, all values of $v(t_i, s_j)$ at t_0 is undefined for a program as denoted by the bottom symbol $\perp$, i.e. $v(0, s_j) = \perp$, $1 \le j \le m$. However, for a statement or a process, it is usually true that $v(0, s_j) \neq \perp$ dependent on the context of previous statement(s) or the initialization of the system.

According to Definitions 7 and 8, the semantic environment and the domain of a semantic function can be illustrated by a semantic diagram as described below (Wang, 2006b, 2007c).

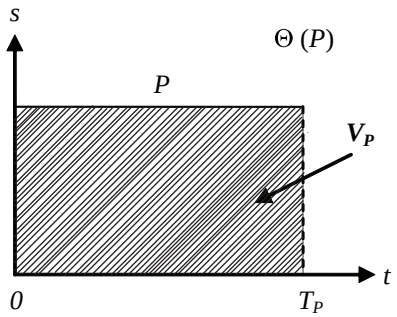
Definition 9. *A semantic diagram is a sub Cartesian-plane in the semantic environment* Θ *that forms the domain of the semantic function for a given process P with* $f_\theta(P) = f: T_P \times S_P \rightarrow V_P$.

For example, the semantic diagram of an abstract process *P*, $f_\theta(P)$, as defined in Definition 9 can be illustrated in Figure 1, where V_P is the domain of dynamic variable values of process *P* over time, i.e., $V_P = T_P \times S_P$. The semantic diagram of two sequential processes, $P \rightarrow Q$, can be referred to Figure 3.

The semantic diagram can be used to analyze complex semantic relations, and to demonstrate semantic functions and their semantic environments. Observing Figures 1 and 3, the flowing properties of process relations can be derived.

Lemma 1. *The variables of two arbitrary processes P and Q,* S_P *and* S_Q*, in the semantic environment* Θ *possess the following properties:*

Figure 1. The semantic diagram of a process



a. *The entire set of variables:*

$$S = S_P \cup S_Q \tag{7}$$

b. *Global variables:*

$$S_G \subseteq S_P \cap S_Q \tag{8}$$

c. *Local variables:*

$$S_L = S - S_G,\ S_L \subseteq S_P \oplus S_Q,$$

where $S_{Lp} = S_L \setminus S_Q$ *and* $S_{Lq} = S_L \setminus S_P$

(9)

Deductive Semantics of Programs at Different Levels of Compositions

According to the generic model and the hierarchical architecture of programs, the semantics of a program in a given programming language can be described and analyzed at various composition levels, such as those of *statement*, *process*, and *system* from the bottom-up (Wang, 2007c, 2008b).

Definition 10. *The semantics of a statement p,* $\theta(p)$*, on a given semantic environment* Θ *is a double partial differential of the semantic function* $f_\theta(p)$ *on executing steps T and the set of variables S, i.e.:*

$$\begin{aligned}
\theta(P) &\triangleq \underset{\#T(p)\ \#S(p)}{\frac{\partial^2}{\partial t\ \partial s}} f_\theta(p) \\
&= \underset{i=0}{\overset{1}{R}} \left(\underset{j=1}{\overset{\#\{s_1, s_2, \ldots, s_m\}}{R}} v_p\ t_i, s_j \right) \\
&= \underset{i=0}{\overset{1}{R}} \left(\underset{j=1}{\overset{\#\{s_1, s_2, \ldots, s_m\}}{R}} v_p\ t_i, s_j \right) \\
&= \begin{pmatrix} & \mathbf{s_1} & \mathbf{s_2} & \cdots & \mathbf{s_m} \\ \mathbf{t_0} & v_{01} & v_{02} & \cdots & v_{0m} \\ (\mathbf{t_0}, \mathbf{t_1}] & v_{11} & v_{12} & \cdots & v_{1m} \end{pmatrix}
\end{aligned} \tag{10}$$

where t denotes the discrete time immediately before and after the execution of p during (t_0, t_1), and # is the cardinal calculus that counts the number of elements in a given set, i.e. n = #T(p) and m=#S(p).

In Definition 10, the first partial differential selects all related variable $S(p)$ of the statement p from Θ. The second partial differential selects a set of discrete steps of p's execution $T(p)$ from Θ. According to Definition 10, the semantics of a statement can be reduced onto a semantic function that results in a 2-D matrix with the changes of values of all variables over time of program execution.

On the basis of Definitions 8 and 10, semantics of individual statements can be analyzed using Equation 10 in a deductive process.

Example 1. *Analyze the semantics of Statement 3, $\theta(p_3)$, in the following program entitled sum:*

```
void sum;
{
  (0) int x, y, z;
  (1) x = 8;
  (2) y = 2;
  (3) z := x + y;
}
```

According to Definition 10, the semantics of Statement p_3 is as follows:

$$\begin{aligned}\theta(p_3) &= \frac{\partial^2}{\partial t\,\partial s} f_\theta(p_3) \\ &= \mathop{R}_{i=2}^{3} (\mathop{R}_{j=1}^{\#S(p_3)} v_{p_3}\ t_i, s_j) \\ &= \mathop{R}_{i=2}^{3} (\mathop{R}_{j=1}^{\#\{x,y,z\}} v_{p_3}\ t_i, s_j) \\ &= \begin{pmatrix} & \mathbf{x} & \mathbf{y} & \mathbf{z} \\ \mathbf{t_2} & 8 & 2 & \perp \\ \mathbf{(t_2, t_3]} & 8 & 2 & 10 \end{pmatrix}\end{aligned} \tag{11}$$

This example shows how the concrete semantics of a statement can be derived on the basis of the generic and abstract semantic function as given in Definition 10.

Definition 11. *The semantic effect of a statement p, $\theta^*(p)$, is the resulted changes of values of vari-*

Box 1.

$$\begin{aligned}\theta^*(p) &= \mathop{R}_{j=1}^{\#S(p)} (v_p(t_i, s_j) \oplus v_p(t_{i+1}, s_j)) \\ &= \mathop{R}_{j=1}^{\#S(p)} < v_p(t_i, s_j) \to v_p(t_{i+1}, s_j) \mid v_p(t_i, s_j) \neq v_p(t_{i+1}, s_j) >\end{aligned} \tag{12}$$

Box 2.

$$\begin{aligned}\theta^*(p_3) &= \mathop{R}_{j=1}^{\#S(p_3)} < v_{p_3}(t_2, s_j) \to v_{p_3}(t_3, s_j) \mid v_{p_3}(t_2, s_j) \neq v_{p_3}(t_3, s_j) > \\ &= \mathop{R}_{j=1}^{\#(x,y,z)} < v_{p_3}(t_2, s_j) \to v_{p_3}(t_3, s_j) \mid v_{p_3}(t_2, s_j) \neq v_{p_3}(t_3, s_j) > \\ &= \{< v_{p_3}(t_2, z) = \perp \ \to v_{p_3}(t_3, z) = 10 >\}\end{aligned}$$

ables by its semantic function θ(p) during the time interval immediately before and after the execution of p, Δt = (t_i, t_{i+1}), see Box 1, where → denotes a transition of values for a given variable.

Example 2. *For the same statement p_3 as given in Example 1, determine its semantic effect θ*(p_3).*

According to Equation 12, the semantic effect θ*(p_3) is seen in Box 2.

It is noteworthy in Examples 1 and 2 that deductive semantics can be used not only to describe the *abstract* and *concrete* semantics of programs, but also to elicit and highlight their semantic effects.

Considering that a program or a process is composed by individual statements with given rules of compositions, the definition and mathematical model of deductive semantics at the statement level can be extended onto the higher levels of program hierarchy.

Definition 12. *The semantics of a process P, θ(P), on a given semantic environment Θ is a double partial differential of the semantic function $f_\theta(\boldsymbol{P})$ on the sets of variables S and executing steps T, see Box 3, where $\mathbf{V}_{\mathbf{p}_k}$, 1≤ k ≤ n-1, is a set of values of local variables that belongs to processes P_k, and $\mathbf{V}_G$ is a finite set of values of global variables.*

On the basis of Definition 12, the semantics of a program at the top-level composition can be deduced to the combination of the semantics of a set of processes, each of which can be further deduced to the composition of all statements' semantics as described below.

Definition 13. *The semantics of a program ℘, θ(℘), on a given semantic environment Θ, is a combination of the semantic functions of all processes θ(P_k), 1≤ k ≤ n, i.e.:*

$$\begin{aligned}\theta(\wp) &= \mathop{R}_{k=1}^{\#K(\wp)} \frac{\partial^2}{\partial t\,\partial s} f_\theta(\wp) \\ &= \mathop{R}_{k=1}^{\#K(\wp)} \theta(P_k) \\ &= \mathop{R}_{k=1}^{\#K(\wp)} [\mathop{R}_{i=0}^{\#T(P_k)} (\mathop{R}_{j=1}^{\#S(P_k)} v_{P_k}(t_i, s_j))]\end{aligned} \tag{14}$$

where #*K*(℘) is the number of processes or components encompassed in the program.

It is noteworthy that Equation 14 will usually result in a very large matrix of semantic space,

Box 3.

$$\begin{aligned}\theta(P) &= \frac{\partial^2}{\partial t\,\partial s} f_\theta(P) \\ &= \mathop{R}_{k=1}^{n-1} \{[\frac{\partial^2}{\partial t\,\partial s} f_\theta(P_k)]\, r_{kl}\, [\frac{\partial^2}{\partial t\,\partial s} f_\theta(P_l)]\}, l = k+1 \\ &= \mathop{R}_{k=1}^{n-1} \{[\mathop{R}_{i=0}^{\#T(P_k)} \mathop{R}_{j=1}^{\#S(P_k)} v_{P_k}(t_i, s_j)]\, r_{kl}\, [\mathop{R}_{i=0}^{\#T(P_l)} \mathop{R}_{j=1}^{\#S(P_l)} v_{P_l}(t_i, s_j)]\} \\ &= \begin{pmatrix} \mathbf{V}_{\mathbf{p}_1} & & & \mathbf{V}_G \\ & \mathbf{V}_{\mathbf{p}_2} & & \mathbf{V}_G \\ & & \ddots & \vdots \\ & & \mathbf{V}_{\mathbf{p}_{n-1}} & \mathbf{V}_G \end{pmatrix}\end{aligned} \tag{13}$$

which can be quantitatively predicated as follows.

Definition 14. *The semantic space of a program $S_\Theta(\wp)$ is a product of $\#S(\wp)$ variables and $\#T(\wp)$ executing steps, i.e.:*

$$S_\Theta(\wp) = \#S(\wp) \bullet \#T(\wp) = \sum_{k=1}^{\#K(\wp)} \#S(\wp_k) \bullet \sum_{k=1}^{\#K(\wp)} \#T(\wp_k) \quad (15)$$

The semantic space of programs provides a useful measure of software complexity. Due to the tremendous size of the semantic space, both program composition and comprehension are innately a hard problem in terms of complexity and cognitive difficulty.

Properties of Software Semantics

Observing the formal definitions and mathematical models of deductive semantics developed in previous subsections, a number of common properties of software semantics may be elicited, which are useful for explaining the fundamental characteristics of software semantics.

One of the most interesting characteristics of program semantics is its invariance against different executing speeds as described in the following theorem.

Theorem 1. *The asynchronicity of program semantics states that the semantics of a relatively timed program is invariant with the changes of executing speed, as long as any absolute time constraint is met.*

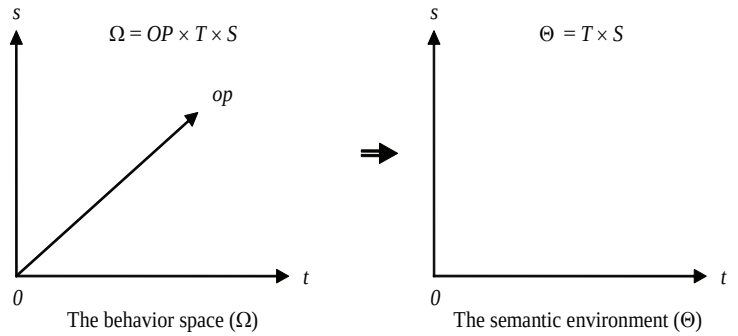
Theorem 1 asserts that, for most non real-time or relatively timed programs, different executing speeds or simulation paces will not alter the semantics of the software system. This explains why a programmer may simulate the run-time behaviors of a given program executing at a speed of up to 10^9 times faster than that of human beings. It also explains why computers with different system clock frequencies may correctly run the same program and obtain the same behavior.

Definition 15. *The behavior of a computational statement is a set of observable actions or changes of status of objects operated by the statement.*

According to Definition 4, the behavioral space of software, Ω, is three dimensional, while as given in Definition 7, the semantic environment Θ is two dimensional. Therefore, to a certain extent, semantic analysis is a projection of the 3-D software behaviors into the 2-D semantic environment Θ as shown in Figure 2.

The theory of deductive semantics can be systematically applied to formally and rigorously model and describe the semantics of the RTPA

Figure 2. Relationship between software behavior space and the semantic environment



metaprocesses and the *process relations* (operations). On the basis of the mathematical models and properties of deductive semantics, the following sections formally describe a comprehensive set of RTPA semantics, particularly the 17 metaprocesses and the 17 process relations (Wang, 2002, 2003, 2007c, 2008a, 2008b). This work extends the coverage of semantic rules of programming languages to a complete set of features that encompasses both basic computing operations and their algebraic composition rules. Because RTPA is a denotational mathematical structure based on process algebra that covers a comprehensive set of computing and programming requirements, any formal semantics that is capable to process RTPA is powerful enough to express the semantics of any programming language.

DEDUCTIVE SEMANTICS OF RTPA METAPROCESSES

Metaprocesses of RTPA are elicited from basic computational requirements. Complex processes can be composed with multiple metaprocesses. RTPA identified 17 metaprocesses, $\mathfrak{P}$, on fundamental computing operations such as assignment, system control, event/time handling, memory and I/O manipulation, i.e., $\mathfrak{P}$ = {:=, ◆, ⇒, ⇐, ⇏, ⩾, ⩽, |⩾, |⩽, @, ≙, ↑, ↓, !, ⊗, ⊠, §}. Detailed descriptions of the metaprocesses of RTPA and their syntaxes may be referred to (Wang, 2002, 2007c, 2008b), where each metaprocess is a basic operation on one or more operands such as variables, memory elements, or I/O ports. Based on Definitions 8 and 12, the deductive semantics of the set of RTPA metaprocesses can be defined in the following subsections.

The Assignment Process

Definition 16. *The semantics of the assignment process on a given semantic environment* Θ, $\theta(y\mathrm{RT} := x\mathrm{RT})$*, is a double partial differential of the semantic function* $f_\theta(y\mathrm{RT} := x\mathrm{RT})$ *on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}\theta(y\mathrm{RT} := x\mathrm{RT}) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(y\mathrm{RT} := x\mathrm{RT}) \\ &= \mathop{R}_{i=0}^{\#T(y\mathrm{RT} := x\mathrm{RT})} \Big(\mathop{R}_{j=1}^{\#S(y\mathrm{RT} := x\mathrm{RT})} v\ t_i, s_j \Big) \\ &= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{2} v(t_i, s_j) \\ &= \begin{pmatrix} & x\mathrm{RT} & y\mathrm{RT} \\ \mathbf{t_0} & x\mathrm{RT} & \perp \\ \mathbf{(t_0, t_1]} & x\mathrm{RT} & x\mathrm{RT} \end{pmatrix}\end{aligned} \tag{16}$$

where the size of the matrix is #T • #S.

The Evaluation Process

Definition 17. *The semantics of the evaluation process on* Θ, $\theta(◆exp\mathbb{T} \to \mathbb{T})$*, is a double partial differential of the semantic function* $f_\theta(\theta(◆exp\mathbb{T} \to \mathbb{T})$ *on the sets of variables S and executing steps T in the following two forms, i.e.:*

$$\begin{aligned}\theta(◆(exp\mathrm{BL}) \to \mathrm{BL}) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(◆(exp\mathrm{BL}) \to \mathrm{BL}) \\ &= \mathop{R}_{i=0}^{\#T(◆exp\mathrm{BL}\to\mathrm{BL})} \mathop{R}_{j=1}^{\#S(◆exp\mathrm{BL}\to\mathrm{L})} v(t_i, s_j) \\ &= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{2} (v\ t_i, s_j) \\ &= \begin{pmatrix} & exp\mathrm{B} & ◆(exp\mathrm{BL})\mathrm{BL} \\ \mathbf{(t_0, t_1]} & \delta(exp\mathrm{BL})\mathrm{BL} & \perp \\ \mathbf{(t_1, t_2]} & \mathsf{T} & \mathsf{T} \\ \mathbf{(t_1, t_{2^-}]} & \mathsf{F} & \mathsf{F} \end{pmatrix}\end{aligned} \tag{17a}$$

or

$$\theta(\blacklozenge exp\mathbb{T} \to \mathbb{T}) \triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(\blacklozenge exp\mathbb{T} \to \mathbb{T})$$
$$= \overset{\#T(\blacklozenge exp\mathbb{T}\to\mathbb{T})}{\underset{i=0}{R}} \left(\overset{\#S(\blacklozenge exp\mathbb{T}\to\mathbb{T})}{\underset{j=1}{R}} v\ t_i, s_j \right)$$
$$= \overset{1}{\underset{i=0}{R}} \overset{2}{\underset{j=1}{R}} v(t_i, s_j)$$
$$= \begin{pmatrix} & exp\mathbb{T} & \blacklozenge(exp\mathbb{T})\mathbb{T} \\ \mathbf{(t_0, t_1]} & \delta(exp\mathbb{T})\mathbb{T} & \bot \\ \mathbf{(t_1, t_2]} & n\mathbb{T} & n\mathbb{T} \end{pmatrix}$$

(17b)

*where ◆(exp*BL*) is the Boolean evaluation function on expBL that results in* T *or* F*. ◆(exp*$\mathbb{T}$*) is a more general cardinal or numerical evaluation function on exp*$\mathbb{T}$ *that results in* $\mathbb{T}$ *= {*N*,* Z*,* R*,* B*}, i.e., in types of nature number, integer, real number, and byte, respectively (Wang, 2002).*

The Addressing Process

Definition 18. *The semantics of the addressing process on* Θ*,* θ*(id*S ⇒ *ptr*P*), is a double partial differential of the semantic function* f_θ*(id*S ⇒ *ptr*P*) on the sets of variables S and executing steps T, i.e.:*

$$\theta(id\mathrm{S} \Rightarrow ptr\mathrm{P}) \triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(\mathrm{idS} \Rightarrow \mathrm{ptrP})$$
$$= \overset{\#T(\mathrm{idS} \Rightarrow \mathrm{trP})}{\underset{i=0}{R}} \left(\overset{\#S(\mathrm{idS} \Rightarrow \mathrm{ptrP})}{\underset{j=1}{R}} v\ t_i, s_j \right)$$
$$= \overset{1}{\underset{i=0}{R}} \overset{2}{\underset{j=1}{R}} v(t_i, s_j)$$
$$= \begin{pmatrix} & \mathbf{id}\mathrm{S} & \mathbf{ptr}\mathrm{P} \\ \mathbf{t_0} & id\mathrm{S} & \bot \\ \mathbf{(t_0, t_1]} & id\mathrm{S} & \pi(id\mathrm{S})\mathrm{H} \end{pmatrix}$$

(18)

where π*(id*S*)*H *is a function that associates a declared identifier id*S *to its hexadecimal memory address located by the pointed ptr*P*.*

The Memory Allocation Process

Definition 19. *The semantics of the memory allocation process on* Θ*,* θ*(id*S ⇐ *MEM(ptr*P*)*RT*), is a double partial differential of the semantic function* f_θ*(id*S ⇐ *MEM(ptr*P*)*RT*) on the sets of variables S and executing steps T, see Box 4. Where* π*(id*S*)*H *is a mapping function that associates an identifier id*S *to a memory block starting at a hexadecimal address located by the pointed ptr*P*. The ending address of the allocated memory block, ptr*P*+size(*RT*)-1, is dependent on a machine implementation of the size of a given variable in type* RT*.*

The Memory Release Process

Definition 20. *The semantics of the memory release process on* Θ*,* θ*(id*S ⇍ *MEM(*⊥*)*RT*), is a double partial differential of the semantic function* f_θ*(id*S ⇍ *MEM(*⊥*)*RT*) on the sets of variables S and executing steps T, i.e.:*

$$\theta(id\mathrm{S} \nLeftarrow \mathrm{MEM}[\ \bot\ ]\mathrm{RT}) \triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(id\mathrm{S} \nLeftarrow \mathrm{MEM}[\ \bot\ ]\mathrm{RT})$$
$$= \overset{\#T(id\mathrm{S} \nLeftarrow \mathrm{MEM}[\bot]\mathrm{RT})}{\underset{i=0}{R}} \left(\overset{\#S(id\mathrm{S} \nLeftarrow \mathrm{MEM}[\bot]\mathrm{RT})}{\underset{j=1}{R}} v\ t_i, s_j \right)$$
$$= \overset{1}{\underset{i=0}{R}} \overset{3}{\underset{j=1}{R}} v(t_i, s_j)$$
$$= \begin{pmatrix} & \mathbf{id}\mathrm{RT} & \mathbf{ptr}\mathrm{P} & \mathbf{MEM}\mathrm{RT} \\ \mathbf{t_0} & (id\mathrm{S}) & \pi(id\mathrm{S})\mathrm{H} & \mathrm{MEM}(ptr\mathrm{P})\mathrm{RT} \\ \mathbf{(t_0, t_1]} & \bot & \bot & \bot \end{pmatrix}$$

(20)

The Read Process

Definition 21. *The semantics of the read process on* Θ*,* θ*(MEM(ptr*P*)*RT*⩾x*RT*), is a double partial differential of the semantic function* f_θ*(MEM(ptr*P*)*RT*⩾x*RT*) on the sets of variables S and executing steps T, see Box 5.*

Box 4.

$$\theta(\text{idS} \Leftarrow \text{MEM[ptrP]RT}) \triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(\text{idS} \Leftarrow \text{MEM[ptrP]RT})$$
$$= \mathop{R}_{i=0}^{\#T(\text{idS} \Leftarrow \text{MEM[ptrP]RT})} \left(\mathop{R}_{j=1}^{\#S(\text{idS} \Leftarrow \text{MEM[ptrP]RT})} v\ t_i, s_j \right)$$
$$= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{3} v(t_i, s_j)$$
$$= \begin{pmatrix} & \textbf{id}\text{S} & \textbf{ptr}\text{P} & \textbf{MEM}\text{RT} \\ \mathbf{t_0} & id\text{S} & \perp & \perp \\ \mathbf{(t_0, t_1]} & id\text{S} & \pi(id\text{S})\text{H} & \text{MEM}[ptr\text{P}]\text{RT} \end{pmatrix} \tag{19}$$

Box 5.

$$\theta(\text{MEM[ptrP]RT} \gg \text{xRT})$$
$$\triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(\text{MEM[ptrP]RT} \gg \text{xRT})$$
$$= \mathop{R}_{i=0}^{\#T(\text{MEM[ptrP]RT} \gg \text{xRT})} \left(\mathop{R}_{j=1}^{\#S(\text{MEM[ptrP]RT} \gg \text{xRT})} v\ t_i, s_j \right)$$
$$= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{3} v(t_i, s_j)$$
$$= \begin{pmatrix} & \textbf{ptr}\text{P} & \textbf{MEM(ptr)}\text{P}\text{RT} & \textbf{x}\text{RT} \\ \mathbf{t_0} & ptr\text{P} & \perp & \perp \\ \mathbf{(t_0, t_1]} & ptr\text{P} & \text{MEM}[ptr\text{P}]\text{RT} & \text{MEM}[ptr\text{P}]\text{RT} \end{pmatrix} \tag{21}$$

The Write Process

Definition 22. *The semantics of the write process on* Θ, θ*(MEM(ptr*P*)*RT≪*x*RT*), is a double partial differential of the semantic function* f_θ*(MEM(ptr*P*)*RT≪*x*RT*) on the sets of variables S and executing steps T, i.e.:*

$$\theta(\text{MEM[ptrP]RT} \ll \text{xRT})$$
$$\triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(\text{MEM[ptrP]RT} \ll \text{xRT})$$
$$= \mathop{R}_{i=0}^{\#T(\text{MEM[ptrP]RT} \ll \text{xRT})} \left(\mathop{R}_{j=1}^{\#S(\text{MEM[ptrP]RT} \quad \text{xRT})} v\ t_i, s_j \right)$$
$$= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{3} v(t_i, s_j)$$
$$= \begin{pmatrix} & \textbf{x}\text{RT} & \textbf{ptr}\text{P} & \textbf{MEM[ptr]}\text{RT} \\ \mathbf{t_0} & x\text{RT} & \perp & \perp \\ \mathbf{(t_0, t_1]} & x\text{RT} & ptr\text{P} & x\text{RT} \end{pmatrix} \tag{22}$$

The Input Process

Definition 23. *The semantics of the input process on* Θ, θ*(PORT(ptr*P*)*RT$|\gg x$RT*), is a double partial differential of the semantic function* f_θ*((PORT(ptr*P*)*RT$|\gg x$RT*) on the sets of variables S and executing steps T, i.e.:*

$$
\begin{aligned}
&\theta(\text{PORT}[\text{ptr}^{\text{P}}]\text{RT} \,|\gg \text{xRT}) \\
&\triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(\text{PORT}[\text{ptr}^{\text{P}}]\text{RT} \,|\gg \text{xRT}) \\
&= \mathop{R}_{i=0}^{\#T(\text{PORT}[\text{ptr}^{\text{P}}]\text{RT}|\gg \text{xRT})} \Big(\mathop{R}_{j=1}^{\#S(\text{PORT}[\text{ptr}^{\text{P}}]\text{RT}|\ \text{xRT})} v\ t_i, s_j \Big) \\
&= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{3} v(t_i, s_j) \\
&= \begin{pmatrix} & \textbf{ptr}^{\text{P}} & \textbf{PORT[ptr}^{\text{P}}\textbf{]RT} & \textbf{x}\text{RT} \\ \mathbf{t_0} & ptr^{\text{P}} & \perp & \perp \\ \mathbf{(t_0, t_1]} & ptr^{\text{P}} & \text{PORT}[ptr^{\text{P}}]\text{RT} & \text{PORT}[ptr^{\text{P}}]\text{RT} \end{pmatrix}
\end{aligned}
\tag{23}
$$

The Output Process

Definition 24. *The semantics of the output process on* Θ, θ*(x*RT $|\ll$ *PORT(ptr*P*)*RT*), is a double partial differential of the semantic function* f_θ*(x*RT $|\ll$ *PORT(ptr*P*)*RT*) on the sets of variables S and executing steps T, i.e.:*

$$
\begin{aligned}
&\theta(\text{xRT} \,|\ll \text{PORT}[\text{ptr}^{\text{P}}]\text{RT}) \\
&\triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(\text{xRT} \,|\ll \text{PORT}[\text{ptr}^{\text{P}}]\text{RT}) \\
&= \mathop{R}_{i=0}^{\#T(\text{xRT}|\ll \text{PORT}[\text{ptr}^{\text{P}}]\text{RT})} \Big(\mathop{R}_{j=1}^{\#S(\text{xRT}|\ll \text{PORT}[\text{ptr}^{\text{P}}]\text{RT})} v\ t_i, s_j \Big) \\
&= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{3} v(t_i, s_j) \\
&= \begin{pmatrix} & \textbf{x}\text{RT} & \textbf{ptr}^{\text{P}} & \textbf{PORT[ptr}^{\text{P}}\textbf{]RT} \\ \mathbf{t_0} & x\text{RT} & \perp & \perp \\ \mathbf{(t_0, t_1]} & x\text{RT} & ptr^{\text{P}} & x\text{RT} \end{pmatrix}
\end{aligned}
\tag{24}
$$

The Timing Process

Definition 25. *The semantics of the timing process on* Θ, θ*(@t*TM $\hat{=}$ *§t*TM*), is a double partial differential of the semantic function* f_θ*(@t*TM $\hat{=}$ *§t*TM*) on the sets of variables S and executing steps T, i.e.:*

$$
\begin{aligned}
\theta(@\,\text{tTM} \hat{=} \S\text{t M}) &\triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(@\,\text{tTM} \hat{=} \S\text{tTM}) \\
&= \mathop{R}_{i=0}^{\#T(@\,\text{tTM} \hat{=} \S\text{t M})} \Big(\mathop{R}_{j=1}^{\#S(@\,\text{tTM} \hat{=} \S\text{tTM})} v\ t_i, s_j \Big) \\
&= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{2} v(t_i, s_j) \\
&= \begin{pmatrix} & \textbf{§t}\text{TM} & \textbf{@t}\text{TM} \\ \mathbf{t_0} & \S\text{tTM} & \perp \\ \mathbf{(t_0, t_1]} & \S\text{tTM} & \S\text{tTM} \end{pmatrix}
\end{aligned}
\tag{25}
$$

where TM *represents the three timing types, i.e.,* TM = *{*yy:MM:dd, hh:mm:ss:ms, yy:MM:dd:hh:mm:ss:ms*}.*

The Duration Process

Definition 26. *The semantics of the duration process on* Θ, θ*(@t*TM$\triangleq$*§t*TM+Δ*dZ), is a double partial differential of the semantic function* f_θ*(@t*TM$\triangleq$*§t*TM+Δ*dN) on the sets of variables S and executing steps T, i.e.:*

$$
\begin{aligned}
&\theta(@\,\text{tTM} \triangleq \S\text{t M}+\Delta\text{dZ}) \\
&\triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(@\,\text{tTM} \triangleq \S\text{t M}+\Delta\text{dZ}) \\
&= \mathop{R}_{i=0}^{\#T(@\,\text{tTM} \triangleq \S\text{t M})} \Big(\mathop{R}_{j=1}^{\#S(@\,\text{tTM} \triangleq \S\text{tTM})} v\ t_i, s_j \Big) \\
&= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{3} v(t_i, s_j) \\
&= \begin{pmatrix} & \textbf{§t}\text{TM} & \Delta\textbf{d}\text{N} & \textbf{@t}\text{TM} \\ \mathbf{t_0} & \S\text{tTM} & \Delta\text{dN} & \perp \\ \mathbf{(t_0, t_1]} & \S\text{tTM} & \Delta\text{dN} & \S\text{tTM}+\Delta d\text{N} \end{pmatrix}
\end{aligned}
\tag{26}
$$

where TM = {yy:MM:dd, hh:mm:ss:ms, yy:MM:dd: hh:mm:ss:ms}.

The Increase Process

Definition 27. *The semantics of the increase process on* Θ, $\theta(\uparrow(x\mathrm{RT}))$, *is a double partial differential of the semantic function* $f_\theta(\uparrow(x\mathrm{RT}))$ *on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}\theta(\uparrow(\mathrm{xRT})) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(\uparrow(\mathrm{xRT}))\\ &= \mathop{R}_{i=0}^{\#T(\uparrow(\mathrm{xRT}))} \mathop{R}_{j=1}^{\#S(\uparrow(\mathrm{xRT}))} v(t_i, s_j)\\ &= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{1} (\nu\ t_i, s_j)\\ &= \begin{pmatrix} & \mathbf{x}\mathrm{RT} \\ \mathbf{t_0} & x\mathrm{RT} \\ \mathbf{(t_0, t_1]} & x\mathrm{RT}+1 \end{pmatrix}\end{aligned} \tag{27}$$

where the run-time type RT = {N, Z, B, H, P, TM}

The Decrease Process

Definition 28. *The semantics of the decrease process on* Θ, $\theta(\downarrow(x\mathrm{RT}))$, *is a double partial differential of the semantic function* $f_\theta(\downarrow(x\mathrm{RT}))$ *on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}\theta(\downarrow(\mathrm{xRT})) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(\downarrow(\mathrm{xRT}))\\ &= \mathop{R}_{i=0}^{\#T(\downarrow(\mathrm{xRT}))} \mathop{R}_{j=1}^{\#S(\downarrow(\mathrm{xRT}))} v(t_i, s_j)\\ &= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{1} (\nu\ t_i, s_j)\\ &= \begin{pmatrix} & \mathbf{x}\mathrm{RT} \\ \mathbf{t_0} & x\mathrm{RT} \\ \mathbf{(t_0, t_1]} & x\mathrm{RT}-1 \end{pmatrix}\end{aligned} \tag{28}$$

where the run-time type RT = {N, Z, B, H, P, TM}

The Exception Detection Process

Definition 29. *The semantics of the exception detection process on* Θ, $\theta(!(@)e\mathrm{S})$, *is a double partial differential of the semantic function* $f_\theta(!(@)e\mathrm{S}))$ *on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}\theta(!(@e\mathrm{S})) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(!(@e\mathrm{S}))\\ &= \mathop{R}_{i=0}^{\#T(!(@e\mathrm{S}))} \mathop{R}_{j=1}^{\#S(!(@e\mathrm{S}))} (\nu\ t_i, s_j)\\ &= \mathop{R}_{i=0}^{1} \mathop{R}_{j=1}^{3} v(t_i, s_j)\\ &= \begin{pmatrix} & \mathbf{@e}\mathrm{S} & \mathbf{ptr}\mathrm{P} & \mathbf{PORT(ptr}\mathrm{P}\mathbf{)}\mathrm{S} \\ \mathbf{t_0} & @e\mathrm{S} & \perp & \perp \\ \mathbf{(t_0, t_1]} & @e\mathrm{S} & ptr\mathrm{P} & @e\mathrm{S} \end{pmatrix}\end{aligned} \tag{29}$$

Equation 29 indicates that the semantics of exception detection is the output of a string @*e*S to a designated port PORT[*ptr*P]S, where the pointer *ptr*P points to a CRT or a printer. Therefore, the semantics of exception detection can be described based on the semantics of the output process as defined in Equation 24, i.e.:

$$\theta((!(@e\mathrm{S})) = \theta(@e\mathrm{S} \mid\!\prec \mathrm{PORT}[ptr\mathrm{P}]\mathrm{S}) \tag{30}$$

The Skip Process

Definition 30. *The semantics of the skip process on* Θ, $\theta(\otimes)$, *is a double partial differential of the semantic function* $f_\theta(\otimes)$ *on the sets of variables S and executing steps T, i.e.:*

$$
\begin{aligned}
\theta(\otimes) &\triangleq \theta(P^k \curvearrowright P^{k-1}) \\
&= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P^k \curvearrowright P^{k-1}) \\
&= \overset{\#T(P^k \curvearrowright P^{k-1})}{\underset{i=0}{R}} \; (\overset{\#S(P^k \curvearrowright P^{k-1})}{\underset{j=1}{R}} \; v\; t_i, s_j) \\
&= \overset{1}{\underset{i=0}{R}} \overset{2}{\underset{j=1}{R}} v(t_i, s_j) \\
&= \begin{pmatrix} & \mathbf{S_{P^{k-1}}} & \mathbf{S_{P^k}} \\ \mathbf{t_0} & S_{P^{k-1}} & S_{P^k} \\ \mathbf{(t_0, t_1]} & S_{P^{k-1}} \setminus S_{P^k} & \perp \end{pmatrix}
\end{aligned}
\tag{31}
$$

where P^k is a process P at a given embedded layer k in a program with P^0 at the uttermost layer, and $\curvearrowright$ denotes the jump process relation where its semantics will be formally defined in the next section.

According to Definition 30, the skip process $\otimes$ has no semantic effect on the current process P^k at the given embedded layer k in a program, such as a branch, loop, or function. However, it redirects the system to jump to execute an upper-layer process P^{k-1} in the embedded hierarchy. Therefore, skip is also known as *exit* or *break* in programming languages.

The Stop Process

Definition 31. *The semantics of the stop process on Θ, θ ($\oiint$), is a double partial differential of the semantic function $f_\theta(\boxtimes)$ on the sets of variables S and executing steps T, i.e.:*

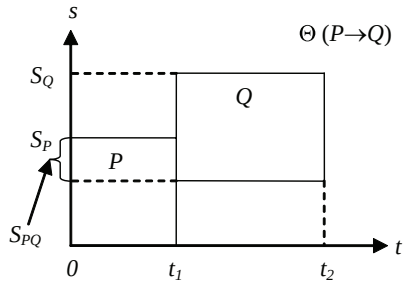
$$
\begin{aligned}
\theta(\boxtimes) &\triangleq \theta(P \curvearrowright \S) \\
&= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P \curvearrowright \S) \\
&= \overset{\#T(P \curvearrowright \S)}{\underset{i=0}{R}} \; (\overset{\#S(P \curvearrowright \S)}{\underset{j=1}{R}} \; v\; t_i, s_j) \\
&= \overset{1}{\underset{i=0}{R}} \overset{2}{\underset{j=1}{R}} v(t_i, s_j) \\
&= \begin{pmatrix} & \mathbf{S_\S} & \mathbf{S_P} \\ \mathbf{t_0} & S_\S & S_P \\ \mathbf{(t_0, t_1]} & S_\S \setminus S_P & \perp \end{pmatrix}
\end{aligned}
\tag{32}
$$

where the stop process $\boxtimes$ does nothing but returns the control of execution to the system.

DEDUCTIVE SEMANTICS OF RTPA PROCESS RELATIONS

The preceding section provides formal definitions of metaprocesses of RTPA for software system modeling. Via the composition of multiple metaprocesses by the 17 process relations, R = {$\rightarrow$, $\curvearrowright$, |, |…|…, R^*, R^+, R^i, $\circlearrowleft$, $\rightarrowtail$, ||, $\oiint$, |||, », $\lightning$, $\hookrightarrow_t$, $\hookrightarrow_e$, $\hookrightarrow_i$}, complex architectures and behaviors of software systems, in the most complicated case, a real-time system, can be sufficiently described (Wang, 2002, 2006a, 2007c, 2008b). On the basis of Definitions 8 and 12, the semantics of the RTPA process relations can be formally defined and analyzed as follows.

Figure 3. The semantic diagram of the sequential process relation



The Sequential Process Relation

Definition 32. *The semantics of the sequential relation of processes on Θ, θ(P→Q), is a double partial differential of the semantic function $f_\theta(P \rightarrow Q)$ on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}
\theta(P \rightarrow Q) &\triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(P \rightarrow Q) \\
&= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P) \rightarrow \frac{\partial^2}{\partial t\, \partial s} f_\theta(Q) \\
&= \overset{\#T(P)}{\underset{i=0}{R}} \left(\overset{\#S(P)}{\underset{j=1}{R}} v_P\ t_i, s_j \right) \rightarrow \overset{\#T(Q)}{\underset{i=0}{R}} \left(\overset{\#S(Q)}{\underset{j=1}{R}} v_Q\ t_i, s_j \right) \\
&= \overset{\#T(\widehat{PQ})}{\underset{i=0}{R}} \left(\overset{\#S(P \cup Q)}{\underset{j=1}{R}} v\ t_i, s_j \right) \\
&= \begin{pmatrix} & \mathbf{s_P} & \mathbf{s_Q} & \mathbf{s_{PQ}} \\ \mathbf{t_0} & \perp & \perp & \perp \\ \mathbf{(t_0, t_1]} & V_{1P} & - & V_{1PQ} \\ \mathbf{(t_1, t_2]} & - & V_{2Q} & V_{2PQ} \end{pmatrix} \\
&= \begin{pmatrix} \mathbf{V_P} & & \mathbf{V_{PQ}} \\ & \mathbf{V_Q} & \mathbf{V_{PQ}} \end{pmatrix}
\end{aligned} \tag{33}$$

where $P^\frown Q$ indicates a concatenation of these two processes over time, and in the simplified notation of the matrix, $V_P = v(t_P, s_P)$, $0 \le t_P \le n_P$, $1 \le s_P \le$

Box 6.

$$\begin{aligned}
\theta(P_0 \rightarrow P_1 \rightarrow \ldots \rightarrow P_5) &= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P_0 \rightarrow P_1 \rightarrow \ldots \rightarrow P_5) \\
&= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P_0) \rightarrow \frac{\partial^2}{\partial t\, \partial s} f_\theta(P_1) \rightarrow \ldots \rightarrow \frac{\partial^2}{\partial t\, \partial s} f_\theta(P_5) \\
&= \overset{\#T(P_0)}{\underset{i=0}{R}} \left(\overset{\#S(P_0)}{\underset{j=1}{R}} v_{P_0}\ t_i, s_j \right) \rightarrow \overset{\#T(P_1)}{\underset{i=0}{R}} \left(\overset{\#S(P_1)}{\underset{j=1}{R}} v_{P_1}\ t_i, s_j \right) \rightarrow \ldots \rightarrow \overset{\#T(P_5)}{\underset{i=0}{R}} \overset{\#S(P_5)}{\underset{j=1}{R}} v_{P_5}(t_i, s_j) \\
&= \overset{\#T(\widehat{P_0 P_1 \ldots P_5})}{\underset{i=0}{R}} \left(\underset{j=1}{\overset{\#S(P_0 \cup P_1 \cup \ldots \cup P_5)}{R}} v\ t_i, s_j \right) \\
&= \overset{5}{\underset{i=0}{R}} \overset{4}{\underset{j=1}{R}} v(t_i, s_j) \\
&= \begin{pmatrix} & \mathbf{x} & \mathbf{y} & \mathbf{z} & \mathbf{PORT[CRTP]N} \\ \mathbf{t_0} & \perp & \perp & \perp & \perp \\ \mathbf{(t_0, t_1]} & 2 & \perp & \perp & \perp \\ \mathbf{(t_1, t_2]} & 2 & 8 & \perp & \perp \\ \mathbf{(t_2, t_3]} & 2 & 8 & 10 & \perp \\ \mathbf{(t_3, t_4]} & 2 & 8 & 20 & \perp \\ \mathbf{(t_4, t_5]} & 2 & 8 & 20 & 20 \end{pmatrix}
\end{aligned} \tag{34}$$

m_P; $V_Q = v(t_Q, s_Q)$, $0 \le t_Q \le n_Q$, $1 \le s_Q \le m_Q$; *and* $V_{PQ} = v(t_{PQ}, s_{PQ})$, $0 \le t_{PQ} \le n_{PQ}$, $1 \le s_{PQ} \le m_{PQ}$.

In Equation 33, the first partial differential selects a set of related variables in the sequential processes P and Q, $S(P \cup Q)$. The second partial differential selects a set of time moments $T(P \frown Q)$. The semantic diagram of the sequential process relation as defined in Equation 33 is illustrated in Figure 3 on Θ.

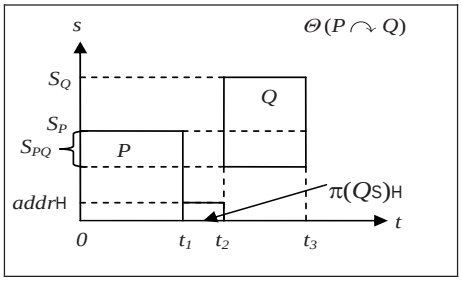
The following example shows the physical meaning of Equation 33 and how the abstract syntaxes and their implied meanings are embodied onto the objects (variables) and their dynamic values in order to obtain the concrete semantics in deductive semantics.

Example 3. *Analyze the semantics of the sequential processes P_0 through P_5 in the following program:*

```
void sequential_sum;
  {
     int x, y, z;          // P0
     x = 2;                // P1
     y = 8;                // P2
     z := x + y;           // P3
     z := x + y + z;       // P4
     print z;              // P5
  }
```

According to Definition 32, the semantics of the above program can be analyzed as seen in Box 6.

Figure 4. The semantic diagram of the jump process relation



Where PORT[*CRT*P]N denotes a system monitor of type N located by the pointer *CRT*P.

The Jump Process Relation

Definition 33. *The semantics of the jump relations of processes on Θ, θ(P ↷ Q), is a double partial differential of the semantic function $f_\theta(P \curvearrowright Q)$ on the sets of variables S and executing steps T, i.e.:*

$$
\begin{aligned}
&\theta(P \curvearrowright Q) \triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(P \curvearrowright Q) \\
&= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P) (\curvearrowright \frac{\partial^2}{\partial t\, \partial s} f_\theta\ Q) \\
&= \mathop{R}_{i=0}^{\#T(P)} (\mathop{R}_{j=1}^{\#S(P)} v_P\ t_i, s_j) \curvearrowright \mathop{R}_{i=0}^{\#T(Q)} (\mathop{R}_{j=1}^{\#S(Q)} v_Q\ t_i, s_j) \\
&= \mathop{R}_{i=0}^{\#T(\widehat{PQ})} (\mathop{R}_{j=1}^{\#S(P \cup Q)} v\ t_i, s_j) \\
&= \begin{pmatrix}
 & \mathbf{S_P} & \mathbf{S_Q} & \mathbf{S_{PQ}} & \mathbf{addr}\mathsf{H} \\
\mathbf{[t_0, t_1]} & V_{1P} & \perp & V_{1PQ} & \perp \\
\mathbf{(t_1, t_2]} & - & - & - & \pi(QS)\mathsf{H} \\
\mathbf{(t_2, t_3]} & - & V_{3Q} & V_{3PQ} &
\end{pmatrix}
\end{aligned}
\tag{35}
$$

*where π(QS)H is a system addressing function of the system that directs the program control flow to execute the new process Q, which physically located in a different memory address at addr*H *= π(QS)H.*

The semantic diagram of the jump process relation as defined in Equation 35 is illustrated in Figure 4 on $\Theta(P \curvearrowright Q)$.

The jump process relation is an important process relation that forms a fundamental part of many other processes and constructs. For instances, the jump process relation has been applied in expressing the semantics of the *skip* and *stop* processes in the preceding section.

Box 7.

$$\theta(\text{exp}_{\text{RT}} \rightarrow P \mid \sim \rightarrow Q) \triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(\text{exp}_{\text{RT}} \rightarrow P \mid \sim \rightarrow Q)$$

$$= \quad \text{exp}_{\text{BL}} \rightarrow \frac{\partial^2}{\partial t\, \partial s} f_\theta(P)$$

$$\mid \quad \rightarrow \frac{\partial^2}{\partial t\, \partial s} f_\theta(Q)$$

$$= \quad \text{exp}_{\text{BL}} \rightarrow \mathop{R}_{i=0}^{\#T(P)} (\mathop{R}_{j=1}^{\#S(P)} v_P\ t_i, s_j)$$

$$\mid \quad \rightarrow \mathop{R}_{i=0}^{\#T(Q)} (\mathop{R}_{j=1}^{\#S(Q)} v_Q\ t_i, s_j)$$

$$= \begin{pmatrix} & \textbf{exp}_{\text{BL}} & \mathbf{S_P} & \mathbf{S_Q} & \mathbf{S_{PQ}} \\ \mathbf{(t_0, t_1]} & \delta(\text{exp}_{\text{BL}}) & \perp & \perp & \perp \\ \mathbf{(t_1, t_2]} & \mathsf{T} & V_{2P} & - & V_{2PQ} \\ \mathbf{(t_1, t_{2'}]} & \mathsf{F} & - & V_{3Q} & V_{3PQ} \end{pmatrix}$$

(36)

Figure 5. The semantic diagram of the branch process relation

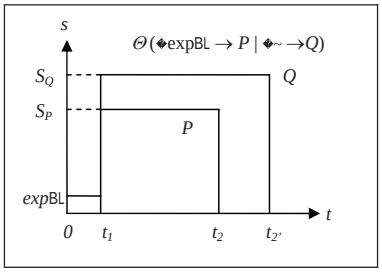


Figure 6. The semantic diagram of the switch process relation

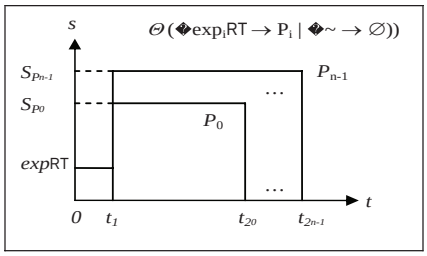


The Branch Process Relation

Definition 34. *The semantics of the branch relation of processes on* Θ, $\theta(\text{exp}_{\text{BL}} = \mathsf{T} \rightarrow P \mid \sim \rightarrow Q)$, *abbreviated by* $\theta(P|Q)$, *is a double partial differential of the semantic function* $f_\theta(P|Q)$ *on the sets of variables S and executing steps T, see Box 7, where* $\delta(\text{exp}_{\text{BL}})$ *is the evaluation function on the value of* exp_{BL}, $\delta(\text{exp}_{\text{BL}}) \in \{\mathsf{T}, \mathsf{F}\}$.

The semantic diagram of the branch process relation as defined in Equation 34 is illustrated in Figure 5 on $\Theta(\text{exp}_{\text{BL}} \rightarrow P \mid \neg\, \text{exp}_{\text{BL}} \rightarrow Q)$.

The Switch Process Relation

Definition 35. *The semantics of the switch relations of processes on* Θ, $\theta(\text{exp}_i\text{RT} \rightarrow P_i \mid \sim \rightarrow \varnothing)$, *abbreviated by* $\theta(P_i \mid \varnothing)$, *is a double partial differential of the semantic function* $f_\theta(P_i \mid \varnothing)$ *on the sets of variables S and executing steps T, i.e.:*

$$
\begin{aligned}
&\theta(\text{◆}exp_i\mathsf{RT} \rightarrow \mathrm{P_i} \mid \text{◆} \quad \rightarrow \otimes) \\
&\triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(\text{◆}exp_i\mathsf{RT} \rightarrow \mathrm{P_i} \mid \text{◆} \quad \rightarrow \otimes) \\
&= \ \text{◆}exp\mathsf{RT} = 0 \rightarrow \frac{\partial^2}{\partial t\ \partial s} f_\theta(P_0) \\
&\quad \mid ... \\
&\quad \mid \text{◆}exp\mathsf{RT} = n-1 \rightarrow \frac{\partial^2}{\partial t\ \partial s} f_\theta(P_{n-1}) \\
&\quad \mid \text{◆}exp\mathsf{RT} = n \rightarrow \frac{\partial^2}{\partial t\ \partial s} f_\theta(\otimes) \\
&= \ \text{◆}exp\mathsf{RT} = 0 \rightarrow \overset{\#T(P_0)}{\underset{i=0}{R}} \ \overset{\#S(P_0)}{\underset{j=1}{R}} v_{P_0}(t_i, s_j) \\
&\quad \mid ... \\
&\quad \mid \text{◆}exp\mathsf{RT} = n-1 \rightarrow \overset{\#T(P_{n-1})}{\underset{i=0}{R}} \ \overset{\#S(P_{n-1})}{\underset{j=1}{R}} v_{P_{n-1}}(t_i, s_j) \\
&\quad \mid \text{◆}exp\mathsf{RT} = n \rightarrow \varnothing \\
&= \begin{pmatrix}
 & \mathbf{exp}\mathsf{RT} & \mathbf{S_{P_0}} & \cdots & \mathbf{S_{P_{n-1}}} & \mathbf{S_G} \\
\mathbf{[t_0, t_1]} & \delta(\mathrm{expRT}) & \perp & \cdots & \perp & \perp \\
\mathbf{(t_1, t_{2_0}]} & 0 & V_{2_0 P} & \cdots & - & V_G \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
\mathbf{(t_1, t_{2_{n-1}}]} & n-1 & - & \cdots & V_{2_{n-1} P} & V_G \\
\mathbf{(t_1, t_{2_n}]} & n & - & \cdots & - & V_G
\end{pmatrix}
\end{aligned}
\tag{37}
$$

where V_G is a set of global variables shared by P_0, P_1, and P_{n-1}.

The semantic diagram of the switch process relation as defined in Equation 37 is illustrated in Figure 6 on Θ(◆exp_iRT $\rightarrow$ $\mathrm{P_i}$ | ◆ ~ $\rightarrow \varnothing$).

The While-Loop Process Relation

Definition 36. *The semantics of the while-loop relations of processes on* Θ*,*

$$\theta(\overset{\mathsf{F}}{\underset{\mathrm{expBL}=\mathsf{T}}{R}}{}^{*}(P)),$$

is a double partial differential of the semantic function

$$f_\theta(\overset{\mathsf{F}}{\underset{\mathrm{expBL}=\mathsf{T}}{R}}{}^{*}(P))$$

on the sets of variables S and executing steps T, i.e.:

$$
\begin{aligned}
\theta(\overset{\mathsf{F}}{\underset{\mathrm{expBL}=\mathsf{T}}{R}}{}^{*}(P)) &\triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(\overset{\mathsf{F}}{\underset{\mathrm{expBL}=\mathsf{T}}{R}}{}^{*}(P)) \\
&= \overset{\mathsf{F}}{\underset{\mathrm{expBL}=\mathsf{T}}{R}}{}^{*}(\frac{\partial^2}{\partial t\ \partial s} f_\theta(P)) \\
&= \overset{\mathsf{F}}{\underset{\mathrm{expBL}=\mathsf{T}}{R}}{}^{*}(\overset{\#T(P)}{\underset{i=0}{R}} \ \overset{\#S(P)}{\underset{j=1}{R}} v_P(t_i, s_j)) \\
&= \begin{pmatrix}
 & \mathbf{exp}\mathsf{BL} & \mathbf{S_P} \\
\mathbf{[t_0, t_1]} & \delta(\mathrm{expBL}) & \perp \\
\mathbf{(t_1, t_2]} & \mathsf{T} & V_P \\
\mathbf{(t_1, t_{2'}]} & \mathsf{F} & \otimes \\
\vdots & \vdots & \vdots \\
\mathbf{(t_3, t_4]} & \delta(\mathrm{expBL}) & - \\
\mathbf{(t_4, t_5]} & \mathsf{T} & V_P \\
\mathbf{(t_4, t_{5'}]} & \mathsf{F} & \otimes
\end{pmatrix}
\end{aligned}
\tag{38}
$$

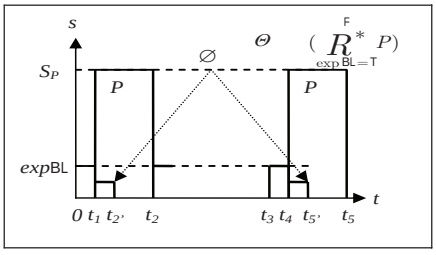
*where $\varnothing$ denotes exit, and δ(exp*BL*) is the evaluation function on the Boolean expression, δ(exp*BL*) $\in$ {T, F}.*

The semantic diagram of the while-loop process relation as defined in Equation 38 is illustrated in Figure 7 on Θ.

The Repeat-Loop Process Relation

Definition 37. *The semantics of the repeat-loop relations of processes on* Θ*,*

Figure 7. The semantic diagram of the while-loop process relation



$\theta(\overset{F}{R}{}^{+}_{\text{expBL=T}}(P))$,

is a double partial differential of the semantic function

$f_\theta(\overset{F}{R}{}^{+}_{\text{expBL=T}}(P))$

on the sets of variables S and executing steps T, i.e.:

$$\theta(\overset{F}{R}{}^{+}_{\text{expBL=T}}(P)) \triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(\overset{F}{R}{}^{+}_{\text{expBL=T}}(P))$$
$$= \overset{F}{R}{}^{+}_{\text{expBL=T}}(\frac{\partial^2}{\partial t\,\partial s} f_\theta(P))$$
$$= P \to \overset{F}{R}{}^{*}_{\text{expBL=T}}(\overset{\#T(P)}{\underset{i=0}{R}}\ \overset{\#S(P)}{\underset{j=1}{R}} v_P(t_i, s_j))$$

The semantic diagram of the for-loop process relation as defined in Equation 40 is illustrated in Figure 9 on Θ .

The Function Call Process Relation

Definition 39. *The semantics of the function call relations of processes on Θ, θ(P ⟼ Q), is a double partial differential of the semantic function f_θ(P ⟼ Q) on the sets of variables S and executing steps T, i.e.:*

$$\theta(P \rightarrowtail Q) \triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(P \rightarrowtail Q)$$

$$= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P) \rightarrowtail \frac{\partial^2}{\partial t\, \partial s} f_\theta(Q)$$

$$= \mathop{R}_{i=0}^{\#T(P)} (\mathop{R}_{j=1}^{\#S(P)} v_P\ t_i, s_j) \rightarrowtail \mathop{R}_{i=0}^{\#T(Q)} (\mathop{R}_{j=1}^{\#S(Q)} v_Q\ t_i, s_j)$$

$$= \mathop{R}_{i=0}^{\#T([t_0,t_1)^\frown(t_1,t_2)^\frown(t_2,t_3])} (\mathop{R}_{j=1}^{\#S(P\cup Q)} v\ t_i, s_j)$$

$$= \begin{pmatrix} & \mathbf{S_P} & \mathbf{S_Q} & \mathbf{S_{PQ}} \\ \mathbf{t_0} & \perp & \perp & \perp \\ \mathbf{(t_0, t_1)} & V_{1P} & - & V_{1PQ} \\ \mathbf{(t_1, t_2)} & - & v_{2Q} & V_{2PQ} \\ \mathbf{(t_2, t_3)} & V_{3P} & - & V_{3PQ} \end{pmatrix} \tag{41}$$

The semantic diagram of the procedure call process relation as defined in Equation 41 is illustrated in Figure 10 on Θ(P ⟼ Q).

The Recursive Process Relation

Definition 40. *The semantics of the recursive relations of processes on Θ, θ(P↻P), is a double partial differential of the semantic function f_θ(P↻P) on the sets of variables S and executing steps T, i.e.:*

$$\theta(P \circlearrowright P) \triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(P \circlearrowright P)$$

$$= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P) \circlearrowright \frac{\partial^2}{\partial t\, \partial s} f_\theta(P)$$

$$= \mathop{R}_{i=0}^{\#T(P)} (\mathop{R}_{j=1}^{\#S(P)} v\ t_i, s_j) \circlearrowright \mathop{R}_{i=0}^{\#T(P)} (\mathop{R}_{j=1}^{\#S(P)} v\ t_i, s_j)$$

$$= \mathop{R}_{i=0}^{\#T(P)} (\mathop{R}_{j=1}^{\#S(P)} v\ t_i, s_j)$$

$$= \begin{pmatrix} & \mathbf{S_P} \\ \mathbf{[t_0, t_1]} & V_{P^n} \\ \mathbf{(t_1, t_2]} & V_{P^{n-1}} \\ \vdots & \vdots \\ \mathbf{(t_3, t_4]} & V_{P^0} \\ \vdots & \vdots \\ \mathbf{(t_5, t_6]} & V_{P'^{n-1}} \\ \mathbf{(t_6, t_7]} & V_{P'^n} \end{pmatrix} \tag{42}$$

The semantic diagram of the recursive process relation as defined in Equation 42 is illustrated in Figure 11 on Θ(P↻P).

Figure 12. The semantic diagram of the parallel process relation

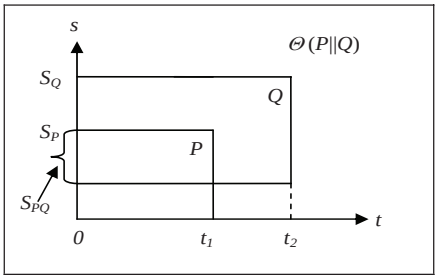

Figure 13. The semantic diagram of the concurrent process relation

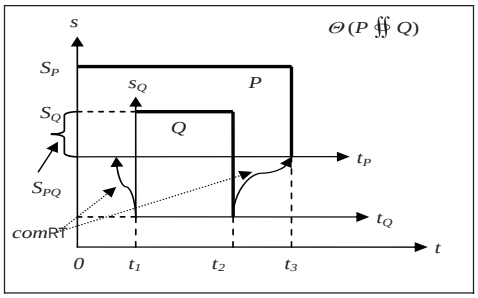

The Parallel Process Relation

Definition 41. *The semantics of the parallel relations of processes on Θ, θ(P||Q), is a double partial differential of the semantic function f_θ(P||Q) on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}
\theta(P \parallel Q) &\triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(P \parallel Q) \\
&= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P) \parallel \frac{\partial^2}{\partial t\, \partial s} f_\theta(Q) \\
&= \mathop{R}_{i=0}^{\#T(P)} (\mathop{R}_{j=1}^{\#S(P)} v_P\ t_i, s_j) \parallel \mathop{R}_{i=0}^{\#T(Q)} (\mathop{R}_{j=1}^{\#S(Q)} v_Q\ t_i, s_j) \\
&= \mathop{R}_{i=0}^{\max(\#T(P),\#T(Q))} (\mathop{R}_{j=1}^{\#S(P\cup Q)} v\ t, s) \\
&= \begin{pmatrix} & \mathbf{S_P} & \mathbf{S_Q} & \mathbf{S_{PQ}} \\ \mathbf{t_0} & V_{0P} & V_{0Q} & V_{0PQ} \\ \mathbf{(t_0, t_1]} & V_{1P} & V_{1Q} & V_{1PQ} \\ \mathbf{(t_1, t_2]} & - & V_{2Q} & V_{2PQ} \end{pmatrix}
\end{aligned} \tag{43}$$

where t_2 = max(#T(P), (#T(Q)) is the synchronization point between two parallel processes.

The semantic diagram of the parallel process relation as defined in Equation 43 is illustrated in Figure 12 on Θ(P||Q).

It is noteworthy that parallel processes *P* and *Q* are interlocked. That is, they should start and end at the same time. In case $t_1 \neq t_2$, the process completed earlier, should wait for the completion of the other. The second condition between parallel processes is that the shared resources, in particular variables, memory space, ports, and devices should be protected. That is, when a process operates on a shared resource, it is locked to the other process until the operation is completed. A variety of interlocking and synchronization techniques, such as *semaphores*, *mutual exclusions*, and *critical regions*, have been proposed in real-time system techniques (McDermid, 1991).

The Concurrent Process Relation

Definition 42. *The semantics of the concurrent relations of processes on Θ, θ(P ⫰ Q), is a double partial differential of the semantic function f_θ(P ⫰ Q) on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}
\theta(P \fint Q) &\triangleq \frac{\partial^2}{\partial t\, \partial s} f_\theta(P \fint Q) \\
&= \frac{\partial^2}{\partial t\, \partial s} f_\theta(P) \fint \frac{\partial^2}{\partial t\, \partial s} f_\theta\ Q) \\
&= \mathop{R}_{i=0}^{\#T(P)} (\mathop{R}_{j=1}^{\#S(P)} v_P\ t_i, s_j) \fint \mathop{R}_{i=0}^{\#T(Q)} \mathop{R}_{j=1}^{\#S(Q)} v_Q(t_i, s_j) \\
&= \mathop{R}_{i=0}^{\max(\#T(P),\#T(Q))} (\mathop{R}_{j=1}^{\#S(P\cup Q)} v\ t_i, s_j) \\
&= \begin{pmatrix} & \mathbf{S_P} & \mathbf{S_Q} & \mathbf{S_{PQ}} & \mathbf{com}\mathrm{RT} \\ \mathbf{t_0} & V_{0P} & V_{0P} & V_{0P} & V_{0com} \\ \mathbf{(t_0, t_1]} & V_{1P} & - & V_{1PQ} & V_{1com} \\ \mathbf{(t_1, t_2]} & V_{2P} & V_{2Q} & V_{2PQ} & V_{2com} \\ \mathbf{(t_2, t_3]} & V_{3P} & - & V_{3PQ} & V_{3com} \end{pmatrix}
\end{aligned} \tag{44}$$

where comRT is a set of interprocess communication variables that are used to synchronize P and Q executing on different machines based on independent system clocks.

The semantic diagram of the concurrent process relation as defined in Equation 44 is illustrated in Figure 13 on $\Theta(P \oiint Q)$.

The Interleave Process Relation

Definition 43. *The semantics of the interleave relations of processes on* Θ, $\theta(P \,|||\, Q)$, *is a double partial differential of the semantic function* $f_\theta(P \,|||\, Q)$ *on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}
\theta(P \,|||\, Q) &\triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(P \,|||\, Q) \\
&= \frac{\partial^2}{\partial t\ \partial s} f_\theta(P) \,|||\, \frac{\partial^2}{\partial t\ \partial s} f_\theta(Q) \\
&= \mathop{R}_{i=0}^{\#T(P)} \Big(\mathop{R}_{j=1}^{\#S(P)} v_P\ t_i, s_j \Big) \,|||\, \mathop{R}_{i=0}^{\#T(Q)} \mathop{R}_{j=1}^{\#S(Q)} v_Q(t_i, s_j) \\
&= \mathop{R}_{i=0}^{\#T([t_0,t_1] \frown (t_1,t_2) \frown (t_2,t_3) \frown (t_3,t_4] \frown (t_4,t_5])} \Big(\mathop{R}_{j=1}^{\#S(P \cup Q)} v\ t_i, s_j \Big) \\
&= \begin{pmatrix}
 & \mathbf{S_P} & \mathbf{S_Q} & \mathbf{S_{PQ}} \\
\mathbf{t_0} & V_{0P} & V_{0Q} & V_{0PQ} \\
\mathbf{(t_0, t_1]} & V_{1P'} & - & V_{1PQ} \\
\mathbf{(t_1, t_2]} & - & V_{2Q'} & V_{2PQ} \\
\mathbf{(t_2, t_3]} & V_{3P''} & - & V_{3PQ} \\
\mathbf{(t_3, t_4]} & - & V_{4Q''} & V_{4PQ} \\
\mathbf{(t_4, t_5]} & V_{5P'''} & - & V_{5PQ}
\end{pmatrix}
\end{aligned} \tag{45}$$

The semantic diagram of the interleave process relation as defined in Equation 45 is illustrated in Figure 14 on $\Theta(P \,|||\, Q)$.

The Pipeline Process Relation

Definition 44. *The semantics of the pipeline relations of processes on* Θ, $\theta(P >> Q)$, *is a double partial differential of the semantic function* $f_\theta(P >> Q)$ *on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}
\theta(P \gg Q) &\triangleq \frac{\partial^2}{\partial t\ \partial s} f_\theta(P \gg Q) \\
&= \frac{\partial^2}{\partial t\ \partial s} f_\theta(P) \gg \frac{\partial^2}{\partial t\ \partial s} f_\theta(Q) \\
&= \mathop{R}_{i=0}^{\#T(P)} \mathop{R}_{j=1}^{\#S(P)} v_P(t_i, s_j) \gg \mathop{R}_{i=0}^{\#T(Q)} \mathop{R}_{j=1}^{\#S(Q)} v_Q(t_i, s_j) \\
&= \mathop{R}_{i=0}^{\#T(\widehat{PQ})} \Big(\mathop{R}_{j=1}^{\#S(P \cup Q)} v\ t_i, s_j \Big) \\
&= \begin{pmatrix}
 & \mathbf{S_P} & \mathbf{S_{Po} = S_{Qi}} & \mathbf{S_Q} \\
\mathbf{t_0} & V_{0P} & V_{0PQ} & V_{0Q} \\
\mathbf{(t_0, t_1]} & V_{1P} & V_{1PQ} & - \\
\mathbf{(t_1, t_2]} & - & V_{2PQ} & V_{2Q}
\end{pmatrix}
\end{aligned} \tag{46}$$

where $\mathbf{S_{P_o}}$ *and* $\mathbf{S_{Q_i}}$ *denote a set of n one-to-one connections between the outputs of P and inputs of Q, respectively, as follows:*

$$\mathop{R}_{k=0}^{n-1} (P_o(i) = Q_i(i)) \tag{47}$$

The semantic diagram of the pipeline process relation as defined in Equation 46 is illustrated in Figure 15 on $\Theta(P >> Q)$.

The Interrupt Process Relation

Definition 45. *The semantics of the interrupt relations of processes,* $\theta(P \leftthreetimes Q)$, *on a given semantic environment* Θ *is a double partial differential*

Figure 14. The semantic diagram of the interleave process relation

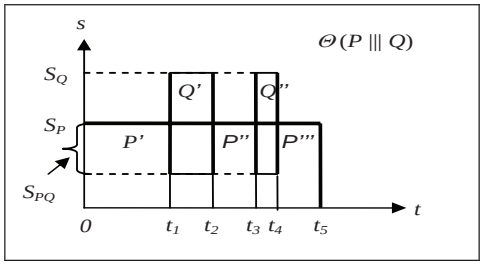

Figure 15. The semantic diagram of the pipeline process relation

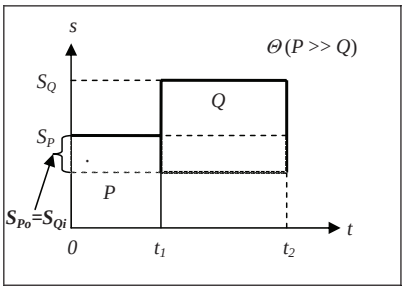

Figure 16. The semantic diagram of the interrupt process relation

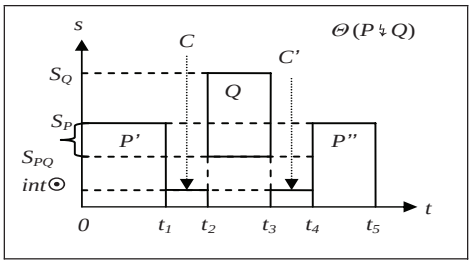

of the semantic function $f_\theta(P \lightning Q)$ on the sets of variables S and executing steps T, i.e.:

$$\begin{aligned}
\theta(P \lightning Q) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(P \lightning Q) \\
&= \frac{\partial^2}{\partial t\,\partial s} f_\theta(P) \lightning \frac{\partial^2}{\partial t\,\partial s} f_\theta(Q) \\
&= \mathop{R}_{i=0}^{\#T(P)} \left(\mathop{R}_{j=1}^{\#S(P)} v_P\ t_i, s_j \right) \lightning \mathop{R}_{i=0}^{\#T(Q)} \left(\mathop{R}_{j=1}^{\#S(Q)} v_Q\ t_i, s_j \right) \\
&= \mathop{R}_{i=0}^{\#T(P' \frown Q \frown P'')} \left(\mathop{R}_{j=1}^{\#S(P \cup Q)} v\ t_i, s_j \right) \\
&= \begin{pmatrix}
 & \mathbf{S_P} & \mathbf{S_Q} & \mathbf{S_{PQ}} & \mathbf{int}\odot \\
[\mathbf{t_0}, \mathbf{t_1}] & V_{1P'} & \perp & V_{1PQ} & \perp \\
(\mathbf{t_1}, \mathbf{t_2}] & - & - & V_{2PQ} & V_{2\mathbf{int}\odot} \\
(\mathbf{t_2}, \mathbf{t_3}] & - & V_{3Q} & V_{3PQ} & - \\
(\mathbf{t_3}, \mathbf{t_4}] & - & - & V_{4PQ} & V_{4\mathbf{int}'\odot} \\
(\mathbf{t_4}, \mathbf{t_5}] & V_{5P''} & - & V_{5PQ} & -
\end{pmatrix}
\end{aligned} \tag{48}$$

The semantic diagram of the interrupt process relation as defined in Equation 48 is illustrated in Figure 16 on $\Theta(P \lightning Q)$, where $C(\text{int}'\odot)$ and $C'(\text{int}'\odot)$ are the interrupt and interrupt-return points, respectively.

The deductive semantics of the three system dispatch process relations will be presented in the next section.

DEDUCTIVE SEMANTICS OF SYSTEM-LEVEL PROCESSES OF RTPA

The deductive semantics of systems at the top level of programs can be reduced onto a dispatch mechanism of a finite set of processes based on the mechanisms known as time, event, and interrupt. This section first describes the deductive semantics of the system process. Then, the three system dispatching processes will be formally modeled.

The System Process

Definition 46. *The semantics of the system process § on Θ, θ(§), is an abstract logical model of the executing platform with a set of parallel dispatched*

processes based on internal system clock, external events, and system interrupts, i.e.:

$$\begin{aligned}\theta(\S) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(\S) \\ &= \frac{\partial^2}{\partial t\,\partial s} f_\theta\{ \mathop{R}_{i=0}^{n_e-1}(@e_i \mathsf{S}\hookrightarrow P_i) \\ &\quad \| (\mathop{R}_{j=0}^{n_t-1} @t_j \mathsf{TM}\hookrightarrow P_j) \\ &\quad \| (\mathop{R}_{k=0}^{n_{int}-1} @int_k \mathsf{S}\hookrightarrow P_k) \\ &\quad \} \\ &= \mathop{R}_{SysShuntDown \mathsf{BL}=\mathsf{F}}^{\mathsf{T}} \{ (\mathop{R}_{i=0}^{n_e-1} @e_i \mathsf{S}\hookrightarrow P_i) \\ &\quad \| (\mathop{R}_{j=0}^{n_t-1} @t_j \mathsf{TM}\hookrightarrow P_j) \\ &\quad \| (\mathop{R}_{k=0}^{n_{int}-1} @int_k \mathsf{S}\hookrightarrow P_k) \\ &\quad \}\end{aligned} \tag{49}$$

where the semantics of the parallel relations has been given in Definition 41, and those of the system dispatch processes will be described in the following subsections.

The Time-Driven Dispatching Process Relation

Definition 47. *The semantics of the time-driven dispatching relations of processes on* Θ, $\theta(@t_k\mathsf{TM} \hookrightarrow_t P_k)$*, is a double partial differential of the semantic function* $f_\theta(@t_k\mathsf{TM} \hookrightarrow_t P_k)$ *on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}\theta(@t_k\mathsf{TM} \hookrightarrow_k P_k) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(@t_k\mathsf{TM} \hookrightarrow_k P_k) \\ &= \mathop{R}_{k=1}^{n}(@t_k\mathsf{TM} \to \frac{\partial^2}{\partial t\,\partial s} f_\theta(P_k)) \\ &= \mathop{R}_{k=1}^{n}(@t_k\mathsf{TM} \to \mathop{R}_{i=0}^{\#T(P_k)} \mathop{R}_{j=1}^{\#S(P_k)} v_{P_k}(t_i, s_j)) \\ &= \blacklozenge @t_1\mathsf{TM} \to \mathop{R}_{i=0}^{\#T(P_1)} (\mathop{R}_{j=1}^{\#S(P_1)} v_{P_1}\ t_i, s_j) \\ &\quad | \ ... \\ &\quad | \ \blacklozenge @t_n\mathsf{TM} \to \mathop{R}_{i=0}^{\#T(P_n)} \mathop{R}_{j=1}^{\#S(P_n)} v_{P_n}(t_i, s_j) \\ &= \begin{pmatrix} & @t_k\mathsf{TM} & \mathbf{S}_{\mathbf{P_1}} & ... & \mathbf{S}_{\mathbf{P_n}} \\ \mathbf{[t_0, t_1]} & \delta(@t_k\mathsf{TM}) & \perp & \cdots & \perp \\ \mathbf{(t_1, t_2]} & @t_1 & V_{P_1} & \cdots & - \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{(t_1, t_n]} & @t_n & - & \cdots & V_{P_n} \end{pmatrix}\end{aligned} \tag{50}$$

where $\blacklozenge(@t_k\mathsf{TM}) = \blacklozenge(@t_k\mathsf{N})$ *is the evaluation function as defined in Equation 17b.*

The semantic diagram of the time-driven dispatching process relation as defined in Equation 50 is illustrated in Figure 17 on Θ.

The Event-Driven Dispatching Process Relation

Definition 48. *The semantics of the event-driven dispatching relations of processes on* Θ, $\theta(@$

Figure 17. The semantic diagram of time-driven dispatch relation

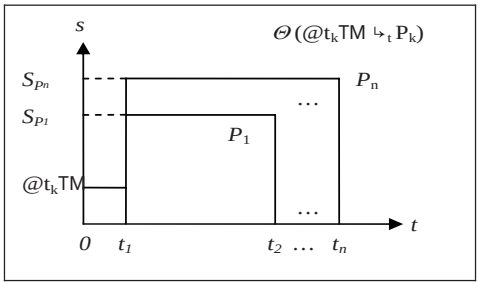

Figure 18. The semantic diagram of the event-driven dispatch relation

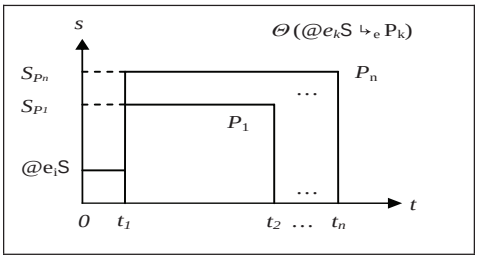


e_kS $\hookrightarrow_e P_k$), is a double partial differential of the semantic function f_θ(@e_kS $\hookrightarrow_e P_k$) on the sets of variables S and executing steps T, i.e.:

$$\begin{aligned}\theta(@e_k\mathrm{S}\hookrightarrow_e \mathrm{P}_k) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(@e_k\mathrm{S}\hookrightarrow_e \mathrm{P}_k)\\ &= \mathop{R}_{k=1}^{n}(@e_k\mathrm{S}\rightarrow \frac{\partial^2}{\partial t(P_k)\partial s(P_k)} f_\theta(P_k))\\ &= \mathop{R}_{k=1}^{n}(@e_k\mathrm{S}\rightarrow \mathop{R}_{i=0}^{\#T(P_k)}\mathop{R}_{j=1}^{\#S(P_k)} v_{P_k}(t_i,s_j))\\ &= \blacklozenge @e_1\mathrm{S}\rightarrow \mathop{R}_{i=0}^{\#T(P_1)}\mathop{R}_{j=1}^{\#S(P_1)} v_{P_1}(t_i,s_j)\\ &\quad |\ \ldots\\ &\quad |\ \blacklozenge @e_n\mathrm{S}\rightarrow \mathop{R}_{i=0}^{\#T(P_n)}\mathop{R}_{j=1}^{\#S(P_n)} v_{P_n}(t_i,s_j)\\ &= \begin{pmatrix} & \mathbf{@e_k}\mathrm{S} & \mathbf{S_{P_1}} & \ldots & \mathbf{S_{P_n}}\\ \mathbf{[t_0,t_1]} & \delta(@e_k\mathrm{S}) & \perp & \cdots & \perp\\ \mathbf{(t_1,t_2]} & @e_1 & V_{P_1} & \cdots & -\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ \mathbf{(t_1,t_n]} & @e_n & - & \cdots & V_{P_n}\end{pmatrix}\end{aligned} \tag{51}$$

The semantic diagram of the event-driven process relation as defined in Equation 51 is illustrated in Figure 18 on Θ.

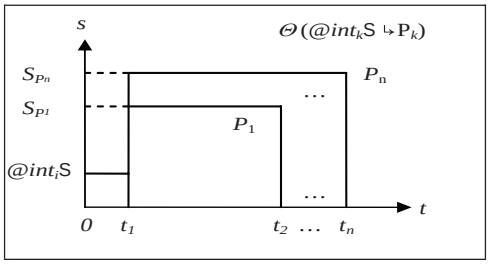
The Interrupt-Driven Dispatching Process Relation

Definition 49. *The semantics of the interrupt-driven dispatching relations of processes on* Θ, *θ(@int_kS $\hookrightarrow_i P_i$), is a double partial differential of the semantic function f_θ(@int_kS $\hookrightarrow_i P_i$) on the sets of variables S and executing steps T, i.e.:*

$$\begin{aligned}\theta(@int_k\mathrm{S}\hookrightarrow_i \mathrm{P}_k) &\triangleq \frac{\partial^2}{\partial t\,\partial s} f_\theta(@int_k\mathrm{S}\hookrightarrow_i \mathrm{P}_k)\\ &= \mathop{R}_{k=1}^{n}(@int_k\mathrm{S}\rightarrow \frac{\partial^2}{\partial t(P_k)\partial s(P_k)} f_\theta(P_k))\\ &= \mathop{R}_{k=1}^{n}(@int_k\mathrm{S}\rightarrow \mathop{R}_{i=0}^{\#T(P_k)}\mathop{R}_{j=1}^{\#S(P_k)} v_{P_k}(t_i,s_j))\\ &= @int_1\mathrm{S}\rightarrow \mathop{R}_{i=0}^{\#T(P_1)}(\mathop{R}_{j=1}^{\#S(P_1)} v_{P_1}\ t_i,s_j)\\ &\quad |\ \ldots\\ &\quad |\ @int_n\mathrm{S}\rightarrow \mathop{R}_{i=0}^{\#T(P_n)}\mathop{R}_{j=1}^{\#S(P_n)} v_{P_n}(t_i,s_j)\\ &= \begin{pmatrix} & \mathbf{@int_k}\mathrm{S} & \mathbf{S_{P_1}} & \ldots & \mathbf{S_{P_n}}\\ \mathbf{[t_0,t_1]} & \delta(@int_k\mathrm{S}) & \perp & \cdots & \perp\\ \mathbf{(t_1,t_2]} & @e_1 & V_{P_1} & \cdots & -\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ \mathbf{(t_1,t_n]} & @e_n & - & \cdots & V_{P_n}\end{pmatrix}\end{aligned} \tag{52}$$

The semantic diagram of the interrupt-driven process relation as defined in Equation 52 is illustrated in Figure 19 on Θ.

Figure 19. The semantic diagram of the interrupt-driven dispatch relation



CONCLUSION

Semantics plays an important role in cognitive informatics, computational linguistics, computing, and software engineering theories. Deductive semantics is a formal software semantics that deduces the semantics of a program in a given programming language from a generic abstract semantic function to the concrete semantics, which are embodied by the changes of statuses of a finite set of variables constituting the semantic environment of computing. Based on the mathematical models and architectural properties of programs at different composing levels, deductive models of software semantics, semantic environment, and semantic matrix have been formally defined. Properties of software semantics and relations between the software behavioral space and semantic environment have been discussed.

Case studies on the deductive semantic rules of RTPA have been presented, which serve not only as a comprehensive paradigm, but also the verification of the expressive and analytic capacity of deductive semantics.

A rigorous treatment of deductive semantics of RTPA has been presented in this article, which enables a new approach towards deductive reasoning of software semantics at all composing levels of the program hierarchy (i.e., statements, processes, and programs) from the bottom up. Deductive semantics has greatly simplified the description and analysis of the semantics of complicated software systems implemented in programming languages or specified in formal notations. Deductive semantics can be used to define both abstract and concrete semantics of large-scale software systems, facilitate software comprehension and recognition, support tool development, enable semantics-based software testing and verification, and explore the semantic complexity of software systems.

Chapter 7.19
RTPA:
A Denotational Mathematics for Manipulating Intelligent and Computational Behaviors

Yingxu Wang
University of Calgary, Canada

ABSTRACT

Real-time process algebra (RTPA) is a denotational mathematical structure for denoting and manipulating system behavioral processes. RTPA is designed as a coherent algebraic system for intelligent and software system modeling, specification, refinement, and implementation. RTPA encompasses 17 metaprocesses and 17 relational process operations. RTPA can be used to describe both logical and physical models of software and intelligent systems. Logic views of system architectures and their physical platforms can be described using the same set of notations. When a system architecture is formally modeled, the static and dynamic behaviors performed on the architectural model can be specified by a three-level refinement scheme at the system, class, and object levels in a top-down approach. RTPA has been successfully applied in real-world system modeling and code generation for software systems, human cognitive processes, and intelligent systems.

INTRODUCTION

The modeling and refinement of software and intelligent systems require new forms of denotational mathematics that possess enough expressive power for rigorously describing system architectures and behaviors. Real-time process algebra (RTPA) is a new denotational mathematical structure for software system modeling, specification, refinement, and implementation for both real-time and nonreal-time systems (Wang, 2002b, 2007d; Wang & King, 2000). An important finding in formal methods is that a software system can be perceived and described as the *composition* of a set of *processes*, which are constructed on the basis of algebraic operations. Theories on process algebras can be traced back

to Hoare's *Communicating Sequential Processes* (CSP) (Hoare, 1978, 1985) and Milner's *Calculus of Communicating Systems* (CCS) (Milner, 1980). The *process metaphor* of software systems has evolved from concurrent processes to real-time process systems in the area of operating system research and formal methods (Boucher & Gerth, 1987; Hoare, 1978, 1985; Milner, 1980, 1989; Reed & Roscoe, 1986; Schneider, 1991).

Definition 1. *A process is an abstract model of a unit of meaningful system behaviors that represents a transition procedure of the system from one state to another by changing values of the sets of inputs, outputs, and/or internal variables.*

It is recognized that generic computing problems are 3-D problems, known as those of the behavior, space, and time dimensions, which require a denotational mathematical means for addressing the requirements in all dimensions, particularly the time dimension (Wang, 2002b, 2003b, 2007d). However, conventional process models are hybrid (Hoare, 1985), which do not distinguish the concepts of fundamental metaprocesses and process operations between them. The CSP notation models a major part of elementary software behaviors that may be used in system specification and description. However, it lacks many useful processes that are perceived essential in system modeling, such as addressing, memory manipulation, timing, and system dispatch. CSP models all input and output (I/O) as abstract channel operations that are not expressive enough to denote complex system interactions, particularly for those of real-time systems.

A number of timed extensions and variations of process algebra have been proposed (Baeten & Bergstra, 1991; Boucher & Gerth, 1987; Cerone, 2000; Corsetti, Montanari, & Ratto, 1991; Dierks, 2000; Fecher, 2001; Gerber, Gunter, & Lee, 1992; Jeffrey, 1992; Klusener, 1992; Nicollin & Sifakis, 1991; Reed & Roscoe, 1986; Schneider, 1991; Vereijken, 1995). It is found that the existing work on process algebra and their timed variations can be extended and refined to a new form of denotational mathematics, RTPA, based on a set of algebraic process operations and laws (Wang, 2002b, 2003b, 2006a, 2006c, 2007d, 2008a). RTPA can be used to formally and precisely describe and specify architectures and behaviors of software systems on the basis of algebraic process notations and rules.

Definition 2. *A process P in RTPA is a composed component of n metastatements s_i and s_j, $1 \le i < n$, $j = i + 1$, according to certain composing relations r_{ij}, i.e.:*

$$P = (...(((s_1)\ r_{12}\ s_2)\ r_{23}\ s_3)\ ...\ r_{n-1,n}\ s_n) \tag{1}$$

where $r_{ij} \in \mathfrak{R}$, which is a set of relational process operators of RTPA that will be formally defined in Lemma 2.

Definition 2 indicates that the mathematical model of a process is a cumulative relational structure among computing operations. The simplest process is a single computational statement. Further discussion will be provided in the section on the unified mathematical model of programs.

Definition 3. *RTPA is a denotational mathematical structure for algebraically denoting and manipulating system behavioral processes and their attributes by a triple, i.e.:*

$$RTPA \triangleq (\mathfrak{T}, \mathfrak{P}, \mathfrak{R}) \tag{2}$$

where $\mathfrak{T}$ is a set of 17 primitive types for modeling system architectures and data objects, $\mathfrak{P}$ is a set of 17 metaprocesses for modeling fundamental system behaviors, and $\mathfrak{R}$ is a set of 17 relational process operations for constructing complex system behaviors.

RTPA provides a coherent notation system and a formal engineering methodology for modeling both software and intelligent systems. RTPA can be used to describe both *logical* and *physical* models of systems, where logical views of the architecture of a software system and its operational platform can be described using the same set of notations. When the system architecture is formally modeled, the static and dynamic behaviors that perform on the system architectural model can be specified by a three-level refinement scheme at the system, class, and object levels in a top-down approach.

This article presents the RTPA structure and methodology for modeling software and intelligent system behaviors. The type system, process notations, process relations, and process composing rules of RTPA are described. The type system and formal type rules of RTPA are formally described, and their usage in data object and system architectural modeling are demonstrated. The fundamental processes and their denotational functionality in modeling both human and system behaviors are presented. A set of algebraic process operations is introduced for constructing complex processes and systems. Then, applications of RTPA in computing and intelligent system modeling and manipulation are explored with case studies. A unified mathematic model of software and programs is derived based on the RTPA theories. The system specification and refinement methodology of RTPA and case studies on real-world problems are provided, which demonstrate the descriptive power of RTAP as a precise and neat algebraic system for software engineering.

THE TYPE SYSTEM OF RTPA

Computational operations of systems can be classified into the categories of *data object*, *behavior*, and *resource* modeling and manipulations. Based on this view, programs are perceived as the coordination of data objects and behaviors in computing. Data object modeling is a process to creatively extract and abstractly represent a real-world problem by computing objects based on the constraints of given computing resources. Using types to model the natural world can be traced back to the mathematical thought of Bertrand Russell (Russell, 1961; Schilpp, 1946) and Godel (van Heijenoort, 1997). A type is a category of variables that share a common property, such as kinds of data, domain, and allowable operations. Types are an important logical property shared by data objects in programming. Although data in their most primitive form is a string of bits, types are found expressively convenient for data representation at the logical level in computing and software engineering.

The Type System for Data Objects Modeling in RTPA

A type is a set in which all member data objects share a common logical property or attribute. The maximum range of values that a variable can assume is a type, and a type is associated with a set of predefined or allowable operations. A type can be classified as *primitive* and *derived* (complex). The former is the most elemental of types that cannot further be divided into simpler ones; the latter is a compound form of multiple primitive types based on given type rules. Most primitive types are provided by programming languages while most user-defined types are derived ones.

Definition 4. *A type system is a set of predefined templates and manipulation rules for modeling data objects and system architectures.*

RTPA types, syntaxes, and properties are given in Table 1, where the 17 primitive types in computing and human cognitive process modeling have been elicited (Cardelli & Wegner, 1985;Martin-Lof, 1975; Mitchell, 1990; Wang, 2002a, 2002b, 2003b, 2006a, 2007d, 2007e). In Table 1, the first

11 primitive types are for mathematical and logical manipulation of data objects, and the remaining 6 are for system architectural modeling.

Lemma 1. *The primary types of computational objects state that the RTPA type system $\mathfrak{T}$ encompasses 17 primitive types elicited from fundamental computing needs, i.e.:*

$$\mathfrak{T} \triangleq \{\mathsf{N}, \mathsf{Z}, \mathsf{R}, \mathsf{S}, \mathsf{BL}, \mathsf{B}, \mathsf{H}, \mathsf{P}, \mathsf{TI}, \mathsf{D}, \mathsf{DT}, \mathsf{RT}, \mathsf{ST}, @e\mathsf{S}, @t\mathsf{TM}, @int\odot, \circledS s\mathsf{BL}\} \quad (3)$$

RTPA adopts the *type suffix convention* in which every variable *x* declared in a type T, *x* : T, by a bold type label attached to the variable in all invocations in the form *x*T, where T is any valid primitive as defined in Table 1 or a derived type based on the table. The advance of the type suffix convention is the improvement of readability. Using the type suffixes, system analysts may easily identify if all variables in a statement or expression are equivalent or compatible without referring to earlier declarations, which may be scattered in a system model across hundreds of pages in a large-scale software. The type suffix convention also greatly simplifies type checking requirements during parsing the RTPA specifications by machines (Tan, Wang, & Noglah, 2004, 2006).

An essence of type theory is that types can be classified into the domains of *mathematical* (logical) D_m, *language defined* D_l, and *user defined* D_u, as shown in Table 1 (2007d).

Theorem 1. *The domain constraints of data objects states that the following relationship between the domains of any data object in computing is always held, i.e.:*

$$D_u \subseteq D_l \subseteq D_m \quad (4)$$

It is noteworthy that although a generic computing behavior is constrained by D_m, an executable program is constrained by D_l, and, at most time, it is further restricted by the user defined domain D_u, where $D_u \subseteq D_l$. According to Theorem 1, the following corollary can be derived.

Corollary 1. *The precedence of domain determinations and type inferences in computing and software engineering is always as follows:*

$$D_u \Rightarrow D_l \Rightarrow D_m \quad (5)$$

Advanced Types of RTPA

The most common and powerful derived type in computing is a *record*, also known as a *construct*, because its flexibility to accommodate different data fields in different primary or composed types. System architectures can be modeled on the basis of structured records. There are also a number of special advanced types introduced in RTPA, such as the *system* type, dynamic *run-time* type, and *event*, *interrupt*, and *status* types (Wang, 2002b, 2007d).

Definition 5. *The run-time type* RT *is a non-deterministic type at compile-time that can be dynamically bound during run-time with one of the predefined primitive types.*

The run-time type RT provides programmers a powerful means to express and handle highly flexible and nondeterministic computing objects in data modeling. Some languages such as Java and IDL (OMG, 2002) label the dynamic type RT as the *anytype*, for which a specific type may be bound until run time.

Definition 6. *An event is an advanced type in computing that captures the occurring of a predefined external or internal change of status, such as an action of users, an external change of environment, and an internal change of the value of a specific variable.*

Table 1. RTPA primitive types and their domains

No.	Type	Syntax	D_m	D_l	Equivalence
1	Natural number	N	[0, +∞]	[0, 65535]	Arithmetic, mathematic, assignment
2	Integer	Z	[-∞, +∞]	[-32768, +32767]	
3	Real	R	[-∞, +∞]	[-2147483648, 2147483647]	
4	String	S	[0, +∞]	[0, 255]	String and character operations
5	Boolean	BL	[T, F]	[T, F]	Logical, assignment
6	Byte	B	[0, 256]	[0, 256]	Arithmetic, assignment, addressing
7	Hexadecimal	H	[0, +∞]	[0, max]	
8	Pointer	P	[0, +∞]	[0, max]	
9	Time	TI = hh:mm:ss:ms	hh: [0, 23] mm: [0, 59] ss: [0, 59] ms: [0, 999]	hh: [0, 23] mm: [0, 59] ss: [0, 59] ms: [0, 999]	Timing, duration, arithmetic (A generic abbreviation: TI={TI, D, DT})
10	Date	D = yy:MM:dd	yy: [0, 99] MM: [1, 12] dd: [1, 31}	yy: [0, 99] MM: [1, 12] dd: [1, 31}	
11	Date/Time	DT = yyyy:MM:dd: hh:mm:ss:ms	yyyy: [0, 9999] MM:[1, 12] dd: [1, 31] hh: [0, 23] mm: [0, 59] ss: [0, 59] ms: [0, 999]	Yyyy: [0, 9999] MM:[1, 12] dd: [1, 31] hh: [0, 23] mm: [0, 59] ss: [0, 59] ms: [0, 999]	
12	Run-time determinable type	RT	–	–	Operations suitable at run-time
13	System architectural type	ST	–	–	Assignment (field reference by '.')
14	Random event	@*e*S	[0, +∞]	[0, 255]	String operations
15	Time event	@*t*TM	[0ms, 9999 yyyy]	[0ms, 9999 yyyy]	Logical
16	Interrupt event	@*int*⊙	[0, 1023]	[0, 1023]	Logical
17	Status	ⓢ*s*BL	[T, F]	[T, F]	Logical

The event types of RTPA can be classified into those of *operation* (@*e*S), *time* (@*t*TM), and *interrupt* (@*int*⊙), as shown in Table 1, where @ is the *event prefix*, and S, TM, and ⊙ the corresponding type suffixes, respectively.

A special set of complex types known as the system type ST is widely used for modeling system architectures in RTPA, particularly real-time, embedded, and distributed systems architectures. All the system types are nontrivial data objects in computing, rather than simple data or logical objects, which play a very important role in the whole lifecycle of complex system development including design, modeling, specification, refinement, comprehension, implementation, and maintenance of such systems.

Definition 7. *A system type* ST *is a system architectural type that models the architectural components of the system and their relations.*

A generic ST type is the *Component Logical Model* (CLM), as defined in RTPA (Wang, 2002b, 2007d). CLMs are powerful modeling means in system architectural modeling.

Definition 8. *CLMs are a record-structured abstract model of a system architectural component that represents a hardware interface, an internal logical model, and/or a common control structure of a system.*

CLMs can be used for unifying user defined complex types in system modeling. A formal treatment of CLMs will be provided in Definition 12.

It is recognized that any form of intelligence is memory based (Wang, 2002a, 2203a, 2006b, 2007c, 2007d, 2007e). All data objects, no matter language generated or user created, should be implemented as physical data objects and be bound to specific memory locations. Therefore, memory models play an important role in system modeling.

Definition 9. *The generic system memory model, MEM*ST*, can be described as a special system type* ST *with a finite linear space, i.e.:*

$$\text{MEMST} \triangleq [addr_1\text{H} \ldots addr_2\text{H}]\text{RT} \tag{6}$$

where addr$_1$H *and addr*$_2$H *are the start and end addresses of the memory space, and* RT *is the type of each of the memory elements, which is usually in Byte* B *in computing.*

Another special system type is the I/O port type for modeling hardware architectures and their interfaces.

Definition 10. *The generic system I/O port model, PORT*ST*, can be described as a system type* ST *with a finite linear space, i.e.:*

$$\text{PORTST} \triangleq [ptr_1\text{H} \ldots ptr_2\text{H}]\text{RT} \tag{7}$$

where ptr$_1$H *and ptr*$_2$H *are the start and end addresses of the port space, and* RT *is the type of each of the port I/O interfaces, which is usually in Byte* B *in computing.*

Formal Type Rules of RTPA

A type system specifies the data objects modeling and composing rules of a programming language as that of a grammar system which specifies the program behavior modeling and composing rules of the language. The basic *properties* of type systems are decidable, transparent, and enforceable (Cardelli & Wegner, 1985; Martin-Lof, 1975; Mitchell, 1990). Type systems should be *decidable* by a type checking system, which ensures that types of variables are both well-declared and referred. Type systems should be *transparent* that helps for diagnoses of reasons for inconsistency between variables or variables and their declarations. Type systems should be *enforceable* in order to check type inconsistence as much as possible.

A *formal type system* is a collection of all type rules for a given programming language or formal notation system. A type rule is a mathematical relation and the constraints on a given type. Type rules are defined on the basis of a type environment.

Definition 11. *The type environment* Θ_t *of RTPA is a collection of all primitive types in the formal notation system, i.e.:*

$$\Theta_t \triangleq \mathfrak{T} = \{\text{N, Z, R, S, BL, B, H, P, TI, D, DT, RT, ST, } @e\text{S, } @t\text{TM, } @int\odot, \circledS s\text{BL}\} \tag{8}$$

where $\mathbb{T}$ is the set of primary types as defined in Table 1.

Complex and derived types of RTPA can be described by composing type rules based on those of the primitive types.

As given in Definition 8, a CLM is a generic system architectural type for modeling and manipulating data objects and system architectures (Wang, 2002b, 2007d).

Definition 12. *The type rule of a CLM type, CLM, is a complex system type* ST *in RTPA derived from* Θ_t*, i.e.:*

$$\frac{\Theta_t \vdash \mathsf{ST}}{\Theta_t \vdash CLM : \mathsf{ST}} \tag{9}$$

The declaration of a variable, *ClmID*, with a given CLM type can be denoted by using the following type rule as given in Equation 10, where the ClmIDST is defined by the string type label ClmIDS with an n-field structure, each of them specifies a metavariable ID_i in type T_i, and its constraints denoted by Constraint($ID_i T_i$), which are a set of expressions.

A *process* in RTPA is a basic behavioral unit for modeling software system operations onto the data objects. A process can be a metaprocess or a complex process composed with multiple metaprocesses by relational process operators. Because processes are so frequently used in system modeling, a derived type in RTPA known as the process type can be introduced as a special system type.

Definition 13. *The type rule of a process type, PROC, is a complex system type* ST *in RTPA derived from* Θ_t*, i.e.:*

$$\frac{\Theta_t \vdash \mathsf{ST}}{\Theta_t \vdash PROC : \mathsf{ST}} \tag{11}$$

The declaration of a variable, *ProcID*, with the *PROC* type can be denoted by using the following type rule as given in Equation 11, where the ProcIDST is defined by the string type label ProcIDS with a set of n inputs and a set of m outputs in a specific type, as well as a set of q I/O constructs or CLMs in a specific ST type.

METAPROCESSES OF RTPA

On the basis of the process metaphor, this section elicits the most general and fundamental system behaviors in computing and intelligent systems. Computational operations in conventional process algebra, such as CSP (Hoare, 1985), Timed-CSP (Boucher & Gerth, 1987; Reed & Roscoe, 1986; Schneider, 1991), and other proposals are treated as a set of processes at the same level. This approach results in an exhaustive listing of processes. Whenever a new operation is identified or required in computing, the existing process system must be extended.

RTPA adopts the foundationalism in order to find the most primitive computational processes

Box 1.

$$\frac{\Theta_t \vdash \mathsf{ST}, \Theta_t \vdash \mathsf{T}, \Theta_t \vdash ClmID{:}\mathsf{ST}, \Theta_t \vdash ID{:}\mathsf{T}}{\Theta_t \vdash ClmID\mathsf{ST} \triangleq ClmID\mathsf{S} :: \{ \mathop{\mathsf{R}}_{i=1}^{n} < ID_i : T_i \mid \text{Constraint}(ID_i T_i) >; \}} \tag{10}$$

Box 2.

$$\frac{\Theta_t \vdash ProcID{:}\mathsf{ST}}{\Theta_t \vdash ProcID\mathsf{ST} \triangleq ProcID\mathsf{S}}$$

$$(\mathrm{I}::<\mathop{\mathrm{R}}_{i=1}^{n} ID_i\mathsf{T}_i>;\ \mathrm{O}::<\mathop{\mathrm{R}}_{j=1}^{m} ID_j\mathsf{T}_j>;\ \mathrm{CLM}::<\mathop{\mathrm{R}}_{k=1}^{q} ClmID_k\mathsf{ST}_k>) \quad (12)$$

known as the *metaprocesses*. In this approach, complex processes are treated as derived processes from these metaprocesses, based on a set of algebraic process composition rules known as the *process relations.*

Definition 14. *A metaprocess in RTPA is a primitive computational operation that cannot be broken down to further individual actions or behaviors.*

A metaprocess is an elementary process that serves as a basic building block for modeling software behaviors. *Complex processes* can be composed from metaprocesses using *process relations*. In RTPA, a set of 17 metaprocesses has been elicited as shown in Table 2, from essential and primary computational operations commonly identified in existing formal methods and modern programming languages (Aho, Sethi, & Ullman, 1985; Higman, 1977; Hoare et al., 1987; Louden, 1993; Wilson & Clark, 1988; Woodcock & Davies, 1996). Mathematical notations and syntaxes of the metaprocesses are formally described in Table 2, while formal semantics of the metaprocesses of RTPA may be found in Wang (2006c, 2008a).

Lemma 2. *The RTPA metaprocess system* $\mathfrak{P}$ *encompasses 17 fundamental computational operations elicited from the most basic computing needs, i.e.:*

$$\mathfrak{P} = \{:=, \blacklozenge, \Rightarrow, \Leftarrow, \nLeftarrow, \gtrdot, \lessdot, |\gtrdot, |\lessdot, @, \triangleq, \uparrow, \downarrow, !, \otimes, \boxtimes, \S\} \quad (13)$$

As shown in Lemma 2 and Table 2, each metaprocess is a basic operation on one or more operands such as variables, memory elements, or I/O ports. Structures of the operands and their allowable operations are constrained by their types, as described in previous sections.

It is noteworthy that not all generally important and fundamental computational operations, as shown in Table 2, had been explicitly identified in conventional formal methods (e.g., the evaluation, addressing, memory allocation/release, timing/duration, and the system processes). However, all these are found necessary and essential in modeling system architectures and behaviors (Wang, 2007d).

ALGEBRAIC PROCESS OPERATIONS IN RTPA

The metaprocesses of RTPA developed in the preceding section identified a set of fundamental elements for modeling the most basic behaviors of computing and intelligent systems. It is interesting to realize that there is only a small set of 17 metaprocesses in system modeling. However, via the combination of a number of the metaprocesses by certain algebraic operations, any architecture and behavior of real-time or nonreal-time systems

Table 2. RTPA Metaprocesses

No.	Meta Process	Notation	Syntax
1	Assignment	:=	$y\mathbb{T} := x\mathbb{T}$
2	Evaluation	$\blacklozenge$	$\blacklozenge_{\mathbb{T}} exp\mathbb{T} \rightarrow \mathbb{T}$
3	Addressing	$\Rightarrow$	$id\mathbb{T} \Rightarrow \text{MEM}[ptr\mathbb{P}]\ \mathbb{T}$
4	Memory allocation	$\Leftarrow$	$id\mathbb{T} \Leftarrow \text{MEM}[ptr\mathbb{P}]\ \mathbb{T}$
5	Memory release	$\nLeftarrow$	$id\mathbb{T} \nLeftarrow \text{MEM}[\perp]\mathbb{T}$
6	Read	$\gtrdot$	$\text{MEM}[ptr\mathbb{P}]\mathbb{T} \gtrdot x\mathbb{T}$
7	Write	$\lessdot$	$x\mathbb{T} \lessdot \text{MEM}[ptr\mathbb{P}]\mathbb{T}$
8	Input	$\mid\gtrdot$	$\text{PORT}[ptr\mathbb{P}]\mathbb{T} \mid\gtrdot x\mathbb{T}$
9	Output	$\mid\lessdot$	$x\mathbb{T} \mid\lessdot \text{PORT}[ptr\mathbb{P}]\mathbb{T}$
10	Timing	$\underline{@}$	$@t\mathbb{TM} \underline{@} \S t\mathbb{TM}$ $\mathbb{TM} =$ yy:MM:dd | hh:mm:ss:ms | yy:MM:dd:hh:mm:ss:ms
11	Duration	$\triangleq$	$@t_n\mathbb{TM} \triangleq \S t_n\mathbb{TM} + \Delta n\mathbb{TM}$
12	Increase	$\uparrow$	$\uparrow(n\mathbb{T})$
13	Decrease	$\downarrow$	$\downarrow(n\mathbb{T})$
14	Exception detection	!	! (@*e*S)
15	Skip	$\otimes$	$\otimes$
16	Stop	$\boxtimes$	$\boxtimes$
17	System	§	§(*SysID*S$\mathbb{T}$)

can be sufficiently described (Wang, 2002b, 2003b, 2006a, 2007d).

Definition 15. *A process relation in RTPA is an algebraic operation and a compositional rule between two or more metaprocesses in order to construct a complex process.*

A set of 17 fundamental process relational operations has been elicited from fundamental algebraic and relational operations in computing in order to build and compose complex processes in the context of real-time software systems. Syntaxes and usages of the 17 RTPA process relations are formally described in Table 3. Deductive semantics of these process relations may be found in Wang (2006c, 2008a).

Lemma 3. *The software composing rules state that the RTPA process relation system $\mathfrak{R}$ encompasses 17 fundamental algebraic and relational operations elicited from basic computing needs, i.e.:*

$$\mathfrak{R} = \{\rightarrow, \curvearrowright, |, |\ldots|\ldots, R^*, R^+, R^i, \circlearrowleft, \rightarrowtail, \|, \oiint, |||, », \nleftrightarrow, \hookrightarrow_t, \hookrightarrow_e, \hookrightarrow_i\} \quad (14)$$

As modeled in Lemma 3 and Table 3, the first seven process relations—i.e., *sequential* (#1), *jump*

Table 3. RTPA process relations and algebraic operations

No.	Process Relation	Notation	Syntax
1	Sequence	$\rightarrow$	$P \rightarrow Q$
2	Jump	$\curvearrowright$	$P \curvearrowright Q$
3	Branch	|	$\begin{array}{l} \text{exp} \\ \mid \sim \rightarrow Q \end{array}$
4	Switch	$\begin{array}{c} \mid \\ \cdots \\ \mid \end{array}$	$\begin{array}{l} \text{exp} \\ \mathrm{i} \rightarrow P_i \\ \mid \sim \rightarrow \varnothing \\ \text{where } \mathbb{T} \in \{\mathrm{N}, \mathrm{Z}, \mathrm{B}, \mathrm{S}\} \end{array}$
5	While-loop	R^*	$\overset{\mathrm{F}}{\underset{\text{exp}=\mathrm{T}}{R}} P$
6	Repeat-loop	R^+	$P \rightarrow \overset{\mathrm{F}}{\underset{\text{exp}=\mathrm{T}}{R}} P$
7	For-loop	R^i	$\overset{n\mathrm{N}}{\underset{i\mathrm{N}=1}{R}} P(i\mathrm{N})$
8	Recursion	$\circlearrowleft$	$\overset{0}{\underset{i\mathrm{N}=n\mathrm{N}}{R}} P^{i\mathrm{N}} \circlearrowleft P^{i\mathrm{N}-1}$
9	Function call	$\rightarrowtail$	$P \rightarrowtail F$
10	Parallel	$\|\|$	$P \mid\mid Q$
11	Concurrence	$\fatslash\!\!\fatslash$	$P \fatslash\!\!\fatslash Q$
12	Interleave	$\|\|\|$	$P \mid\mid\mid Q$
13	Pipeline	»	$P \gg Q$
14	Interrupt	$\lightning$	$P \lightning Q$
15	Time-driven dispatch	$\hookrightarrow_t$	$@t_i \mathrm{TM} \hookrightarrow_t P_i$
16	Event-driven dispatch	$\hookrightarrow_e$	$@e_i \mathrm{S} \hookrightarrow_e P_i$
17	Interrupt-driven dispatch	$\hookrightarrow_i$	$@int_j \circledcirc \hookrightarrow_i P_j$

(#2), *branch* (#3), *switch* (#4), and *iterations* (#5 through #7)—may be identified as the Basic Control Structures (BCSs) of system behaviors (Aho et al., 1985; Hoare et al., 1987; Wilson & Clark, 1988). To represent the modern programming structural concepts, CSP (Hoare, 1985) identified the following seven additional process relations such as *recursion* (#8), *function call* (#9), *parallel* (#10), *concurrency* (#11), *interleave* (#12), *pipeline* (#13), and *interrupt* (#14). However, these process relations or operations were treated as the same of the metaprocesses in existing formal methods. That is, the conventional notation systems are not an algebraic production system rather than an exhaustive instruction system, which do not distinguish the basic computational operations and their composing rules.

RTPA (Wang, 2002b) extends the BCS's and process relations to *time-driven dispatch* (#15), *event-driven dispatch* (#16), *and interrupt-driven*

dispatch (#17) in order to model the top-level system behaviors, particularly those of real-time systems. The 17 process relations (BCSs) are regarded as the foundation of programming and system behavioral design, because any complex process can be combinatory implemented by the algebraic process composing operations onto the set of the 17 metaprocesses. In Table 3, the big-R used in process relations #5 through #8 is a special calculus recently created for denoting iterative and recursive behaviors of software systems (Wang, 2008b).

Theorem 2. *The express power of algebraic modeling states that the total number of the possible computational behaviors (operations) $\mathcal{N}$ is a set of combinations between two arbitrary metaprocesses $\mathbb{P}_1, \mathbb{P}_2 \in \mathfrak{P}$ composed by each of the process relations $\mathbb{R} \in \mathfrak{R}$ in RTPA, i.e.:*

$$\begin{aligned}\mathcal{N} &= \#\mathfrak{R} \bullet \mathbf{C}^2_{\#\mathfrak{P}} \\ &= 17 \bullet \frac{17!}{2!(17\text{-}2)!} \\ &= 17 \bullet 136 \\ &= 2{,}312\end{aligned} \tag{15}$$

Theorem 2 demonstrates the expressive power of the algebraic structure of RTPA towards computational behavior modeling and programming. It is noteworthy that an ordinary high-level programming language may introduce about 150 to 300 individual instructions. However, the expressive power of RTPA is much higher than those of programming languages and other exhaustive formal notation systems, although it just adopts a small set of 17 metaprocesses and 17 process relations.

MANIPULATION OF COMPUTATIONAL BEHAVIORS BY RTPA

As presented in previous sections, RTPA provides a neat and powerful denotational mathematics structure, which is capable to be used as a generic notation system for system architecture and behavior modeling and specifications. This section describes the usage and methodology of RTPA for software system modeling and refinement. Its applications in formally modeling intelligent systems and human cognitive processes will be presented in the next section.

The Universal Mathematical Model of Programs Based on RTPA

Program modeling is on coordination of computational behaviors with given data objects. On the basis of RTPA, a generic program model can be described by a formal treatment of statements, processes, and complex processes from the bottom up in the program hierarchy.

Definition 16. *A process P is the basic unit of an applied computational behavior that is composed by a set of statements s_i, $1 \le i \le n\text{-}1$, with left-associated cumulative relations, i.e.:*

$$\begin{aligned}P &= \mathop{R}_{i=1}^{n-1} (s_i\ r_{ij}\ s_j),\ j = i+1 \\ &= (...(((s_1)\ r_{12}\ s_2)\ r_{23}\ s_3)\ ...\ r_{n-1,n}\ s_n)\end{aligned} \tag{16}$$

where $s_i \in P$ and $r_{ij} \in R$.

With the formal process model as defined above, the universal mathematical model of programs can be derived below.

Definition 17. *A program $\wp$ is a composition of a finite set of m processes according to the time-,*

event-, and interrupt-based process dispatching rules of RTPA, i.e.:

$$\wp = \mathop{R}_{k=1}^{m}(@e_k \hookrightarrow P_k) \tag{17}$$

Equations 16 and 17 indicate that a program is an *embedded relational algebraic* entity, where a statement *s* in a program is an instantiation of a metainstruction of a programming language that executes a basic unit of coherent function and leads to a predictable behavior.

Theorem 3. *The Embedded Relational Model (ERM) states that a software system or a program $\wp$ is a set of complex embedded relational processes, in which all previous processes of a given process form the context of the current process, i.e.:*

$$\begin{aligned}\wp &= \mathop{R}_{k=1}^{m}(@e_k \hookrightarrow P_k) \\ &= \mathop{R}_{k=1}^{m}[@e_k \hookrightarrow \mathop{R}_{i=1}^{n-1}(p_i(k) \rightarrow_{ij} k)\, p_j(k))],\ j = i+1\end{aligned} \tag{18}$$

The ERM model presented in Theorem 3 reveals that a program is a finite and nonempty set of embedded binary relations between a current statement and *all previous ones* that formed the *semantic context* or environment of computing. Theorem 3 provides a unified software model, which is a formalization of the well accepted but informal process metaphor for software systems in computing.

ADT Modeling and Specification in RTPA

Abstract data types (ADTs) are perfect software architectures at component level that will be used to explain the modeling methodology of computing architectures and behaviors in RTPA. An ADT is a logical model of complex and/or user defined data type with a set of predefined operations on it. A queue as a typical ADT is presented in this subsection to demonstrate how the RTPA notation system is used to model and specify the architecture, static behaviors, and dynamic behaviors of software systems.

There are a number of approaches to the specification of ADTs, which can be classified into the logical and algebraic approaches. The logic approach is good at specifying the static properties of ADT operations, usually in forms of preconditions and post-conditions of operations of ADTs; while the algebraic approach is good at describing dynamic and run-time behaviors of ADTs.

A queue in RTPA is modeled as an algebraic entity, which has predefined operations on a set of data objects in given types. Unlike the conventional approaches to ADT specifications that treat ADTs as static data types, ADTs in RTPA are treated as dynamic finite state machines, which have both architectures and behaviors, in order to model both structural and operational components in system design.

Architectural Modeling in RTPA

At the top level, an RTPA specification of the queue, *Queue*ST, has three parallel facets, which are architecture, static behaviors, and dynamic behaviors, as given below.

$$\begin{aligned}\text{QueueST} \triangleq\ & \text{QueueST.Architecture} \\ & \| \text{QueueST.StaticBehaviors} \\ & \| \text{QueueST.DynamicBehaviors}\end{aligned} \tag{19}$$

Then, QueueST can be further refined by detailed specifications according to the RTPA methodology (Wang, 2007d).

The key modeling methodology for system architectures in RTPA is CLMs, as described in the subsection of advanced types. Any system architecture and data object, including their control structures, internal logic model, and hardware

interface model can be rigorously described and specified by using a set of CLMs.

Example 1. *The architecture of Queue*ST *modeled in RTPA is given in Figure 1, where both the architectural CLM and an access model are provided for the Queue.*

In Figure 1, the *access model* of QueueST is a logic model for supporting external invocation of the QueueST in operations, such as enqueue and service. The other parts of the model are designed for internal manipulation of the QueueST, such as creation, memory allocation, and memory release.

Static Behavior Modeling in RTPA

System static behaviors in RTPA are valid operations of systems that can be determined at compile-time, which describe the configuration of processes of the component and their relations. The set of static behaviors of QueueST can be modeled by a set of behavioral processes encompassing *create, release, enqueue, serve, clear, empty test,* and *full test.*

Example 2. *The detailed specification of one of the Queue's static behaviors, Queue*ST.*serve, is given in Figure 2.*

Contrasting the static behavior model of QueueST.serve in RTPA as shown in Figure 2 and in conventional propositional logic (Stubbs & Webre, 1985), the advances of RTAP method and notations may be well demonstrated. Among them, the most important advantage is that an RTPA model may be seamlessly refined into code

Figure 1. The architectural model of the Queue in RTPA

```

        → (QueueID(1))RT ≻Element RT
        → QueueID(i))RT ≻QueueID(i-1)RT
        → ↓ (QueueID.CurrentPosP)
        → ⓢQueueID.ServedBL := T
    | ◆ ~
        → ⓢQueueID.ServedBL := F
        → ! (@'QueueIDExistBL = F  ∨  QueueEmptyBL = T')
    )
}
```

in a programming language in the succeeding phase of software engineering.

Dynamic Behavior Modeling in RTPA

System dynamic behaviors in RTPA are process relations determined at run time. According to the RTPA system modeling and refinement scheme, models of system static behaviors are process models of the system. To put the component processes into a live and interacting system, the dynamic behaviors of the system in terms of process deployment and dispatch are yet to be specified.

Example 3. *The dynamic behaviors of Queue*ST *are specified in RTPA as shown in Figure 3, where the process dispatch mechanisms of the Queue specifies detailed dynamic process relations at run time by a set of event-driven relations.*

Figures 1 through 3 model an ADT, *Queue*ST, in a coherent system from three facets. With the RTPA specification and refinement methodology and the expressive power of the RTPA notation system, the features of ADTs as both static data types and dynamic finite machines can be specified formally and precisely.

MANIPULATION OF INTELLIGENT BEHAVIORS BY RTPA

RTPA may be used not only for modeling and description of computing behaviors but also for modeling and denoting the cognitive processes of the brain in cognitive informatics (Wang, 2002a, 2003a, 2003b, 2006a, 2006b, 2007a, 2007e, 2007f; Wang & Wang, 2006; Wang et al., 2006). A formal treatment of memorization as a cognitive process is presented in this section by a rigorous RTPA model based on the cognitive model of human memorization (Wang, 2007a).

The Cognitive Process of Memorization

Memorization as a cognitive process can be described by two phases: the *establishment* phase and the *reconstruction* phase. The former represents the target information in the form of an object-attribute-relation (OAR) model (Wang, 2007c) and creates a memory in long-term memory (LTM). The letter retrieves the memorized information and reconstructs it in the form of a concept in the short-term memory (STM). Therefore, memorization can be perceived as the transformation of information and knowledge between STM and LTM, where the forward transformation from STM to LTM is for memory establishment, and

Figure 3. The dynamic behavioral model of the Queue in RTPA

QueueST**.DynamicBehaviors** $\triangleq$ { § $\rightarrow$
(@CreateQueueS ↳ Queue.Create (<**I::** QueueInstS, ElementInstRT, SizeInstN>;
<**O::** ⓢQueueID.AllocatedBL, ⓢQueueID.ExistBL>)
| @ReleaseQueueS ↳ Queue.Release (<**I::** QueueInstS>; <**O::** ⓢQueueID.ReleasedBL>)
| @EnqueueS ↳ Queue.Enqueue (<**I::** QueueInstS, ElementInstRT>; <**O::** ⓢQueueID.EnqueuedBL>)
| @ServeS ↳ Queue.Serve (<**I::** QueueInstS>; <**O::** ⓢQueueID.ServedBL, ElementRT>)
| @ClearS ↳ Queue.Clear (<**I::** QueueInstS>; <**O::** ⓢQueueID.ClearedBL>)
| @QueueEmptyS ↳ Queue.EmptyTest (<**I::** QueueInstS>; <**O::** ⓢQueueID.FullBL>)
| @QueueFullS ↳ Queue.FullTest (<**I::** QueueInstS>; <**O::** ⓢQueueID.FullBL>)
) $\rightarrow$ §
}

the backward transformation from LTM to STM is for memory reconstruction.

Algorithm 1. *The cognitive process of memorization can be carried out by the following steps:*

(0) Begin.
(1) Encoding: This step generates a representation of a given concept by transferring it into a sub-OAR model;
(2) Retention: This step updates the entire OAR in LTM with the sub-OAR for memorization by creating new synaptic connections between the sub-OAR and the entire OAR;
(3) Rehearsal test: This step checks if the memorization result in LTM needs to be rehearsed. If yes, it continues to practice Steps (4) and (5); otherwise, it jumps to Step (7);
(4) Retrieval: This step retrieves the memorized object in the form of sub-OAR by searching the entire OAR with clues of the initial concept;
(5) Decoding: This step transfers the retrieved sub-OAR from LTM into a concept and represents it in STM;
(6) Repetitive memory test: This step tests if the memorization process was succeeded or not by comparing the recovered concept with the original concept. If need, repetitive memorization will be called.
(7) End.

It is noteworthy that the input of memorization is a structured concept formulated by learning or other cognitive processes (Wang, 2007d, 2007f; Wang et al., 2006).

Formal Description of the Memorization Process in RTPA

The cognitive process of memorization described in Algorithm 1 can be formally modeled using RTPA as given in Figure 4. According to the LRMB model (Wang et al., 2006) and the OAR model (Wang, 2007c) of internal knowledge representation in the brain, the input of the memorization process is a structured concept c(OS, AS, RS)ST, which will be transformed to update the entire OAR model of knowledge in LTM in order to create a permanent memory. Therefore, the output of memorization is the updated OAR'ST in LTM.

In the RTPA memorization process, as shown in Figure 4, the *encoding* subprocess is modeled as a function that maps the given concept *c*ST into a sub-OAR, sOARST. The *retention* subprocess composes the sOARST with the entire OARST in LTM that maintains the whole knowledge of an individual. In order to check the memorization quality, rehearsals are usually needed. In a rehearsal, the *retrieval* subproecss searches a related sOARST in LTM by giving clues of previously memorized objects and attributes in cST. Then, the *decoding* subprocess transfers the sOARST into a recovered concept c'ST. In the repetitive memory test subprocess, the reconstructed c'ST will be compared with the original input of cST in order to determine if further memorization is recursively needed.

According to the 24-hour law of memorization as stated in Wang and Wang (2006), the memorization process may be completed with a period at least 24 hours by several cycles of repetitions. Although almost all steps in the process shown in Figure 4 are conscious, the key step of *retention* is subconscious or nonintentionally controllable. Based on the LRMB model (Wang et al., 2006), the memorization process is closely related to learning (Wang, 2007f). In other words, memorization is a back-end process of learning, which retains learning results in LTM and retrieves them when rehearsals or applications are needed. The retrieve process is search-based by contents or sOARST matching.

The cognitive process of memorization formally modeled in RTPA provides a rigorous description of one of the important and complicated mental processes of the brain. This case study explains the second usage of RTPA in intelligent

system modeling and human behavioral manipulation. Further models and applications of RTPA in intelligent system modeling may be referred to (Wang, 2007d; Wang & Ngolah, 2002, 2003). The applications of RTPA in modeling cognitive processes of the brain and natural intelligence may be found in Wang (2003b, 2007a, 2007f).

CONCLUSION

RTPA has been developed as a denotational mathematical means, which can be used as algebra-based, expressive, easy-to-comprehend, and language-independent notation system, and a practical specification and refinement method for software and intelligent system modeling. RTPA is capable to support top-down software system design and implementation by algebraic modeling and seamless refinement methodologies. The RTPA methodology covers the entire system lifecycle from high-level design to code generation in a coherent algebraic notation system.

This article has demonstrated that RTPA is not only useful as a generic notation and methodology for computing and software system modeling but is also good at modeling human cognitive processes and intelligent systems. A number of case studies on large-scale software system modeling and specifications have been carried out, such as the Telephone Switching System (TSS) (Wang, 2003b), the Lift Dispatching System (LDS) (Wang & Ngolah, 2002), and the Automated Teller Machine (ATM) (Wang & Zhang, 2003). The application results have encouragingly demonstrated that RTPA is a powerful and practical algebraic

system for both academics and practitioners in software and intelligent system engineering.

A set of support tools for RTPA have been developed (Ngolah, Wang, & Tan, 2005b, 2006; Tan & Wang, 2006; Tan, Wang, & Ngolah, 2004a, 2004b, 2005, 2006), which encompasses the RTPA parser, type checker, and code generator in C++ and Java. The RTPA code generator enables system specifications in RTPA to be automatically translated into fully executable code. The RTPA tools will support system architects, analysts, and practitioners for developing consistent and correct specifications and architectural models of large-scale software and intelligent systems, and the automatic generation of code based on formal models and rigorous specifications in the denotational mathematical notations.

Chapter 7.20
Measuring the Efficiency of Free and Open Source Software Projects Using Data Envelopment Analysis

Stefan Koch
Vienna University of Economics and Business Administration, Austria

ABSTRACT

In this chapter, we propose for the first time a method to compare the efficiency of free and open source projects, based on the data envelopment analysis (DEA) methodology. DEA offers several advantages in this context, as it is a non-parametric optimization method without any need for the user to define any relations between different factors or a production function, can account for economies or diseconomies of scale, and is able to deal with multi-input, multi-output systems in which the factors have different scales. Using a data set of 43 large F/OS projects retrieved from SourceForge.net, we demonstrate the application of DEA, and show that DEA indeed is usable for comparing the efficiency of projects. We will also show additional analyses based on the results, exploring whether the inequality in work distribution within the projects, the licensing schem,e or the intended audience have an effect on their efficiency. As this is a first attempt at using this method for F/OS projects, several future research directions are possible. These include additional work on determining input and output factors, comparisons within application areas, and comparison to commercial or mixed-mode development projects.

INTRODUCTION

In the last years, free and open source software (also sometimes termed libre software) has gathered increasing interest, both from the business and academic world. As some projects in different application domains like most notably the operating system Linux together with the suite of GNU utilities, the office suites GNOME and KDE, Apache, sendmail, bind, and several programming languages have achieved huge success in their respective markets, both the adoption by

commercial companies, and also the development of new business models by corporations both small and large like Netscape or IBM have increased.

Currently, any comparison of free and open source (F/OS) software projects is very difficult. There is increased discussion on how the success of F/OS projects can be defined (Stewart, 2004; Stewart and Ammeter, 2002; Crowston et al., 2004; Crowston et al., 2003), using for example search engine results as proxies (Weiss, 2005). In addition, the process applied in these projects can differ significantly.

In this paper, we propose to compare F/OS projects according to their efficiency in transforming inputs into outputs. For any production process, this efficiency and productivity is a key indicator in comparison to other processes. For F/OS projects, two levels of analysis are of interest: The F/OS process in general is different to commercial software development processes, and the process variance between F/OS projects is also high. In both cases, a main difference, and a main argument for adopting a process or elements from it, is the efficiency. Neither a commercial enterprise, nor an F/OS project would knowingly and willingly waste scarce resources by using an inefficient development process. This necessitates to compute and compare the efficiency of F/OS projects to gain an understanding of the results any process decision has on the outputs, which could lead to identifying best practices, and thus to increasing the overall efficiency and thus output of all projects.

To this end, we propose to apply the method of Data Envelopment Analysis (DEA), which is a non-parametric optimization method for efficiency comparisons without any need for the user to define any relations between different factors or a production function. In addition, DEA can account for economies or diseconomies of scale, and is able to deal with multi-input, multi-output systems in which the factors have different scales. Efficiency and productivity in software development is most often denoted by the relation of an effort measure to an output measure, using either lines-of-code (Park, 1992) or, preferably due to independence from programming language, function points (Albrecht and Gaffney, 1983). While this approach can be problematic in an environment of commercial software development as well due to missing components especially of the output, for example also Kitchenham and Mendes (2004) agree that productivity measures need to be based on multiple size measures, there are additional problems in the context of F/OS development which point towards DEA as an appropriate method.

In F/OS projects, normally the effort invested is unknown, and therefore might need to be estimated (Koch, 2004; Koch, 2005), and is also more diverse than in commercial projects, as it includes core team member, committers, bug reporters and several other groups with varying intensity of participation. Besides that, also the outputs can be more diverse. In the general case, the inputs of an F/OS project can encompass a set of metrics, especially concerned with the participants. So, in the simplest case, the number of programmers and other participants can be used. The output of a project can be measured using several software metrics like most easily the number of LOC, files, checkins to the source code control system, postings, bug reports, characteristics of development speed (e.g. coefficients of a software evolution equation estimated) or even metrics for product attributes like McCabe's cyclomatic complexity (McCabe, 1976) or object-oriented metrics, e.g. the Chidamber-Kemerer suite (Chidamber and Kemerer, 1994). This range of metrics both for inputs and outputs, and their different scales necessitates application of an appropriate method, which DEA can be.

The main result of applying DEA for a set of projects is an efficiency score for each project. This score can serve different purposes as mentioned above: First, single projects can be compared accordingly, but also groups of projects, for example those following similar process models,

located in different application domains or simply of different scale can be compared to determine whether any of these characteristics lead to higher efficiency. Lastly, this method could also be used for a comparison with traditional, commercial or even hybrid projects, which in addition to volunteer resources also feature monetary input from an organization. In this way, important questions concerning software development in general and especially in F/OS projects can be answered: Which methods allow for the most efficient application of the available manpower? Is F/OS software development a new, more efficient way of producing software? Are projects on a larger scale more efficient than those on smaller scale? Is a high concentration of work on a small number of heads efficient?

In this paper, we will demonstrate a first application of DEA to compare the efficiency of a set of F/OS projects. After a short introduction to F/OS, we will describe the method of DEA in general. Based on this, the application will be detailed, starting with a description of the methodology of data retrieval and the respective data set to be used. We will then discuss how to set up the DEA model in this case, taking into account the available data, and give the results. In a section on future research, possible enhancements to this work will be given, in addition to applications of the results obtained.

FREE AND OPEN SOURCE SOFTWARE

For a quick definition of free and open source software, both terms needs to be analyzed (Laurent, 2004; Dixon, 2003; Rosen, 2004). The term open source as used by the Open Source Initiative (OSI) is defined using the Open Source Definition (Perens, 1999), which lists a number of rights which a license has to grant in order to constitute an open source license. These include most notably free redistribution, inclusion of source code, to allow for derived works which can be redistributed under the same license, and integrity of author's source code. The Free Software Foundation (FSF) advocates the term free software (Stallman, 2002). A software is defined as free if the user has the freedom to run the program, for any purpose, to study how the program works, and adapt it to his needs, to redistribute copies and to improve the program, and release these improvements to the public. Access to the source code is a necessary precondition. In this definition, open source and free software are largely interchangeable. The GNU project itself prefers copylefted software, which is free software whose distribution terms do not let redistributors add any additional restrictions when they redistribute or modify the software. This means that every copy of the software, even if it has been modified, must be free software, a prescription embodied in the most well-known and important license, the GNU General Public License (GPL).

Not only is F/OS software unique in its licenses and legal implications, but also in its development process. The main ideas of this development model are described in the seminal work of Raymond (1999), 'The Cathedral and the Bazaar', in which he contrasts the traditional type of software development of a few people planning a cathedral in splendid isolation with the new collaborative bazaar form of open source software development. In this, a large number of developer-turned users come together without monetary compensation (Raymond, 1999; Hertel et al., 2003) to cooperate under a model of rigorous peer-review and take advantage of parallel debugging that leads to innovation and rapid advancement in developing and evolving software products. In order to allow for this to happen and to minimize duplicated work, the source code of the software needs to be accessible which necessitates suitable licenses, and new versions need to be released often. Today, agile methods like eXtreme Programming or the strict release processes in place in several

open source projects (Holck & Jorgensen, 2004) give evidence to mixed forms of development. Currently, empirical research on similarities and dissimilarities between F/OS development and other development models is still proceeding (Mockus et al., 2002; Koch, 2004).

DATA ENVELOPMENT ANALYSIS

Production and Efficiency

The production of a good or service can be formalized using a production function, which gives the maximum possible output for a given amount of input (Varian, 2005). Several mathematical forms for production functions have been used in literature, including a linear form or a Cobb-Douglas production function, necessitating an appropriate number of parameters for defining the function in a concrete case. The notion of returns to scale is intimately linked to this concept: If the inputs are scaled by a constant factor, e.g. twice as much input is used, constant returns to scale would mean that the output is scaled by the same amount. If increasing returns to scale are present, the output would increase more than that, less with decreasing returns to scale (Varian, 2005). Of course, the returns to scale might be different at different levels of production, leading to an ideal size of production (or firm). The term of economies of scale refers to the decreased per unit cost as output increases. Both the production function to be used (Hu, 1997), and the returns to scale (Banker & Kemerer, 1989; Banker & Slaughter, 1997) have long been a topic of discussion in software development.

For comparing the efficiency of different firms (or units), the most basic approach is to compute the ratio of an output to an input. Those firms (or units) exhibiting the highest ration are able to produce the most output given an input, thus are most efficient. For the area of software development, efficiency or productivity is most often denoted as lines-of-code, or preferably function points (Albrecht and Gaffney, 1983) due to their technology neutrality, per person-month of effort. Problems with this approach are that it is computationally not usable for multi-input, multi-output situations, and that it assumes constant returns to scale.

Main Concepts of DEA

The principle of the border production function was introduced by Farell (1957) for measuring the technical efficiency and enhanced by Charnes, Cooper and Rhodes (1978a) into the first Data Envelopment Analysis model (the CCR model). The term DEA is used for the first time in an evaluation of school programs for the support of handicapped children. The object of analysis the DEA considers is very generally termed Decision Making Unit (DMU). This term includes relatively flexibly each unit which is responsible for the transformation of inputs into outputs. As different applications show, this definition covers therefore hospitals, supermarkets, schools, bank branches and others.

The basic principle of DEA can be understood as a generalization of the normal efficiency evaluation as described above by means of the relationship from an output to an input into the general case of a multi-output, multi-input system without a any given conversion rates or same units for all factors. For the area of software development, this can be understood as adding for example pages of documentation to lines-of-code and function points as an output factor. In contrast to other approaches, which require the parametric specification of a production function, DEA measures production behavior directly and uses this data for the evaluation of all DMUs. The DEA derives a production function from mean relations between inputs and outputs (whereby it is only assumed that the relation is monotonous and concave), by determining the outside cover of all production relations, while for example a regression analysis

estimates a straight line through the centre of all production relations. The DEA identifies "best practicing" DMUs, which lie on the production border. Thus any outliers and measuring and / or data errors may exert a strong influence on the results, and therefore special attention is to be given to sensitivity analyses. In order to determine the production function, the efficient DMUs are linked in sections with one another. A DMU is understood as being efficient if none of the outputs can be increased, without either or several of the inputs increasing or other outputs being reduced, as well as none of the inputs can be reduced, without reducing either one or more outputs or increasing other inputs.

Computation

For each DMU an individual weighting procedure is used over all inputs and outputs. These form a weighted positive linear combination, whereby the weights are specified in such a way that they maximize the production relationship of the examined unit, in order to let these become as efficient as possible. The efficiency of an examined unit is limited with 1. That means it that no a-priori weightings are made by the user, and that the weights between the DMUs can be different. However, the definition of the relevant inputs and outputs is necessary. For each evaluation object the DEA supplies a solution vector of weighting factors and a DEA efficiency score. If this score is equal to 1, then the DMU is DEA efficient. In this context, DEA efficiency means that within the selected model variant no weighting vector could be found which would have led to a higher efficiency value. DEA efficient are thus all those DMUs which are not clearly DEA inefficient compared with the others. Any inefficiency can therefore not be ruled out completely. For inefficient DMUs weighting factors were found in the context of the selected model variant which resulted in a higher efficiency value in the case of at least another DMU.

For each inefficient DMU the DEA returns a set of efficient DMUs which exhibit a similar input/output structure and lie on the production border near to the inefficient DMU (this is also termed reference set or DEA benchmark). Using this information, an idea in which direction an increase in efficiency is possible can be gained. Because the relative efficiency measure is based on the distances from actually existing DMUs and is thus easily comprehensible, DEA is suitable as an analysis tool better than other methods.

Models of DEA

The first model of the DEA was introduced by Charnes, Cooper and Rhodes (1978b) and is designated with the initial letters of their surnames as CCR model. They pose four assumptions for the production possibility set, which are convexity (each linear combination of two DMUs results in a production possibility within the valid range), possibility for inefficient production (all production possibilities which are more inefficient than the known DMUs are permissible), constant returns to scale and minimum extrapolation (the production possibility range covers all observed DMUs). The CCR model measures the efficiency of each DMU by examining the relationship of the outputs to the inputs, optimally weighted for the DMU. This optimization happens under the constraint that equivalent conditions for no other DMU result in a value exceeding 1. By this maximization each DMU receives the optimum weighting given the constraint.

The different basic models of the DEA can be divided on the basis of two criteria: This is on the one hand the orientation of the model, on the other hand the underlying assumption regarding the returns to scale of the production process. With input-oriented models the reduction of the input vector maximally possible with the given manufacturing technology is determined, whereas with output-oriented models the maximally possible proportional increase of the output vector is

determined. Input orientation is generally present, if an enterprise function (for example manufacturing) is to be analyzed which minimizes the resources consumption, but can only affect the output in a limited way. The returns to scale can be assumed either as being constant as in the CCR model described above, or variable. With constant returns to scale size-induced productivity differences are considered into the efficiency evaluation, with variable returns to scale the differences are neutralized by the model. The most common example of a model with variable returns to scale is an advancement to the CCR model by Banker, Charnes and Cooper (1984), the BCC model. This model includes an additional measuring variable in the fundamental equation to capture rising, falling or constant returns to scale.

Applications

DEA models are generally used where scarce resources are to be used goal-oriented. The first DEA models were developed to measure the efficiency of non-profit units, for whose inputs and outputs no clear market prices exist and also otherwise no clear evaluation relations are present. The entire public sector therefore represents a typical area of application. Emphases of the first investigations were therefore health service, in particular hospitals, as well as school advancement programs (Charnes et al., 1978a). In further consequence the DEA was also applied to the evaluation of the efficiency of private business units as for instance branches of banks or supermarkets, especially if the efficiency is not only to be measured in profit, but also by parameters as for instance environmental condition, downtimes or customer satisfaction.

In the area of software development, DEA was so far only rarely applied. Banker and Kemerer (1989) use this approach in order to prove the existence of both rising and falling returns to scale. First arise in small, the others in larger software development projects. Based on published collections of project data records the authors compute in each case the point of the maximum productivity (most productive scale size) within the set of projects, starting from which the returns to scale begin to fall. Banker and Slaughter (1997) use the DEA in the area of maintenance and enhancement projects. It can be proven that rising returns to scale are present, which would have made a cost reduction of around 36 per cent possible when utilized. This was prevented however by organizational constraints, for example high punishments for exceeding the completion date. Mayrhauser et al. (2000) also report applying DEA on a data set consisting of 46 software projects from the NASA-SEL database to analyze objective variables and their impact on efficiency. They suggest combining this with the results of applying principal component analysis (PCA) in an analysis of subjective variables. An investigation of ERP projects was done by Myrtveit and Stensrud (1999). They used 30 SAP R/3-projects of a consulting firm for the application of the DEA. Kitchenham (2002) gives an in-depth discussion on the application of DEA in software development.

APPLICATION OF DEA FOR FREE AND OPEN SOURCE SOFTWARE PROJECTS

Methodology

For performing the proposed efficiency comparison of F/OS software projects, the information contained in software development repositories will be used. These repositories contain a plethora of information on the underlying software and the associated development processes (Cook et al., 1998; Atkins et al., 1999). Studying software systems and development processes using these sources of data offers several advantages (Cook et al., 1998): This approach is very cost-effective, as no additional instrumentation is necessary, and

it does not influence the software process under consideration. In addition, longitudinal data is available, allowing for analyses considering the whole project history.

Depending on the tools used in a project, possible repositories available for analysis include source code versioning systems, bug reporting systems, or mailing lists. Many of these have already been used as information sources for closed source software development projects. For example, Cook et al. (1998) present a case study to illustrate their proposed methodology of analyzing in-place software processes. They describe an update process for large telecommunications software, analyzing several instances of this process using event data from customer request database, source code control, modification request tracking database and inspection information database. Atkins et al. (1999) use data from a version control system in order to quantify the impact of a software tool, a version-sensitive editor, on developer effort.

In open source software development projects, repositories in several forms are also in use, in fact form the most important communication and coordination channels, as the participants in any project are not collocated. Therefore only a small amount of information can not be captured by repository analyses because it is transmitted inter-personally. As a side effect, the repositories in use must be available openly and publicly, in order to enable as many persons as possible to access them and to participate in the project. Therefore open source software development repositories form an optimal data source for studying the associated type of software development.

Given this situation, repository data have already been used in research on open source software development. This includes in-depth analyses of small numbers of successful projects like Apache and Mozilla (Mockus et al., 2002), GNOME (Koch and Schneider, 2002) using mostly information provided by version-control-systems, but sometimes in combination with other repository data like from mailing list archives. Large-scale quantitative investigations spanning several projects going into software development issues are not yet as common, and have mostly been limited to using aggregated data provided by software project repositories (Crowston and Scozzi, 2002; Hunt and Johnson, 2002; Krishnamurthy, 2002), meta-information included in Linux Software Map entries (Dempsey et al., 2002), or data retrieved directly from the source code itself (Ghosh and Prakash, 2000).

Data Collection and Data Set

For this efficiency comparison, a data set covering several projects was needed. Therefore, we used a subset of a data set already available from prior research derived from SourceForge.net, the software development and hosting site. The mission of SourceForge.net is 'to enrich the open source community by providing a centralized place for open source developers to control and manage open source software development'. To fulfill this mission goal, a variety of services is offered to hosted projects, including tools for managing support, mailing lists and discussion forums, web server space, shell services and compile farm, and source code control. While SourceForge.net publishes several statistics, e.g. on activity in their hosted projects, this information was not detailed enough for the proposed analysis. For example, Crowston and Scozzi (2002) used the available data for validating a theory for competency rallying, which suggests factors important for the success of a project. Hunt and Johnson (2002) have analyzed the number of downloads of projects occurring, and Krishnamurthy (2002) used the available data of the 100 most active mature projects for an analysis.

The data collection method utilized is described in detail in Hahsler and Koch (2005). It is based on automatically extracting data from the web pages and especially the source code control system, in the form of CVS, and subsequently

parsing the results and storing the relevant results, e.g. size, date and programmer of each checkin, in a database. Most of this work was done using Perl scripts. This resulted in a number of 8,621 projects for which all relevant information could be retrieved. More detailed analyses of these data can be found in Koch (2004). For this research, we chose to use the subset of largest projects, in order to have a limited set exhibiting similar characteristics. We therefore defined a threshold of at least five developers and 500,000 lines-of-code, which resulted in 43 projects. Table 1 gives descriptive statistics for these projects. While most of the variables are self-descriptive, a few notes are in order: The total number of programmers gives all different persons who have over the complete lifetime contributed code. In contrast, a programmer is defined to be active in a month if he showed activity during this time interval. The mean number of programmers per month is based on this definition, as are the cumulated active programmers. This last number can be seen as an effort indicator, denoting the sum of the active programmers for each month over the total lifetime. It is also given in person-years, although an F/OS programmer active in a given month will not necessarily have worked 40 hours per week. For example, Hertel et al. (2003) report that in the developer group of Linux kernel contributors participating in their survey, about 18.4 hours per week are spent on open source development by each person. This number could be used to convert the effort to "real" person-years, but, as only F/OS projects are to be compared here, this is not done. The status is an indicator assigned by the project administrator within SourceForge.net and aims at reflecting the phase of a project in the development lifecycle. It has seven possible values, reaching from planning, pre-alpha, alpha, beta to production/stable and mature, and to inactive. The last variable is used to depict the inequality of work distribution within the development team (Robles et al., 2004), with values nearer to 1 showing higher inequality.

Table 1. Descriptive statistics of data set (n=43)

	Min.	Max.	Mean	Std. Dev.
Size (LOC)	533321,00	7669643,00	2014731,09	2124643,99

DEA Model Definition

For computing DEA models, different software products are available, some of which are freeware. In this case, the program accompanying the book by Cooper, Seiford and Tone (2000) was used, which can solve different DEA models, input or output-oriented, as well as with constant or variable returns to scale.

The first choices to be taken concern the definition of input and output factors, as well as the model to be applied. Banker and Kemerer (1989) have demonstrated the existence of both increasing and decreasing returns to scale in software projects, also Myrtveit and Stensrud (1999) recommend to use a model with variable returns to scale. Using a data set of maintenance and extension projects Banker and Slaughter (1997) have found increasing returns to scale. Kitchenham (2002) gives an overview of research result and reasons for differences on economies and diseconomies of scale in software development. Regarding the orientation of the model, an output-orientation might seem more appropriate. Given a certain input which can be acquired, i.e. participants attracted, the output is to be maximized. According to this reasoning, the BCC-O model is applied.

Regarding the definition which factors are to be used as inputs and outputs, it is to be considered that with an increase in the number of factors more DMUs, i.e. projects, are estimated to be efficient, in particular if the database is small in relation. Also the availability of factors in the data set limits the possibilities. In this case, we selected to use the total number of programmers and their effort as inputs, and size, LOC added and deleted, files, checkins and status as output factors. Naturally, this selection is based on the available data, and could be changed. This point will be discussed in more detail within the section on future research.

Results

The results of a DEA analysis give for each DMU, in this case F/OS project, an efficiency measure as defined above, i.e. of value 1 if no possibilities for improvements in transforming inputs into outputs have been detected given the data. As the DEA model set up in this paper is output-oriented, any other value below 1 means that a proportional increase of outputs seems possible given the inputs of a project. A DEA efficiency of 0,75 would translate into a possible output increase of 25% for this project. In addition, a reference set is reported, which contains DMUs with similar input-output relations and lie on the production border near to the inefficient DMU. Table 2 gives an extract of the DEA results on project level from the data set, showing two different projects, one of which is deemed DEA efficient. As can be seen, project number 27, mysql, is DEA efficient, while number 3, berlin, has a lower efficiency score of

Table 2. Results from DEA on project level (extract)

No.	DMU	Score	Reference set					
...								
3	berlin	0,518	gkernel	0,211	mysql	0,597	python	0,192
...								
27	mysql	1,000	mysql	0,999				
...								

Table 3. Ranking of projects according to DEA efficiency

Rank	DMU	Score
1	aaf, crossfire, gkernel, lpr, musickit, mysql, nfs, python, u4x, winex	1,000
11	ceps, mesa3d, tcl	0,999
14	linuxsh	0,995
15	linux-apus	0,963
16	Xfce	0,954
17	linux-mac68k	0,903
18	jboss	0,896
19	firebird	0,878
20	cvsgui	0,866
21	enlightenment	0,860
22	quake	0,852
23	sdcc	0,852
24	zangband	0,847
25	opensta	0,840
26	lesstif	0,837
27	ghostscript	0,835
28	qpe	0,833
28	htdig	0,833
30	wf-gdk	0,829
31	dri	0,823
32	crystal	0,769
33	lsb	0,742
34	acs-pg	0,701
35	mahogany	0,691
36	squid	0,670
37	omseek	0,671
38	clocc	0,667
39	linux-vr	0,574

0,518 which translates into a respective possible increase in outputs. The reference set reported contains the efficient projects mysql, gkernel and python, which also have weights assigned relating to their relative importance in showing the inefficiency of berlin. In this case, mysql is the most important project, which means that it is most similar in input-output relation, and orienting at this project would show the most promising path for efficiency increase.

From all DEA efficiency scores, an efficiency ranking over all projects can be derived, which is given in Table 3 for the data set used here. As can be seen, several projects are deemed DEA efficient, therefore have a value of 1 and are ranked at the top. This list gives two major informations

Table 4. Overview of DEA results for data set

No. of DMUs	43
Average	0,828
Std. Dev.	0,196
Maximum	1,000
Minimum	0,085
Number of DEA-efficient DMUs	10
Frequency in Reference Set	
Peer set	**Frequency to other DMUs**
aaf	4
crossfire	8
gkernel	24
lpr	3
musickit	3
mysql	28
nfs	2
python	18
u4x	1
winex	0

per project: Their rank is a measure of the standing within the total group, while the efficiency score gives an indication of the amount of output increase possible.

For an overview of the results, see also Table 4. In this table, statistics on the efficiency scores in the total population are given. Overall, 10 different projects have been classified as DEA efficient (which is also visible from Table 3), the mean efficiency score with 0,828 seems relatively high. For each efficient project, the number of times it appears in the reference sets of non-efficient projects is also given. This can be used as an indicator of the relative importance of this project in determining efficiency scores, and would also be important for performing sensitivity analyses.

These results, besides demonstrating that differences in efficiency between F/OS projects do indeed exist, can then be used in several ways: First, for each single project, both an easy-to-interpret examination of the current status is given, and an indication for possible improvements in form of the reference set of similar but efficient projects is offered. Secondly, and more important, the results allow for additional analyses beyond single projects, but spanning groups of projects. Using measures of centrality like the mean or median efficiency score, groups of projects can be compared. The groups to be considered can be based on different characteristics available, including software process, application domains, scale or even license. Using any of the criteria, the population can be divided in two or more groups, and the distribution of efficiency scores can be compared statistically, using the hypothesis that the dividing variable has an effect on efficiency. If any statistically significant difference in efficiency shows up, the hypothesis is validated, meaning that indeed projects showing a certain

characteristic tend to be more (or less) efficient.

In this paper, first an example is detailed based on comparing different software process designs, using the inequality of contributions within projects as dividing factor. We will therefore compute a correlation coefficient between the inequality measure as given above, and the efficiency score of projects. In this case, the underlying hypothesis, that a relationship between group working style as depicted by the resulting inequality and efficiency exists, can not be confirmed: There is no significant correlation between both measures, which shows that a higher inequality does not have any effect on efficiency.

As a second example, the hypothesis that a very stringent copyleft-licensing scheme increases the productivity of the participants is explored. We therefore divide the set of projects into two groups, one consisting of projects licensed under GNU GPL only, resulting in 18 projects out of 43, the other with all remaining projects. Then, a non-parametric Mann-Whitney U-test is employed to test the distribution of the efficiency scores between the groups. In this case, there is no significant difference, so the hypothesis that a copyleft-licensing scheme has an impact on efficiency has to be discarded.

As a last example, we base the grouping of projects on the intended audience, with one group targeting developers and system administrators only, resulting in 20 projects, and others, to explore whether this characteristic has any impact on efficiency. Also in this case, there is no significant difference in efficiency between the two groups, again showing that the intended audience does not lead to a change in efficiency.

FUTURE RESEARCH

As this has been a very first attempt of applying DEA to the context of F/OS projects, numerous directions for future research exist. The first area of research identified with the data set in this paper is the definition of relevant input and output factors. We propose to add at least two additional factors, the first one being contributors other than programmers as an input factor, the second one being a mix of different product metrics to capture aspects of the software system produced. This could include concepts like McCabe's cyclomatic complexity (McCabe, 1976) or object-oriented metrics, e.g. the Chidamber-Kemerer suite (Chidamber and Kemerer, 1994). Also other outputs could be measured and included, for example postings to mailing lists, website metrics, and even popularity measures (Weiss, 2005).

In this paper, we have compared a set of relatively large F/OS projects. It would also be interesting to include smaller projects, in which case the issue of variable or constant returns to scale would increase in importance. A comparison might also be useful to be done within a certain application area only, for example frameworks for web service implementation, to eliminate additional influences.

Of maybe even more interest than those considerations given above on setting up a DEA might be analyses based on the respective results. After having computed efficiency scores for a set of projects, other characteristics of these can be used in order to explore reasons for any differences in efficiency. Possible characteristics would include mostly aspects of the software development process employed, similar to this paper, which used the inequality within the development team as explanatory variable. Respective comparisons could also be extended to include projects following very different approaches, like commercial projects employing for example agile methodologies, or projects with mixed participation from volunteers and paid contributors. To allow for these comparisons, additional characteristics of the projects considered need to be collected.

CONCLUSION

In this paper, we have proposed for the first time a method to compare the efficiency of F/OS projects. The method used is the DEA, which is well-established in other fields and offers several advantages in this context as well: It is a non-parametric optimization method without any need for the user to define any relations between different factors or a production function, can account for economies or diseconomies of scale, and is able to deal with multi-input, multi-output systems in which the factors have different scales. Using a data set of 43 large F/OS project retrieved from SourceForge.net, we have demonstrated the application of DEA. Results show that DEA indeed is usable for comparing the efficiency of projects in transforming inputs into outputs, that differences in efficiency exist, and that single projects can be judged and ranked accordingly. We have also detailed additional analyses based on these results, which stated that neither the inequality in work distribution within the projects, nor the licensing scheme, nor the intended audience has an effect on the efficiency of a project. As this is a first attempt at using this method for F/OS projects, several future research directions are possible. These include additional work on determining input and output factors, and additional analyses based on the results using other project characteristics. These could include comparisons within application areas, different project scales, and also comparisons to commercial or mixed-mode development projects.

Chapter 7.21
Examining Open Source Software Licenses through the Creative Commons Licensing Model

Kwei-Jay Lin

Tung-Mei Ko
OSSF Project, Taiwan

ABSTRACT

In this chapter, the authors present a novel perspective by using the Creative Commons (CC) licensing model to compare 10 commonly used OSS licenses. The authors also propose a license compatibility table to show that whether it is possible to combine OSS with CC-licensed open content in a creative work. By using the CC licensing concept to interpret OSS licenses, the authors hope that users can get a deeper understanding on the ideas and issues behind many of the OSS licenses. In addition, the authors hope that by means of this table, users can make a better decision on the license selection while combining open source with CC-licensed works.

INTRODUCTION

With the rapid growth of the open source software (OSS) community in the past decade, many users now are convinced that OSS is a practical and attractive alternative to proprietary software. Since almost all OSS licenses allow worldwide, royalty-free usage and encourage users to copy, modify,

and enhance original codes, OSS has attracted many users and programmers. Some other benefits include significantly lower development and deployment cost, and software quality improvement due to open inspections and discussions.

To meet the needs of various authors and users, different software licenses have been defined. The diversity and complexity of these licenses, on the other hand, create confusions for many potential OSS authors and users. It has been a constant community effort through articles, reviews, and books to discuss and to elaborate on the subtle differences among these licenses.

For non-software publications, such as Web sites, graphics, music, film, photography, literature, courseware, and so on, that normally fall under the current copyright law, some authors may want to open up part of their rights to the public with a spirit similar to those of OSS licenses. To allow for such possibilities, Creative Commons (CC) was founded in 2001 to define the licenses beyond the traditional "all rights reserved" copyright definition. CC licenses, motivated in part by the GNU General Public License (GPL) of the Free Software Foundation (FSF), provide a similar function to OSS licenses for non-software creative works.

Both OSS and CC licensing models are about promoting the ideas of free access. Therefore, it is not a rare case to combine open software released under OSS licenses with CC-licensed creative material. Nevertheless, there are differences between these two models. For users who combine these two types of materials to create a new resulting work, some questions are of deep concern. For example, whether a specific OSS license is compatible with CC licenses? Which license should the resulting work apply to? Unfortunately, so far there is hardly any study discussing these issues in depth.

As participants of the open source movement in Taiwan, we have witnessed the flourishing innovation and creativity of OSS activities in Taiwan. However, the license selection issue has continued to be an obstacle for many potential local contributors. Part of the charters of the Open Foundry project in Taiwan (called OSSF, http://www.openfoundry.org) is to help people easily capture a basic understanding of the licenses that govern OSS, related documentations and open content.

In this chapter, we present a novel perspective by using the CC licensing model to compare 10 commonly-used OSS licenses. Specifically, we have defined a license compatibility table that shows whether it is possible to combine OSS with CC-licensed open content in a creative work. The idea of comparing the two types of licenses is partly inspired by Rosen (2004). In Chapter 10 (pp. 244-251) of his book, Rosen takes four commonly used OSS licenses as examples and discusses the compatibility of these licenses. Similarly, our study may help people understand if they can re-license a resulting work under a specific CC license. The reason for our study on the compatibility table is from the observation that many new OSS contributors are primarily interested in getting their software known and accepted by the community, and circulated as widely as possible. They do not want to interfere with licensees' use of the software nor constraining the licensing of derivative works. Their goal is to create works that people may share and enjoy, much like open content. Therefore, by using the CC licensing concept (such as *attribution* and *share alike*) to interpret OSS licenses, people may get a deeper understanding on the ideas and issues behind many of the OSS licenses, and make a better decision on the license selection.

The rest of the chapter is organized as follows. The following section reviews the basic elements of OSS licenses and CC licenses. Subsequently, the comparison of the two licenses classes is presented. Next, we discuss two new license concepts, then the chapter is concluded in the last section.

BACKGROUND: FROM GPL TO ATTRIBUTION

OSS Licenses and FDL

There are many types of OSS licenses. According to the statistics from FSF and the Open Source Initiative (OSI), there are over 60 OSS licenses. In general, these licenses have three common characteristics (Free Software Foundation, 2005a; The Open Source Initiative, 2006a):

1. No royalties
2. No geographical restrictions on distribution
3. No specific licensees

Among them, we have chosen 10 more commonly-used OSS licenses (including GNU General Public License, GNU Library/Lesser General Public License, BSD license, MIT license, Apache Software License 1.1, zlib/libpng License, Artistic License, Common Public License, Qt Public License, and Mozilla Public License) plus the GNU Free Documentation License (FDL) for discussion in this paper. These licenses, excluding the FDL, have all been approved by the OSI and conform to the Open Source Definition (OSD) (The Open Source Initiative, 2006b).

The most well-known OSS license is GPL, which was drafted by Richard M. Stallman, the founder of the FSF and the Project GNU. The GPL is developed on the basis of the *copyleft* mechanism. According to the *copyleft* mechanism, a licensee has to adopt the same license as that of the licensor for his (or her) program. Using the *copyleft* mechanism, source code can always remain open and royalty free. The GNU Library/Lesser General Public License 2.1 (LGPL) is the other OSS license implementing the *copyleft* mechanism (Free Software Foundation, 2005b). The LGPL is designed specifically for library code, and is less strict than the GPL.

On the other hand, the *copyleft* mechanism does not limit any right arising from *fair use*. Thus, when an author uses GPL-licensed or LGPL-licensed codes as examples in a book or as references, he (or she) may not have to apply the GPL or LGPL to the book as long as the application falls within the scope of *fair use*. Under this circumstance, the author can choose a license at his (or her) will, for example, any traditional proprietary copyright license or any CC license for the book. Similarly, in accordance with the *fair use* doctrine, when the author attaches a whole copy of the GPL-licensed or LGPL-licensed codes with the book while published or distributed, the license adoption of the book will not be restricted to the GPL or LGPL.

Compared with the GPL, the BSD license, another popular OSS license, does not impose any restriction on the licensee in terms of future license selection. In other words, the licensee is allowed to use any license (even make it proprietary) for his (or her) program and is also allowed to collect royalties. The Apache Software License 1.1 (Apache 1.1), zlib/libpng License (zlib/libpng), and MIT License have similar characteristics as that of the BSD license.

The other four licenses discussed in this chapter are the Mozill Public License 1.1 (MPL), Common Public License 1.0 (CPL), Qt Public License 1.0 (QPL), and the Artistic License (Artistic). Basically, the MPL, CPL, and QPL are all designed for the commercial use of OSS, thus their regulations about licensees' rights and obligations are very similar. The MPL employs a partial *copyleft* mechanism in that the licensee can only use the MPL for his (or her) program in principle (Mozilla.org, 2006). However, the licensee is allowed to adopt another license for certain parts of the program. The CPL adopts the *copyleft* mechanism and is the first license to regulate commercial distribution of OSS with separate terms. Artistic has its own legal logic, which is different from the other nine OSS licenses.

Same as the GPL, the FDL is drafted by Stallman and also adopts the *copyleft* mechanism. However, the FDL is normally used for textbooks or teaching materials written for some equipment or software (Free Software Foundation, 2005b). Wikipedia, a famous online encyclopedia, adopted the FDL for its text content, is a noted example (Wikipedia, 2006).

The Inception of Creative Commons

A group of professionals from various fields, including intellectual property and cyberlaw experts James Boyle, Michael Carroll, and Lawrence Lessig, and MIT science professor Hal Abelson, founded Creative Commons in 2001 (Lessig, 2005). CC advocates the "some rights reserved" concept in contrast to the default "all rights reserved" in current copyright laws. CC also takes ideas in part from the FSF and produces a series of copyright licenses to help creators declare to the world what freedom they want their works to carry. These freedoms are composed by four elements: *Attribution* (denoted as "by" or ), *noncommercial* ("nc" or ), *no derivatives* ("nd" or ) and *share alike* ("sa" or ). When CC licenses v. 1 were first released in December 2002, these four elements were all optional. Later on, CC found that 98% of the adopters have chosen "attribution" as a requisite; thus CC sets "attribution" as a default in v. 2, and offers six licenses (Lessig, 2005).

CC Licenses

CC licenses are designed to bridge creators and users in that users have no need to ask for creators' prior permission to use the works as long as they follow the rules the creators set. For example, if a work is released under the "by-nc" CC license (i.e., attribution and noncommercial), a user can freely make use of the work under the condition that the user uses this work for noncommercial purposes only and must always credit the original creator. The six CC licenses are defined as follows:

1. **Attribution:** It means that a user can freely use the work, provided that he (or she) credits the creator.
2. **Attribution-share alike:** It means that a user can freely use the work, provided that he (or she) credits the creator and also licenses any derivative under the same license as that of the original work.
3. **Attribution-no derivatives:** It means that a user can only make use of verbatim copies of the work and have to credit the creator.
4. **Attribution-noncommercial:** It means that a user can only use the work for noncommercial purpose, and have to credit the creator.
5. **Attribution-noncommercial-no derivatives:** It means that a user can only make use of verbatim copies of the work, for noncommercial purposes only, and have to credit the creator.
6. **Attribution-noncommercial-sharealike:** It means that a user can only use the work for noncommercial purposes, credit the creator, and license any derivative under the same license as that of the original work.

In addition to the above six licenses, CC also offers other licenses for more specialized situations. For example, sampling licenses allow people to use a part of some creative works and mix with some original or other parts to create a new work. One can use founders copyright to free works from copyright completely, after it has been created for 14 or 28 years. In general, CC provides the vehicle that "does not mean giving up your copyright. It means offering some of your rights to any member of the public but only on certain conditions" (Creative Commons, n.d.).

Reviews of Issues on OSS and CC Licenses

Since the OSS licensing model appeared in the 1990s, it has started a lot of discussion, for example: What is the free/open source software movement? How does it run? How does it work with the current legal system? (Hill, 1999). Many have questioned about the enforceability of OSS licenses (Nadan, 2002; Ravicher, 2000). Later, because of the lack of precedents regarding OSS licenses' enforceability, Gomulkiewicz (2002) proposes to create an open source license organization (OSLO) to solve issues relating to OSS licenses. Gomulkiewicz thinks that the OSLO could play a role in calling programmers and lawyers together to built up useful licensing practices of OSS and further solve related licensing problems.

Among these various OSS licenses, the GPL receives the most attention. Stoltz (2005) discusses the scope of derivative works under current US copyright laws and how the extent of derivative works affects the GPL. Besides, along with the rising number of successful open source commercial cases, the issues about OSS license policies started to get much attention. For example, Satchwell (2005) provides users a basic understanding of OSS; how to choose a suitable OSS license and how to establish an appropriate OSS policy.

With the increase of OSS licenses, there are more and more articles discussing issues of OSS licenses. However, among these articles, only a few have addressed the OSS license compatibility. Perens (1999) and Maher (2000) point out that OSS license compatibility is a noteworthy issue, but neither offers any concrete solution to the compatibility problem. Rosen (2004) provides some discussion on the issue of OSS license compatibility but does not come up with any concrete solution. Therefore, sensing the need of a simple and clear explanation for various OSS licenses, we use a relatively intuitive licensing model, CC licenses, to examine OSS licenses.

Since CC licenses' release in December 2002, these licenses spread quickly and dramatically. There have been more than 50 million Web pages linked to CC licenses as of August 2005 (Katz, 2006). However, with the rising popularity of CC licenses, many skeptical views have appeared. Some challenge the compatibilities between certain CC licenses or between different free-content contracts (e.g., Elkin-Koren, 2005; Katz, 2006); while others question that a variety of CC licenses will cause confusion or increase the information cost (e.g., Elkin-Koren, 2005; Katz, 2006). Moreover, license translation and legal adaptation may undermine the success of CC licensing (Valimaki, 2005).

Katz (2006) questions that a variety of CC licenses would puzzle users in that users may run into difficulties in determining which CC license is the most suitable for them. Elkin-Koren (2005) challenges the consistency of CC's strategy over license selection. He argues that CC attempts to reduce external information cost by its license choosing platform, but the variety of CC licenses would on the contrary impose extra informational burden on authors. He uses musical works as an example: In addition to six CC core licenses composed of four elements (i.e., attribution, noncommercial, no derivatives, and share alike), there are the other three sampling licenses (i.e., sampling, sampling plus, and noncommercial sampling plus). To find out which license is the most suitable one for musical works would unwittingly increase information costs. Elkin-Koren (2005) further states that the lack of standardization in CC licenses would increase the cost of ascertaining the rights and obligation related to any specific work.

In addition, Katz (2006) argues about the incompatibilities of CC licenses. He concludes that the viral effect of the "share alike" element will result in the incompatibilities problem between different share alike licenses and would further restrict the distribution of derivative works.

Some of the above mentioned literatures discuss the compatibility among different CC licenses, but none offers a systematic analysis on the problem of CC license incompatibility or combining OSS with CC-licensed content. Therefore, we attempt to illustrate what license a user may choose when he (or she) combines OSS with CC-licensed content by a clearly defined table to be discussed next.

MAIN FOCUS OF THE CHAPTER

Examining Compatibility between OSS and CC Licenses

Our study in this chapter is to define a license compatibility table that shows whether the combination of OSS and CC-licensed open content in a creative work may be properly licensed. The table (Table 1) may help people understand if they can continue to re-license a derived work under a specific CC license.

In Table 1, we use "by," "nd," "nc," and "sa" to denote CC's four elements "attribution," "no derivatives," "noncommercial," and "share alike" respectively. The mark "○" indicates that when a derivative work incorporates two or more works under licenses listed in a specific column and a specific row, it can be re-licensed under the CC license shown in the column. The mark "X," on the other hand, shows that a derivative work, incorporating two or more works under licenses listed in a specific column and a specific row, cannot be re-licensed under the license shown in the column. For example, if one combines a program A released under the GPL, with an open content B issued under the CC attribution license, and produces a new work C. One may not re-license C under the CC attribution license because the GPL requires that GPL-applied program or its derivative work must always be governed by the GPL.[1] Thus, A and C must be licensed similarly, and C work will not be able to release under any CC license.

In the following sections, we discuss the table entries in details.

No Derivatives

The 10 OSS licenses chosen to compare with CC licenses in this chapter are all approved by the

Table 1. License compatibility table

	by	by-nd	by-nd-nc	by-nc	by-nc-sa	by-sa	FDL
GPL	X	X	X	X	X	X	X
LGPL	X	X	X	X	X	X	X
MPL	X	X	X	X	X	X	X
QPL	O	X	X	X	X	O	O
CPL	O	X	X	X	X	O	O
Artistic	O	X	X	X	X	O	O
Apache	O	X	X	X	X	O	O
Zlib/libpng	O	X	X	X	X	O	O
BSD	O	X	X	X	X	O	O
MIT	O	X	X	X	X	O	O

OSI. An OSI-certified license must conform to the OSD (The Open Source Initiative, 2006b). Under criterion 3 of the OSD, the license must permit making modifications and derived works (The Open Source Initiative, 2006c). Therefore, these 10 OSS licenses allow modification to the original program. Thus, any of the six CC licenses which contains "No Derivative" element (i.e., CC attribution-no derivatives license, CC attribution-no derivatives-noncommercial license) is not compatible with any of the 10 OSS licenses, and "X" is shown in all cells of the "by-nd" and "by-nd-nc" columns in the table.

Noncommercial

Criterion 1 of the OSD states that an OSS license should not "restrict any party from selling or giving away the software as a component of an aggregate software distribution containing programs from several different sources" (The Open Source Initiative, 2006c). It thus implies that any OSD-compliant license should not restrict any use of commercial purposes. This results in the conflict between 10 OSS licenses and any CC license with "noncommercial" element (i.e., CC attribution-noncommercial licenses, CC attribution-noncommercial-share alike licenses). An "X" is shown in all cells of "by-nc" and "by-nc-sa" in the table.

Copyleft

The *copyleft* mechanism provides that anyone will be granted the rights to use, copy, modify, or distribute a program or its derivative works on the condition that when redistributing a program, with or without change, all rights he (or she) gained must be passed on to subsequent users (Free Software Foundation, 2005b). The GPL, LGPL, FDL, and CPL are terms to implement the *copyleft* mechanism. The implemented result will be the original work and its derivative works must be redistributed under the same license as the original work.

Although not originated from the FSF, the MPL partially employs a *copyleft* mechanism. MPL requires that modifications to MPL-licensed program must be governed by MPL (Mozilla.org, 2006). Because of this viral nature of *copyleft*, the GPL, LGP, MPL, and CPL is not compatible with any of the CC licenses, and thus "X" is shown in all cells of the top four rows.

Author Credit

The Apache, zlib/libpng, BSD, and MIT explicitly indicate that the authors of original work must be credited (Lin, Ko, Chuang, & Lin, 2006). QPL, CPL, and Artistic have copyright notices related regulations, and do not exclude the authors' names of the original work from the copyright notices.Yet, CPL implements copyleft mechanism. Therefore, GPL, LGPL, MPL, in addition to CPL are not compatible with CC attribution licenses. A work incorporating a program licensed under the QPL, Artistic, Apache, zlib/libpng, BSD, or MIT with other works issued under CC attribution license could be re-licensed under CC attribution license. Excluding the GPL, LGPL, CPL, and MPL, "○" is shown in the other cells of the "by" column in the table.

Share Alike

The compatibility between the 10 OSS licenses and the CC attribution-share alike license is discussed next. The GPL, LGPL, CPL, and MPL implement the *copyleft* mechanism. But the other six OSS licenses do not explicitly adopt it and do not have the viral effect on the resulting derivative work. Thus, when a work incorporates a program licensed under the QPL, Artistic, Apache, zlib/libpng, BSD, or MIT with the other work issued under the CC attribution-share alike license, this newly created work may be re-licensed under the

CC attribution-share alike license. Except the top four cells, the mark "○" is shown in the other cells of the "by-sa" column in the table.

FDL

Finally, we examine the compatibility between the 10 OSS licenses and the FDL.

Even though the GPL, LGPL and FDL are all developed by the FSF, because of *copyleft* mechanism's viral effect, when a work incorporates a GPL-licensed or LGPL-licensed program with other FDL-released work, the resulting work may not be re-licensed under the FDL. The same result applies to CPL because CPL implements copyleft as well. The MPL partially employs the *copyleft* mechanism; thus, a created derivative work incorporating a MPL-licensed program with the other FDL-released work may not be re-licensed under the FDL, either.

In principle, the FDL enables the same freedom as the CC attribution-share alike license (Creative Commons, 2005). Due to the *copyleft* mechanism, when a work incorporates a program licensed under the GPL, LGPL, CPL, or MPL with the other FDL-released work, this resulting derivative work may not be re-licensed under the FDL. Except the GPL, LGPL, CPL, and MPL, a work incorporating a program governed by the QPL, CPL, Artistic, Apache, zlib/libpng, BSD, or MIT with the other work issued under the FDL, this new created work could be re-licensed under the FDL. Except the top four cells, "○" is shown in the other cells of the "FDL" column in the table.

Using License Compatibility Table for License Selection

From Table 1, we could identify the following license selection strategies. If a user would like a creative work which combines OSS with CC-licensed open content to be re-licensed under the CC license or the FDL, he (or she) should avoid using OSS licensed under GPL, LGPL, or MPL. In other words, if a creative work is combining OSS licensed under the GPL, LGPL, CPL, or MPL with CC-licensed open content, this work is not possible to be re-licensed under any CC license.

If a user would like a creative work which combines OSS with CC-licensed open content to be re-licensed under some CC licenses, he (or she) should choose OSS licensed under the QPL, Artistic, Apache, zlib/libpng, BSD, or MIT. However, not all CC licenses are compatible with the QPL, Artistic, Apache, zlib/libpng, BSD, or MIT; only CC by and by-sa licenses are compatible with these six licenses. In other words, a creative work combing an OSS license under QPL, Artistic, Apache, zlib/libpng, BSD, or MIT with CC by or by-sa licensed open content, the resulting work could be re-licensed under CC license identical to the original open content. Similar to CC by or by-sa license, FDL is not compatible with the GPL, LGPL, CPL, or MPL, but is compatible with QPL, Artistic, Apache, zlib/libpng, BSD, or MIT. Therefore, if a user would like a creative work which combines OSS with FDL-licensed open content to be re-licensed under the FDL, he (or she) may use OSS licensed under any of these six OSS licenses.

From the above discussions, we can make two simple conclusions. Firstly, OSD-compliant OSS licenses should not restrict any use of commercial purposes[2], and OSD-compliant OSS licenses must allow modifications and derived works.[3] Therefore, CC licenses containing "noncommercial" or "no derivatives" element are not compatible with 10 OSS licenses discussed in this chapter.

The second conclusion is that the *copyleft*'s viral effect requires the original work and its derivative works to be redistributed under the same license as the original work. Thus, the GPL, LGPL, CPL, and FDL, which adopt the *copyleft* mechanism completely, plus MPL, which partially adopts the *copyleft* mechanism, are not compatible with any CC license.

For authors that are not combining OSS with open content, the above discussion may provide some useful insights as well. The *copyleft* mechanism is a strong license requirement that may prevent others from producing derivative works mixed with even the "share alike" element. It is probably better to select other licenses if such a requirement may present a problem in the future.

FUTURE TRENDS

Open Access Publishing

CC licenses are inspired from the GPL. In addition to OSS and CC licensing models, other models have been developed in different fields sharing similar notions with that of OSS and CC. Open access publishing is one of them.

Typically, publishers charge readers a subscription fee, and sometimes also charge authors a page fee. Open access publishing, on the contrary, allows the author to retain his (or her) article's copyright; at the same time, authors or their sponsors, not the users, pay the publishers.

Although the open access publishing model will make authors bear more cost than traditional publishing models, the charged fees are possible to be transferred to the authors' sponsor institutes or even be waived (Suber, 2004). Moreover, open access publishing will increase the possibility that the authors' articles are searched, and help to build the authors' prestige (Harmel, 2005). Recent studies also show the same result: online articles are more frequently cited (Lawrence, 2001) and more often used than offline articles (Lawrence, 2001; Walker, 2004). Therefore, more and more leading publishers, such as the Public Library of Science (PLoS) and BioMed Central have joined the open access movement.

Science Commons, a newly launched project of Creative Commons, was founded to support the sharing of scientific research, such as the field of biotechnology, medicine, and even law[4], with the same "some rights reserved" spirit Creative Commons holds.

Studies have found that the open access publishing model is practicable (Gonzalez, 2005; Odlyzko, 1998), and there are already publishers gain profits from it (Walker, 2004). It is foreseeable that with the increasing subscription fees of academic journals the open access publishing model will continue to gain more support, especially on academic content.

New OSS Elements

Compared with numerous OSS licenses, the CC licensing model built on the basis of four elements is relatively simple. However, although these four elements are less complex and easier to understand, they are not broad enough to cover all major considerations of OSS licenses. Here we include two new concepts, "no endorsement" and "modification record" that should be considered by OSS users when selecting a license.

No Endorsement

One of the OSS's common characteristics is that anyone is free to create derivative works (The Open Source Initiative, 2006c). Because of this, the quality of derivatives is hard to control. When the quality of a derivative is not as good as the original program, but the name of the original developer or the copyright holder is still shown on the derivative, new users may not have enough acknowledgement of this and relies on the name of the original developer or the copyright holder to evaluate the derivatives. Under the circumstance, it may harm the reputation of the original developer or the copyright holder. Sometimes, the developer of the derivatives may intentionally show the name of the original developer or the copyright holder on the derivative work to endorse or promote his (or her) own works.

Therefore, to prevent OSS adopters from using the authorship to implicitly or explicitly show the

support, association of the initial developers or to promote their derivative work, and, even more, to prevent the derivatives from being wrongly trusted, the original program's developer should choose a license which contains "no endorsement" or disclaimer clause[5], such as BSD and Artistic. The Creative Archive License developed by BBC adopts the main ideas of CC licenses but injects such a new element into the license.[6]

Modification Record

We also notice that many OSS licenses have regulations regarding the modification records.[7] Take the 10 OSS licenses we analyze in this chapter for example. Only the QPL does not require that a modification record must be made. Instead, the QPL forbids users to directly make modifications to the original works and requires that all modifications be in a form that is separate from the original works (e.g., patches).[8] All of the other nine licenses have modification record related regulation. These records are very helpful for the convenience of follow-up software modifications. Moreover, they are beneficial to maintain the original works' integrity.[9]

CONCLUSION

OSS licenses have triggered a lot of discussions in the past few years because of their complicacy. The OSI even appeals to reduce the number of approved OSI-licenses to allow programmers and users to understand OSS licenses more easily. In contrast with OSS licenses, CC licenses provide a cleaner licensing model. In this chapter we investigate the compatibility between the six CC licenses and 10 commonly-used OSS licenses including the FDL. OSS authors may use the table to identify which CC license he (or she) can use for his (or her) work that combines OSS with CC-licensed work.

However, CC's four simple elements do not capture all major issues of OSS. We thus raise two new issues, "no endorsement" and "modification record", to address some main concerns by OSS. We believe that by employing CC's four elements, plus our proposed two new elements, OSS community, including both authors and users, will be able to get a more complete picture of OSS licenses.

KEY TERMS

Copyleft: Copyleft is a kind of licensing mechanism, with which licensees have to apply the same license the original works adopted to the derivative works.

Creative Commons Licenses: Creative Commons licenses are a kind of licensing model which applies to open content. Creative Commons licenses are composed by four elements (attribution, noncommercial, no derivatives, and share alike). Creative Commons licenses allow the licensees to make use of CC-licensed works with no need to get prior permission from the licensors as long as the licensees follow the conditions the licensors chose for the works.

License: It is a legal permission to commit some act.

License Compatibility: It is an abstract idea to illustrate whether two portions of content regulated by two different licenses can be combined within a work compatibly and produce the other resulting work.

Open Access Publishing: Open access publishing is a kind of publishing model, under which journals open access to the public immediate on publication and usually the authors of the journal articles do not need to pay the page fee for the publication.

Open Content: Open content describes the creative work which allows copying and modifying with no need to get extra permission from the licensors, such as works licensed under Creative Commons licenses.

Open Source Software Licenses: Open source software licenses apply to open source software. Open source software licenses feature that licensees can use, copy, distribute, and modify the regulated software on a royalty-free, worldwide basis.

ENDNOTES

1 Article 2(b) of the GPL stipulates that "You (licensee) must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program (GPL-applied program) or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License (GPL)."

2 OSD # 1 states that an OSS license should not "restrict any party from selling or giving away the software as a component of an aggregate software distribution containing programs from several different sources."

3 OSD # 3 states that "The license must allow modifications and derived works, and must allow them to be distributed under the same terms as the license of the original software."

4 Open Access Law Project is established under Science Commons' publishing project to promote open access to legal scholarship. For more detailed information about Open Access Law Program, please see http://sciencecommons.org/literature/oalaw

5 Our "no endorsement" wordings are motivated by BBC's Creative Archive License. The detailed terms can be found on http://creativearchive.bbc.co.uk/licence/nc_sa_by_ne/uk/prov/.

6 BBC proposes five rules for Creative Archive Group License, which comprises "non-commercial," "share alike," "crediting" (attribu-

tion), "no endorsement and no derogatory use" and "UK." The first three rules are very similar to CC's; the last two are innovations created by BBC. For more details, please see http://creativearchive.bbc.co.uk/archives/2005/03/the_rules_in_br_1.html

[7] "Modification record" in this chapter includes several possible meanings, e.g., the record about who did the modification; the record about when the modification was made; the record about which part of the original programs has been changed.

[8] See article 2,3 of QPL.

[9] According to Andrew M. St. Laurent's opinion, QPL's requirement that a licensee distributes modifications separately with the initial work can protect the reputation of the initial developers and make clear the primacy of the initial developers' works. See Andrew M. St. Laurent, "Understanding Open Source & Free Software Licensing" (2004, p. 87, O'Reilly). In this chapter, we further extend St. Laurent's viewpoints and come up with the new element "modification record" for OSS's licenses.

This work was previously published in Handbook of Research on Open Source Software: Technological, Economic, and Social Perspectives, edited by K. St.Amant & B. Still, pp. 382-393, copyright 2007 by Information Science Reference (an imprint of IGI Global).

Chapter 7.22
Integration of Libre Software Applications to Create a Collaborative Work Platform for Researchers at GET

Olivier Berger
GET/INT, France

Christian Bac
GET/INT, France

Benoît Hamet
GET/INT, France

ABSTRACT

Libre software provides powerful applications ready to be integrated for the build-up of platforms for internal use in organisations. We describe the architecture of the collaborative work platform which we have integrated and designed for researchers at GET. We present the elements we have learned during this project in particular, with respect to contribution to external libre projects, in order to better ensure the maintainability of the internal applications, and to phpGroupware as a framework for specific applications development.

INTRODUCTION

ProGET is a collaborative work platform, built out of a set of specialised libre software applications integrated together. ProGET is designed for the whole of teachers/researchers at GET. It provides every GET research project with the best features found in each application (wiki, mailing-lists management, shared WebDAV folders, Web portal, etc.).

We start with a description of the libre components that have been integrated and of the features that have been selected, as well as elements of architecture of the developed platform. We will

then introduce the strategy for collaboration that we have devised for our contribution to phpGroupware. We finish with a first evaluation at the end of the initial development phase.

RESEARCH AT GET

The *Groupe des Écoles des Télécommunications*[1] (GET) is composed of several engineering and business schools together with research centers in Paris (ENST), Brest (ENST Bretagne), and Évry (INT), in France. The research teams are made up of more than 600 full-time research equivalents. The range of the researchers' expertise is from technologies to social sciences, and enables an integrated approach of characteristic of GET research and fosters its adaptability to new application sectors and new usages in response to current challenges in the fields of information and communication.

To give a clearer view of research at GET, the Research Office started to catalogue the activities from the different locations so that the research may be described in terms of research *projects* and *programmes*. A project is made-up of a group of people working together on closely related subjects. For example the authors belong to the "Collaborative Platforms for Research" (PFTCR) project. A programme associates different projects loosely related. For example our project is related to the "Web and Information Society" programme. Due to the fact that GET teams are located in different areas, the research office also decided to propose a Web platform to help researchers collaborate through groupware tools and animate their research work.

PROGET INTEGRATED PLATFORM FOR COLLABORATIVE WORK

ProGet has been launched in July 2003 with the following goals:

1. Provide all research teams in GET and their external partners (more than 1,250 users) with cutting-edge technologies in terms of Web based groupware tools

Figure 1. Homepage of the GET public research portal

2. Allow the Research Office to manage the *administrative* records describing research projects
3. Generate a public *Web portal* based on information extracted from both previous components.[2] The home page of the Web portal is shown Figure 1.[3]

Groupware Tools for Researchers/ Teachers

The following features have been selected as corresponding to the basic needs for collaborative work in the context of research activities at GET:

- **Document sharing:** People in the same project must have a way to share the documents they produce, whatever the type of document.
- **Asynchronous communication:** Each project manages predefined *mailing lists* and may also create mailing lists as it needs.
- **Online editing:** People in the same project group are allowed to write easily and collaborate on simple hypertext pages using their Web browsers, to create a collaborative Web, in a wiki-type tool.
- **Publishing short announcements:** The project manager can write short news items about the project, and have the project news published online on the public Web portal very easily.

The platform must provide secure access, from any point on the Internet, to a set of tools. These tools will have to be accessible through a Web interface, to allow people to use them without the need to install any specific application on the computer from which they are connected.

Some features must also be accessible through non-Web client tools, in the Microsoft Windows™, or GNU/Linux environments. For instance, as explained in the section entitled, Project Documents Repository Accessible through WebDAV, access to the DAV repositories through DAV-compatible file managers. Information generated in this collaborative part of the platform may be made accessible to the public portal directly by the research teams, without further interaction with a Webmaster.

Tools for the Research Office

The Research Office is supervising the setup and evolution in time of the research projects and programs. In ProGET, it uses, for this purpose, a dedicated tool, which helps managing the life cycle of the *project description forms.*

This module does not provide a replacement for the research information system under development at the present time at GET. It only allows the management of information on the projects which are necessary for the other parts of the platform. It handles the initial list of persons participating in projects teams, people who are project managers, the projects' descriptions, and their yearly goals.

The project description forms are initially filled by the researchers who will be responsible for the projects. They are then validated by the research offices. This validation allows the creation of the collaboration projects in the platform. Those forms are also used to feed the contents of the research public Web portal.

Public Web Portal

The platform publishes a public Web portal which reflects the state of research activity at GET. This portal describes essential information relating to the research programmes and projects at GET. Figure 1 shows the home page of the portal.

This public Web site corresponds to a dynamic extraction of the contents of the project description forms stored in the database. That is why it will be updated immediately whenever the GET Research Office validates new projects creation, or updates the contents of existing forms.

Since the data extraction is dynamic, this portal Web site can be duplicated in several flavors according to the origin of the visit. So when the Web site is browsed from inside the GET intranet, it will provide more detailed information, including some facts about the research projects which are considered to be published to a restricted audience only (teams composition, detailed yearly goals of the projects, etc.).

PREVIOUS WORK WITH LIBRE SOFTWARE COLLABORATION TOOLS

As described by Cousin, Ouvradou, Pucci, and Tardieu (2001), we and other GET researchers and students contributed in the development of a collaborative platform called *PicoLibre*. This platform is targeted at collaborative software development, to help students in computer science curricula and researchers to develop and host their software projects. It provides the necessary collaboration tools (mailing lists, CVS repository, issue trackers, etc.) in a similar way to SourceForge. Another goal of the PicoLibre project was to foster the publication of projects as libre software, since it would be a way to introduce the users to the practice of the common tools used everyday by libre software developers.

This platform was created as a free software tool (published under the GNU GPL license[4]), using free software components and adapting them for PicoLibre. Several PicoLibre instances are in operation since Fall 2001 in GET sites and outside.

In some aspects, PicoLibre is a very successful project, since it allows GET to host a large number of software projects with a minimum burden for its administrators. It is also sometimes used for projects not specifically targeted at software development, for teams that need a collaboration space and associated *groupware* tools. The PicoLibre project has helped us attain a better knowledge of the specifics of the design and development, but also the administration, of a collaborative Web-based platform in the context of a higher education institution.

But PicoLibre also failed to certain extents, especially with respect to its maintainability, and in its capacity to be integrated into a libre software distribution. The project was done in such short time that developers only concentrated on the innovative parts and spent too few efforts in keeping the software they developed in the mainstream of the libre projects it was based on (in particular with respect to phpGroupware [phpgw]).

Although having been used intensively by teams of researchers or students investigating software development, PicoLibre was not well suited for generic needs of teams of nonsoftware developers. For example, the CVS[5] revision management repository is a central tool in PicoLibre. It is very useful for software development, but does not fit well for casual researchers' use. For example, although it is possible with CVS to manage the revisions of a document written with an office suite, it is not very convenient, since it requires installation of a specific CVS client program. Most nonsoftware developers (e.g., researchers in the field of finance or business administration) are thus not comfortable in using such a tool.

To build on top of our previous developments, and considering the aforementioned perspective, we proposed to start and build the ProGet platform using some of the free software modules that had been used to create PicoLibre, and to combine these modules with other existing libre software projects to fulfill new capabilities. We intended also to do our developments and the integration of the numerous applications necessary in a much more maintainable way.

STRUCTURE OF THE PLATFORM

The ProGET platform is composed of several specialised software applications, installed together

on a dedicated machine running the GNU/Linux operating system (Debian). This article does not describe all of the components of the system, but only the modules which provide the highest level features, and the way they have been integrated into a single platform.

The development team has been participating for a long time in communities of research and practice in libre software: development of PicoLibre (see previous work with libre software collaboration tools), organisation of the *Autour du Libre* conference, participation in the *CALIBRE* FP6 European project,[6] and so forth. We have then naturally preferred to use exclusively libre software for the development of the platform, in order to ensure the complete control of all technical aspects, and the conformance to open standards.

Integration Principles

To deliver the required features, we have integrated different existing libre software applications that we will list in the section entitled, Integrated Libre Software High-level Applications. Most of these applications rely on the Apache Web server, in particular for the PHP execution engine.

Each one of the products, taken apart, was often not covering all required features. So instead of trying to add to one of these applications the missing features, we have preferred to integrate several rather specialised applications. We are therefore able to take advantage of the best aspects of each, even if there is a risk of partial redundancy. For instance, phpGroupware provides a wiki module, but a rather limited one. We have preferred to plug phpGroupware and TWiki, an advanced wiki engine, instead of engaging in a tougher effort of enhancement of phpGroupware.

In each integrated libre software application, we have been careful to allow the possibility of a logical *partition* of the data stored in the application, to ensure that the research projects can be kept autonomous and enhance privacy (see data partition).

To make sure users will not have to deal with a set of authentication tokens (login + password), the authentication will be done in the same way in all the modules, although they may be operated by separate applications. This is done in a classical way, by relying on interaction with a dedicated directory implemented by OpenLDAP. Some components also share a database stored in a dedicated MySQL server.

Integration of the applications for the realisation of ProGET was done in a rather traditional way, by sharing the lowest layers (OpenLDAP, MySQL) and with adapters (code: *glue*), when the applications themselves were rather monolithic. It would have been preferable to take advantage of libre applications organised in a more modular way and supporting a Web service paradigm. But very few mature versions of libre software which may have been integrated offered such interoperability mechanisms at the start of our project. Even today, this kind of interface is not always entirely present, even if this approach seems to be preferred now for the future versions of projects like phpGroupware or Sympa, for instance.

Integrated Libre Software High-Level Applications

The main libre software applications that have been integrated in the ProGET platform are:

- **The Apache Web server.** The server provides the link between the client tools (browsers) and the Web applications.
- **A WebDAV repository.** The `mod_dav` Apache module implements the shared Web folders which implement the documents repositories for the projects (see Project Documents Repository Accessible Through WebDAV).

- **The phpGroupware engine and applications.** PhpGroupware provides the Web interface of the "virtual desktop" of the collaborative workspace (see Researchers/ teachers Virtual Desktop in phpGroupware), and brings in standard groupware components. It also serves as the basis for the software infrastructure of the public portal. In addition to standard phpGroupware modules, we have added two new modules developed for the needs of GET. One module which extracts information out of the collaborative work applications to deliver the public portal (see Public Web Portal) and a module which enables the administrative management for the Research Office (see Tools for the Research Office).
- **The Sympa mailing list manager (Sympa).** This powerful mailing-list manager provides some asynchronous communication means inside and outside of the projects.
- **The TWiki wiki server (Wiki).** This wiki system, among the most advanced, provides a whiteboard-like interface to implement the "knowledge base" of the projects.
- **The Agata Reports reporting tool.**[8] It helps the Research Office to issue queries on the projects description forms in order to answer internal or external requests about research activity at GET.

We hereafter describe some of the characteristics of the ProGET modules and the obtained features.

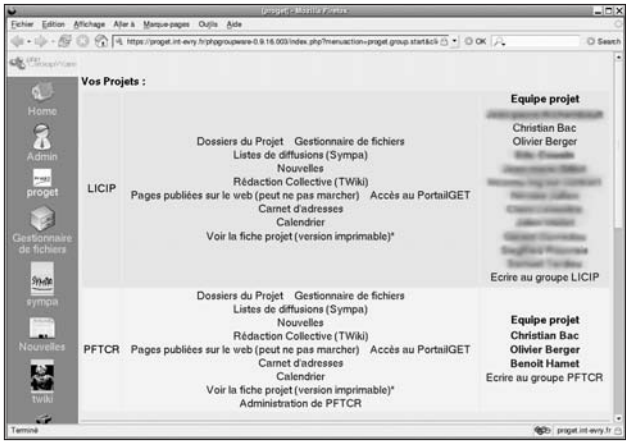
Researchers/Teachers Virtual Desktop in phpGroupware

Each researcher who connects to the platform gets access to the user's own "virtual desktop," provided through phpGroupware. Figure 2 shows this start page for a researcher who belongs to two research projects (here LICIP and PFTCR).

The user will then be provided directly, for each project the user belongs to, with a set of collaboration tools (with the corresponding links in the central column of Figure 2):

- Direct access to browsing of the contents of the documents repository of the project (see

Figure 2. ProGET Collaborative workspace start page



Project Documents Repository Accessible Through WebDAV);
- Web-based file manager (Web interface for the management of the contents of this repository);
- Mailing lists (access to the Web interface of Sympa for the lists of the project);
- News (management of the project's news displayed in the public portal);
- Project's wiki (see Project's Wiki);
- Project's specific Web pages (see Project Dedicated Web Sites);
- Access to the project's description page in the GET research portal (see Project Dedicated Web Sites;
- Shared address book and calendar (standard phpGroupware tool);
- Printable project form (including restricted access information).

Some of these tools are described in more detail hereafter.

Project Documents Repository Accessible Through WebDAV

As described in Dridi and Neuman (1999), WebDAV suits well to create a groupware portal that helps people share their documents. In ProGet each project is provided, for its internal use, with a unique secured documents repository, in the form of a specific Web folder. It is shared among members of the project team. It can be accessed via HTTPS for browsing or through WebDAV (Goland, Whitehead, Faizi, & Jensen, 1999) (over HTTPS) for modification of contents of the repository. Figure 3 shows the contents of a repository through HTTPS in a Web browser (here, the `public_html` subfolder in project PFTCR's folder).

The use of the WebDAV protocol enables transparent access in browsing or modification in the office applications, allowing for instance drag-and-drop in file managers for uploading. The uploading is thus extremely simplified[9] com-

Figure 3. Contents of a project's DAV folder (Web folder)

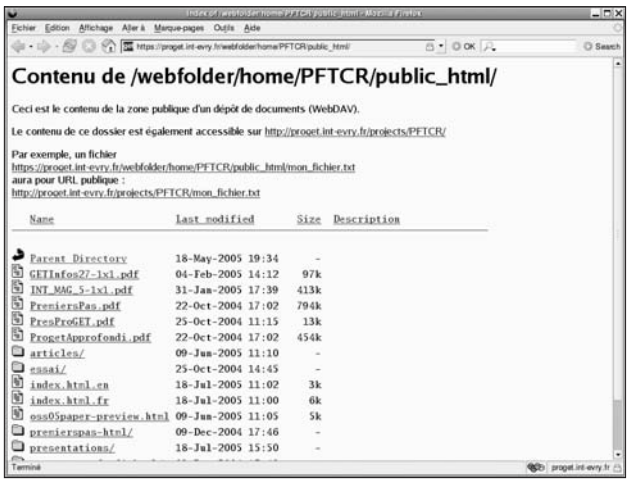


Figure 4. Contents of a project's DAV folder in KDE

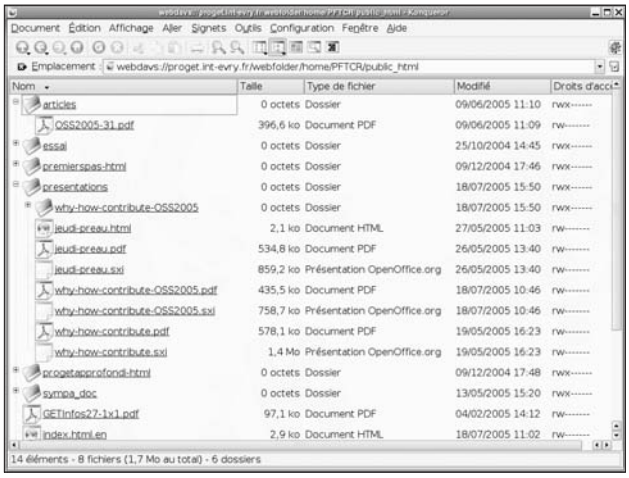

pared to the use of protocols like FTP or CVS. DAV compatible clients exist on all platforms, for instance, under KDE (see Figure 4) or on Windows XP.

A simple file manager is also available as a Web application in the phpGroupware collaborative work environment of the project, for cases where the nomad users will not have the possibility to access the repository with DAV clients.

A specific subsection of each project's documents repository, corresponding to the **public_html** subdirectory, may contain the public Web site specific to the project (see Project Dedicated Web Sites). This subtree can then host a set of public pages very easily maintained, in addition to the stereotyped information displayed in the project's form on the portal. Figure 3 shows the contents via DAV of this subdirectory, which is displayed, in this case, as the contents of a folder, a list of documents, instead of as a set of Web pages (pages would be displayed as in Figure 6).

Project's Wiki

Each project is provided, internally, with a *wiki*[10] which can be used to share, in an authenticated way, in the form of Web pages, a set of simple hypertext documents, not necessarily very structured up front.

This wiki can serve many uses. Each project may for example use it as a hypertext repository to set up a knowledge base, which will hold all elements of the project's life, its productions, and ongoing works. The wiki enables the progressive elaboration of information, in a way less structured and more open than by using the project's documents repository.

Of course, the TWiki wiki engine provides all classical features of these tools (most recent modifications list, notifications, search tool, backlinks, etc.) allowing users to better apprehend the mass of hypertextual information such a tool can host. Figure 5 shows an example of a list of most recent changes in a project's wiki.

Figure 5. Most recent changes in a project's wiki

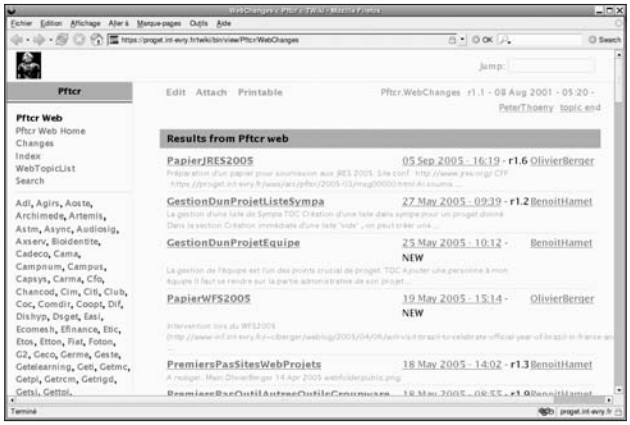

Figure 6. Dedicated project's Web site for project PFTCR

A portion of the wiki can be used to put online hypertextual contents in the project's public Web site, in an automated way (see Project Dedicated Web Sites). To this end, the wiki pages must have been identified individually as *public*. This feature may be used for instance to prepublish on the Web some of the information being elaborated inside the project, which has not yet achieved a sufficiently finalised or structured form required for publication of the documents available on the project's Web site. This is a way to offer some means of transparency on the research works,

by allowing the public to directly view the "lab notepads" of the projects.

Project Dedicated Web Sites

On the same platform, each research project benefits from several dedicated publication spaces, for its external communication on the Web.

Stereotyped Page in the Public Portal

This page describes briefly the research activity and the team. It represents a stereotyped description of a project which has been validated by the Research Office. In addition, the page contains a dedicated news zone for the project which is updated directly by each project manager. This zone helps spreading news about the life of the project. To this end, an RSS[11] feed comes alongside each project's news pages.

Project stereotyped pages are created in the research portal through a phpGroupware module named **sitemgr**. This module is configured specifically and relies on information extracted from the administrative database of project forms.

Specific Web Space

This Web site is made of static HTML pages. The content of this space is managed directly by each project, at will. It may be produced with the HTML editing software of its choice. The upload is made directly by members of the project via publications in the **`public_html2`** subdirectory of the project's WebDAV folder (see Project Documents Repository Accessible Through WebDAV).

No specific competence is required in the teams to be able to contribute to the project's Web site. Figure 6 shows an example of such a Web page. The URL to access this Web space is stereotyped from the project's acronym: `http://proget.intevry.fr/projects/PROJECT_NAME/`

Wiki Excerpts Publication Space

This space complements the previous spaces by allowing the direct publication of excerpts (pages declared *public*) of the resources elaborated by the project inside its internal wiki (see Project's Wiki). This may help with prepublishing, issuing short reference papers, providing a knowledge base, and so forth.

GET Research Projects Administrative Management Module

Whereas other modules of the platform existed previously as generic libre software tools fulfilling the classical needs of every organisation, this project administrative management module has been developed specifically for the needs of the GET Research Office. This module implements the workflow of the contents of research projects forms, during the life cycle of GET research projects (creation, approval, yearly updates, etc.). It was developed in PHP on top of the phpGroupware API, by using the **templates** component, which allows the creation of input masks and screens for the update of the data stored in the underlying MySQL database.

It also uses a set of query and report templates built with *Agata Reports*, a tool for creation of database queries without programming skills, in Web mode. An expert of the domain, who knows the database schema, can then improve the set of queries initially integrated in ProGET, for instance, to produce complex reports in the form of spreadsheet files or even synthetic booklets in the form of word-processor or PDF files.

Data Partition

Inside the same collaborative work platform, each research project must be able to host its own information and documents, which may be confidential. Thus, a partition of the whole data handled by ProGET was set up, relative to the

project groups. This applies in particular to the documents stored in the document repositories (including its dedicated Web site), the messages on the mailing lists in Sympa, the information from the projects description forms in restricted access, and some of the information in the phpGroupware tools.

In a classical way, the OpenLDAP directory is used to allow the authentication of the user's work sessions with a unique password for the different tools integrated in the same platform. The directory is also used as a reference for the description of project teams and their access authorisation for the data handled by the different applications. The system relies on persons and groups defined in a single place, in the LDAP directory. The information are managed through the users and groups management modules in phpGroupware.

A list of persons responsible for the project and a list of participants are associated to each research project. Members of the first group have the right to modify the list of members of the second group via the Web interface in phpGroupware, and to add new co-opted members in their group of responsible persons. The management of the teams for the collaborative work is then done directly in the projects, in an autonomous way, for a better reactivity.

In each of the applications integrated in the platform, access to the data relating to the research projects is controlled by checking if one belongs to these groups. For instance, Sympa is configured to query OpenLDAP directly, which helps defining automatic subscription of members of a project group to a mailing list. That way, each research project receives automatically a discussion list whenever it is created. The record of discussions on this list is only accessible to its subscribers, the members of this research project.

For the phpGroupware tools (calendar, address book, news, etc.), the partition of the data is implemented on the basis of stereotyped phpGroupware *categories*. So each project group defined in the underlying OpenLDAP directory receives a corresponding phpGroupware category automatically, which is then used as an umbrella for classifying the information.

In TWiki, this principle is implemented through standard mechanisms which are devised to host several autonomous wikis on the same site (known as *Webs* in TWiki). All the pages of a project are contained in a TWiki Web, that is a dedicated autonomous wiki. The creation of this space is done at the time a group of users is created, and corresponding privileges are granted to this group (allowed to modify pages, to add new members to the group, etc.). Unlike the other applications integrated in ProGET, it was not possible to let TWiki (at least the standard version we used) interface directly with the LDAP directory for the definition of groups of persons. An adapter module has been developed, to synchronise the groups defined in TWiki with the contents of the research project teams.

Modification and Customisation Efforts

Most of our software development effort has been targeted on:

- **phpGroupware custom components** for administrative management of research projects (see Tools for the Research Office) and Web portal (see Public Web Portal). These developments were very specific to the needs of GET, and should not be released.
- **phpGroupware low-level components.** We have in particular improved the interaction mechanisms between phpGroupware and OpenLDAP, and the code used to access WebDAV. These developments do not specifically fit only our own needs, and improve in a sensible way the standard phpGroupware platform.
- **Bug fixes** and modifications to the other components. Many small modifications

and bug fixes were necessary in particular on the WebDAV server, and in the LDAP server interface of Apache, or on the *TWiki* and *Sympa* programs. These modifications make it easier to integrate these components on top of OpenLDAP. These developments were contributed to the community in the form of patches when they were of general interest.

STRATEGY FOR CONTRIBUTION

This section deals with some methodological aspects of the development project of the ProGET platform. Our project is more an in-house project than an Open Source project and thus case studies like Mockus, Fielding, and Herbsleb (2002), do not always apply to it. Despite the fact that the project was not open to outsiders, it relies profoundly on libre software and we felt the need to set up a strategy for contributing to libre projects. The strategy was adopted in order to establish the conditions of a greater maintainability of the developed system and a clean integration of our patches and improvements to the original projects. These aspects have been described in more detail by the authors in a previous article; see Bac, Berger, Deborde, and Hamet (2005).

Benefits of Libre Software for Their Integration in In-House Applications

Libre software offer today an opportunity to lower the duration and cost of software projects. They also help to raise the quality of the applications (Bauer & Pizka, 2003). The software components are numerous and available for integration or adaptation in order to create applications that fit the needs of organisations (Wheeler, 2005). The development of the initial version of an in-house application can be done quickly, even in a "brutal" way, by modifying components in order to combine them. To be able to use them for its internal projects, one may not be forced to participate directly, or in an indirect way, to their development in the libre communities.[13] These tasks of integration can then be done in a classical way, as if the components had been completely developed internally, without trying to contribute to the initial "upstream" projects. But it is also possible, and even advisable, to contribute, whenever it is possible.

Maintainability of In-House Specific Developments

After the initial integration phase comes the issue of the midterm evolution of the obtained product. This issue becomes crucial when it becomes necessary to react to recurring external evolutions of the integrated components (for instance in case of a published fix for a security problem). We profess, out of the experience gained during this project, that it is necessary to define a policy for contributions on the most important integrated components.

This active contribution brings the possibility of transferring the evolutions that were required by the internal developments into the libre modules that were used. Once they have been adopted by the external projects, they will become part of all future releases of these components, which will remove the need to keep on applying internally some specific patches each time a new update is issued for the original module. In this respect, some amount of the maintenance effort for the internal solution is "outsourced" to the libre community, which helps lower the internal costs.

Strategy Adopted

To make some adaptation on phpGroupware components, we have not limited ourselves to only modifying internally this software (as it had been done before for PicoLibre), but on the contrary, we have decided to collaborate actively with the phpGroupware project. This led us to

undertaking the process for the official application of a member of our team to the phpGroupware project, and the transfer of the copyright on our developments to the FSF which holds the rights for phpGroupware.

Again, our goal, by doing so, is to have our modifications integrated in the standard code base of phpGroupware, so that they will be part of future releases of the software, and we may not have to apply again and again the same changes whenever a new version of phpGroupware is released. This way, we intend to lower the cost for the future maintenance of ProGET.

FIRST OUTCOMES AND PROSPECTS

Even if integration of existing applications requires extensive adaptation (Adams, Boldyreff, Nutter, & Rank, 2005), the effort is far lower than what would have been necessary for a project entirely developed internally. The vast range of features that we thought necessary for our platform was only achievable at a reasonable cost by taking advantage of existing libre software. This platform brings generic tools for nonprogrammer researchers but also features appealing to the most demanding researchers, like DAV repositories or a wiki.

The ProGET platform is in production now and opened for its users since June 2005. The GET research portal and the projects administrative management application are already used on a day to day basis. It is however too early to proceed to an assessment of the use of collaborative work tools, which are still used regularly by only a few research projects.

The use of the collaborative work environment is at the present time proposed for volunteers. Its roll-out to the whole GET research teams is not yet envisioned, some uncertainties remaining on the general infrastructure to be set up, for instance, for the necessary training phase of the users, or the financial costs to ensure the maintenance of the production platform with maximum availability. Some findings can still be learned from the return on experience of the first users.

Conformance to Requirements

The tools which have been integrated offer a far range of features, which address most of the generic needs of the research teams at GET. The TWiki tool, quite versatile, provides in particular a great potential, although it requires some amount of training. Some shortcomings have however appeared during the first months of usage of the platform.

ProGET was devised by focusing on an organisation structured around the notion of research project with a clearly defined perimeter, validated by the GET Research Office. However, needs for collaborative work tools also come from contexts outside the precise boundaries of already validated research projects. Thus, during upstream exploratory phases leading to the creation of projects, for instance, some collaboration is often necessary between members of teams which have already been established independently, and who often work part-time on these exploratory activities. Several users have requested that the kind of tools available in ProGET be offered also for these upstream phases, where they could greatly facilitate participation, reactivity, and communication between various actors. It then seems necessary to be able to handle also collaborative work groups linked to exploratory phases, outside the rigid frame of validated research projects already approved for the GET research portal.

It was also identified, through the first steps of take-up of the tools by research teams, that the principle of partition of data that was implemented, based on a lowest granularity corresponding to the research projects, was not fitting that well. Inside a GET research project, teams have to work for different research contracts, which all have their own list of partners, and their own privacy require-

ments. The granularity chosen for teams which have to access the same set of documents and information in the project is thus not well adapted in the current version of the platform. It seems necessary to be able to define, for collaborative work, some subprojects more or less autonomous in the realm of the same research project, which will each define a specific list of participants and associated access privileges.

Evolution Towards Other Collaborative Activities

The users of the platform are also participating, besides their research activities, in teaching activities, and numerous other work groups, for which Web-based collaborative work tools may not always be available, either at GET or at its partners.'

There is thus a need for the availability of one or more platforms supporting collaborative work, which would be as feature-full as the ProGET platform, but which may allow the easy and quick creation of projects and their work groups, progressively, in a loose environment, as was the case with the PicoLibre platforms.

Need for such a platform could lead to the creation of a "new generation" PicoLibre system, which could integrate the whole set of generic components that have been integrated in ProGET, together with a generic module for creation of collaborative work spaces, and which could be more maintainable than the previous generation.

The ProGET platform could then be split in two parts: on the one hand a module for the administrative management of GET research projects and a GET research Web portal, and on the other hand the use of a "PicoLibre V2" kind of platform, in which the groups corresponding to the GET research projects could be hosted, among others.

Constraints for Administration

The ProGET platform was devised in an effort for reuse and modularisation in integrating the existing libre components, in order to lower the maintenance efforts to be made internally (see Strategy for Contribution). However, the installation and maintenance tasks for such a platform are quite demanding and require specific competence (good knowledge of the internals of the various integrated software), which imply a necessary precise planning in the event of the outsourcing of its administration to the regular IT department which is in charge of the GET information systems.

In this respect, one first hypothesis for improvement would be the availability of the whole set of components in a standard packaging. It would be interesting to have all the components used, and their new adapters, available in the form of packages for the libre software distributions already known by the support teams. For instance, in the Debian distribution, the phpGroupware, Sympa, and TWiki tools are already packaged in the ordinary way. It would be interesting if all modules that have been developed for ProGET were packaged too. This could be achieved by taking advantage of the recent efforts made to package the modules of the PicoLibre application for Debian.

PhpGroupware for the Development of Custom Applications

Several findings can be stated, looking at the use of phpGroupware as the basis for the development of custom applications. PhpGroupware brings a large choice of components which have not all achieved a common level of quality. Some functions suffered from numerous bugs preventing them to be put into production as such, in particular regarding the conditions required for ProGET, for instance if using underlying OpenLDAP and WebDAV layers.

In addition, the structure of data in phpGroupware is in general organised from the perspective of one phpGroupware instance deployed in an organisation where, by default, the whole of the information handled by the system will be available to all the users. This may fit, for instance, to SMEs or very small virtual organisations where all actors have to be informed of everything happening in the organisation. This model happened however to be poorly convenient in our case which requires that projects hosted on the same phpGroupware platform be kept separate, and that a strong level of confidentiality be preserved on the information (see Data Partition).The use of phpGroupware categories partially helps to solve this kind of constraint, but by paying the price of some usage precautions which degrade the global usability of the application.

PhpGroupware provides an interesting API for the PHP developer, for Web based collaborative work applications that will be relatively simple. It happens to be somehow limited though, for advanced needs for the development of complex applications, in particular concerning the ACLs, the corresponding data model, and the independence of the lowest level modules. PhpGroupware lacks also of a module providing applicative workflow facilities.

The use of the *template* "RAD tool" integrated in phpGroupware turns out a poor choice in the case of a complex application, despite its ease of use for relatively simple needs. Indeed, its associate documentation and tutorial only scarcely refer to the *MVC* model which is however generalised in the more complex modules of phpGroupware. In the latest modules developed for ProGET, we thus have preferred to use these more classic MVC *patterns* and rely more on the HTML templating system, that happen to be more maintainable. This choice was made with a midterm vision, as the learning curve for developers is bigger in this case.

PhpGroupware is still an interesting project for a rather simple use of its existing modules. And although it provides rich and quite generic APIs, which allow the development of new applications, it cannot constitute a really generic application development *framework* like other libre environments (Zope, Apache Tomcat, etc.).

CONCLUSION

Although it may be enhanced on numerous aspects, the ProGET platform delivers a range of features without competition in existing libre software collaborative work platforms, for a modest development cost.

There are strong needs in higher-grade research and teaching institutions for tools supporting collaborative work. ProGET can then constitute a reference point for organisations wishing to integrate, for their custom needs, existing libre software applications for collaborative work.

Even if a policy is adopted for the contribution to the libre software projects used, in order to lower certain maintenance costs, the generalisation of the use of the present platform at GET and the future developments necessary to enhance it will only be possible through a substantial investment, which may be far more important than what was spent for the first initial developments.

One possibility for the reduction of these costs could be the mutualisation of the development between several organisations. It could be articulated around the industrialisation as well-packaged libre software programs of the most generic elements of ProGET, leading the way to a new generation PicoLibre platform.

Chapter 7.23
Exploring the Effects of Process Characteristics on Product Quality in Open Source Software Development

Stefan Koch
Vienna University of Economics and Business Administration, Austria

Christian Neumann
Vienna University of Economics and Business Administration, Austria

ABSTRACT

There has been considerable discussion on the possible impacts of open source software development practices, especially in regard to the quality of the resulting software product. Recent studies have shown that analyzing data from source code repositories is an efficient way to gather information about project characteristics and programmers, showing that OSS projects are very heterogeneous in their team structures and software processes. However, one problem is that the resulting process metrics measuring attributes of the development process and of the development environment do not give any hints about the quality, complexity, or structure of the resulting software. Therefore, we expanded the analysis by calculating several product metrics, most of them specifically tailored to object-oriented software. We then analyzed the relationship between these product metrics and process metrics derived from a CVS repository. The aim was to establish whether different variants of open source development processes have a significant impact on the resulting software products. In particular we analyzed the impact on quality and design associated with the numbers of contributors and the amount of their work, using the GINI coefficient as a measure of inequality within the developer group.

INTRODUCTION

In recent years, free and open source software (OSS) has drawn increasing interest, both from the business and academic worlds. Projects in different application domains, like most notably the operating system Linux, together with the suite of GNU utilities, the office suites GNOME and KDE, Apache, sendmail, bind, and several programming languages, have achieved huge successes in their respective markets. Undeniably, they constitute software systems of high quality. This has led to discussions and analyses of the underlying development process, as OSS is unique not only in its licenses and legal implications.

The main ideas of this development model are described in the seminal work of Raymond (1999), *The Cathedral and the Bazaar*, first published in 1997. Raymond contrasts the traditional model of software development, which he likens to a few people planning a cathedral in splendid isolation, with the new 'collaborative bazaar' form of open source software development. In the latter model, a large number of developer-turned-users come together without monetary compensation to cooperate under a model of rigorous peer review and take advantage of parallel debugging, which altogether leads to innovation and rapid advancement in developing and evolving software products. In order to enable this while minimizing duplicated work, the source code of the software needs to be accessible, which necessitates suitable licenses, and new versions need to be released often. Most often, the license a software is under is used to define whether it is open source software, applying for example the open source definition (Perens, 1999) or the approach of free software as embodied in the GNU GPL (Stallman, 2002). Nevertheless, usually a certain development style and culture are also implicitly assumed, although no formal definition or description of an open source development process exists, and there is considerable variance in the practices actually employed by open source projects. Also the relationship to and insights regarding practices of agile software development (Erickson, Lyytinen, & Siau, 2005; Turk, France, & Rumpe, 2005; Merisalo-Rantanen, Tuunanen, & Rossi, 2005) have been discussed (Koch, 2004a).

Possible advantages and disadvantages to the development of software of this new development model have been hotly debated (Vixie, 1999; McConnell, 1999; Bollinger, Nelson, Self, & Turnbull, 1999; Cusumano, 2004; Feller, Fitzgerald, Hissam, & Lakhani, 2005). For example the question of whether open source development positively or negatively impacts quality and security has been a topic of several analyses (Witten, Landwehr, & Caloyannides, 2001; Hansen, Köhntopp, & Pfitzmann, 2002; Payne, 2002; Stamelos, Angelos, Oikonomou, & Bleris, 2002; Koru & Tian, 2004; Feller et al., 2005). Different viewpoints have also developed regarding whether or not the open source development approach increases efficiency of software production (Feller et al., 2005). Critics argue that the largely missing requirements engineering and design phases, together with the trend to search for bugs in the source code late in the lifecycle, lead to unnecessarily high effort hidden by the relative ease of spreading it throughout the world (McConnell, 1999; Vixie, 1999). Proponents of the OSS development model counter with arguments of very high modularity, fast release cycles, and efficient communication and coordination using the Internet (Bollinger et al., 1999; Raymond, 1999).

Currently, much empirical research is proceeding on OSS processes. Often, the research relies on data available through mining the communication and coordination tools and their repositories (Cook, Votta, & Wolf, 1998; Dutoit & Bruegge, 1998; Atkins, Ball, Graves, & Mockus, 1999; Kemerer & Slaughter, 1999) in place in OSS projects in order to describe and characterize the development team and processes. Most notably, the source code control systems used have been found to be a source of information, together with mailing lists and bug tracking systems. These analyses

have been useful in providing an indication of how OSS development works in practice. Work performed has included both in-depth analyses of small numbers of successful projects (Gallivan, 2001) like Apache and Mozilla (Mockus, Fielding, & Herbsleb, 2002), GNOME (Koch & Schneider, 2002), or FreeBSD (Dinh-Tong & Bieman, 2005) and also large data samples, such as those derived from Sourceforge.net (Koch, 2004; Long & Siau, 2007). Primarily, information provided by version control systems has been used, but so have aggregated data provided by software repositories (Crowston & Scozzi, 2002; Hunt & Johnson, 2002; Krishnamurthy, 2002), meta-information included in Linux Software Map entries (Dempsey, Weiss, Jones, & Greenberg, 2002), or data retrieved directly from the source code itself (Ghosh & Prakash, 2000). Other approaches taken include ethnographic studies of development communities (Coleman & Hill, 2004; Elliott & Scacchi, 2004), sometimes coupled with repository mining (Basset, 2004). Indeed, it can be shown that important information about project characteristics and participating programmers can be retrieved in this fashion.

However, a key problem is that the resulting process metrics (Conte, Dunsmore, & Shen, 1986; Fenton, 1991; Henderson-Seller, 1996) measuring attributes of the development process and of the development environment, such as distinct programmers, number of commits, or inequality, do not address the quality, complexity, or structure of the resulting software product. Therefore, we expanded the analysis in this article by selecting and calculating several product metrics pertaining to these characteristics of the software product.

This allows us to analyze whether different development practices have an impact on product quality. We will use process metrics derived from the respective source code control systems as predictors for quality as portrayed by relevant product metrics. Uncovering these relationships will answer the question of which values for these variables—for example, low inequality in participation—lead to a higher product quality. For this analysis, we use OSS Java frameworks as a data set. The most similar work available is by Koru and Tian (2005), who have used two large open source projects as a dataset to uncover a relationship between high-change modules and those modules rating highly on several structural measures. They used, among others, size measures such as lines-of-code or number of methods, coupling measures such as coupling between objects, cohesion measures such as lack of cohesion in methods, and inheritance measures such as depth in inheritance tree.

The research objective of this article therefore is as follows: We investigate whether there is an influence of different forms of open source software development processes characterized by process metrics on the resulting software. Most importantly, we check for impacts on different quality aspects as measured by appropriate product metrics. A comparison with proprietary products and processes is out of scope and will not be treated in this study.

In the following section the method employed for arriving at the necessary data is described, starting with the data set chosen and its importance, and proceeding to the data collection of both product and process metrics and their combination. Then we present the analysis regarding any relationship between process and product metrics, both on the level of classes and of projects, followed by a discussion. The article finishes with conclusions and future research directions.

METHOD

Data Set

For this empirical study, a certain fixed domain of OSS was chosen, in order to limit variance to the areas of interest by holding the application domain constant. All projects included therefore roughly implement the same requirements and

with the same programming language, so differences in software design and quality can directly be attributed to different development practices in place.

We examine 12 OSS frameworks for the presentation layer of Web applications. A framework is a reference architecture for a concrete application which offers basic structures and well-defined mechanisms for communication. Only specific application functionality has to be implemented by the programmer, which is achieved by using abstract classes and interfaces that have to be overridden (Johnson, 1997; Fayad & Schmidt, 1997). All frameworks are based on J2EE components like JSP, Servlets, and XML, and can be used within every Servlet container that implements the J2EE standard. The frameworks are: ActionServlet, Barracuda, Cocoon, Expresso, Jetspeed, Struts, Tapestry, Turbine, Japple, Jpublish, Maverick, and Echo.

Besides having a fixed domain thus reducing any noise in the results, frameworks are an important part in modern software development. Frameworks are one possibility of reusing existing software, thus promising reduced costs, faster time to market, and improved quality (Morisio, Romano, & Stamelos, 2002). OSS especially lends itself to white box reuse (Prieto-Diaz, 1993), as it per definition contains the source code, offers a deeper view into the architecture, and may be modified or adapted. This reduces the disadvantages encountered with using components-off-the-shelf (COTS) offered by software companies. Another critical issue that can be solved by using OSS is the maintenance of frameworks, which is usually done by the contributors of project. On the other hand, although the source code is available and the program could be maintained by the community, some serious problems could accompany the development process, due to low-quality code, design, or documentation. Object-oriented metrics as used here provide a capability for assessing these qualities (Chidamber & Kemerer, 1991, 1994) and may help to estimate the development effort for adaptation and adjustment.

First, all classes are treated as a single data set; afterwards an analysis on project level is presented. An analysis on class level is performed for two reasons: As we analyze the development process and style, the differences between classes might be larger than those between projects, and indeed for some metrics the variation is higher within the projects than between them. For example an abstract class for database access might be developed similarly in all projects. We therefore might find paired classes among different projects. In addition, using a framework does not necessarily mean adopting all classes within this framework. Therefore an analysis on this detailed level is of interest out of a reuse perspective. Afterwards, we will try to consolidate both perspectives by using multilevel modeling which explicitly incorporates effects on both levels.

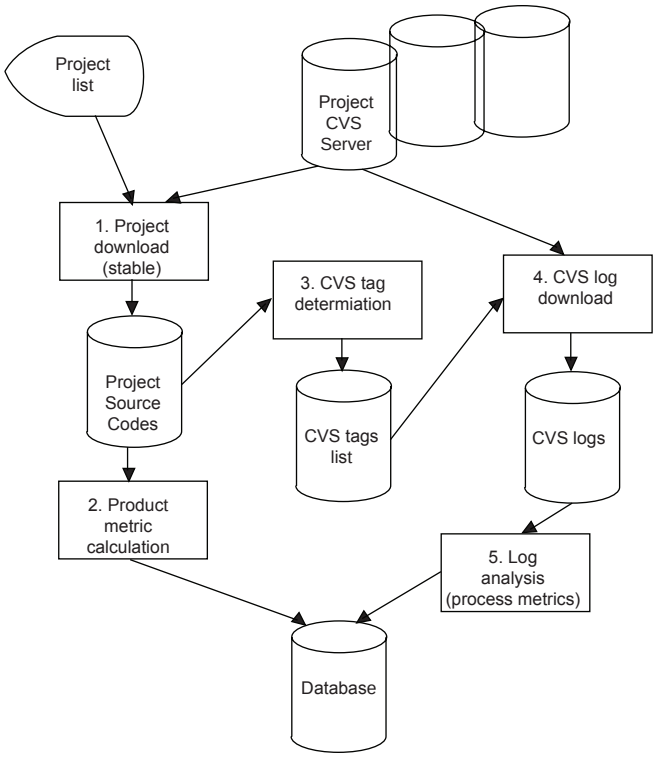
Data Collection

For the following analysis, several steps of data collection were conducted. As mentioned above, this study focuses on frameworks for Web applications written in an object-oriented language. Many of the available frameworks are not written in object-oriented languages but scripting languages like Perl or PHP. This would preclude using most of the product metrics designed for object-oriented languages. Therefore we focused on frameworks written in Java. We conducted preliminary research to identify potential candidates that fulfilled the criteria of both language and application area. This initial phase consisted of performing extended Web research (online developer forums, search engines) and perusing reports in professional publications for developers. This led to the identification of 12 frameworks. The functions and features of the resulting frameworks were compared in a prior study (Neumann, 2002) and are not part of this article.

After the data set as defined above had been identified, both product and process metrics had to be retrieved and merged for further analysis. In order to calculate the product metrics, the latest stable version of each framework was determined and downloaded as a packed distribution. We used the metric plug-in (*http://metrics.sourceforge.net/*) for the Eclipse SDK (*http://www.eclipse.org*) to calculate these product metrics. The necessary compilation of the downloaded source files required utilization of stable versions over the current snapshot from the source code repository, the latter of which might produce complications due to inconsistent code and the exclusion of additional libraries. The plug-in creates an XML representation of the calculated metrics which we used in our study. This is done for source code files only (i.e., .java-files in Java). A simple Java program was written to process this XML file and to store the metrics on class level into a database. The resulting product metrics will be described in the next section.

To retrieve the required process metrics, we used the methodology applied in other studies (Mockus et al., 2002; Koch & Schneider, 2002; Robles-Martinez, Gonzalez-Barahona, Centeno-Gonzalez, Matellan-Olivera, & Rodero-Merino, 2003; Dinh-Tong & Bieman, 2005; Hahsler & Koch, 2005), relying on mining the source code control repositories, for the data set in all cases of the concurrent version system (CVS). First, we looked up the CVS tag associated in the repository with the stable version already downloaded. Using this information, a local checkout of the files

Figure 1. Data-collection process



was performed, and a log file was generated from the initial check-in until the corresponding date of the stable release. This assures that the same source code is used to calculate both the product and process metrics. Data from the log files were extracted for every check-in for every available file in the local CVS repository. Once extracted, these were stored in a normal database as has been done in prior studies (Fischer, Pinzger, & Gall, 2003; Koch & Schneider, 2002; Koch, 2004; Hahsler & Koch, 2005). Each database entry therefore consists of the filename, the name of the committer which was anonymized for privacy reasons (Thuraisingham, 2005), LOC added and deleted, and the date. The end result was a total of 45,164 records within a single table. We then used database queries to calculate process metrics, for example, overall commits, number of different committers, and so on, for each class (i.e., .java-file). Using another program, additional metrics like the standardized GINI coefficient were computed for every file and again stored in the database. The product and process metrics were merged using the file name as a unique key, resulting in one entry for every class containing both types of metrics. We therefore only consider source code files (i.e., .java-files) and exclude additional files possibly found in the CVS repository, like documentation files or the projects' Web sites. Figure 1 gives a graphical overview of the data-collection process.

Description of Process Metrics

In selecting the metrics used in this study, we both considered the goals of the analysis (i.e., to be able to both characterize the software process and quality aspects of the resulting product) and the availability of metrics within the data. We use several well-discussed process metrics to characterize the OSS development processes in the projects analyzed. The metric of commit refers to a single change of a file by a single programmer. Therefore the number of commits of a file is the sum of changes conducted over a certain period of time and is also an indicator for the activity of a file. In our study we cover the time from the initial commit of a file until the last commit before the stable version was released. The total lifetime of a file includes all the time elapsed, not only that time which was spent on developing and coding. Another important process metric is the total number of distinct programmers involved in writing and maintaining a file. A programmer is defined by counting those people committing source code changes through their CVS account, thus only people with such accounts are measured. In some projects, depending on the change and commit policy in place, people could be contributing code without CVS account, which sometimes is only granted to long-time participants, by sending it to one of those persons who then does the actual commit. For example, German (2006) found that 110 out of 364 modification records of a user were patches submitted by 46 different individuals. Therefore, the number of programmers might actually be higher than the number reported here. This fact is very problematic to check. In general, there are several possibilities of attributing authorship of source code to persons, which are to use the associated CVS account (as done here), to mine the versioning system comments for any additional attributions, to infer from attributions in the source code itself, or by questionnaires or intimate knowledge of a project and its participants. Attributions in source code or commit comments are highly dependent on existence and form of a project's standards, and therefore are also difficult to implement for larger data sets. Ghosh and Prakash (2000) have implemented a solution based on source code attributions for a set of more than 3,000 projects, with about 8.4% of the code base remaining uncredited, and with the top authors containing organizations like the Free Software Foundation or Sun Microsystems. Nevertheless, they have found a similar distribution of participation as found in this study's data set, as have most other approaches like question-

naires (Hertel, Niedner, & Hermann, 2003) or case studies of larger projects (Mockus et al., 2002, Koch & Schneider, 2002; Dinh-Trong & Bieman, 2005). In a case study of the OpenACS project under participation of project insiders and using the strict standards for CVS comments, Demetriou, Koch, and Neumann (2006) have found that only 1.6% of revisions pertained to code committed for someone without CVS privilege. In this study, we have used two approaches for checking the validity of this measure: Using simple heuristics, we have checked all commit comments for attributions. This shows that 11.7% of revisions seem to be contributed by other people. We have also manually inspected all revisions of the Maverick project: no revision seemed to have been committed for somebody else, which was identical to the heuristics result.

As the participation of programmers in open source projects is less continuous than in commercial development, the number of programmers alone does not adequately reflect the effort invested. Therefore we include the open source software person month (OSSPM) as a new process metric that characterizes the amount of work that is committed to the object considered. This is defined as the cumulated number of distinct active programmers per month over the lifetime of the object of analysis. As Koch and Schneider (2002) have shown, this number of active programmers can be used as an effort predictor. It should be noted that this measure assumes that the mean time spent is constant between objects of analysis.

As several prior studies (Koch, 2004; Mockus et al., 2002; Ghosh & Prakash, 2000; Dinh-Tong & Bieman, 2005) have shown the distribution of effort between participants to be highly skewed and differing from commercial software development, we add an additional process metric to characterize the development style. We used the normalized GINI coefficient (Robles-Martinez et al., 2003), a measure of concentration, for this. The GINI coefficient is a number between 0 and 1, where 0 is an indicator for perfect equality and 1 for total inequality or concentration. We calculated the GINI coefficient both based on LOC added per person (which can be extracted from the CVS repository) and on the number of commits a person has done. As the further analyses did not show significant differences between both measures, we will only report the findings for the GINI coefficient based on LOC added. Therefore in the terms of OSS development, a GINI coefficient of 1 means that one person has written all the code. We performed a slight modification: As some files only have one author, calculating the normalized GINI coefficient results in 0 (equality). For these cases we changed the value from 0 to 1 because, for us, the fact that one person has written all the code is an indicator of inequality rather than equality.

Description of Product Metrics

The most popular product metric is the size of a program, which can be derived by counting the number of lines-of-code (LOCs). There are many different ways to count LOCs (Humphrey, 1995; Park, 1992; Jones, 1986). In this analysis we apply the definition used by the CVS repository, therefore including all types of LOCs: source code lines as well as commentaries (Fogel, 1999). The size of the largest method (*LOCm*) is another important descriptor in object-oriented classes which can also be measured by counting LOCs. These size metrics can be regarded as indicators for complexity as it is very difficult to read and understand classes with long methods and many fields (Henderson-Seller, 1996). Other indicators are the number of regular/static methods (NOM/NSM) and the number of regular/static fields (NOF/NSF). We propose that these size measures are affected by nearly all process metrics: If more people are working on a class, its size will increase. The same will tend to be true for the time the class exists and the number of commits performed. Especially the amount of effort invested in the

class will increase the size. Most importantly, we propose that the inequality in contributions will affect different size measures: If the class is programmed and maintained by a small team, or a small core group within a team, these participants will tend not to see the need for promoting higher modularity. This would presumably lead to them not splitting up a class, thus affecting LOC, or a method, thus affecting LOCm.

The probably most well-known complexity metric is McCabe's definition of cyclomatic complexity (VG) (McCabe, 1976). *VG* counts the number of flows through a piece of code, (i.e., a method). Each time a branch occurs (if, for, while, do, case, catch, and logic operators), this metric is incremented by one. We determined the maximum (*VGmax*) and the average (*VGavg*) method complexity on class level. Weighted Methods per Class (WMC) are part of the Chidamber and Kemerer suite, but they leave the weighting scheme as an implementation decision (Chidamber & Kemerer, 1994). In our study WMC is defined as the sum of all method's complexities (*VG*) that occur within a class. VG and WMC are indicators of how much time and effort must be spent to understand, test, maintain, or extend this component (Chidamber & Kemerer, 1991; 1994), with McCabe giving *VG = 10* as a reasonable limit for proper testing (McCabe, 1976). But this measure should be treated with special care, as this metric is based on experiences in procedural languages including C or COBOL (Lorenz & Kidd, 1995). Subramanyam and Krishnan (2003) have shown that WMC is highly correlated to LOC, which supports the thesis that LOC can be used as a low-level complexity metric. The influence of WMC on software quality was examined in several studies (Basili, Briand, & Melo, 1996; Subramanyam & Krishnan, 2003). Regarding the relationship of complexity measures with process metrics, the most important effect is proposed to exist in connection with the inequality: Analogous to the reasoning for size, complexity reduction will not be a high priority when a small core group who would know the code in any case is present. Also, classes, and software overall, tend to accumulate more complexity as time passes, if no counter-measures are taken. This will decrease maintainability, which again is less of an issue if the software is consistently maintained by a small group.

The object-oriented product metrics we investigated are mostly based on a subset of the Chidamber-Kemerer-Suite (Chidamber & Kemerer, 1991, 1994; Chidamber, Darcy, & Kemerer, 1998). The authors argued that the product metrics commonly used before were not suitable for object-oriented development (Chidamber & Kemerer, 1991). From their point of view, the modern object-oriented analysis, design, and programming processes, which encapsulate functionality and entities in objects, were too different from the traditional software engineering process. The prior product metrics were not designed to measure object-oriented characteristics like classes, inheritance, and the usage of methods and attributes. They proposed six metrics, derived from a theoretical analysis, which should be able to assist in making predictions about the complexity and quality of object-oriented programs. We used a subset of the CK-suite (NOC, DIT, WMC) for which concrete threshold values were suggested. The remaining metrics (LCOM, RFC, CBO) are not part of this study, as no threshold values are available. In addition, CBO and RFC have been found to be highly correlated with WMC (Chidamber et al., 1998), so they would not give additional information. These CK-metrics for our analysis are complemented by some of the metrics defined by Lorenz and Kidd (1995).

Number of Children (NOC) and Depth in Inheritance Tree (DIT) are metrics for the level of inheritance of a class. Chidamber and Kemerer (1994) state that the deeper a class in the hierarchy, the more complicated it is to predict its behavior and the greater its design complexity. Though this may lead to greater effort in maintenance and testing, it has greater potential for the reuse of inherited methods. In a Java environment, DIT

is defined as the longest path from the class to the root in the inheritance hierarchy—that is, the class Object. Some studies have shown that DIT is related to fault-proneness (Basili et al., 1996; Briand, Wüst, Ikonomovski, & Lounis, 1998). NOC counts the number of classes inherited from a particular ancestor—that is, the number of children in the inheritance hierarchy beneath a class. A class implementing an interface counts as a direct child of that interface. Chidamber and Kemerer (1991) expose a similar relationship between design complexity and NOC. The greater the number of children of a class, the greater is the reuse. However, an excessive number of children may indicate the misuse of sub-classing. NOC also hints to the importance of that class within the application, as well as to the corresponding additional effort likely required for testing and maintaining. NOC was evaluated by Basili et al. (1996) and Briand et al. (1998), who differ in their findings related to fault-proneness. NORM, like NOC and DIT, is an inheritance metric for class design (Lorenz & Kidd, 1995). It measures the number of inherited methods overridden by a subclass. Lorenz and Kidd (1995) state that, especially in the context of frameworks, methods are often defined in a way that requires them to be overridden. However, very high values may indicate a design problem because a subclass should extend new abilities to its super-class that should result in new method names. Similar to the other product measures, we again propose a relationship of the process metrics with these object-oriented metrics. Especially the metrics giving an indication of the use of inheritance will be affected by different process attributes, most importantly on project level. The correct use of inheritance helps in achieving a modular design which in turn allows for parallel work by many participants. In addition, it significantly enhances maintainability. We therefore propose that analogous mechanisms will be found here as for complexity measures.

We suggest two additional metrics that can be used to describe the interior design of a class. The number of classes (NCL) counts the number of classes within a class and should be either 0 for interfaces or 1 for classes. Other values indicate the utilization of interior classes, which should be avoided in object-oriented design. The number of interfaces within a class (NOI) aims at the same direction. Interfaces are used to define entry points within or even across applications and therefore should not be defined within a class but in separate files.

Most of these product metrics presented are discrete variables, where increasing (or decreasing) values are not necessarily a sign of good or bad quality, or aspects thereof. For example, whether the cyclomatic complexity VG of an entity is 4 or 6 is mostly determined by its function, and does not signal any deviation from good practice or negatively influence maintainability. Only if a certain value is surpassed does this metric give an indication of possible problems. Therefore, most of these metrics can be assigned a threshold for this purpose. Currently, there is a paucity of threshold values for the defined metrics provided by literature based on empirical studies, especially using Java. This requires us for most metrics to use the values proposed by Lorenz and Kidd (1995) for C++ classes.

Based on the threshold values in Table 1, we created dummy variables that take on the value of one or zero, depending on whether the associated metric values exceed the threshold value for that class. These dichotomous variables try to categorize the given metrics based on different aspects to be explored like size or complexity (see Box 1).

MSIZE and *CSIZE* depend on metrics that measure size, *MCOMP* on complexity, *CINH* on inheritance, and *CDESIGN* on interior class design.

Table 1. Overview of metrics with corresponding threshold values

Metric	Name	Thresh-old	Definition
NOC	Number of Children		Total number of direct subclasses of a class
NOI	Number of Interfaces		Total number of interfaces of the file
DIT	Depth of Inheritance Tree	< 6	Distance from class Object in the inheritance hierarchy
NORM	Number of Overridden Methods	< 3	Total number of methods that are overridden from an ancestor class
NOM	Number of Methods	< 30-40	Total number of methods
NOF	Number of Fields	< 3-9	Total number of class variables
NSM	Number of Static Methods	< 4	Total number of static methods
NSF	Number of Static Fields	< 3	Total number of static variables
LOCm	Lines of Code	< 24	Total lines of code of the greatest method in the selected scope
VG-max	McCabe Cyclomatic Complexity Maximum	< 10	Maximum VG for all methods within a class
VGavg	McCabe Cyclomatic Complexity Average	< 10	Average VG for all methods within a class
WMC	Weighted Methods per Class	< 65	Sum of the McCabe Cyclomatic Complexity for all methods in a class
NCL	Number of Classes	= 1	Indicates possible interior classes

$$

ANALYSIS ON CLASS LEVEL

In total, 6,235 Java classes (i.e., distinct files) have been analyzed, for which a total of 45,164 commits were made, with 2,109,989 LOCs added and 913,455 LOCs deleted. A total of 133 distinct programmers have contributed with at least one commit. The number of classes investigated therefore is considerably higher than the datasets used in former studies on object-oriented metrics (634 by Chidamber & Kemerer, 1994; 97 by Chidamber et al., 1998; 180 by Basili et al., 1996; 698 by Subramanian & Corbin, 2001; 180 by Briand, Wüst, Daly, & Porter, 2000).

Descriptive Statistics

Descriptive statistics for all product and process metrics can be found in Table 2. The highest number of commits (209) can be found in the Barracuda project. This file is a change history in Java format containing only comments. The file with the second highest number of commits (188) is also the class with the highest value of LOCs added (19,252), LOCs deleted (11,706), and the largest file overall (7,546 LOCs). This file is one of the most important classes of the Expresso framework (DBObject.Java) and is responsible for DB communication. The class that

is responsible for dispatching the requests of the Struts framework (ActionServlet.Java) is the file with the third highest number of commits (150). An abstract class of the Jetspeed framework that forms the behavior of a portlet has another high value of commits. It is obvious that components providing key functionalities need a special amount of interest because they are usually engaged with several other objects. In accordance with prior studies, all of the process metrics are not 'normal distributed' which can be ascertained using a Kolmogorov-Smirnov test.

In accordance with other studies (Koch, 2004), the number of distinct programmers is quite small with low standard deviation. The histogram of distinct programmers per file shows a heavily skewed distribution. Only 12.2% of the files have more than three distinct authors. Most of the files have one (24.0%) or two (56.1%) programmers, and only 3% have more than five distinct authors. The number of commits per file follows a similar distribution. Only 16.3% have more than 10 commits. Although our values depend on files' respective classes, there are similarities to other studies that have investigated the distribution of distinct authors and commits (Koch, 2004; Krishnamurthy, 2002; Mockus et al., 2002; Ghosh & Prakash, 2000) on the project level.

All of the product metrics are clearly not 'normal distributed' as well. The distribution of LOC is also heavily skewed, which is in accordance with other studies (Koch, 2004; Krishnamurthy, 2002).

Due to the fact that most of the metrics mentioned above measure attributes of classes, we regard real interfaces as missing values (*NOI = 1 and NCL = 0*). Classes that have interior interfaces are valid. Most of the median values are below the threshold suggested by Lorenz and Kidd (1995), as are most of the values for the 75% percentile. The only metric that exceeds this recommendation is the 75% percentile of the size of a method (30>24). The median of the average method complexity per class *VGavg* (1.67) and of the maximum method complexity (3) are below the threshold of 10 suggested by McCabe (1976), and only 11.5% of the classes have a maximum method's complexity greater than 10. Most of the studies which investigate object-oriented metrics used C++ source files (Briand et al., 2000; Chidamber & Kemerer, 1994), so our results cannot directly be compared to them. We are aware of only one study that investigates Java classes (Subramanyam & Krishnan, 2003). Compared to that study we have higher WMC values and our classes are more deeply nested in the inheritance hierarchy. One possible reason for this may be the fact that we examined frameworks that provide abstract classes that are meant to be overridden. The percentage of classes that exceed our dichotomous variables are 5.3% (*CINH*), 6.0% (*MCOMP*), 6.1% (*CDESIGN*), 14.9% (*CSIZE*), and 34.9% (*MSIZE*). The fact that one-third of the classes investigated do not meet the requirements for small method size gives rise to the question whether these threshold values are suitable for object-oriented Java programs. Our data set consists of frameworks that provide functionality for a lot of different scopes. Therefore the average and maximum values may be greater than in normal applications. However we do not adjust the threshold value as it is an indicator for easy understanding and maintenance. The remaining values for the dichotomous variables seem to be reasonable.

RESULTS

In this analysis, we explore relationships between the metrics mentioned above. Results for correlations between the different process metrics can be found in Table 3, respectively Figure 2, using ellipses (Murdoch & Chow, 1996). Due to the fact that all metrics are not 'normal distributed', we used the nonparametric Spearman coefficient.

The correlation analysis shows expected relationships, like the older a file the more distinct

Table 3. Correlation between process metrics (Spearman coefficient, all at a significance level of p<0.01)

programmers are involved (0.471), the more commits are conducted (0.685), and the more work is contributed (0.689). The amount of work (OSSPM) is highly correlated to authors, commits, and the active time, what is indeed reasonable. More interesting are the relations between the inequality as measured by the GINI coefficients and the remaining process metrics. The results show that the older a file, the more homogeneous is the distribution of the added input. The negative correlation between authors and GINI reveals the same tendencies. The more people are involved, the more the work is equally distributed among the participating authors. The number of commits only has slight influence on the GINI coefficient. The correlation between product metrics is not

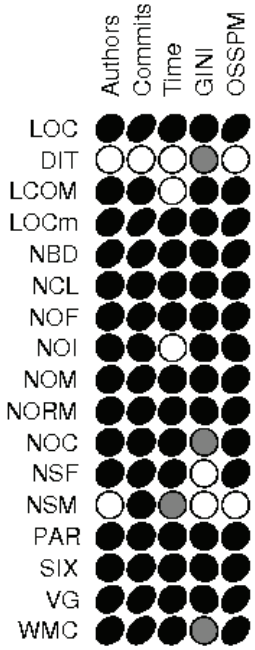
that important, but it should be mentioned that metrics that measure size attributes of a class (NOM, NSM, NOF, and NSF) are positively correlated to the total size in LOC. Furthermore there is a very strong correlation of WMC to LOC (0.734), which is almost identical to the correlation coefficient of 0.741 found by Subramanyam and Krishnan (2003). More importantly, correlations between product and process metrics have been explored, and the results are shown in Table 4, respectively Figure 3, using ellipses (Murdoch & Chow, 1996).

The complexity metrics *WMC* and *VGavg* have a slight correlation to the number of authors and commits as well as to the effort indicator OSSPM. A similar slight relationship appears regarding the group of metrics that measure the size of a class like *LOC*, *LOCm*, or *NOM*. The influence of the active time on the product metrics can be disregarded. Metrics concerned with the use of inheritance (DIT and NOC) do not seem to be correlated to any of the process attributes. As DIT and NOC are important indicators of reuse and well-structured programming, a deeper look into source code is necessary to gather that kind of information. The GINI coefficient does not seem to be correlated to any product metric.

As described above we created dichotomous variables that indicate whether a class exceeds a certain quality threshold or not and compared these two samples with a non-parametric rank-sum test, the Mann-Whitney-U test, also known as Wilcoxon rank-sum test, for example also applied by Koru and Tian (2005). The test assesses whether

Figure 3. Correlation between selected process and product metrics (Spearman coefficient, grey $p < 0.05$, black $p < 0.01$)



the degree of overlap between the two observed distributions is less than would be expected by chance. The resulting hypotheses are:

H0: *There is no difference in process characteristics between the group S1 that exceeds the threshold values and the group S0 that does not.*

HA: *There is a difference between these groups.*

If H0 is rejected, an additional, one-sided Mann-Whitney U-test is used with the hypotheses:

HA1: *The rank-sum in S1 is greater than in S0, indicating that high values of process metrics foster bad quality.*

HA0: *The rank-sum in S1 is lesser than in S0, indicating that high values of process metrics foster good quality.*

The results of these tests are shown in Table 5. Except for the combinations *MCOMP*/*GINI* and *CSIZE*/*GINI*, the significance is smaller than 0.05, so in these cases we can accept the alternative hypothesis *HA* that the corresponding process metrics have an influence on the product metric. In this case we performed a one-sided Mann-

Whitney U-test to determine the direction of relationship—that is, whether the process metrics have a positive (accept HA1) or negative (accept HA0) influence on the product metrics.

In case of a positive relationship (↑), the sum of the ranks in the group that exceeds the limit is higher than in the group that does not. In quality terms, these results indicate that the higher the process metric is, the lower the quality is. Therefore a higher number of distinct programmers, commits, time, and invested effort have a negative influence on the quality.

To validate our results we performed the same tests only with classes that have at least five different authors (n=668). The results are mainly the same, but we could not reject H0 for the combinations *MCOMP*/Time, *CSIZE*/Authors, and *CSIZE*/Time. The change in the number of authors had an influence on the relationship between GINI and the dichotome product metrics. All combinations had a positive influence (accept HA1 with $p<0.01$), which confirms our prior results that the more the work is concentrated, the worse is the quality of software. Or the other way around, an equal distribution of commits fosters good quality. We will discuss this important finding in more detail later on.

ANALYSIS ON PROJECT LEVEL

For an analysis on project level, we aggregated the product metrics from class level and calculated the process metrics for the whole project, based on those files that were examined in the former section. We stored these results in another table in the database.

Descriptive Statistics

Cocoon is the project with the highest number of distinct programmers, commits, and Java classes. The project ActionServlet, Jpublish, and Echo only have one author. Whether these should be included in further analysis can be discussed. Using a definition of OSS based on the respective license, these projects constitute open source projects, but they conflict with the development model normally associated. On the other hand, these projects might possibly have more participants but a very central control regarding the source code, such that any change must be reviewed and committed by the single maintainer, although other people actually write the code and submit it to this person. We have already discussed this problem with the respective metric description. In the following, we base the analysis on both the full set and a subset with these projects removed.

Struts is the framework with the lowest GINI coefficient, which is an indicator for equality of input. Cocoon, Jetspeed, Struts, Tapestry, and Turbine are projects that are hosted by the Apache Software Foundation. The great popularity of the Apache Web server may explain the encourage-

ment of these frameworks. The very low number of commits for the ActionServlet is an indicator for inactivity of the project.

Table 7 shows the mean values of the most important product metrics. The Japple framework has the largest files and the highest WMC. As we have discussed in the previous chapter, there is a very strong linear relationship between LOC and WMC. Therefore this combination is not astonishing. Struts and Jetspeed are the projects with the highest DIT, which indicates extensive usage of subclassing, a form of reuse. The number of children differs across the projects. The frameworks with the lowest average number of children only have one author (ActionServlet, Jpublish).

To get an indication of quality and design, we again apply the dichotomous variables used for capturing different possible problem areas (*MSIZE, MCOMP, CSIZE, CINH,* and *DESIGN*). As the total number of classes that exceed our limits is not appropriate due to different numbers of classes between projects, we calculated the relative amount of faulty classes within a project (see Table 8). Metric *MSIZE* depicting problems with method size has rather high values for all projects, but more than 35% of the classes of Japple, Expresso, and Jetspeed exceed the limit. These three frameworks also have a large amount of methods that outrun the upper bound for complexity. The relative amount of misuse of inheritance *CINH* is small except for the Maverick framework (14.1%). The number of classes with interior classes or interfaces is small except for Barracuda, Maverick, and Echo.

Results

Due to the fact that only a small data set on project level is available, the usage of correlation analysis is not sufficient as the small number precludes any statistically significant findings. Therefore we performed a simple ranking based on the relative amount of classes that exceed our threshold values. High relative amounts of 'faulty' classes result in high ranks (i.e., the project with the highest percentage of classes violating the threshold is ranked on the first place in this variable), and therefore the higher the sum of ranks the higher the overall quality. We do not weight the quality indicators. This ranking can be used to choose the best alternative among concurrent projects depending on their software quality. This ranking is on an ordinal scale and therefore should not be misused to perform any kind of quantitative comparisons, but we try to find some indicators for our findings on class level.

It is interesting that the two projects with only one author have the highest rank overall. Jpublish and ActionServlet also have very low numbers of Java-files and commits, and the OSS development effort is rather low as well. In contrast to these one-man-projects, Tapestry has nine distinct authors but the same Ranksum as Jpublish. But this project is not that old and the invested development

Table 9. Ranks and sum (ordered by decreasing ranksum)

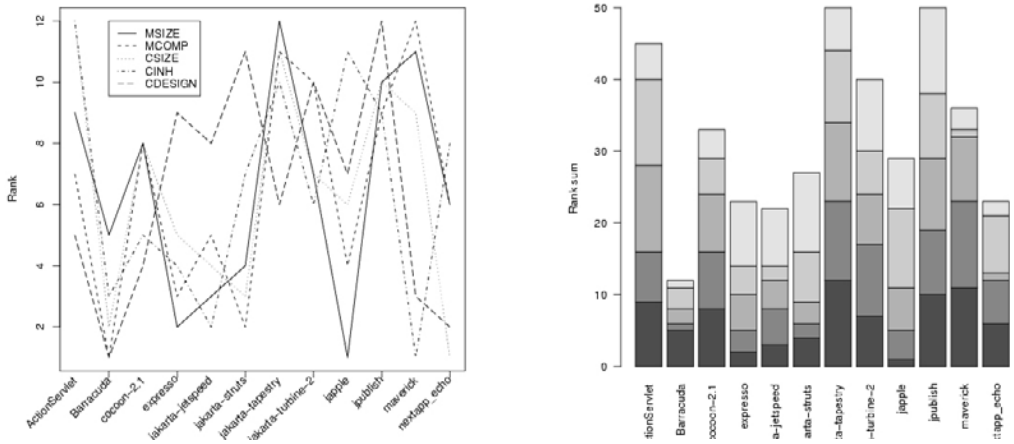
Figure 4. Ranking of projects based on the dichotomous variables (high relative amounts result in low ranks, the higher the sum of the ranks the better the quality)



(a) ranks *(b) sum*

effort is rather small. This can be seen as another proof for the hypothesis that over project lifetime, the quality decreases due to a missing necessary redesign of the software structure.

The largest project overall with 40 distinct authors, more than 10,000, commits and 244 OSSPM is Cocoon. Cocoon is ranked in sixth place—right in the middle—so that we cannot state the quality as extremely bad or good. The second largest project measured by OSSPM and .java-files is Jetspeed, which has the second worst quality ranking, which supports the findings on class level.

In order to statistically underline these results, we used the order produced by the ranksum to compare those projects ranking highly overall to those ranking very low. This was done by a set of Mann-Whitney U-tests as applied above. This time, membership in a project was used as a dividing factor for the classes, and the distribution of relevant process metrics was tested to uncover whether the top projects consistently have different distributions than the lower rated ones. We tested each of the top three projects against each of the bottom three projects, resulting in nine comparisons per process metric. For validation, we also eliminated the one-person projects within the top group, using the next lower ones with more participants. The results indicate that projects in the high-quality region have more authors and commits, but consistently lower GINI coefficient representing more equal distributions (in six, respectively seven, out of nine comparisons in the validation sample). While the first result seems in contradiction with the results on class level, the effects of a high concentration are valid on both levels. These results will be discussed in the following section.

MULTILEVEL ANALYSIS

Multilevel models (also sometimes termed nested or mixed-effect models) are statistical models with parameters arranged in a hierarchical structure (Goldstein, 1999; Snijders & Bosker, 2003; Kreft & de Leeuw, 2002). They are appropriate for data which involves multiple levels, for example on individual level and group level. A classical example is a study of students from different schools, attributes of which might have an impact on individual performance, or research in organizational science (Klein, Tosi, & Cannella, 1999). Multilevel models can account for direct effects of variables on each other within any one level, and also cross-level interaction effects between variables located at different levels.

In our study, we have data within two distinct levels: class and project, with classes being grouped into projects. Therefore, it is possible that aspects of a project like different processes or practices have an influence on the quality of a class. Using a multilevel model, these effects can be accounted for and tested. In the following, we use Akaike's information criterion (AIC) to compare the goodness of fit of the estimated models, which incorporates the number of parameters in selecting the best model, thus penalizing overfitting. For all analysis, we employed R, a freely available language and environment for statistical computing, using the nlme package for multilevel modeling.

First, we computed for comparison classical linear models without hierarchical effects for each dichotomous quality metric (*MSIZE, MCOMP,* etc.), using the independent factors Authors, Commits, Time, and GINI. The results are congruent with the class-level analysis and show the same general trend of negative effects on quality: In general, all of the parameters are significant, positive, and introducing them in a stepwise linear regression increases model quality significantly (all at $p < 0.01$). The following exceptions apply: Time has generally a positive effect on quality (except for *CINH* where the effect is negative, and for *CDESIGN* where it is not significant), and for *MSIZE* the GINI coefficient has a positive influence as well (again congruent with the prior analysis). The GINI coefficient also does not have a significant effect on *CINH*. Overall, the resulting models only account for a relatively small part in overall variation, as the R-squared value ranges from about 0.05 to 0.10.

Following from this, we expand the analysis into multilevel models. We therefore both introduce additional fixed variables from the project level (i.e., the overall effort OSSPM of a project); the total number of programmers, files, and commits; total lifetime and GINI coefficient; and define an increasing range of first-level variables as random. This implies that for each unit, a different slope and intercept is estimated, so that the effect of these can differ between units. These different setups resulted in more than 10 different models being estimated for each quality indicator. Using statistical tests based on AIC, these models were compared with each other and also with the linear models without hierarchical effects computed before.

The first result is that the inclusion of project attributes like total number of programmers does not increase model quality. In all cases, these parameters are not significant in the regression. In the model comparison, introducing these terms does therefore lead to a significant reduction in model fit measured by AIC (except for introducing the project's GINI coefficient, where the reduction is not significant) due to the penalty associated with a higher number of parameters. In comparison to the linear models without hierarchical effects, the results are generally slightly better if no or a small number of project attributes are included, due to the random slope introduced. This underlines that differences between the projects are significant. If the models which define more variables like authors as random (i.e., these are allowed to have a

different intercept and slope depending on project) are inspected, the model quality does in all cases increase significantly. This is, with a few exceptions, true for an increasing number of variables becoming random, even though more parameters are penalized by AIC. The exceptions are: the GINI coefficient for both *MCOMP* and *CINH* does not exhibit significant random effects. This again shows that the differences between projects are manifold and encompass the effects of several attributes like concentration or number of developers. If the random effects estimated are evaluated further, we find that there are even differences in effect direction between projects: for example, the number of authors has a positive effect on method size in six projects, a negative effect in the others. For problems in inheritance structure on the other hand, the number of authors almost uniformly shows a negative effect throughout the projects. Also the concentration has negative effects almost throughout the project set.

From this analysis, we can draw the conclusion that the results achieved by other means hold mostly valid, but that the multilevel approach shows additional insights. We found that there are indeed differences between the projects in the way that the different process metrics have a relationship with product quality concepts, which can be accounted for with this analysis. We also found that the mechanisms and attributes of projects mitigating these effects do not currently seem to be captured by the measurements performed, as the metrics like total number of developers of projects did not show a significant impact. The reasons for the different effects might therefore lie in other attributes like process design which need to be incorporated in future analyses and models.

DISCUSSION

The analyses on class and project level showed several results which need to be discussed in their reasons and in their implications. As shown, a high number of programmers and commits, as well as a high concentration, is associated with problems in quality on class level, mostly to violations of size and design guidelines. This underlines the results of Koru and Tian (2005), who have found that modules with many changes rate quite high on structural measures like size or inheritance. On project level, there is a distinct difference: those projects with high overall quality ranking have more authors and commits, but a smaller concentration than those ranking poorly. We will first address the effects associated with high concentration on few heads, which turn out on both levels, afterwards touching on the differences found.

A high concentration is often seen as a trademark of open source software development and has turned up in almost any study of open source projects (e.g., Koch, 2004; Ghosh & Prakash, 2000; Dinh-Tong & Bieman, 2005). Mockus et al. (2002) have shown this difference to commercial projects in a comparison. Reasons for this concentration are manifold: they reach from motivational aspects like status games which lead to different invested effort between participants, hugely different skills sets of participants in combination with self-selection for tasks, the founding process by one or a few people, to possible delays in achieving commiter status in some projects. On the other hand, we find that a high concentration is correlated with possible problems in the product quality and maintainability. It has to be noted that the direction of this relationship between design aspects and development organization is not determined: If the architecture is not modular enough, a high concentration might show up as a result of this, as it can preclude more diverse participation. The other explanation is that classes that are programmed and/or maintained by a small core team are more complex due to the fact that these programmers ‘know’ their own code and do not see the need for splitting large and complex methods. One possibility in this case is a refactoring

(Fowler, 1999) for a more modular architecture with smaller classes and more pronounced use of inheritance. This would increase the possible participation, thus maybe in turn leading to lower concentration and maintainability, together with other quality aspects. At the beginning of the development process, a core developer team sets up the design which is not adjusted to cope with the increasing number of classes and complexity. In this case it might be better to split huge classes into several subclasses, which may also improve the quality of inheritance and abstraction.

Underlining these results, MacCormack, Rusnak, and Baldwin (2006) have in a similar study used design structure matrices to study the difference between open source and proprietary developed software, without further discrimination in development practices. They find significant differences between Linux, which is more modular, and the first version of Mozilla. The evolution of Mozilla then shows purposeful redesign aiming for a more modular architecture, which resulted in modularity even higher than Linux. They conclude that a product's design mirrors the organization developing it, in that a product developed by a distributed team such as Linux was more modular compared to Mozilla developed by a collocated team. Alternatively, the design also reflects purposeful choices made by the developers based on contextual challenges, in that Mozilla was successfully redesigned for higher modularity at a later stage.

Regarding the number of authors, the results need to be explored further and put into context of the findings on concentration: We found on class level a negative impact, while on project level a positive effect. This underlines a central statement of open source software development on a general level, that as many people as possible should be attracted to a project. On the other hand, these resources should, from the viewpoint of product quality, be organized in small teams. Ideally, on both levels, the effort is not concentrated on too few of the relevant participants. This is certainly not contrary to conventional software engineering knowledge, which can be found to hold in this context as well.

The implications of these findings need to be discussed in two different contexts, the first one being within open source projects, and also in general. These two settings differ significantly, most relevantly in the general aims, the possibilities for intervention by project management, and also the motivation of participants. In an open source project, a management in classical form does not exist, although often a maintainer, inner circle, or other authority (although with mostly minimal impact) could be interested in the organization of work within the project. Also the aims of a project, and interwoven with this, the motivations of participants are very much different from commercial settings, and they need to be considered. Therefore there are very limited possibilities for any central agency to manage and steer the participants, or they might lose motivation and leave the project. On the other hand, management responsibilities are often taken up by the founding group of a project. In case of early phases of a project, the design should therefore strive to allow for these teams to form by providing an appropriate number of classes within a modular architecture, termed by MacCormack et al. (2006) as "architecture of participation." Executing a refactoring within the context of a large and well-established open source project often might prove difficult, but a central agency should carefully monitor the respective metrics as described in this article to gain an understanding of possible future problems, both in quality and participation aspects. If those are identified, soft measures might be applied to encourage the participants to adjust, for example by using increased reputation and recognition for people participating in such efforts. In addition, the lack of formal design specification often associated with open source projects should be overcome. Again, taking up these tasks should be rewarded within the reputation structure, while other possible motivational factors like training

are naturally offered in this context. MacCormack et al. (2006) have shown with the Mozilla case that such efforts can be successful. In our study, we have found evidence for a refactoring having taken place in the Maverick project based on log messages, which is now top ranking in method size and complexity measures.

In a commercial context, many of the problems as discussed above do not apply, so management has more possibilities to enforce a certain organization of work or a necessary refactoring. The organizational form of 'chief programmer team organization' (Mills, 1971; Baker, 1972), also termed 'surgical team' by Brooks (1995), has system development divided into tasks each handled by a chief programmer who is responsible for the most part of the actual design and coding, supported by a larger number of other specialists like a documentation writer or a tester. A similar form of development seems to be adopted by open source projects, although a too highly concentrated form does not perform well given the negative effects associated with high concentration. Possibly the single-author projects in our sample form an example of this organization. Only one person has access to the source code and is assisted by a larger number of other participants.

In arriving at the results of this study, we found that the creation of dichotomous variables helped in several ways, although the thresholds remain a problematic point. The huge number of available and sometimes highly correlated product metrics can be aggregated into a more manageable and interpretable set in this way, and effects on quality can more easily be analyzed. For the process metrics applied, we found that different calculation approaches for the GINI coefficient did not change the results in a significant way. The effort indicator OSSPM introduced did not give much additional information as well, although the high correlation to other metrics like commits need not be present in all data sets. We propose that the invested effort might still be considered as an important factor.

CONCLUSION

The analysis described in this article has tried to enhance prior studies on OSS by providing an empirical validation of relationships between process attributes and product quality. We presented and applied a method to calculate and merge both metrics, addressing both dimensions from online versioning repositories. In this article we have focused on the investigation of frameworks for the development of Web-based applications, which therefore offer similar functionalities and are suitable for a comparison. The results clearly show that it is possible to gather the necessary information to find relationships between process and product metrics. Using mostly object-oriented product metrics focusing on quality by employing a subset of the well-known Chidamber and Kemerer (1994) metrics, complemented with several metrics proposed by Lorenz and Kidd (1995) and several process metrics including total number of commits and the number of distinct programmers as well as the GINI coefficient as a measure of inequality within the developer group, we found that indeed significant relationships exist. This underlines the results of MacCormack et al. (2006). We identify the number of commits, the number of distinct programmers, and the active time as factors of influence which have a negative effect on quality. In particular, complexity and size are negatively influenced by these process metrics. Furthermore a high concentration of added work fosters bad quality. In discussing reasons for this finding, one explanation for this relationship might be found in a missing necessary refactoring of the design. We have also discussed the reasons for this and implications for practice.

Limitations of this work can certainly be found in the thresholds applied for defining methods as faulty based on experiences with C++ projects. Using preliminary sensitivity analysis, we have explored the impact of small changes of up to 20% on the threshold values and found that the main results presented here are still valid. Nevertheless,

more work should be invested in this area to arrive at sensible thresholds, especially for Java and related programming languages. Another issue to be further explored in later studies are effects on different levels: we have tried to account for project-level influences on classes using a multilevel modeling approach, but the fact that some classes might be matched pairs across projects, while others are not, might still pose a problem. We have also found that differences between the projects in the effects of process metrics exist, but the attributes mitigating these still remain to be explored. Although we have tried to achieve a relatively homogeneous set of projects, differences in functionality and other aspects persist. Naturally, larger data samples would also be of high interest, especially a comparison of OSS projects with commercial software development, which might more prominently show differences in the development process. Furthermore, a longitudinal study of both product and process metrics over the lifetime and evolution of a project might provide more insights, as well as exploring the influence of process metrics on maintainability, which has been investigated in some studies (Deligiannis, Shepperd, Roumeliotis, & Stamelos, 2003; Fioravanti & Nesi, 2001; Samoladas, Stamelos, Angelis, & Oikonomou, 2004). Our study only gives qualitative evidence of maintainability.

Overall, we think that this study provides a first step despite these limitations. We have provided evidence regarding relationships between process and product measures in open source software development, and pointed out several characteristics tending to lead to lower product quality. This serves as a starting point for devising strategies to effectively manage projects for achieving higher quality and maintainability. Additional research can also benefit from observations regarding the method applied in this study, and might yield even more insights, leading to improvements in OSS and other software development processes.

Abad Shah
R & D Center of Computer Science, Pakistan

ABSTRACT

Software testing in general and graphical user interface (GUI) testing in particular is one of the major challenges in the lifecycle of any software system. GUI testing is inherently more difficult than the traditional and command-line interface testing. Some of the factors that make GUI testing different from the traditional software testing and significantly more difficult are: a large number of objects, different look and feel of objects, many parameters associated with each object, progressive disclosure, complex inputs from multiple sources, and graphical outputs. The existing testing techniques for the creation and management of test suites need to be adapted/enhanced for GUIs, and new testing techniques are desired to make the creation and management of test suites more efficient and effective. In this article, a methodology is proposed to create test suites for a GUI. The proposed methodology organizes the testing activity into various levels. The tests created at a particular level can be reused at higher levels. This methodology extends the notion of modularity and reusability to the testing phase. The organization and management of the created test suites resembles closely to the structure of the GUI under test.

INTRODUCTION

Graphical user interfaces (GUl) are an important part of any end-user software application today and can consume significant design, development, and testing activities. As much as half

of the source code of a typical user-interaction intensive application can be related to user interfaces (Harold, Gupta, & Soffa, 1993; Horowitz & Singhera, 1993). GUIs provide an easier way of using various functions of the application by organizing them in a hierarchy of options and presenting only the options which make sense in the current working context. GUIs help users concentrate on the problem instead of putting efforts in remembering all the options provided by the software application that is being used to solve the problem, or searching for the right option from a huge list of options provided by the application. Graphical user interfaces organize the standard user actions and working paradigms into various components that are presented graphically to the user during various usage and application contexts. GUIs enhance the usability of an application significantly. However it also makes application development, testing and maintenance significantly more difficult (Myers, 1993; Wittel & Lewis,1991). The nature of GUI applications, their asynchronous mode of operation, nontraditional input and output, and hierarchical structure for user interaction make their testing significantly different and difficult from the traditional software testing.

Functional and regression testing of graphical user interfaces is significantly more complex than testing of traditional non-GUI applications because of the additional complexities mentioned in the previous paragraph. A number of commercial tools, like Mercury Interactive's WinRunner, XRunner and Segue Software's SilkPerformer, are used in the industry to test graphical user interfaces. These tools provide capture/replay capabilities to test a graphical user interface. Although functionality provided by these tools is sufficient for typical recored/replay scenarios but they lack an underlying model that can provide more information about the test coverage or to determine the quality of the user interface from a particular functional or implementation perspective. These tools also do not provide a framework that assists in organized and modular testing. The methodology presented in this article uses user interface graphs (UIG) as a framework for organization of test scripts, generation of modular test suites, and coverage analysis of a test execution.

In this article, we propose a methodology for regression testing of graphical user interfaces, with and without a formal specification of the application under test. The remainder of this article is organized as follows: Section 2 highlights some of the best practices and recommendations that help in testing a GUI application in an organized fashion, improve efficiency and effectiveness of testing, reduces possibility of errors, and minimizes repeated work. Section 3 describes the major steps of the proposed methodology. It also introduces a sample X application, called Xman, which is used to demonstrate the effectiveness of the suggested strategy. Section 4 demonstrates the testing methodology when formal specifications of the application under test are not available. Section 5 illustrates the proposed testing methodology when the formal specifications of the application under test are available. This section also describes the way statistics are collected during a testing activity and how those can be used to improve the quality of the testing. Section 6 points out the situations when a modification to the application under test might require tuning or recapturing of some of the test scripts. Section 7 concludes the article by summarizing our contribution and providing hints about the future related work.

GUI TESTING: BEST PRACTICES AND RECOMMENDATIONS

In this section, we highlight some of the sought features, well-knows best practices and recommendations for planning a testing activity for a graphical user interface.

- Every element of the GUI should be considered as an object uniquely identifiable by a name. The objects should have a well-defined set of parameters and their response to the outside events should also be well defined.
- The testing activity should be planned carefully around a formal model of the application under test. This model should be powerful enough to provide automatic test generation and coverage analysis.
- Testing of a GUI should be performed in a layered fashion. The list of objects to be tested at a particular level, is either built dynamically while testing at lower levels or from the specifications of the application under test. The list of objects for the lowest level is the basic widget, supported by the underlying toolkit. While testing the highest level, it considers the entire application as a single object. The decision about the number of testing levels and the qualifying criteria for a particular testing level must be made before creating any tests.
- The tests should be organized as a hierarchy of scripts, that is, files containing commands to simulate user actions and verify results. This hierarchy should closely correspond to the object hierarchy of the application under test. Each directory in the hierarchy holds scripts that are related to a particular object and its descendents. The individual scripts should be as small as possible and should test one particular feature of each object. However, if the features are related and simple, then they can be grouped together in the same script.
- Each script should begin with a cleat and precise description of the intended purpose of the script and the state of the application required for its proper execution. A script should be divided into three sections. The first section of the script builds the environment required to test the particular feature of the application, the script is intended for. The second section of the script tests the intended feature of the application being tested by the script. The third section restores the state of the AUT and the operating environment, to a point that existed before entering the script.
- A script should be created in such a way that some or all the sections of the script can be executed by calling the script from another script. It provides reusability feature in testing also.
- Instead of manually capturing or replaying the test scripts, a tool should be used to perform these functions automatically and verify the behavior of the application under test. The tool should be capable of addressing an object in the GUI by its symbolic name, instead of its location, dimensions or any other contextual information.
- The data for the result verification should be captured in terms of object attributes when possible and only those attributes should be captured which are critical to verify the functions of the application, being tested by the current script. If image comparisons are unavoidable, then the images should be captured with reference to the smallest enclosing object and area of the captured images should not be more than absolutely required. The number of verifications should also be kept to an absolute minimum especially when image comparisons are involved.
- The script commands to simulate user actions during the replay and the data for verification of the AUT behavior should be kept separately. This separation is required because the verification data might change depending on the environment while the script commands should be independent of the environment and should be valid across multiple platforms. If script commands and verification data are stored separately, then

it is easier to port a test suite across multiple platforms. In fact, a good tool should automatically perform the porting from one hardware platform to the other.

Proposed Methodology for GUI Testing

This section proposes a methodology for the testing of a graphical user interface (GUI). This proposed methodology is suitable particularly when one has a tool similar to Xtester (Horowitz & Singhera, 1993). It follows the recommendations provided in the previous section. The methodology works in the following two scenarios:

i. Testing without formal specifications/model of the application under test
ii. Testing with a formal model of the application.

Both these scenarios are described in the following subsections.

Testing without a Formal Model

Creation of formal specifications of a GUI application for its testing purposes is a difficult task and requires a significant amount of effort. It is also not feasible to invest resources in creating the formal specifications of the application; hence the testing has to be performed without it. The best thing that can be done in such a situation is to incrementally build a test hierarchy for the application, by capturing-user sessions in an organized way. Automatic test generation or coverage analysis is not possible without formal specifications of the application under test. The major steps of the proposed methodology to test an application without a specification are given below:

Step 1: Initialization

Make basic decisions about the testing activity. Some of the most important decisions, which must be taken at this point, are:

- The number of testing levels and criteria to build list of objects for a particular level.
- Initialize a list of objects for each level that holds the names and some information about the objects of the user interface. The information includes the way the object can be mapped on the screen, the mechanism to unmap it from the screen, and if it has been tested or not.
- The location of the test suite and its organization.
- The application resources that will be used during this testing activity should be listed.

Step 2: Building the Initial Object List

Go through the documentation of the application under test and find all the top-level windows, which might appear as starting windows of the application. These windows and, their related information is added to the list of objects for the first testing level and marked as tested.

Step 3: Building Test Suite

Take the first object from the top of the object list, which has not been tested, and create test scripts for it. The procedure for creating test scripts for a particular object is given in Figure 1. The sub-objects of the object under test are added to the list of objects by scanning the object from left to right and top to bottom. Keep on taking objects from the top of the object list and testing them until all the objects in the list are marked as tested. When the list associated with a particular level has no

Figure 1. Strategy for testing without specifications

```
Display the_ object on the screen and verify its ap-
pearance;
If the object has sub-objects
    Add its immediate sub-objects at the top of the
list;
If the object qualifies for a higher testing level
Add it to the list of objects for the higher level;
Send expected events to the object and verify its
response;
If a new object appears in response to the event
if the new object is not listed as a tested object
    Add it to the end of the list;
```

untested object, start testing objects from the list, associated with the next higher level. This process continues until all the levels are tested.

Step 4: Creating Script Drivers

Write higher level scripts for all the top level windows for any other complex objects, each of the testing levels and for the entire test suite. These scripts will replay all the scripts related to the object and its descendents. The highest-level script driver should replay each and every script in the suite.

Step 5: Testing the Test Suite

Make sure that all the scripts and script drivers work properly and cover all the features of the application, which needs to be tested. One cannot do much automatically to determine the quality of a test suite, in the absence of a formal model of the application under test. After the creation of the test suite, run the highest-level script driver to verify that all the scripts in the suite are capable of properly replaying and trying to match the features covered by the test suite with those included in the test requirements or application documentation

Testing with a Formal Model

The strategy to build test scripts without a formal specification, discussed in the previous subsection, puts a lot of responsibility on the person creating those scripts. The strategy also requires that the application under test should be running reliably before the capturing of script is even started. The scripts created without any formal specification are also vulnerable to any modification in the application, which affects its window hierarchy. It requires that after making any changes to the application under test, the affected scripts should be located manually and recaptured or tuned to offset the modification in the application. It is also

not possible to create test scripts automatically or to get a coverage measure after running a set of test suites. To overcome these drawbacks and get access to advanced features like automatic test generation and coverage analysis, one has to invest some effort to formally specify the application under test. This section provides a methodology to test an application when its formal specification is provided or resources are available to build such a specification. The following are the major steps of the testing methodology when a formal specification of an application under test is available.

Step1: Building the Model

Build a user interface graph of an application under test. When resources permit, the very first step in testing the application should be to build a formal model of the application under test. XTester provides such a formal model, called *user interface graph (UIG).* UIG provides information about the object hierarchy of the application. It also provides information about the nature of a particular object and the effects of an event in an object to the other objects in the user interface. A UIG can be built manually by creating a user interface description language (UIDL) file, or it can be created semi-automatically by steering through the application under test and filling in the missing information about the objects (see Horowitz & Singhera, 1993) for more details on syntax of UIDL and UIG).

Step 2: Initialization

Make basic decisions about the testing activity. Some of the most important decisions, which must be taken at this point, are listed as follows:

- The number of testing levels and qualifying criteria for each testing level.
- The location of the test suite and its organization.
- The application resources that will be used during this testing activity.

Step 3: Build Object Lists

Build a list of objects for each testing level. After building the formal model, it is possible to build the object lists for all testing levels. The procedure for building those lists is to start from the root of the UIG and perform a post-order walk of the object hierarchy. Add each visited node to the object lists associated with the levels, for which it qualifies.

Step 4: Building Test Suite

The strategy for capturing scripts without any formal specification, which has been discussed in the previous section, can also be used for capturing scripts when the application has been specified formally. However, capturing scripts with formal specifications provides us some additional advantages over the scripts which have been captured without any specification. These advantages include an overall picture of the application under test, and hence a more efficient test suite, a test suite which is less affected by the changes in the application, automatic test generation, and coverage analysis.

Step 5: Creating Script Drivers

Write higher level scripts for all the top level windows or any other complex objects, each of the testing levels and for the entire test suite. These scripts will replay all the scripts related to the object and its descendents. A highest-level script driver should replay each and every script in the suite. These scripts can also be created automatically.

Step 6: Coverage Analysis

Once a test suite has been created; it should be replayed in its entirety to determine the coverage provided by the test suite. This coverage should be performed at each level, that is, the coverage criteria for level-I should be the verification of all the objects in the application that have been created, mapped, unmapped and destroyed, at least once and every event expected by an object, has been exercised on it at least once. The criteria for higher levels is to make sure that all the interactions and side effects among objects which make a composite object at the corresponding level, has been verified.

AN INTRODUCTION TO XMAN

In this section, we introduce the application Xman, which is used to demonstrate the effectiveness of the methodology, discussed in the previous section. Xman is a small application which is distributed with the standard *X* release. It provides a graphical user interface to the UNIX *man* utility. It has been developed using the Athena widget set and some of its windows are shown in Figure 1. The following paragraphs briefly describe the functionality of Xman.

When Xman is started, it displays its main window, called Xman, by default. This main window contains three buttons: Help, Manual Page and Quit. Clicking on the manual page button, it displays a window, called manual page. A Help window is displayed when the help button is clicked. The quit button is used to exit from Xman.

The manual page window is organized into various sections. A breathe top of the window contains two menu buttons, options and sections, in the left half and a message area in the right. The rest of the area below the bar, called text area, is used to display the names of the available manual pages in the currently selected section, and the contents of the currently selected manual page. Both the names and contents portions of the text area are resizable and have vertical scrollbars on the left.

The Options menu contains the following entries:

- **Display Directory:** It displays names of manual pages in the entire text area.
- **Display Manual Page:** It displays contents of the currently selected manual page in the entire text area.
- **Help:** It displays a help window.
- **Search:** It displays a dialog box to enter the name of a manual page to search for.
- To show both screens, the area is vertically divided into two halves, with the upper half showing the directory contents of currently selected man page section and the lower half showing the contents of the currently selected manual page. This option toggles to Show One Screen and also disables menu entries Display Directory and Display Manual Page.
- **Remove This Manpage:** It removes the Manual Page window from the screen.
- **Open New Manpage:** It creates another Manual Page window.
- **Show Version:** It displays the current version of Xman in the Message area
- **Quit:** exits from the Xman application.

The Sections menu contains one option for each manual page section available on the system. The standard options are User Commands, System Calls, Subroutines, Devices, File Format, Games, Miscellaneous, and System Administration.

The Help window displays a limited version of the Manual Page window. The window has exactly the same structure as the Manual Page window but the Sections menu button and the first five options in the Opt ions menu are disabled.

It displays man page for Xman itself. No more than one Help window can exist at a time while an arbitrary number of Manual Page windows can be created.

The testing of Xman has been organized in three layers. The first layer verifies the behavior of individual GUI objects. The second layer verifies the inter-object effects among objects belonging to the same top level window. The third layer verifies the inter-object effects among objects belonging to different top level windows. The following sections provide details of this testing activity.

TESTING WITHOUT FORMAL SPECIFICATIONS

This section provides a demonstration for the testing of Xman, when no formal model is available for it. The following subsections demonstrate each step of the methodology, described in Section 2.

Initialization

- **Number of testing levels:** As Xman is a fairly small and simple application, so the testing activity is organized in three (3) levels. The first level tests the individual objects in Xman. The second and third levels verify the interactions and side effects of the objects which belong to the same top level window and different top level windows, respectively.
- **Location of the test suite:** Suppose that the root directory for the test suite being captured, is Xman Test. This directory contains resource file(s) used during testing, and the result files are created in the directory, by default. It also has three subdirectories, that is, *Leve1-1*, *Leve1-2* and *Leve1-3*, one for each testing level.
- **Object list:** A list of objects, called *Obj List*, is initialized. This list contains information about the objects and is initialized to be empty.
- **Application resources:** ~/XmanTest/Xman.Defaults is the file which contains the default application resources of Xman for this testing activity and these resources always remains the same.

Building the Initial Object List

By default, Xman starts with a top *box*, called Main Window in Figure 2. However, a command line option, -notopbox, is available which can be used to bypass the Main Window and display the Manual Page window directly. As Main Window and Manual Page window are the only windows, which can appear when Xman is started, so the initial object list contains only these two objects.

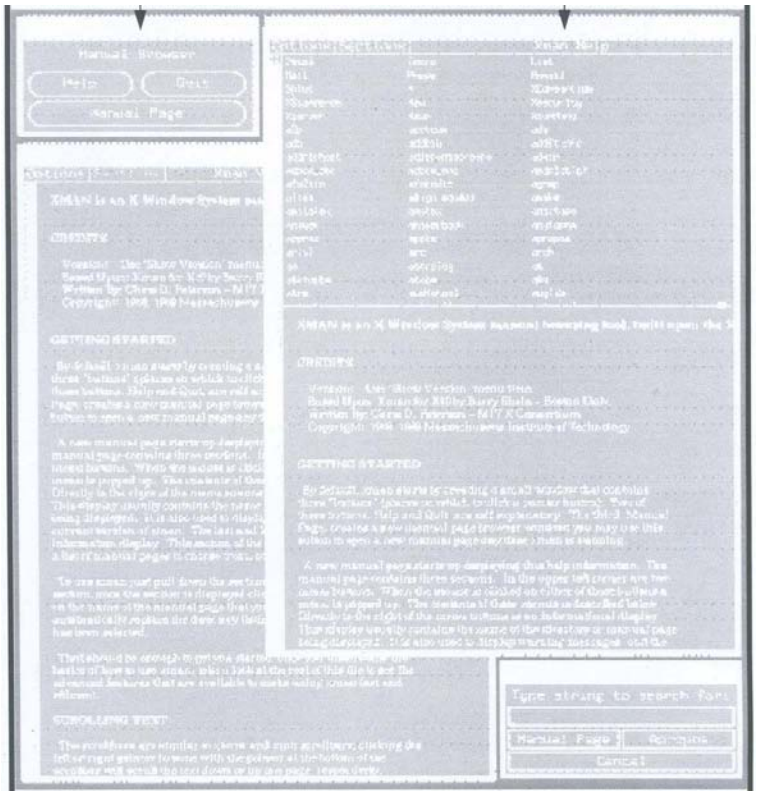
Building the Test Suite

This section provides the details on building all the three testing levels for Xman. To make things simple, we only discuss the creation of test suites related to the Main Window of Xman. We ignore any keyboard accelerators to which Xman responds. The test suites for other windows can be created in a similar way. Figure 3 provides the hierarchy of scripts related to the Main Window for all the three testing levels.

First Level

Suppose that the initial object list is built in such a way so that Xman Main Window is on the top of the list. We select it as the object under test and create a new directory, called ~/Xman Test/Leve1-1/Xman to build test scripts related to the first level testing. The scripts related to XMan Main window object display itself the window on the screen, exercise all the window manager

Figure 2. Main windows of Xman

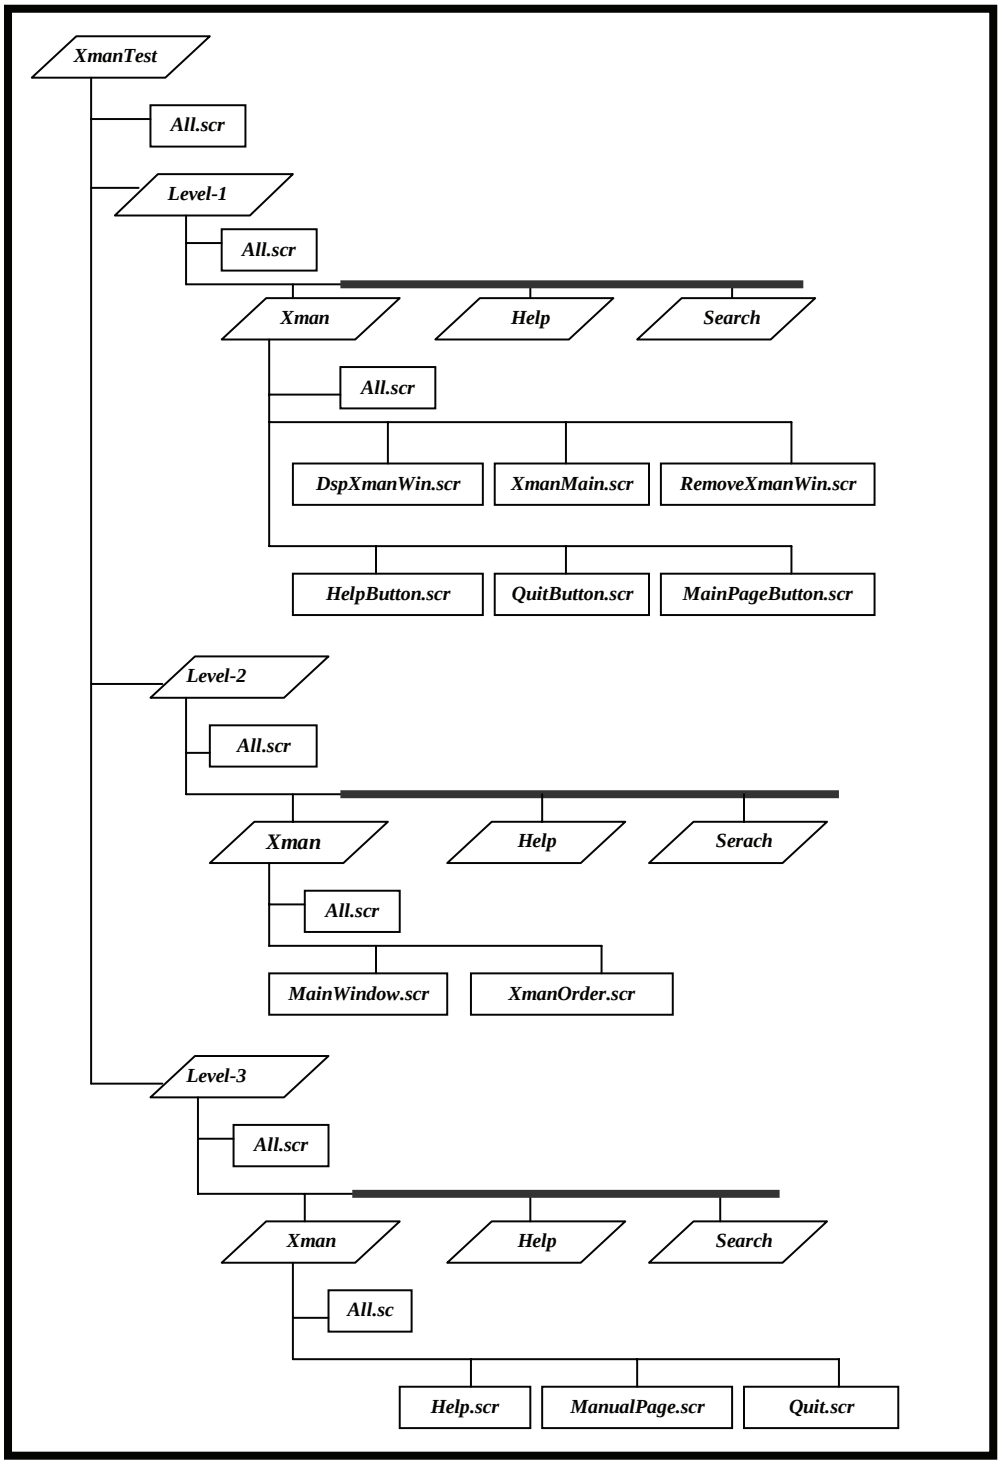


operations on it, and then finally pop-down the window. DspXmanWin.scr script pop-up the Xman window and verifies that looks right RemoveXman Win.scr pops down the Xman window. The script XmanMain.scr ruses DspXmanWin.scr in its entering section to display the Xman window. It verifies the window manager operations in its core section and then uses RemoveHe1p Win. scr script in its leaving section to pop-down the Xman Window. As soon as the Xman window pops up on the screen, we see that it contains *four* objects, i.e., Manual

Browser Label, Help

There are buttons which are Quit and Manual Page. Manual Browser label is a static piece of text and does not respond to any user actions, so we do not need a script for it. The other three (3) objects are active objects and respond to user events so we create one script for each of them. The entering section of each one of these scripts calls DspXmanWin.scr to display the Xman Main Window on the screen. The ending section of each of these scripts call RemoveXmanwin.

Figure 3: Test Suite Hierarchy of Xman



scr to remove the Xman Main Window from the screen. The core section of Help Button.scr script verifies the behavior of Help button in Xman Main Window when it is clicked on by a mouse button. The core sections of QuitButton. scr and ManPageBut ton.scr scripts verify the same thing for Qui t and Manual Page buttons in Xman Main Window.

Second Level

The object list of the second level contains all the top level windows of Xman. As we are considering the Main Window only in this discussion so we assume that it is at the top of the list and is selected for the testing. There is not much interaction going on in the objects which belong to the Xman Main Window. The only interaction is the disappearance of Main Window, in response to click on the Quit button. So there will be only one script related to the Main Window which will verify that a click on the Quit button actually destroys the Main Window of Xman. This script is called MainWindow.scr and is located in ~/XmanTest/Level2/. This script is also used DspXmanWin. scr and RemoveXman.scr script to display and remove the Main Window from the screen. Another potential script, let us call it XmanOrder. scr, related to the Main Window verifies that the order in which Help or Manual Page buttons are pressed is insignificant. No matter the Help button is pressed before or after the Manual Page button, it displays the Help window properly. The same is also true for the Manual Page button.

Third Level

The object list of the third level includes the root object only, and tests any interactions among the top level windows of Xman can be done. Such interactions which involve the Main Window of Xman include display of the Help window and the Manual Page window in response to mouse clicks on the Help and the Manual page buttons, respectively. Similarly, it also includes disappearance of all the windows related to Xman in response to a click on the Quit button. The three scripts provided at this level, that is, Help.scr, ManualPage.scr and Quit.scr, verify the behavior, related to the corresponding button, mentioned above. This level might also include scripts which verify application behavior, like multiple clicks on the Help button and do not create more than one Help windows while each click on the Manual Page button create a new Manual Page window.

Creating Script Drivers

Once all the scripts for Xman has been captured, we need driver scripts so that all the scripts in the entire suite, all the scripts in a particular testing level or all the scripts related to a particular object can be executed automatically in the desired sequence. For example, we create a script driver, at each testing level, which executes all the scripts created for testing Xman Main Window and its descendents, at that particular level. These scripts are ~/XmanTest/Level-l/Xman/All.scr,-/XmanTest/Level-2/Xman/All. scr, and ~/XmanTest/Level-3/Xman/All. scr, respectively. The script ~/ XmanTest/Level-l/All.scr drive all the scripts created for the first testing level and similarly the other two drivers execute scripts related to the other two levels. The script ~/XmanTest/All.scr drives all the scripts in all the three levels of the test suite.

Testing the Test Suite

After the creation of the test suite, it is necessary to replay all the scripts in the suite and verify if they work properly and also to make sure that they cover all the features which need to be tested. Although, without a formal specification, it is impossible to perform any reasonable automatic coverage analysis but at least the replayed events and the objects which appear during the replay,

can be matched against application documentation to determine if any object or event has not been covered by the generated test suite.

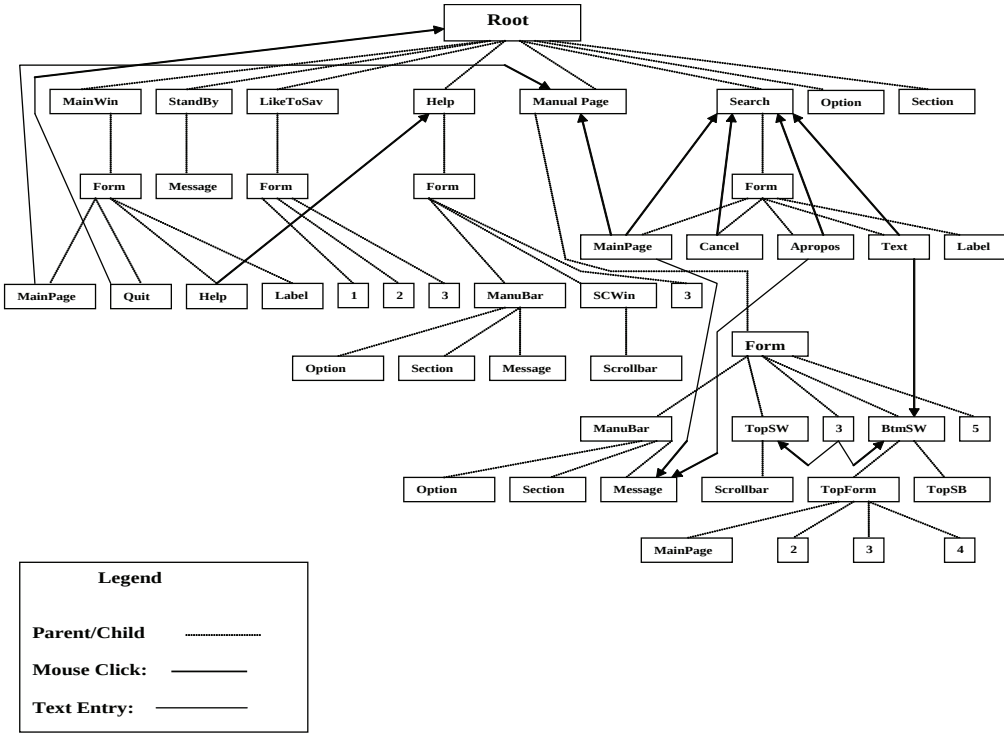
TESTING WITH FORMAL SPECIFICATIONS

This section demonstrates the testing of Xman when we have enough resources to build a formal model for Xman. The following subsection illustrates each step of the methodology, described in Section 2.2.

Building the Model

When the resources permit, the first step for testing is building a formal model for the application under test. Figure 4 displays a User Interface Graph built for Xman. The Root node of the graph represents the root window of the screen. The children of the Root node represent the six top level windows of Xman. The nodes at lower levels in the graph represent the descendents of the top level windows. Let us take the main window of Xman as an example. It is represented as MainWin node in the User Interface Graph. The child of the MainWin node is the Form node which acts as a container widget for the buttons and the label in the main window. The ManPage, Quit and Help nodes represent the Manual. Page, Quit and Help command buttons in the main window, respectively. The label node represents the Manual Browser label in the main window. The dark black arc from the Manpage noqe to the Manual Page node represents the fact that clicking a mouse button over the Manpage

Figure 4. User interface graph built for Xman



button in the main window affects the top level window, called Manual Page. The arc from the Quit node to the Root node represents that a click on the Quit button affects all the top level windows of Xman. The type of event represented by an arc is reflected by the drawing pattern of the arc. The two arcs mentioned above have the same pattern and represent button clicks. An arc with a different pattern is the arc from the Text node to the search node. This pattern represents text entry and the arc represents that entering text in the Text node affect the search dialog box.

Initialization

All the decision and actions taken at the initialization step, that is, the number of testing levels and their organization, the location of the test suite and the application default resources, is kept the same as for testing without a formal specification, described in Section 4.1.

Building Object Lists

After building the user interface graph for Xman, it is possible to build object lists for all levels of testing. This can be done either manually or automatically by scanning each and every node in the User Interface Graph and verifying if it qualifies to be tested on a particular testing level. All the objects in Xman qualify for the first testing level and hence are placed on the list associated with it. The qualifying criterion for the second level is that the object must be a top level window, that is, its corresponding node must be a child of the root of the user interface graph. Some of the objects which qualify for the second testing level are Xman Main Window, Manual Page window, Help window, Search dialog box and so forth. The third level treats the entire Xman application as a single object, and its corresponding node, the root, is the only object which qualifies for the third level of testing.

Building Test Suite

The strategy for capturing scripts without any formal specifications, discussed in Section 4.3, can be used for capturing scripts when the application has been specified formally. However, capturing scripts with formal specifications also provides us the capability to write the test scripts manually or generate test scripts automatically by using the formal model and the test requirements. All of these three techniques for building a test suite are explained in the following section.

Capturing Scripts

A tool can be used for capturing user sessions for building a test suite, in exactly the same way as for capturing without a formal model, as mentioned in Section 4.3. However, the presence of a formal model makes the generated scripts more robust and easy to follow and debug. A formal model also provides the flexibility that the captured scripts can be executed in any order without any conflict in window names. It becomes easier to modify the test suite in case of a modification to the application under test. In fact in most cases the modification can be reflected in the specification file and the test suite remains valid without making any changes.

Writing Scripts Manually

The formal specifications of the application, under test, also allows the user to write scripts manually, even for the first level of testing. This feature is particularly helpful when the test scripts need to be created in parallel with the application development in order to reduce the total development time. The way it can be organized is to formally specify the graphical user interface of the application once the design is complete. The developers and testers agree on this formal specification and any future changes are properly communicated

between the two groups. Having the formal specification of the graphical user interface at hand, the testers can develop the scripts manually in parallel with the application development. Once the object hierarchy and the behavior of the objects is known, the manual writing of test scripts is as easy as writing a UNIX shell script.

Automatic Test Generation

The formal specifications of an application under test also provide capabilities to generate test scripts automatically. A tool can be developed, which will read the specifications of an application and create test scripts for a particular level of testing or the entire test suite. Similar tools can be developed and used to generate test scripts to test all the objects of a particular type or all the user actions of a particular type. For example, such a tool can generate test scripts to exercise clicks on each command button in an entire application. A similar tool can generate a suite of test scripts to verify that all windows in an application under test are displayed on the screen at least once. Another tool might generate scripts to individually select all the options of each menu in the application and verify that the application responds in the expected manner. There can be another tool that will create scripts for the selection of multiple menu options and/or command buttons in different sequences to verify the application response. All the mentioned tools will only create scripts

Figure 5. Pseudo Code for Automatic Test Generator

```
Build the User Interface Graph of the application under
test;
Build an object list by a pre-order traversal of the User
Interface Graph using parent-child relationship arcs.
for each "element on the list
do
   If the element is a top level window
         Create a new directory and change to the
      directory.
         Display the element on the screen.
   fi
   if the element accepts any user events
         Create a script for the element
         for each kind of user event accepted by the
   element
         do
               Add commands in script to
                     Generate the event on the element;
                     Verify the effect of that event;
                     Undo the effect of the event;

         done
   fi
done
```

and validation data that have to be captured by replaying these scripts and by using caprep (Horowitz & Singhera, 1993) or a similar tool to replay these scripts in Update mode.

The logic behind these automatic test generation tools is the same as it is used in Section 5 for manual creation of test suites. The tool starts at the root of the UIG and builds a list of GUI elements by performing a pre-order walk of the UIG. During this walk only the arcs that represent parent-child relationships are considered. After building this list, its entries are taken one by one to create test scripts for them. If the current GUI element, taken from the list, is a top-level

ManPage*Serollbar :             27  23 27 1  8   8    0 0
ManPage.Form.3 :                27  23 27 1  0   0    0 0
ManPage*DirArea :               27  23 27 1  0   0    0 0
ManPage*DirList :               27  23 27 1  0   0    0 0
ManPage*List :                  27  23 27 1  0   0    0 0
```

window, then a separate directory is created for it and the scripts for the element and all of its descendents are created in that directory. If the currently selected element belongs to the category for which a script is required, then following the arcs that represent user actions on the element creates one. Figure 4 shows the pseudo code for such an automatic test generator.

Coverage Analysis

No testing activity is useful unless it provides some coverage measures/analysis. This coverage measure reflects the quality of the testing activity. The UIG provides us with a framework to determine such a coverage. During capture or replay of scripts, XTester keeps track of the user actions and their effects on individual objects. This information is available in a .stt file at the end of the testing activity. Currently, the information captured in .stt about a particular object includes the number of times it was created, mapped, unmapped, and destroyed. It also accumulates the number of times a mouse button or keyboard key was pressed or released over the object. This information helps the user to locate any particular objects in the application which have not been created, destroyed, mapped, unmapped, or received a user event. These statistics can also be used for improving the efficiency of the test suite by removing the repetitive testing of the same characteristics, whenever possible. Figure 6 shows a file created by XTester after replaying a certain test suite for Xman. The legend is displayed at the top of the file to describe acronyms for various actions. The next line after the legend provides the heading for the table. Each line in the table provides statistics about a particular object. For example, the very first line of the table provides statistics about the Main Window of Xman, named Xman. This particular line shows that the object named Xman was created once, never destroyed, mapped twice on the screen and unmapped once, by the corresponding test script. It also shows that the corresponding test suite never exercised a button press/release or key press/release events on the Xman object.

Tools can be developed to extract information from a .stt file. Analysis tools are developed that take a .uidl file to build a UIG of the application under test, and a .stt file to get statistics collected from a particular test run. The tool maps the collected statistics on to the object hierarchy and produces an annotated graph. Queries can be run on this annotated graph to determine the effectiveness of the test suite. For example, one can see how many nodes and arcs in the object hierarchy have not been exercised by this particular test suite, or see the objects and inter-object arcs to determine objects that did not receive an expected user action. Similarly, one can filter out the objects that did not receive an expected user event to create an annotated graph that satisfies a particular criterion.

INVALIDATION OF TEST DATA

XTester captures information as two entities, script commands and verification data and saves them in different files, .scr and .img, respectively. This section describes the scenario in which created test script(s) might fail and has to be re-captured or re-written. The following scenarios invalidate some of the captured scripts:

- An application is modified in such a way that WM _NAME property of a top-level window is changed. This modification will only affect the scripts that have been captured without a specification and are related to the window whose WM _NAME property was changed. The scripts captured with a formal specification remain unaffected, provided the relevant specifications are also modified to reflect the change in the application.
- The application is changed so that the order or number of children of a particular node

Figure 7. Pseudo code for quality analyzer

```
Read in the required criteria for analysis;
Build the User Interface Graph of the application
under test;
Read in the specified statistics file(s);
for each element in the User Interface Graph
do
    If the element qualifies for the given criteria
        Display the required information in proper
```

is changed. The scripts that are captured without a specification and address objects in the modified hierarchy, are affected and have to be recaptured or tuned. However, the scripts captured with a formal specification remain unaffected provided the specification is also modified accordingly. XTester provides option to build either full or short object names. If the application is modified so that the depth of a hierarchy is changed, then all the fully qualified names belonging to that hierarchy will no longer be valid names and has to be modified to reflect the change. However, short names that are relative to their immediate parents will still remain valid.

- If object information has been captured as an image, then trying to replay the scripts on another workstation that is incompatible with the workstation on which image was captured will give false alarms. The scripts work fine across multiple platforms, however, verification data is the platform specific in case of images. An easier way of creating verification data for a new hardware platform will be to replay all the scripts in Update mode that replaces the current verification data with the newly available one.

CONCLUSION AND FUTURE DIRECTIONS

In this article, we have suggested guidelines that are useful in planning a testing activity for a graphical user interface (GUI). We have also presented a methodology for testing a GUI, both when specifications of an application under test is not available, and when such specifications are provided or resource code is available to build such a specification. This article also demonstrates the use of the proposed methodology to test a sample X application, Xman, with or without specifications. It also illustrates how the model is helpful in automatic test generation and coverage analysis. In the end, we describe the situations in which the scripts captured by XTester become invalid.

The methodology and the underlying UIG framework discussed in this article can be very effectively used to model and test web sites and web applications. We are actively working to extend this proposed methodology to be used

for testing web-based applications and semantic web applications.

Chapter 7.25
On Concept Algebra:
A Denotational Mathematical Structure for Knowledge and Software Modeling

Yingxu Wang
University of Calgary, Canada

ABSTRACT

Concepts are the most fundamental unit of cognition that carries certain meanings in expression, thinking, reasoning, and system modeling. In denotational mathematics, a concept is formally modeled as an abstract and dynamic mathematical structure that encapsulates attributes, objects, and relations. The most important property of an abstract concept is its adaptive capability to autonomously interrelate itself to other concepts. This article presents a formal theory for abstract concepts and knowledge manipulation known as "concept algebra." The mathematical models of concepts and knowledge are developed based on the object-attribute-relation (OAR) theory. The formal methodology for manipulating knowledge as a concept network is described. Case studies demonstrate that concept algebra provides a generic and formal knowledge manipulation means, which is capable to deal with complex knowledge and software structures as well as their algebraic operations.

INTRODUCTION

In cognitive informatics, logic, linguistics, psychology, software engineering, and knowledge engineering, concepts are identified as the basic unit of both knowledge and reasoning (Anderson, 1983; Colins & Loftus, 1975; Ganter & Wille, 1999; Hampton, 1997; Hurley, 1997; Matlin, 1998; Murphy, 1993; Wang, 2006a, 2006b, 2006c, 2007a, 2007c; Wang & Wang, 2006; Wilson & Keil, 1999). The rigorous modeling and formal treatment of concepts are at the center of theories for knowledge presentation and manipulation (Smith & Medin, 1981; Wille, 1982; Murphy, 1993; Codin, Missaoui, & Alaoui, 1995; Wilson & Keil, 1999; Yao, 2004; Chen & Yao, 2005). A *concept* in linguistics is a noun or noun-phrase that serves

as the subject of a *to-be* statement (Hurley, 1997; Wang, 2002a, 2006a, 2006c, 2007d). Concepts in cognitive informatics (Wang, 2002a, 2006c, 2007b, 2007e) are an abstract structure that carries certain meaning in almost all cognitive processes such as thinking, learning, and reasoning.

Definition 1. *A concept is a cognitive unit to identify and/or model a real-world concrete entity and a perceived-world abstract subject.*

Based on concepts and their relations, meanings of real-world concrete entities may be represented and semantics of abstract subjects may be embodied. Concepts can be classified into two categories, known as the *concrete* and *abstract* concepts. The former are proper concepts that identify and model real-world entities such as the sun, a pen, and a computer. The latter are virtual concepts that identify and model abstract subjects, which cannot be directly mapped to a real-world entity, such as the mind, a set, and an idea. The abstract concepts may be further classified into *collective* concepts, such as collective nouns and complex concepts, or *attributive* concepts such as qualitative and quantitative adjectives. The concrete concepts are used to embody meanings of subjects in reasoning while the abstract concepts are used as intermediate representatives or modifiers in reasoning.

A concept can be identified by its intension and extension (Hurley, 1997; Smith & Medin, 1981; Wang, 2006c; Wille, 1982; Yao, 2004).

Definition 2. *The intension of a concept is the attributes or properties that a concept connotes.*

Definition 3. *The extension of a concept is the members or instances that the concept denotes.*

For example, the intension of the concept *pen* connotes the attributes of being a writing tool, with a nib, and with ink. The extension of the pen denotes all kinds of pens that share the common attributes as specified in the intension of the concept, such as a ballpoint pen, a fountain pen, and a quill pen.

In computing, a concept is an identifier or a name of a class. The intension of the class is a set of operational attributes of the class. The extension of the class is all its instantiations or objects and derived classes. Concept algebra provides a rigorous mathematical model and a formal semantics for object-oriented class modeling and analyses. The formal modeling of computational classes as a dynamic concept with predesigned behaviors may be referred to "system algebra" (Wang, 2006b, 2007d, 2008b, 2008d).

This article presents a formal treatment of abstract concepts and an entire set of algebraic operations on them. The mathematical model of concepts is established first. Then, the abstract mathematical structure, *concept algebra*, is developed for knowledge representation and manipulation. Based on concept algebra, a knowledge system is formally modeled as a concept network, where the methodology for knowledge manipulating is presented. Case studies demonstrate that concept algebra provides a denotational mathematical means for manipulating complicated abstract and concrete knowledge structures as well as their algebraic operations.

THE MATHEMATICAL MODEL OF ABSTRACT CONCEPTS

This section describes the formal treatment of abstract concepts and a new mathematical structure known as concept algebra in cognitive informatics and knowledge engineering. Before an abstract concept is defined, the semantic environment or context (Chen & Yao, 2005; Ganter & Wille, 1999; Hampton, 1997; Hurley, 1997; Medin & Shoben, 1988) in a given language, is introduced.

Definition 4. *Let $\mathcal{O}$ denote a finite or infinite nonempty set of objects, and $\mathcal{A}$ be a finite or in-*

finite nonempty set of attributes, then a semantic environment or context Θ *is denoted as a triple, i.e.:*

$$\Theta \triangleq (\mathcal{O}, \mathcal{A}, \mathcal{R}) = \mathcal{R} : \mathcal{O} \to \mathcal{O} \,|\, \mathcal{O} \to \mathcal{A} \,|\, \mathcal{A} \to \mathcal{O} \,|\, \mathcal{A} \to \mathcal{A} \quad (1)$$

where $\mathcal{R}$ is a set of relations between $\mathcal{O}$ and $\mathcal{A}$, and | demotes alternative relations.

According to the Object-Attribute-Relation (OAR) model (Wang, 2007c, 2007d; Wang & Wang, 2006), the three essences in Θ can be defined as follows.

Definition 5. *An object o is an instantiation of a concrete entity and/or an abstract concept.*

In a narrow sense, an object is the identifier of a given instantiation of a concept.

Definition 6. *An attribute a is a subconcept that is used to characterize the properties of a given concept by more specific or precise concepts in the abstract hierarchy.*

In a narrow sense, an attribute is the identifier of a subconcept of the given concept.

Definition *7. A relation r is an association between any pair of object-object, object-attribute, attribute-object, and/or attribute-attribute.*

On the basis of OAR and Θ, an abstract concept is a composition of the above three elements as given below.

Definition 8. *An abstract concept c on* Θ *is a 5-tuple, i.e.:*

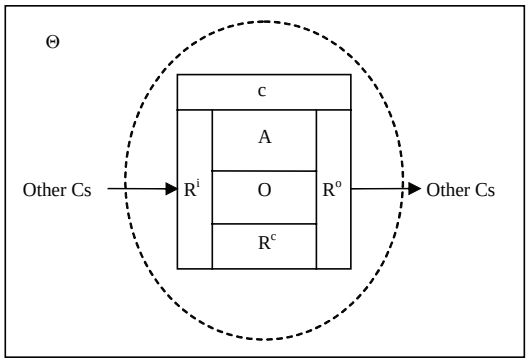
$$c \triangleq (O, A, R^c, R^i, R^o) \quad (2)$$

where

- O is a nonempty set of objects of the concept, $O = \{o_1, o_2, \ldots, o_m\} \subseteq \text{Þ}\mathcal{O}$, where Þ$\mathcal{O}$ denotes a power set of $\mathcal{O}$.
- A is a nonempty set of attributes, $A = \{a_1, a_2, \ldots, a_n\} \subseteq \text{Þ}\mathcal{A}$.
- $R^c = O \times A$ is a set of internal relations.
- $R^i \subseteq C' \times C$ is a set of input relations, where C′ is a set of external concepts.
- $R^o \subseteq C \times C'$ is a set of output relations.

The structure of the concept model $c = (O, A, R^c, R^i, R^o)$ can be illustrated in Figure 1, where c,

Figure 1. The structured model of an abstract concept



A, O, and R, $R = \{R^c, R^i, R^o\}$, denote the identifier of the concept, its attributes, objects, and internal/external relations, respectively.

It is interesting to compare the formal model of abstract concepts as given in Definition 8 with the notion of the concept lattice proposed by Wille (1982). Wille defined a formal concept as a pair of sets of objects and attributes, i.e.:

$$c \triangleq (O, A),\ O \subseteq \mathcal{O} \wedge A \subseteq \mathcal{A} \qquad (3)$$

It is obvious that the abstract concept extends Wille's concept model from a pair to a triple, where the set of relations is explicitly and formally modeled in three categories known as the internal, input, and output relations. The I/O relations enable a conventional static concept to be dynamically associated to other concepts in order to represent and manipulate complicated concept operations and compositions in a concept network and knowledge hierarchy.

Theorem 1. *The dynamic and adaptive property of concepts states that an abstract concept is a dynamic mathematical structure that possesses the adaptive capability to interrelate itself to other concepts via R^i and R^o.*

Based on Definition 8, an object derived from a concept and the intension/extension of a concept can be formally defined as follows.

Definition 9. *An object of a concept o is a derived instantiation of the concept that implements an end product of the concept,$o \subset O$, i.e.:*

$$\forall c(O, A, R^c, R^i, R^o), o = c.o_i, o_i \subset O, R^o{}_o \equiv \varnothing$$
$$\Rightarrow o(A_o, R^c{}_o, R^i{}_o \mid A_o \supseteq A, R^c{}_o = o \times A_o, R^i{}_o = \{(c, o)\}) \qquad (4)$$

Equation 4 indicates that an object is a tailored end-product of a concrete concept where there is no any output-oriented relation to another concept.

Definition 10. *The intension of a concept $c = (O, A, R^c, R^i, R^o)$, c^*, is represented by its set of attributes A, i.e.:*

$$c^*(O, A, R^c, R^i, R^o) \triangleq A = \bigcap_{i=1}^{\#O} A_{o_j} \subseteq \mathbb{P}\mathcal{A} \qquad (5)$$

where $\mathbb{P}\mathcal{A}$ denotes a power set of $\mathcal{A}$, and # is the cardinal operator that counts the number of elements in a given set.

Definition 10 indicates that the *narrow* sense or the exact semantics of a concept is determined by the set of common attributes shared by all of its objects. In contrary, the *broad* sense or the rough semantics of a concept is referred to the set of all attributes identified by any of its objects as defined below.

Definition 11. *The complete set of attributes of a concept $c = (O, A, R^c, R^i, R^o)$, or the instant attributes denoted by all objects of c, is a closure of all objects' intensions, A^*, i.e.:*

$$A^* \triangleq \bigcup_{j=1}^{\#O} A_{o_j} \qquad (6)$$

Definitions 10 and 11 specify that (a) The intension of a concept is a finite set of objectively identifiable attributes at a given level of abstraction, and (b) the intension of a concept is dynamic. When more objects for the same concept are denoted, the domain of the intension is usually shrinking in order to accommodate the new objects in the same structure of the concept.

Conventionally, the *domain* of a concept's intension is used to be perceived subjectively in literature (Hurley, 1997; Matlin, 1998). In this approach, it is deemed that a concept connotes the attributes, which occur in the minds of people who use that concept, or where something must have in order to be denoted by the concept. Both the above informal perceptions are not objectively operational in defining a complete and unambiguity domain of intensions. To solve this

fundamental problem, Definition 10 provides a unique and objective determination of any given concept.

Definition 12. *The extension of a concept $c = (O, A, R^c, R^i, R^o)$, c^+, is represented by its set of objects O, i.e.:*

$$c^+(O,A,R^c,R^i,R^o) \triangleq O = \{o_1, o_2, ..., o_m\} \subseteq \wp\mathcal{O} \tag{7}$$

A formal and objective definition of the domain of intension is provided below.

Definition 13. *The domain of a concept $c = (O, A, R^c, R^i, R^o)$ is a set of attributes with a narrow sense D_{min} referring to its intension and a broad sense D_{max} referring to its closure, i.e.:*

$$D(c) \triangleq \begin{cases} D_{\min}(c) = A = \bigcap_{j=1}^{\#O} A_{o_j} \\ D_{\max}(c) = A^* = \bigcup_{j=1}^{\#O} A_{o_j} \end{cases} \tag{8}$$

It is noteworthy that in conventional literature, it is only believed that the intension of a concept determines its extension (Hurley, 1997; Matlin, 1998). However, Definition 13 reveals that the extension of a concept, particularly the common attributes elicited from the extension, determines its intension as well.

Theorem 2. *The nature of concept hierarchy states that in an abstraction hierarchy, the higher the level of a concept in abstraction, the smaller the intension of the concept; and vice versa.*

Relationships between concepts in a concept hierarchy can be illustrated in Figure 2 at three levels known as the knowledge, object, and attribute levels. The internal relations of concepts, $R^c = O \times A$ can be formally represented by concept matrixes.

Example 1. *The concept matrix of concept c_1 is given in Table 1. According to Definition 13, the intension and extension of concepts c_1 as specified in Table 1 can be objectively and uniquely*

Figure 2. The hierarchical relations of concepts and their internal structures

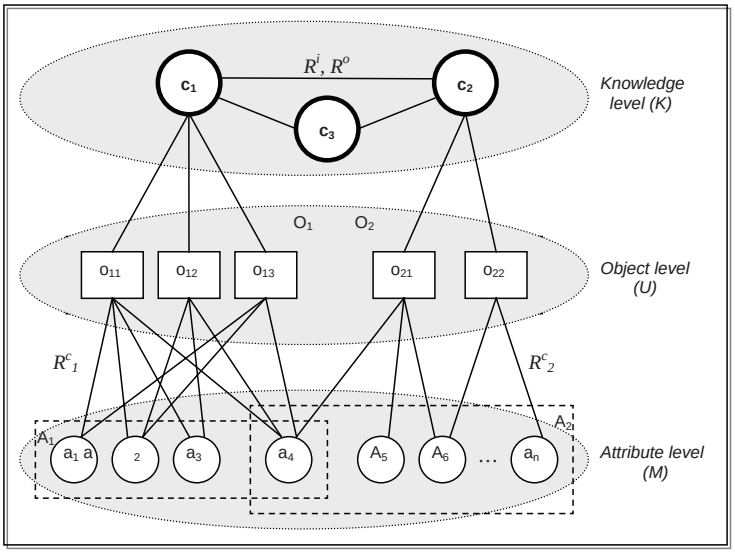


Table 1. The concept matrix of c_1

$\mathbf{c_1}$	$\mathbf{a_1}$	$\mathbf{a_2}$	$\mathbf{a_3}$	$\mathbf{a_4}$
$\mathbf{o_{11}}$	1	1	1	1
$\mathbf{o_{12}}$		1	1	1
$\mathbf{o_{13}}$	1	1		1

determined as: $A_{c1} = \{a_2, a_4\}$ and $O_{c1} = \{o_{11}, o_{12}, o_{13}\}$.

Definition 14. *The identification of a new concept $c(O, A, R^c, R^i, R^o)$ is the elicitation of its objects O, attributes A, and internal relations R^c, from the semantic environment $\Theta = (\mathcal{O}, \mathcal{A}, \mathcal{R})$, i.e.:*

$$c \triangleq (O, A, R^c, R^i, R^o \mid O \subset U \ \ A \subset M, R^c = O \times A, R^i = \varnothing, R^c = \varnothing) \quad (9)$$

In Definition 14, $R^i = R^o = \varnothing$ denotes that the identification operation is an initialization of a newly created concept where the input and output relations may be established later.

Definition 15. *A qualification of a concept $c(O, A, R^c, R^i, R^o)$, denoted by $*c$, is the identification of its domain, i.e.:*

$$*c \triangleq D(c) = \begin{cases} D_{\min}(c) = A = \bigcap_{j=1}^{\#O} A_{o_j} \\ D_{\max}(c) = A* = \bigcup_{j=1}^{\#O} A_{o_j} \end{cases} \quad (10)$$

Definition 16. *A quantification of a concept $c(O, A, R^c, R^i, R^o)$, denoted by $\#c$, is the cardinal evaluation of its domain in term of the number of attributes included in it, i.e.:*

$$\#c \triangleq \#D(c) = \begin{cases} \#D_{\min}(c) = \#A = \#(\bigcap_{j=1}^{\#O} A_{o_j}) \\ \#D_{\max}(c) = \#A* = \#(\bigcup_{j=1}^{\#O} A_{o_j}) \end{cases} \quad (11)$$

Example 2. *According to Definitions 15 and 16, the qualification and quantification of concept c_1 as given in Figure 2 are as follows, respectively:*

$$*c_1 = D(c_1) = \begin{cases} D_{\min}(c_1) = A_{c_1} = \{a_2, a_4\} \\ D_{\max}(c_1) = A_{c_1}* = \{a_1, a_2, a_3, a_4\} \end{cases}$$

$$\#c_1 = \#D(c_1) = \begin{cases} \#D_{\min}(c_1) = \#A_{c_1} = 2 \\ \#D_{\max}(c_1) = \#A_{c_1}* = 4 \end{cases}$$

Concept algebra is an abstract mathematical structure for the formal treatment of concepts and their algebraic relations, operations, and associative rules for composing complex concepts.

Definition 17. *A concept algebra CA on a given semantic environment Θ is a triple, i.e.:*

$$CA \triangleq (C, OP, \Theta) = (\{O, A, R^c, R^i, R^o\}, \{\bullet_r, \bullet_c\}, \Theta) \quad (12)$$

where $OP = \{\bullet_r, \bullet_c\}$ are the sets of relational and compositional operations on abstract concepts.

Concept algebra provides a denotational mathematical means for algebraic manipulations of abstract concepts. Concept algebra can be used to model, specify, and manipulate generic "to be" type problems, particularly system architectures, knowledge bases, and detail-level system designs in computing, software engineering, system engineering, and cognitive informatics. The relational and compositional operations on concepts will be formally described in the following sections.

RELATIONAL OPERATIONS OF CONCEPTS

The relational operations of abstract concepts are static and comparative operations that do not change the concepts involved. It is recognized that *relationships* between concepts are solely determined by the relations of both their intensions *A* and extensions *O*. The relational operations on abstract concepts in concept algebra are described below.

Lemma 1. *The relational operations* $\bullet_r$ *in concept algebra encompasses 8 comparative operators for manipulating the algebraic relations between concepts, i.e.:*

$$\bullet_r \triangleq \{\leftrightarrow, \nleftrightarrow, \prec, \succ, =, \cong, \sim, \triangleq\} \tag{13}$$

where the relational operators stand for *related, independent, subconcept, superconcept, equivalent, consistent, comparison,* and *definition*, respectively.

Definition 18. *The related concepts* c_1 *and* c_2 *on* Θ*, denoted by* $\leftrightarrow$*, are a pair of concepts that share some common attributes in their intensions* A_1 *and* A_2*, i.e.:*

$$c_1 \leftrightarrow c_2 \triangleq A_1 \cap A_2 \neq \varnothing \tag{14}$$

Definition 19. *The independent concepts* c_1 *and* c_2 *on* Θ*, denoted by* $\nleftrightarrow$*, are two concepts that their intensions* A_1 *and* A_2 *are disjoint, i.e.:*

$$c_1 \nleftrightarrow c_2 \triangleq A_1 \cap A_2 = \varnothing \tag{15}$$

It is obvious that related and independent concepts are mutually exclusive. That is, if $c_1 \leftrightarrow c_2$, then $\neg (c_1 \nleftrightarrow c_2)$; and vice versa.

Definition 20. *A subconcept* c_1 *of concept* c_2 *on* Θ*, denoted by* $\prec$*, is a concept that its intension* A_1 *is a superset of* A_2*, i.e.:*

$$c_1 \prec c_2 \triangleq A_1 \supset A_2 \tag{16}$$

Definition 21. *A superconcept* c_2 *over concept* c_1 *on* Θ*, denoted by* $\succ$*, is a concept that its intension* A_2 *is a subset of* A_1*, i.e.:*

$$c_2 \succ c_1 \triangleq A_2 \subset A_1 \tag{17}$$

According to Definitions 20 and 21, a subconcept and a superconcept are reflective. That is, *if* $c_1 \prec c_2$, then $c_2 \succ c_1$.

Definition 22. *The equivalent concepts* c_1 *and* c_2 *on* Θ*, denoted by* $=$*, are two concepts that their intensions* (A_1, A_2)*, and extensions* (O_1, O_2) *are identical, i.e.:*

$$c_1 = c_2 \triangleq (A_1 = A_2) \wedge (O_1 = O_2) \tag{18}$$

Definition 23. *The consistent concepts* c_1 *and* c_2 *on* Θ*, denoted by* $\cong$*, are two concepts with a relation of being either a sub- or superconcept, i.e.:*

$$\begin{aligned} c_1 \cong c_2 &\triangleq (c_1 \succ c_1) \vee (c_1 \prec c_2) \\ &= (A_1 \subset A_1) \vee (A_1 \supset A_2) \end{aligned} \tag{19}$$

Definition 24. *A comparison between two concepts* c_1 *and* c_2 *on* Θ*, denoted by* $\sim$*, is an operation that determines the equivalency or similarity level of their intensions, i.e.:*

$$c_1 \sim c_2 \triangleq \frac{\#(A_1 \cap A_2)}{\#(A_1 \cup A_2)} * 100\% \tag{20}$$

The range of equivalency between two concepts is among 0 to 100 %, where 0% means no similarity and 100% means a full similarity. According to Definition 24, It is obvious that:

$$c_1 \sim c_2 = \begin{cases} 100\%, & c_1 = c_2 \\ \frac{\#A_2}{\#A_1} \bullet 100\%, & c_1 \prec c_2 \\ \frac{\#A_1}{\#A_2} \bullet 100\%, & c_1 \succ c_2 \end{cases} \quad (21)$$

Definition 25. *A definition of a concept c_1 by c_2 on Θ, denoted by $\triangleq$, is an association between two concepts where they are equivalent, i.e.:*

$$c_1(O_1, A_1, R^c_1, R^i_1, R^o_1) \triangleq c_2(O_2, A_2, R^c_2, R^i_2, R^o_2)$$
$$\triangleq c_1(O_1, A_1, R^c_1, R^i_1, R^o_1 \mid O_1 = O_2, A_1 = A_2,$$
$$R^c_1 = O_1 \times A_1, R^i_1 = R^i_2, R^o_1 = R^o_2) \quad (22)$$

COMPOSITIONAL OPERATIONS OF CONCEPTS

The compositional operations of concept algebra are dynamic and integrative operations that always change all concepts involved in parallel.

Compositional operations on concepts provide a set of fundamental mathematical means to construct complex concepts on the basis of simple ones or to derive new concepts on the basis of exiting ones.

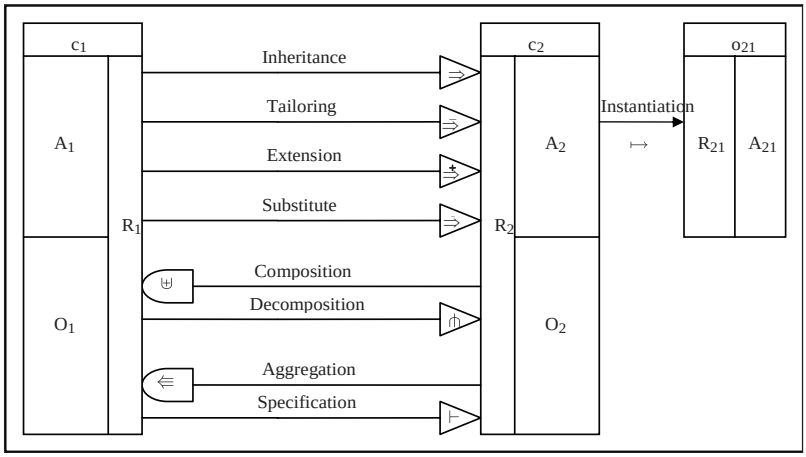
Lemma 2. *The compositional operations $\bullet_c$ in concept algebra encompasses nine associative operators for manipulating the algebraic compositions among concepts, i.e.:*

$$\bullet_c \triangleq \{\Rightarrow, \overset{-}{\Rightarrow}, \overset{+}{\Rightarrow}, \overset{\sim}{\Rightarrow}, \uplus, \pitchfork, \Leftarrow, \vdash, \mapsto\} \quad (23)$$

where the compositional operators stand for *inheritance, tailoring, extension, substitute, composition, decomposition, aggregation, specification,* and *instantiation*, respectively.

The compositional operations of concept algebra can be illustrated in Figure. 3. In Figure 3, $R = \{R^c, R^i, R^o\}$, and all nine compositional operations define composing rules among concepts, except instantiation that is an operation between a concept and a specific object.

Figure 3. The compositional operations of concept algebra as concept manipulation rules



Definition 26. *An inheritance of concept c_2 from concept c_1, denoted by $\Rightarrow$, is the creation of the new concept c_2 by reproducing c_1, and the establishment of new associations between them in parallel, see Box 1, where c_1 is called the parent concept, c_2 is the child concept, and || denotes that an inheritance creates new associations between c_1 and c_2 in parallel via (R^o_1, R^i_2) and (R^o_2, R^i_1).*

Definition 27. *The multiple inheritance of concept c from n parent concepts c_1, c_2, …, c_n, denoted by $\Rightarrow$, is an inheritance that creates the new concept c via a set of n conjoint concepts and establishes new associations among them, see Box 2, where $\overset{n}{\underset{i=1}{R}}(\kappa_i)$ is known as the big-R notation (Wang, 2002b, 2008c) that denotes a repetitive behavior or recurrent structure.*

Definition 28. *The tailoring of concept c_2 from the parent concept c_1, denoted by $\overset{-}{\Rightarrow}$, is a special inheritance that creates the new concept c_2 based on c_1 with the removal of the subsets of objects O′ and attributes A′; at the same time, it establishes new associations between the two concepts, see Box 3.*

Definition 29. *The extension of concept c_2 from the parent concept c_1, denoted by $\overset{+}{\Rightarrow}$, is a special inheritance that creates the new concept c_2 based c_1 with additional objects O′ and/or attributes A′, and establishes new associations between the two concepts, see Box 4.*

Definition 30. *The substitute of concept c_2 from the parent concept c_1, denoted by $\tilde{\Rightarrow}$, is a special*

\tag{28}
$$

inheritance that creates the new concept c_2 based on c_1 by replacing the inherited subsets of objects O'_{c1} and attributes A'_{c1} with corresponding ones O'_{c2} and A'_{c2} that share the same identifiers but possess different objects or attributes; at the same time, it establishes new associations between the two concepts, see Box 5, where $O'_{c1} \subset O_1 \wedge O'_{c2} \subset O_2 \wedge \#O'_{c1} = \#O'_{c2}$ and $A'_{c1} \subset A_1 \wedge A'_{c2} \subset A_2 \wedge \#A'_{c1} = \#A'_{c2}$.

Binary concept tailoring, extension, and substitution can be extended to corresponding *n*-nary

operations, similar to that of inheritance as given in Definition 27.

Definition 31. *The composition of concept c from n subconcepts c_1, c_2, …, c_n, denoted by $\uplus$, is an integration of them that creates the new super concept c via concept conjunction; at the same time, it establishes new associations between them, see Box 6.*

It is noteworthy that, according to the calculus of incremental union $\boxplus$ (Wang, 2006b, 2008b), the composition operation as given in Definition 31 results in the generation of new internal relations, which do not belong to any of its subconcepts. This is the most important property of concept composition.

Corollary 1. *The composition of multiple concepts is an incremental union operation, where the newly generated internal relations ΔR^c can be determined as:*

$$\Delta R^c = \bigcup_{i=1}^{n} \{(c, c_i), (c_i, c)\} \tag{30}$$

Box 6.

$$\begin{aligned} & c(O, A, R^c, R^i, R^o) \triangleq \biguplus_{i=1}^{n} c_i(O_i, A_i, R_i^c, R_i^i, R_i^o) \\ & = c(O, A, R^c, R^i, R^o \mid O = \bigcup_{i=1}^{n} O_{c_i}, A = \bigcup_{i=1}^{n} A_{c_i}, R^c = \bigcup_{i=1}^{n} R^c{}_{c_i} \cup \{(c, c_i), (c_i, c)\}, \\ & \quad R^i = \bigcup_{i=1}^{n} R^i{}_{c_i} \;\; R^o = \bigcup_{i=1}^{n} R^o{}_{c_i}) \\ & \| \mathop{\mathrm{R}}_{i=1}^{n} c_i(O_i, A_i, R^c{}_i, R^{i'}{}_i, R^{o'}{}_i \mid R^{i'}{}_i = R^i{}_i \cup \{(c, c_i)\}, R^{o'}{}_i = R^o{}_i \cup \{(c_i, c)\}) \end{aligned} \tag{29}$$

Box 7.

$$\begin{aligned} & c(O, A, R^c, R^i, R^o) \Cap \mathop{\mathrm{R}}_{i=1}^{n} c_i \\ & \triangleq \mathop{\mathrm{R}}_{i=1}^{n} \{ c_i(O_i, A_i, R^c{}_i, R^{i'}{}_i, R^{o'}{}_i \mid R^{i'}{}_i = R^i{}_i \cup \{(c, c_i)\}, R^{o'}{}_i = R^o{}_i \cup \{(c_i, c)\}) \\ & \quad \| c(O, A, R^{c'}, R^{i'}, R^{o'} \mid R^{c'} = \bigcup_{i=1}^{n} (R^c{}_{c_i} \setminus \{(c, c_i)(c_i, c)\}), \\ & \quad \{R^{i'} = R^i \cup \mathop{\mathrm{R}}_{i=1}^{n} (c_i, c)\}, R^{o'} = R^o \cup \{\mathop{\mathrm{R}}_{i=1}^{n} (c, c_i)\}) \\ & \quad \setminus c_i(O_i, A_i, R^c{}_i, R^i{}_i, R^o{}_i) \\ & \quad \} \end{aligned} \tag{31}$$

A concept decomposition is an inverse operation of concept compositions.

Definition 32. *The decomposition of concept c into n subconcepts c_1, c_2, …, c_n, denoted by ⫛, is a partition of the superconcept into multiple subconcepts; at the same time, it establishes new associations between them, see Box 7.*

As specified in Definition 32, the decomposition operation results in the removal of all internal relations $\Delta R^c = \bigcup_{i=1}^{n} \{(c, c_i), (c_i, c)\}$ that are no longer belong to any of its subconcepts.

Definition 33. *The aggregation of concept c_1 from concept c_2, denoted by ⇚, is a creation of c_1 via abstraction of c_2 with a reduced intension of more generic attributes; at the same time, it establishes new associations between them, see Box 8.*

Concept aggregation is also known as concept *generalization*, *abstraction*, or *elicitation*. Binary aggregations can be extended to *n*-nary parallel or serial aggregations.

Definition 34. *The parallel aggregation of a concept c from a set of n concepts c_1, c_2, …, c_n,*

Box 8.

$$
\begin{aligned}
& c_1(O_1, A_1, R^c{}_1, R^i{}_1, R^o{}_1) \Leftarrow c_2(O_2, A_2, R^c{}_2, R^i{}_2, R^o{}_2) \\
& \triangleq c_1(O_1, A_1, R^c{}_1, R^i{}_1, R^o{}_1 \mid O_1 \supset O_2, A_1 \subset A_2, R^c{}_1 = (O_1 \times A_1) \cup \\
& \qquad \{(c_1, c_2), (c_2, c_1)\}, R^i{}_1 = R^i{}_2 \cup \{(c_2, c_1)\}, R^o{}_1 = R^o{}_2 \cup \{(c_1, c_2)\}) \\
& \| c_2(O_2, A_2, R^c{}_2, R^{i'}{}_2, R^{o'}{}_2 \mid R^{i'}{}_2 = R^i{}_2 \cup \{(c_1, c_2)\}, R^{o'}{}_2 = R^o{}_2 \cup \{(c_2, c_1)\})
\end{aligned}
\tag{32}
$$

Box 9.

$$
\begin{aligned}
& c(O, A, R^c, R^i, R^o) \Leftarrow \mathop{R}_{i=1}^{n} c_i \\
& \triangleq c(O, A, R^c, R^i, R^o \mid O = \bigcup_{i=1}^{n} O_i, A = \bigcap_{i=1}^{n} A_i, R^c = \bigcup_{i=1}^{n} (R^c{}_{c_i} \cup \{(c, c_i), (c_i, c)\}), \\
& \qquad (R^i = \bigcup_{i=1}^{n} R^i{}_{c_i} \cup \{(c_i, c)\}), R^o = \bigcup_{i=1}^{n} (R^o{}_{c_i} \cup \{(c, c_i)\}), \\
& \| \mathop{R}_{i=1}^{n} c_i(O_i, A_i, R^c{}_i, R^{i'}{}_i, R^{o'}{}_i \mid R^{i'}{}_i = R^i{}_i \cup \{(c, c_i)\}, R^{o'}{}_i = R^o{}_i \cup \{(c_i, c)\})
\end{aligned}
\tag{33}
$$

denoted by ⇐, is an aggregation of c with the elicitation of all concepts in the set, see Box 9.

Based on Definition 34, a concept may be inductively generalized by a series of aggregations with a smaller set of more abstract (super) attributes.

Definition 35. *The serial aggregation of a concept c from a set of n concepts c_1, c_2, …, c_n, denoted by ⇐, is an aggregation with a total order of a series of decreasing intensions of the concepts by more abstract and generic attributes, see Box 10.*

A concept specification is an inverse operation of concept aggregations.

Definition 36. *The specification of concept c_1 by concept c_2, denoted by ⊢, is a deductive refinement of c_1 by an increasing intension with more specific and precise attributes in c_2; at the same time, it establishes new associations between them, see Box 11.*

Binary specifications can be extended to *n*-nary parallel or serial aggregations.

Definition 37. *The parallel specification of concept c by a set of n concepts c_1, c_2, …, c_n, denoted by ⊢, is a specification of c with the elicitation of all concepts in the set, see Box 12.*

Box 10.

& \triangleq c(O, A, R^c, R^i, R^o \mid O \supset O_1 \supset O_2 \supset \ldots \supset O_n, A \subset A_1 \subset A_2 \subset \ldots \subset A_n, \\
& \quad R^c = (O \times A) \cup \{(c, c_1), (c_1, c)\}, R^i = R^i{}_1 \cup \{\mathop{R}_{i=1}^{n}(c_i, c)\}, \\
& \quad R^o = R^o{}_1 \cup \{\mathop{R}_{i=1}^{n}(c, c_i)\}) \\
& \| \mathop{R}_{i=1}^{n} c_i(O_i, A_i, R^c{}_i, R^{i'}{}_i, R^{o'}{}_i \mid R^{i'}{}_i = R^i{}_i \cup \{(c, c_i)\}, R^{o'}{}_i = R^o{}_i \cup \{(c_i, c)\})
\end{aligned}
\tag{34}
$$

Box 11.

$$
\begin{aligned}
& c_1(O_1, A_1, R^c{}_1, R^i{}_1, R^o{}_1) \vdash c_2(O_2, A_2, R^c{}_2, R^i{}_2, R^o{}_2) \\
& \triangleq c_2(O_2, A_2, R^c{}_2, R^i{}_2, R^o{}_2 \mid O_2 \subset O_1, A_2 \supset A_1, R^c{}_2 = (O_2 \times A_2) \cup \\
& \quad \{(c_2, c_1), (c_1, c_2)\}, R^i{}_2 = R^i{}_1 \cup \{(c_1, c_2)\}, R^o{}_2 = R^o{}_1 \cup \{(c_2, c_1)\}) \\
& \| c_1(O_1, A_1, R^c{}_1, R^{i'}{}_1, R^{o'}{}_1 \mid R^{i'}{}_1 = R^i{}_1 \cup \{(c, c_1)\}, R^{o'}{}_1 = R^o{}_1 \cup \{(c_1, c)\})
\end{aligned}
\tag{35}
$$

Box 12.

$$\begin{aligned}
&\mathop{R}_{i=1}^{n} c_i \vdash c(O, A, R^c, R^i, R^o) \\
&\triangleq c(O, A, R^c, R^i, R^o \mid O \subset \bigcup_{i=1}^{n} O_i, A = \bigcap_{i=1}^{n} A_i, R^c = \bigcup_{i=1}^{n} (R^c_{c_i} \cup \{(c, c_i), (c_i, c)\}), \\
&\quad R^i = \bigcup_{i=1}^{n} (R^i_{c_i} \cup \{(c_i, c)\}), R^o = \bigcup_{i=1}^{n} (R^o_{c_i} \cup \{(c, c_i)\})) \\
&\mid\mid \mathop{R}_{i=1}^{n} c_i(O_i, A_i, R^c{}_i, R^{i'}{}_i, R^{o'}{}_i \mid R^{i'}{}_i = R^i{}_i \cup \{(c, c_i)\}, R^{o'}{}_i = R^o{}_i \cup \{(c_i, c)\})
\end{aligned} \tag{36}$$

Definition 38. *The serial specification of concept c by a set of concepts c_1, c_2, …, c_n, denoted by $\vdash$, is a specification with a total order of a series of refinements by increasing intensions of the concepts with more specific and precise attributes, see Box 13.*

The *binary, parallel,* and *series* specifications and aggregations of concepts provide a generic means for forming a hierarchical structure of concepts in knowledge engineering.

Theorem 3. *A totally ordered series of decreasing intensions in a serial concept aggregation is reversely proportional to a totally ordered series of increasing extensions, i.e.:*

Box 13.

$$\begin{aligned}
&(c_n \vdash ... \vdash c_2 \vdash c_1) \vdash c(O, A, R^c, R^i, R^o) \\
&\triangleq c(O, A, R^c, R^i, R^o \mid O_n \supset ... \supset O_2 \supset O_1 \supset O, A_n \subset ... \subset A_2 \subset A_1 \subset A, \\
&\quad R^c = (O \times A) \cup \mathop{R}_{i=1}^{n} \{(c, c_i), (c_i, c)\}, \\
&\quad R^i = R^i{}_n \cup \mathop{R}_{i=1}^{n} \{(c_i, c)\}), R^o = R^o{}_n \cup \mathop{R}_{i=1}^{n} \{(c, c_i)\}) \\
&\mid\mid \mathop{R}_{i=1}^{n} c_i(O_i, A_i, R^c{}_i, R^{i'}{}_i, R^{o'}{}_i \mid R^{i'}{}_i = R^i{}_i \cup \{(c, c_i)\}, R^{o'}{}_i = R^o{}_i \cup \{(c_i, c)\})
\end{aligned} \tag{37}$$

$$\forall c \Leftarrow c_1 \Leftarrow c_2 \Leftarrow ... \Leftarrow c_n,$$
$$A \subset A_1 \subset A_2 \subset ... \subset A_n \Rightarrow O \supset O_1 \supset O_2 \supset ... \supset O_n \quad (38)$$

Example 3. *The relationships between series of specifications and aggregations on the concept animal can be described as follows:*

$$(animal \vdash mammal \vdash feline \vdash tiger) \Rightarrow$$
$$(animal \Leftarrow mammal \Leftarrow feline \Leftarrow tiger)$$

where, according Theorem 3, it can be obtained:

$$A_{animal} \subset A_{mammal} \subset A_{feline} \subset A_{tiger}, \text{and}$$
$$O_{animal} \supset O_{mammal} \supset O_{feline} \supset O_{tiger}$$

The compositional operations of concepts formally defined so far are those among abstract concepts. The remainder of this section describes a special compositional operation between a given concept and its objects.

Definition 39. *The instantiation of a concept c, denoted by* $\mapsto$*, is an embodiment of its generic semantics onto a specific case or implementation known as an object o, see Box 14.*

It is noteworthy that the output relation of an object is always empty (i.e., $R^o_o \equiv \varnothing$), which means that the object is an end product of a concept where there is no further deduction of meanings in the hierarchy of the inheritance chain.

Definition 40. *The multiple instantiation of a concept c onto n objects, denoted by* $\mapsto$*, is a compound parallel instantiation that creates a set of new objects {o_1, o_2, …, o_n} based on c, and establishes new associations between them, see Box 15.*

Box 14.

$$c(O, A, R^c, R^i, R^o) \mapsto o(A_o, R^c{}_o, R^i{}_o)$$
$$\triangleq o(A_o, R^c{}_o, R^{i'}{}_o \mid o \subset O, A_o = A, R^c{}_o = o \times A_o, R^{i'}{}_o = R^i{}_o \cup \{(c, o)\})$$
$$||\, c(O, A, R^c, R^{i'}, R^{o'} \mid R^{i'} = R^i \cup \{(o, c)\}, R^{o'} = R^o \cup \{(c, o)\}) \quad (39)$$

Box 15.

$$c(O, A, R^c, R^i, R^o) \mapsto \mathop{R}_{i=1}^{n} o_i(A_{o_i}, R^c{}_{o_i}, R^i{}_{o_i})$$
$$\triangleq \mathop{R}_{i=1}^{n} o_i(A_{o_i}, R^c{}_{o_i}, R^{i'}{}_{o_i} \mid o_i \subseteq O, A_{o_i} = A, R^c{}_{o_i} = o_i \times A_{o_i},$$
$$R^{i'}{}_{o_i} = R^i{}_{o_i} \cup (c, o_i)\})$$
$$||\, c(O, A, R^c, R^{i'}, R^{o'} \mid R^{i'} = R^i \cup \{\mathop{R}_{i=1}^{n}(o_i, c)\}, R^{o'} = R^o \cup \{\mathop{R}_{i=1}^{n}(c, o_i)\}) \quad (40)$$

CONCEPT ALGEBRA FOR KNOWLEDGE MANIPULATION

This section describes applications of concept algebra in the manipulation of abstract models of knowledge and the methodology for knowledge representation and manipulation.

The Mathematical Model of Knowledge

In cognitive informatics (Wang, 2002a, 2006a, 2007e), particularly the OAR model (Wang, 2007c; Wang & Wang, 2006) on internal knowledge representation in the brain, human *knowledge* is modeled as a concept network, where concept algebra is applied as a set of rules for knowledge composition in order to construct complex and dynamic concept networks.

Definition 41. *A generic knowledge K is an n-nary relation* $\Re$ *among a set of n concepts and the entire set of concepts C, i.e.:*

$$K = \Re : (\bigtimes_{i=1}^{n} C_i) \to C \tag{41}$$

where $\biguplus_{i=1}^{n} C_i = C$, *and*

$$\Re = \bullet_c = \{\Rightarrow, \overline{\Rightarrow}, \overset{+}{\Rightarrow}, \overset{\sim}{\Rightarrow}, \uplus, \sqcap, \Leftarrow, \vdash, \mapsto\}.$$

According to Definition 41, the most simple knowledge *k* is a binary relation $\Re$ between two concepts in *C*, i.e.:

$$k = \Re : C \times C \to C. \tag{42}$$

Definition 41 indicates that the compositional operations of concept algebra, $\bullet_c$, provide a set of coherent mathematical means and rules for knowledge manipulation. Because the relations between concepts are transitive, the generic topology of knowledge is a hierarchical network as shown in Figures 2 and 3.

Theorem 4. *The generic topology of abstract knowledge systems K is a hierarchical concept network.*

Theorem 4 can be proved by the nine compositional rules in concept algebra, particularly the composition/decomposition and aggregation/specification operations, as defined in the previous section.

Corollary 2. *The property of the hierarchical knowledge architecture K in the form of concept networks is as follows:*

a. **Dynamic:** *The knowledge network may be updated dynamically along with information acquisition and learning without destructing the existing concept nodes and relational links.*
b. **Evolvable:** *The knowledge network may grow adaptively without changing the overall and existing structure of the hierarchical network.*

The Hierarchical Model of Concept Networks

A concept network as a generic knowledge model has been widely studied in linguistics, computing, and cognitive informatics. The notion of the *semantic network* model for knowledge representation is first proposed by Quillian in 1968 (Matlin, 1998; Quillian, 1968; Reisberg, 2001), where the semantic memory is perceived as information represented in network structures with conceptual nodes and interrelations. The meaning of a given concept depends on other concepts to which it is connected in the network. The semantic network has been extended by a number of theories such as the *hypothetical network* (Colins & Loftus, 1975), the *adaptive control of thought - star* (ADT*) model (Anderson, 1983, 1991). The latter proposes that all cognition processes in thought are controlled by unitary network models.

This subsection develops the concept network model based on concept algebra and Wang's OAR model (Wang, 2007c; Wang & Wang, 2006) for knowledge representation, which treat a concept as a basic and adaptive unit for knowledge representation and thinking.

Definition 42. *A concept network CN is a hierarchical network of concepts interlinked by the set of nine composing rules ℜ concept algebra, i.e.:*

$$CN = \Re : \sum_{i=1}^{n} C_i \rightarrow \sum_{j=1}^{n} C_j \tag{43}$$

Theorem 5. *In a concept network CN, the abstract levels of concepts ℓ_c form a partial order of a series of superconcepts, i.e.:*

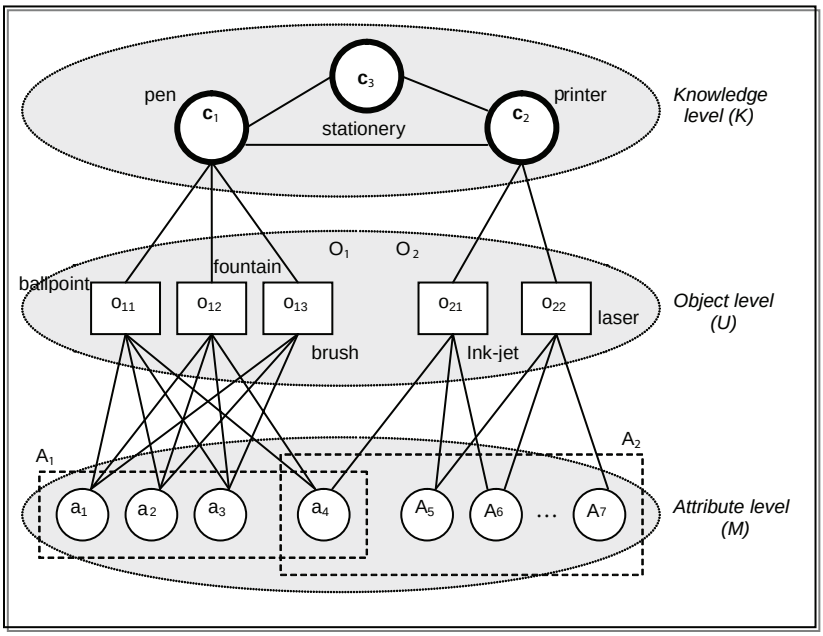
$$\ell_c = (\varnothing \preccurlyeq c_1 \preccurlyeq c_2 \preccurlyeq \ldots \preccurlyeq c_n \preccurlyeq \ldots \preccurlyeq \Omega) \tag{44}$$

where ∅ is the empty concept ∅ = (⊥, ⊥), and Ω the universal concept, Ω = (𝒪, 𝒜).

According to Theorem 5 and Definition 42, a hierarchical structure of concepts in a given semantic environment Θ can be formally described by concept algebra. The algebraic relations and compositional operations of concept algebra enable the construction of hierarchical concept networks in a dynamic process.

Example 4. *A concrete concept network, pen and printer, can be illustrated in Figure 4. The concept network may be dynamically extended along with the development of related knowledge such as to extend it to a more abstract concept network of stationery. In Figure 4, concept c_1(pen) may be formally described in concept algebra, see Box 16.*

Figure 4. A concrete concept network



Box 16.

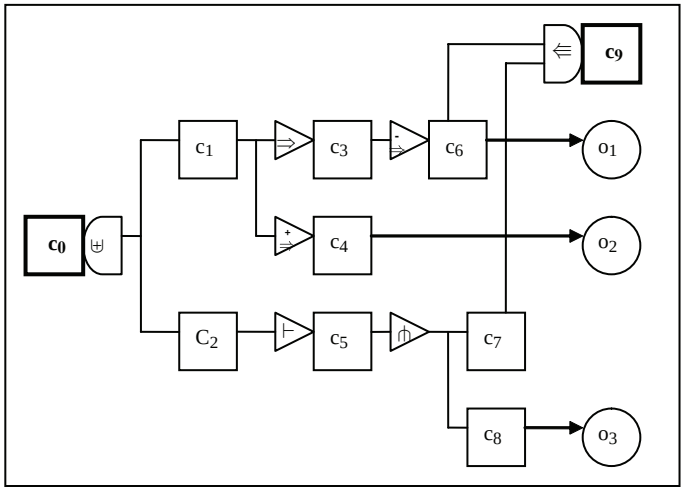
$$
\begin{aligned}
& c_1(pen) = c_1(O_1, A_1, R^c{}_1, R^i{}_1, R^o{}_1) \\
& \text{where } O_1 = \{o_{11}, o_{12}, o_{13}\} = \{ballpoinbt, fountain, brush\}; \\
& \quad A_1 = \{a_1, a_2, a_3\} = \{a\_writing\_tool, using\_ink, having\_a\_nib\}; \\
& \quad A^*{}_1 = \{a_1, a_2, a_3, a_4\} = A \cup \{with\_an\_ink\_container\}; \\
& \quad R^c{}_1 = O_1 \times A_1 = \{(o_{11}, a_1), (o_{11}, a_2), (o_{11}, a_3)\} \cup \\
& \qquad \{(o_{12}, a_1), (o_{12}, a_2), (o_{12}, a_3)\} \cup \{(o_{13}, a_1), (o_{13}, a_2), (o_{13}, a_3)\}
\end{aligned}
\tag{45}
$$

It is noteworthy that, according to Definition 10, the intension of c_1(*pen*) does not include the attribute a_4, because it is not commonly shared by all objects of the given concept. However, A_1* does include a_4 in the closure of attributes of the given concept *pen*.

Example 5. *An abstract concept network that is formed by the composition and aggregation of a set of related concepts c_0 through c_9, as well as objects o_1 through o_3, can be expressed in Figure 5.*

A formal description corresponding to the above concept network can be carried out using concept algebra as given below:

Figure 5. An abstract concept network



$$c_0 \uplus ((c_1 \Rightarrow c_3 \overline{\Rightarrow} c_6 \mapsto o_1) \parallel (c_1 \overset{+}{\Rightarrow} c_4 \mapsto o_2)) \parallel (c_2 \vdash c_5 \pitchfork (c_7 \parallel (c_8 \mapsto o_3)))$$

$$c_9 \Leftarrow (c_6 \parallel c_7) \tag{46}$$

The case studies in Examples 4 and 5 demonstrate that concept algebra and concept network are a generic and formal knowledge manipulation means that are capable to deal with complicated abstract or concrete knowledge structures and their algebraic operations. Further, detailed concept operations of concept algebra may be extended into a set of inference processes, which can be formally described by RTPA (Wang, 2002b, 2003, 2006a, 2007b, 2007d, 2008a, 2008d) as a set of behavioral processes.

CONCLUSION

A new mathematical structure, known as concept algebra, has been presented for abstract concepts and knowledge representation and manipulation. Concepts have been treated as the basic unit of cognition that carries certain meanings in almost all cognitive processes such as thinking, learning, reasoning, and system design. Abstract concepts have been formally modeled as a dynamic mathematical structure with internal attributes, objects, and their relations that possess the adaptive capability to grow in concept networks. The formal methodology for manipulating knowledge has been developed using concept algebra and concept networks. A number of case studies have been used to demonstrate the expressive power of concept algebra in knowledge representation and manipulation. A wide range of applications of concept algebra has been identified for solving common problems in cognitive informatics, logic, linguistics, psychology, knowledge engineering, data mining, software engineering, and intelligence science. One of the important applications of concept algebra is the formalization of object-oriented methodologies and the development of a rigorous semantics of UML as an industrial OO design languages. Autonomic machine learning and searching engines can be developed on the basis of concept algebra.

ACKNOWLEDGMENT

The author would like to acknowledge the Natural Science and Engineering Council of Canada (NSERC) for its partial support of this work. The author would like to thank anonymous reviewers for their valuable comments and suggestions. The author is grateful to Dr. Y. Y. Yao for many insightful discussions.

Chapter 7.26
On System Algebra:
A Denotational Mathematical Structure for Abstract System Modeling

Yingxu Wang
University of Calgary, Canada

ABSTRACT

Systems are the most complicated entities and phenomena in abstract, physical, information, and social worlds across all science and engineering disciplines. System algebra is an abstract mathematical structure for the formal treatment of abstract and general systems as well as their algebraic relations, operations, and associative rules for composing and manipulating complex systems. This article presents a mathematical theory of system algebra and its applications in cognitive informatics, system engineering, software engineering, and cognitive informatics. A rigorous treatment of abstract systems is described, and the algebraic relations and compositional operations of abstract systems are analyzed. System algebra provides a denotational mathematical means that can be used to model, specify, and manipulate generic "to be" and "to have" type problems, particularly system architectures and high-level system designs, in computing, software engineering, system engineering, and cognitive informatics.

INTRODUCTION

Systems are the most complicated entities and phenomena in abstract, physical, information, and social worlds across all science and engineering disciplines. Systems are needed because the physical and/or cognitive power of an individual component or a person is not enough to carry out a work or solve a problem. System philosophy intends to treat everything as a system, and it perceives that a system always belongs to other super system(s) and contains more subsystems.

The system concept can be traced back to the 17th century, when René Descartes (1596-1650) noticed the interrelationships among scientific disciplines as a system. The general system notion was then proposed by Ludwig von Bertalanffy in the 1920s (von Bertalanffy, 1952; Ellis & Fred,

1962). The theories of system science have evolved from classic theories (Ashby, 1958, 1962; Ellis & Fred, 1962; Heylighen, 1989; G. J. Klir, 1992; R. G. Klir, 1988; Rapoport, 1962) to contemporary theories in the mid-20th century, such as I. Prigogine's dissipative structure theory (Prigogine et al., 1972), H. Haken's synergetics (Haken, 1977), and Eigen's hypercycle theory (Eigen & Schuster, 1979). Then, during the late part of the last century, there are proposals of complex systems theories (G. J. Klir, 1992; Zadeh, 1973), fuzzy theories (Zadeh, 1965, 1973), and chaos theories (Ford, 1986; Skarda & Freeman, 1987).

System algebra is an abstract mathematical structure for the formal treatment of abstract and general systems as well as their algebraic relations, operations, and associative rules for composing and manipulating complex systems. System algebra (Wang, 2005, 2006a, 2006b, 2007a, 2007c) presented in this article is the latest attempt to provide a formal and rigorous treatment of abstract systems and their properties. This article treats systems as a mathematic entity and it studies the generic rules and theories of abstract systems. A new mathematical structure of abstract systems as the most complicated mathematical entities beyond sets, functions, and processes is presented. Properties of abstract systems are modeled and analyzed. System algebra is introduced as a set of relational and compositional operations for manipulating abstract systems and their composing rules. The relational operations of system algebra are described encompassing *independent, related, overlapped, equivalent, subsystem,* and *supersystem.* The compositional operations of system algebra are explored encompassing *inheritance, tailoring, extension, substitute, difference, composition, decomposition, aggregation,* and *specification*. A wide range of applications of system algebra are identified in cognitive informatics, system science, system engineering, computing, software engineering, and intelligent systems.

THE ABSTRACT SYSTEM THEORY

This section demonstrates that systems may be treated rigorously as a new mathematical structure beyond conventional mathematical entities. Based on this view, the concept of abstract systems and their mathematical models are introduced.

Definition 1. *An abstract system is a collection of coherent and interactive entities that has stable functions and a clear boundary with the external environment.*

An abstract system forms the generic model of various real-world systems and represents the most common characteristics and properties of them.

Lemma 1. *The generality principle of system abstraction states that a system can be represented as a whole in a given level k of reasoning, $1 \le k \le n$, without knowing the details at levels below k.*

Definition 2. *Let $\mathcal{C}$ be a finite or infinite nonempty set of components, and $\mathcal{B}$ a finite or infinite nonempty set of behaviors, then the universal system environment U is denoted as a triple, i.e.:*

$$\begin{aligned} \mathfrak{U} &\triangleq (\mathcal{C}, \mathcal{B}, \mathcal{R}) \\ &= \mathcal{R} : \mathcal{C} \to \mathcal{C} \mid \mathcal{C} \to \mathcal{B} \mid \mathcal{B} \to \mathcal{C} \mid \mathcal{B} \to \mathcal{B} \end{aligned} \tag{1}$$

where $\mathcal{R}$ is a set of relations between $\mathcal{C}$ and $\mathcal{B}$, and | demotes alternative relations.

Abstract systems can be classified into two categories known as the *closed* and *open* systems. Most practical and useful systems in nature are open systems in which there are interactions between the system and its environment. However, in order to develop the theoretical framework of abstract systems, the closed systems in which there is no interaction with the external environment will be modeled first in the following subsection.

The Mathematical Model of Closed Systems

The axiom of the abstract system theory is based on the Object-Attribute-Relation (OAR) model (Wang, 2007b, 2007d; Wang & Wang, 2006c), in which the architecture of a system object O_s can be modeled by a set of attributes A and a set of binary relations R among A and O_s, i.e.:

$$O_s \triangleq (A, R) \tag{2}$$

Encompassing both architectures and behaviors of a system on the basis of Equation 2, an abstract closed system without interactions with the environment can be formally described as follows.

Definition 3. *A closed system $\hat{S}$ on $\mathfrak{U}$ is a 4-tuple, i.e.:*

$$\hat{S} \triangleq (C, R, B, \Omega) \tag{3}$$

where

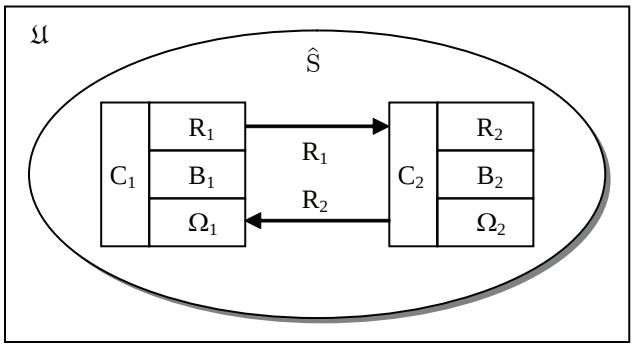
- C is a nonempty set of components of the system, $C = \{c_1, c_2, \ldots, c_n\} \subseteq \wp\mathcal{C} \sqsubseteq \mathfrak{U}$.
- R is a nonempty set of relations between pairs of the components in the system, $R = \{r_1, r_2, \ldots, r_m\} \subseteq C \times C$.
- B is a set of behaviors (or functions), $B = \{b_1, b_2, \ldots, b_p\} \subseteq \wp\mathcal{B} \sqsubseteq \mathfrak{U}$.
- Ω is a set of constraints on the memberships of components, the conditions of relations, and the scopes of behaviors, $\Omega = \{\omega_1, \omega_2, \ldots, \omega_q\}$.

According to Definition 3, a closed system $\hat{S} = (C, R, B, \Omega)$ on $\mathfrak{U}$ can be illustrated in Figure 1.

It is noteworthy that system behaviors B is the most broad set of system actions implemented or embodied on the given layout of the systems, including any kind of system functions, interactions, and communications. This is the major difference that distinguishes an abstract system from other mathematical structures such as a set, lattice, group, or concept (Wang, 2008b).

Lemma 2. *A closed system $\hat{S} = (C, R, B, \Omega)$ is an asymmetric (directed) and reflective system because the relations R in it are constrained by the following rules:*

Figure 1. The abstract model of a closed system



a. *Asymmetric*:

$$\forall a, b \in C \wedge a \neq b \wedge r \in R, r(a, b) \nRightarrow r(b, a) \quad (4)$$

b. *Reflective*:

$$\forall c \in C, r(c, c) \in R \quad (5)$$

Corollary 1. *The maximum number of binary relations n_r between all pairs of the n_c components in a closed system $\widehat{S} = (C, R, B, \Omega)$ can be determined as follows:*

$$n_r = \#R = \#(C \times C) = n_c^{\,2} \quad (6)$$

if all reflective self-relations are not considered, n_r becomes the maximum number of binary relations of fully connected systems, n'_r, i.e.:

$$n'_r = n'_r - n_c = n_c(n_c - 1) \quad (7)$$

Example 1. *According to Corollary 1, the creation of relations in a closed system is solely determined by the number of components possessed in the system. This property can be illustrated in Figure 2, where $\uplus$ denotes a system composition for both closed or open systems, which will be formally explained later. The relations of the three closed systems $\widehat{S_1}$, $\widehat{S_2}$, and $\widehat{S}$ are as follows, observing that all pairwise relations are asymmetric or different:*

$$n_{r_1}(\widehat{S_1}) = n_{c_1}^{\,2} = 3^2 = 9;\ n_{r_1}(\widehat{S_2}) = 2^2 = 4;$$
$$n_r(\widehat{S}) = 5^2 = 25$$

and

$$n'_{r_1}(\widehat{S_1}) = n_{r_1} - n_{c_1} = 9 - 3 = 6;$$
$$n'_{r_2}(\widehat{S_2}) = 4 - 2 = 2;\ n'_r(\widehat{S}) = 25 - 5 = 20$$

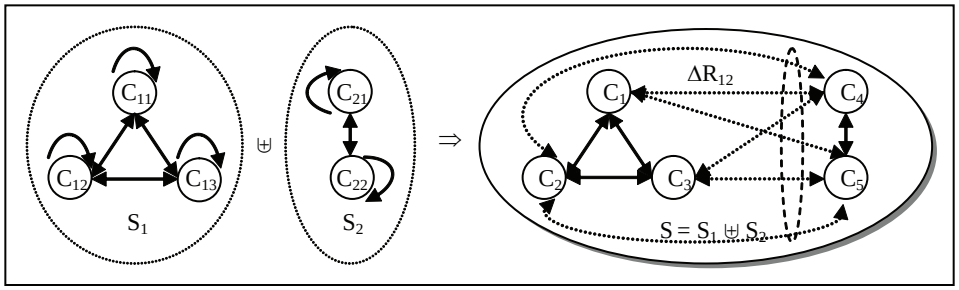
The Mathematical Model of Open Systems

Most practical systems in the real world are not closed. That is, they need to interact with external world known as the *environment* Θ in order to exchange energy, matter, and/or information. Such systems are called "open systems." Typical interactions between an open system and the environment are inputs and outputs.

Contrary to that the relations of a closed system are defined on the Cartesian product of internal components, the set of relations R of an open system needs to be extended to include both internal relations R^c and external (input/output) relations R^i and R^o, i.e.:

$$R = \{R^c \cup R^i \cup R^o\} \quad (8)$$

Figure 2. Creation of relations in open and closed systems



Definition 4. *An open system S on U is a 7-tuple, i.e.:*

$$S \triangleq (C, R, B, \Omega, \Theta),\ R = \{R^c, R^i, R^o\} = (C, R^c, R^i, R^o, B, \Omega, \Theta) \quad (9)$$

where the extensions of entities beyond the closed system as given in Definition 3 are as follows:

- Θ is the environment of S with a nonempty set of components C_Θ outside C, i.e., $\Theta = C_\Theta \sqsubseteq \mathfrak{U}$.
- $R^c = C \times C$ is a set of internal relations.
- $R^i \subseteq C_\Theta \times C$ is a set of external input relations.
- $R^o \subseteq C \times C_\Theta$ is a set of external output relations.

An open system $S = (C, R^c, R^i, R^o, B, \Omega, \Theta)$ can be illustrated in Figure 3.

Lemma 3. *An open system S(C, R^c, R^i, R^o, B, Ω, Θ) on $\mathfrak{U}$ is an asymmetric and reflective system because its relations R^c, R^i, and R^o are constrained by the following rules:*

a. *Internally asymmetric*:

$$\forall a, b \in C \wedge a \neq b \wedge r \in R^c,\ r(a,b) \Rightarrow r(b,a) \quad (10)$$

b *Externally asymmetric*:

$$\forall a \in C \wedge \forall x \in C_\Theta \wedge r \in R^i \vee r \in R^o,\ r(x,a) \Rightarrow r(a,x) \quad (11)$$

c. *Reflective*:

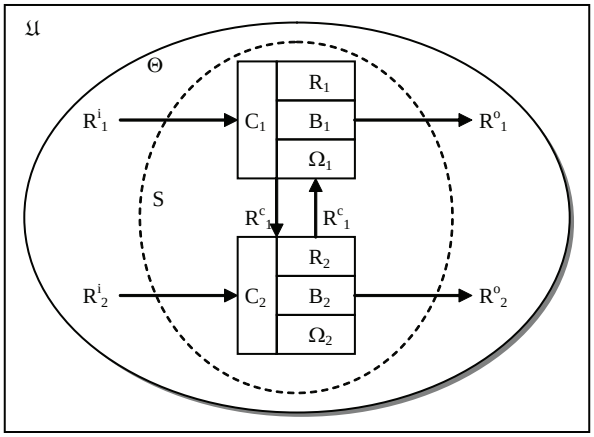
$$\forall c \in C,\ r(c, c) \in R^c \quad (12)$$

Corollary 2. *The maximum number of binary relations n_r and n'_r in an open system S(C, R^c, R^i, R^o, B, Ω, Θ) is determined by the numbers of internal relations R^c as well as external relations R^i and R^o, i.e.:*

$$n_r(S) = \#R^c + \#R^i + \#R^o = {n_c}^2 + 2(n_c \bullet n_{c_\Theta}) = n_c(n_c + 2n_{c_\Theta}) \quad (13)$$

$$n'_r(S) = n_r(S) - n_c = n_c \bullet (n_c + 2n_{c_\Theta}) - n_c = n_c \bullet (n_c + 2n_{c_\Theta} - 1) \quad (14)$$

Figure 3. The abstract model of an open system



Example 2. *According to Corollary 2, the creation of relations in an open system is solely determined by the number of components possessed in the system and its environment. This property can also be illustrated in Figure 2, where S_1 is treated as the open system and S_2 as the environment* Θ*:*

$$n_r(S) = n_c(n_c + 2n_{c_\Theta}) = 3(3 + 2\bullet 2) = 21$$

and

$$n'_r(S) = n_r(S) - n_c = 21 - 3 = 18$$

According to Corollaries 1 and 2, as well as Examples 1 and 2, it is apparent that either a closed or an open system may result in a huge number of relations n_r and the exponential increases of complexity, when the number of components possessed in them is considerably large. Therefore, system algebra is introduced to formally and efficiently manipulate abstract and general systems.

Definition 5. *A system algebra SA on a given universal system environment* $\mathfrak{U}$ *is a triple, i.e.:*

$$SA \triangleq (S, OP, \Theta) = (\{C, R^c, R^i, R^o, B, \Omega\}, \{\bullet_r, \bullet_c\}, \Theta) \quad (15)$$

where OP = {$\bullet_r$, $\bullet_c$}are the sets of relational and compositional operations on abstract systems.

System algebra provides a denotational mathematical means for algebraic manipulations of abstract systems. System algebra can be used to model, specify, and manipulate generic "to be" and "to have" type problems, particularly system architectures and high-level system designs, in computing, software engineering, system engineering, and cognitive informatics. The *relational* and *compositional* operations on abstract systems will be formally described in the following sections.

PROPERTIES OF ABSTRACT SYSTEMS

Taxonomy of Systems

Systems as the most complex entities in the physical and abstract worlds may be classified into various categories according to the key characteristics of their components (*C*), relations (*R*), behaviors (*B*), constraints (Ω), and/or environments (Θ). A summary of the system taxonomy is shown in Table 1, according to Definitions 3 and 4.

Table 1 shows that all types of systems fit the unified framework of system taxonomy. There are hybrid systems that may fall in two or more categories, such as a dynamic nonlinear system and a discrete fuzzy social system. The types of systems may also classified by their magnitudes as described in the following subsection.

Magnitude of Systems

Abstract and real-world systems may be very small or extremely large (Qian et al, 1990; Rosen, 1977). Therefore, a formal model of system magnitudes is needed to classify the size properties of systems and their relationship with other basic system attributes. In order to derive such a model, a set of measures on system sizes, magnitudes, and complexities is introduced next.

Definition 6. *The size of a system S_s is the number of components encompassed in the system, i.e.:*

$$S_s = \#C = n_c \quad (16)$$

Definition 7. *The magnitude of a system M_s is the number of asymmetric binary relations among the n_c components of the system including the reflexive relations, i.e.:*

$$M_s = \#R = n_r = \#(C \times C) = n_c^2 \quad (17)$$

Table 1. Taxonomy of systems

	System	Key Characteristics			
		Components (C)	**Relations (R)**	**Behaviors (B)**	**Environment (Θ)**
1	Concrete	Natural or real entities			
2	Abstract	Mathematical or virtual entities			
3	Physical	Natural entities			
4	Social	Humans			
5	Finite	$\#C \neq \infty$			
6	Infinite	$\#C = \infty$			
7	Closed		$R^i = \varnothing \wedge R^o = \varnothing$		
8	Open		$R^i \neq \varnothing \wedge R^o \neq \varnothing$		
9	Static			Invariable	
10	Dynamic			Variable	
11	Linear			Linear functions	
12	Nonlinear			Nonlinear functions	
13	Continuous			Continuous functions	
14	Discrete			Discrete functions	
15	Precise			Precise functions	
16	Fuzzy			Fuzzy functions	
17	Determinate			Response predictable to same stimulates	
18	Indeterminate			Response unpredictable to same stimulates	
19	White-box	Observable	Transparent	Fully observable	
20	Black-box	Unobservable	Non-transparent	Partially observable	
21	Intelligent			Autonomic	Adaptive
22	Non-intelligent			Imperative	Nonadaptive
23	Maintainable	Fixable		Recoverable	
24	Non-maintainable	Nonfixable		Nonrecoverable	

If all self-reflective relations are ruled out in n_r, the pure number of binary relations M'_s in the given system is determined as follows:

$$M'_s = M_s - n_c = n_c^2 - n_c = n_c(n_c - 1) \quad (18)$$

Lemma 4. *The pure number of binary relations M'_s equals to exactly two times of the number of pairwise combinations among n_c, i.e.:*

$$M'_s = n_c(n_c - 1) = 2 \bullet \frac{n_c(n_c - 1)}{2} = 2 \bullet \mathrm{C}_{n_c}^2 \quad (19)$$

where the factor 2 represents the asymmetric binary relation r, i.e., arb ≠ bra.

The magnitude of a system determines its complexity. The complexities of systems can be classified based on if they are fully or partially connected. The former is the theoretical upper-bound complexity of systems in which all components are potentially interconnected with each other in all *n*-nary ways, $1 \le n \le n_c = \#C$. The latter is the more typical complexity of systems where components are only pairwisely connected.

Definition 8. *The complexity of a fully connected system C_{max} is a closure of all possible n-nary relations R*, $1 \le n \le n_c$, among all components of the given system $n_c = \#C$, i.e.:*

$$C_{max} = R^* = 2\sum_{k=0}^{n_r} \mathrm{C}_{n_r}^k \approx 2 \bullet 2^{n_r} = 2^{n_r+1} = 2^{n_c^2+1} = 2^{M_s+1} \quad (20)$$

where C_{max} is also called the maximum complexity of systems.

According to Definition 8, the closure of all possible *n*-nary relations *R** may easily result in an extremely huge degree of complexity for a system with few components. For example, when $n_c = 10$, $C_{max} = 2^{101}$. This explains why most of the real-world systems are really too hard to be modeled and handled in conventional models and techniques.

It is noteworthy that almost all functioning systems are partially connected, because a fully connected system may not represent or provide anything meaningful. Therefore, the complexity of partially connected systems can be simplified as follows on the basis of Definition 8.

Definition 9. *The complexity of a partially connected system C_r is determined by the number of asymmetric binary relations M'_s of the system, i.e.:*

$$C_r = M'_s = 2 \bullet \mathrm{C}_{n_c}^2 = n_c(n_c - 1) \quad (21)$$

where C_r can be referred to the relational complexity of systems.

The extent of system magnitudes (Wang, 2006d, 2007c) can be classified at seven levels known as the *empty, small, medium, large, giant, immense,* and *infinite* systems from the bottom up. A summary of the relationships between system magnitudes, sizes, internal relations, and complexities can be described in the *system magnitude model,* shown in Table 2.

Table 2 indicates that the complexity of a small system may easily be out of control of human cognitive manageability. This leads to the following theorem.

Theorem 1. *The holism complexity of systems states that within the 7-level scale of system magnitudes, known as the empty, small, medium, large, giant, immense, and infinite systems, almost all systems are too complicated to be cognitively understood or mentally handled as a whole, except small systems or those that can be decomposed into small systems.*

According to Theorem 1, the basic principle for dealing with complicated systems is system

Table 2. The system magnitude model

Level	Category	Size of systems ($S_s = n_c$)	Magnitude of systems ($M_s = n_r = n_c^2$)	Relational complexity of systems ($C_r = n_c(n_c - 1)$)	Maximum complexity of systems ($C_{max} = 2^{n_c^2}$)
1	The empty system ($\mathfrak{O}$)	0	0	0	-
2	Small system	[1, 10]	[1, 10^2]	[0, 90]	[2, 2^{100}]
3	Medium system	(10, 10^2]	(10^2, 10^4]	(90, $0.99 \bullet 10^4$]	(2^{100}, $2^{10,000}$]
4	Large system	(10^2, 10^3]	(10^4, 10^6]	($0.99 \bullet 10^4$, $0.999 \bullet 10^6$]	∞
5	Giant system	(10^3, 10^4]	(10^6, 10^8]	($0.999 \bullet 10^6$, $0.9999 \bullet 10^8$]	∞
6	Immense system	(10^4, 10^5]	(10^8, 10^{10}]	($0.9999 \bullet 10^8$, $0.99999 \bullet 10^{10}$]	∞
7	The infinite system ($\mathfrak{U}$)	∞	∞	∞	∞

decomposition or modularity, in which the complexity of a lower level subsystem must be small enough to be cognitively manageable. Details of system decomposition theories and the art of system architectures will be developed in the following sections.

RELATIONAL OPERATIONS ON SYSTEMS

The relational operations of abstract systems are static and comparative operations that do not change the systems involved. The relational operations on abstract systems are described below.

Lemma 5. *The relational operations $\bullet_r$ in system algebra encompasses 6 comparative operators for manipulating the algebraic relations between abstract systems, i.e.:*

$$\bullet_r \triangleq \{\nleftrightarrow, \leftrightarrow, \prod, =, \sqsubset, \sqsupset\} \tag{22}$$

where the relational operators stand for independent, related, overlapped, equivalent, subsystem, and supersystem, respectively.

Algebraic Relations of Closed Systems

Relationships between two closed systems can be independent, equivalent, being subsystem, and being super system. The four relational operations of closed systems are defined as follows.

Definition 10. *Two closed systems $\widehat{S_1}$ and $\widehat{S_2}$ are independent, denoted by $\nleftrightarrow$, if both their component sets and relation sets are disjoint, i.e.:*

$$\widehat{S}_1(C_1, R_1, B_1, \Omega_1) \nleftrightarrow (\widehat{S}_2\ C_2, R_2, B_2, \Omega_2)$$
$$\triangleq C_1 \cap C_2 = \varnothing \wedge R_1 \cap R_2 = \varnothing \quad (23)$$

Definition 11. *Two closed systems $\widehat{S_1}$ and $\widehat{S_2}$ are equivalent, denoted by =, if all sets of components, relations, behaviors, and constraints are identical, i.e.:*

$$\widehat{S}_1(C_1, R_1, B_1, \Omega_1) = \widehat{S}_2(C_2, R_2, B_2, \Omega_2)$$
$$\triangleq C_1 = C_2 \wedge R_1 = R_2 \wedge B_1 = B_2 \wedge \Omega_1 = \Omega_2 \quad (24)$$

Definition 12. *A subsystem $\widehat{S}'$ is a system that is implicated in another system $\widehat{S}$, denoted by $\sqsubseteq$, i.e.:*

$$\widehat{S}'(C, R, B, \Omega) \sqsubseteq \widehat{S}(C, R, B, \Omega)$$
$$\triangleq C' \subseteq C \wedge R' \subseteq R \wedge B' \subseteq B \wedge \Omega' \subseteq \Omega \quad (25)$$

The aforementioned definition indicates that a subsystem of a closed system is a coherent part with all integrated components, internal/input/output relations, behaviors, constraints, and the environment.

Definition 13. *A supersystem $\widehat{S}$ is a system that consists of one or more subsystems S', denoted by $\sqsupseteq$, i.e.:*

$$\widehat{S}(C, R, B, \Omega) \sqsupseteq \widehat{S}'(C', R', B', \Omega')$$
$$\triangleq C' \subseteq C \wedge R' \subseteq R \wedge B' \subseteq B \wedge \Omega' \subseteq \Omega \quad (26)$$

Algebraic Relations of Open Systems

Relationships between two open systems can be independent, overlapped, related, equivalent, being subsystem, and being supersystem. The six compositional operations of open systems are defined as follows.

Definition 14. *Two open systems S_1 and S_2 are independent, denoted by $\nleftrightarrow$, if both their component sets and external relation sets are disjoint, i.e.:*

$$S_1(C_1, R_1^c, R_1^i, R_1^o, B_1, \Omega_1, \Theta_1) \nleftrightarrow$$
$$S_2(C_2, R_2^c, R_2^i, R_2^o, B_2, \Omega_2, \Theta_2)$$
$$\triangleq C_1 \cap C_2 = \varnothing \wedge R_1^i \cap R_2^i =$$
$$\varnothing \wedge R_1^o \cap R_2^o = \varnothing \quad (27)$$

Definition 15. *Two open systems S_1 and S_2 are overlapped, denoted by Π, if their component sets are joint, i.e.:*

$$S_1(C_1, R_1^c, R_1^i, R_1^o, B_1, \Omega_1, \Theta_1) \prod$$
$$S_2(C_2, R_2^c, R_2^i, R_2^o, B_2, \Omega_2, \Theta_2)$$
$$\triangleq C_1 \cap C_2 \neq \varnothing \quad (28)$$

Definition 16. *Two open systems S_1 and S_2 are related, denoted by $\leftrightarrow$, if either the sets of their input relations or output relations are overlapped, i.e.:*

$$S_1(C_1, R_1^c, R_1^i, R_1^o, B_1, \Omega_1, \Theta_1) \leftrightarrow$$
$$S_2(C_2, R_2^c, R_2^i, R_2^o, B_2, \Omega_2, \Theta_2)$$
$$\triangleq R_1^i \cap (R_2^0)^{-1} \neq \varnothing \vee R_2^i \cap (R_1^0)^{-1} \neq \varnothing \quad (29)$$

where $(R^0_1)^{-1}$ or $(R^0_2)^{-1}$ denotes an inverse relation, i.e., $\forall a \in C_1 \wedge b \in C_2$, $r(a, b) \in R^0_1 \Rightarrow r(b, a) \in (R^i_2) = (R^0_1)^{-1}$.

It is noteworthy that, by definition, there is no closed system that is related or overlapped.

Definition 17. *Two open systems S_1 and S_2 are equivalent, denoted by =, if all sets of components, relations, behaviors, constraints, and environments are identical, i.e.:*

$$S_1(C_1, R_1^c, R_1^i, R_1^o, B_1, \Omega_1, \Theta_1) =$$
$$S_2(C_2, R_2^c, R_2^i, R_2^o, B_2, \Omega_2, \Theta_2) \triangleq$$
$$C_1 = C_2 \wedge R_1^c = R_2^c \wedge R_1^i = R_2^i \wedge R_1^o =$$
$$R_2^o \wedge B_1 = B_2 \wedge \Omega_1 = \Omega_2 \wedge \Theta_1 = \Theta_2 \quad (30)$$

Definition 18. *A subsystem S' is a system that is implicated in another system S, denoted by* $\sqsubseteq$, *i.e.:*

$$S'(C', R^{c'}, R^{i'}, R^{o'}, B', \Omega', \Theta') \sqsubseteq S(C, R^c, R^i, R^o, B, \Omega, \Theta) \triangleq C' \subseteq C \wedge R^{c'} \subseteq R^c \wedge R^{i'} \subseteq R^i \wedge R^{o'} \subseteq R^o \wedge B' \subseteq B \wedge \Omega' \subseteq \Omega \wedge \Theta' = \Theta \quad (31)$$

The above definition indicates that a subsystem of an open system is a coherent part of it with all integrated components, internal/input/output relations, behaviors, and constraints. However, they share the same environment.

Definition 19. *A supersystem S is a system that consists of one or more subsystems S', denoted by* $\sqsupseteq$, *i.e.:*

$$S(C, R^c, R^i, R^o, B, \Omega, \Theta) \sqsupseteq S'(C', R^{c'}, R^{i'}, R^{o'}, B', \Omega', \Theta') \triangleq C' \subseteq C \wedge R^{c'} \subseteq R^c \wedge R^{i'} \subseteq R^i \wedge R^{o'} \subseteq R^o \wedge B' \subseteq B \wedge \Omega' \subseteq \Omega \wedge \Theta' = \Theta \quad (32)$$

Relations between Open and Closed Systems

Although, the previous subsections analyze the relations of closed and open systems separately, it is noteworthy that closed and open systems are transformable, when the environment of them is treated as a supersystem as well. This notion can be described in the following theorem and corollaries on the basis of Definitions 3 and 4.

Theorem 2. *The equivalence between open and closed systems states that an open system S is equivalent to a closed system* $\widehat{S}$, *or vice versa, when its environment* Θ_S *or* $\Theta_{\widehat{S}}$ *is conjoined, respectively, i.e.:*

$$\begin{cases} \widehat{S} = \mathrm{S} \sqcup \Theta_{\mathrm{S}} \\ \mathrm{S} = \widehat{S} \sqcup \Theta_{\widehat{\mathrm{S}}} \end{cases} \quad (33)$$

Theorem 2 can be proved by observing the embedded relation of close and open systems as illustrated in Figure 3. According to Theorem 2, the following properties of equivalence between closed and open systems can be derived.

Corollary 3. *Any subsystem* $\widehat{S_k}$ *of a closed system* $\widehat{S}$ *is an open system, i.e.:*

$$\forall \widehat{S_k} \subseteq \widehat{S} \Rightarrow R^i{}_k \neq \varnothing \wedge R^o{}_k \neq \varnothing \wedge \Theta_k = C_s \neq \varnothing \quad (34)$$

Corollary 4. *Any supersystem S of a given set of n open systems* S_k, *conjoining with their environments* Θ_k, $1 \le k \le n$, *is a closed systems, i.e.:*

$$\forall S_k, \forall \Theta_k, \ \widehat{S} = \mathop{R}_{k=1}^{n} (S_k \sqcup \Theta_k) \Rightarrow R_S{}^i = \varnothing \wedge R_S{}^o = \varnothing \wedge \Theta_S = \varnothing \quad (35)$$

where $\mathop{R}_{k=1}^{n} s_k$ is an operator known as the *big-R notation* (Wang, 2002, 2008a, 2008b, 2008c) that denotes a repetitive behavior or recurrent structure as defined in real-time process algebra (RTPA) (Wang, 2002, 2003, 2006a, 2006c, 2007a, 2007c, 2008a, 2008d).

COMPOSITIONAL OPERATIONS ON SYSTEMS

This section describes how abstract systems and their relations as modeled in previous sections may be manipulated by an algebraic system. The compositional operations of system algebra are dynamic and integrative operations that manipulate all systems involved in parallel. Compositional operations on abstract systems provide a set of fundamental mathematical means to construct complex systems on the basis of simple ones or to derive new systems on the basis of exiting ones.

Lemma 6. *The compositional operations* $\bullet_c$ *in system algebra encompasses 9 associative opera-*

tors for manipulating the algebraic compositions among abstract systems, i.e.:

$$\bullet_c \triangleq \{\Rightarrow, \underset{-}{\Rightarrow}, \underset{+}{\Rightarrow}, \underset{\sim}{\Rightarrow}, \boxminus, \uplus, \pitchfork, \Leftarrow, \vdash\} \tag{36}$$

where the compositional operators stand for system inheritance, tailoring, extension, substitute, difference, composition, decomposition, aggregation, and specification, respectively.

System Inheritance

Definition 20. *The inheritance of a closed system $\widehat{S_2}$ from a given system $\widehat{S_1}$, denoted by $\Rightarrow$, is the creation of the new system $\widehat{S_2}$ by reproducing $\widehat{S_1}$, i.e.:*

$$\begin{aligned}&\widehat{S_1}(C_1, R_1, B_1, \Omega_1) \Rightarrow \widehat{S_2}(C_2, R_2, B_2, \Omega_2)\\ &\triangleq \widehat{S_2}(C_2, R_2, B_2, \Omega_2 \mid C_2 = C_1, R_2 = R_1, B_2 = B_1, \Omega_2 = \Omega_1)\end{aligned} \tag{37}$$

where $\widehat{S_1}$ is called the parent system, $\widehat{S_2}$ the child system.

Similarly, the inheritance of open systems can be defined as follows.

Box 1.

$$\begin{aligned}&S_1(C_1, R_1^c, R_1^i, R_1^o, B_1, \Omega_1, \Theta_1) \Rightarrow S_2(C_2, R_2^c, R_2^i, R_2^o, B_2, \Omega_2, \Theta_2)\\ &\triangleq S_2(C_2, R_2^c, R_2^i, R_2^o, B_2, \Omega_2, \Theta_2 \mid C_2 = C_1, R_2^c = R_1^c,\\ &\quad R^i{}_2 = R^i{}_1 \cup \{C_1 \times C_2\}, R^o{}_2 = R^o{}_1 \cup \{C_2 \times C_1\},\\ &\quad B_2 = B_1\ \Omega_2 = \Omega_1, \Theta_2 = \Theta_1)\\ &\|\, S_1(C_1, R_1^c, R_1^{i'}, R_1^{o'}, B_1, \Omega_1, \Theta'_1 \mid R^{i'}{}_1 = R^i{}_1 \cup \{C_2 \times C_1\},\\ &\quad R^{o'}{}_1 = R^o{}_1 \cup \{C_1 \times C_2\}, \Theta'{}_1 = \Theta_1 \cup C_2)\end{aligned} \tag{38}$$

Box 2.

$$\begin{aligned}&\mathop{\|}_{i=1}^{n} S_i \Rightarrow (S\ C, R^c, R^i, R^o, B, \Omega, \Theta)\\ &\triangleq S(C, R^c, R^i, R^o, B, \Omega, \Theta \mid C = \bigcup_{i=1}^{n} C_i, R^c = \bigcup_{i=1}^{n} R^c{}_i, R^i = \bigcup_{i=1}^{n} R^i{}_i \cup \{\mathop{\|}_{i=1}^{n}(C_i \times C)\},\\ &\quad R^o = \bigcup_{i=1}^{n} R^o{}_i \cup \{\mathop{\|}_{i=1}^{n}(C \times C_i)\}, B = \bigcup_{i=1}^{n} B_i, \Omega = \bigcup_{i=1}^{n} \Omega_i, \Theta = \bigcup_{i=1}^{n} \Theta_i)\\ &\|\, \mathop{\|}_{i=1}^{n} S_i(C_i, R_i^c, R_i^i, R_i^o, B_i, \Omega_i, \Theta'_i \mid R^{i'}{}_i = R^i{}_i \cup \{C \times C_i\},\\ &\quad R^{o'}{}_i = R^o{}_i \cup \{C_i \times C\}, \Theta'{}_i = \Theta_i \cup C)\end{aligned} \tag{39}$$

Definition 21. *The inheritance of an open system S_2 from the parent system S_1, denoted by $\Rightarrow$, is the creation of the new system S_2 by reproducing S_1, and the establishment of new associations between them, see Box 1, where $||$ denotes that an open system inheritance creates new associations between S_1 and S_2 in parallel via (R^o_1, R^i_2) and (R^o_2, R^i_1).*

Definition 22. *The multiple inheritance of an open system S from n parent systems $S_1, S_2, \ldots, S_n$, denoted by $\Rightarrow$, is an inheritance that creates the new system S via a set of n conjoint systems and establishes new associations among them, see Box 2.*

System Tailoring

Definition 23. *The tailoring of a closed system $\widehat{S_2}$ from the parent system $\widehat{S_1}$, denoted by $\bar{\Rightarrow}$, is a special system inheritance that creates the new system $\widehat{S_2}$ based on $\widehat{S_1}$ with the removal of specific subsets of components C', behaviors B', and constraints Ω', see Box 3.*

Similarly, the tailoring of open systems can be defined as follows.

Definition 24. *The tailoring of an open system S_2 from the parent system S_1, denoted by $\bar{\Rightarrow}$, is a special system inheritance that creates the new system S_2 based on S_1 with the removal of specific subsets of components C', behaviors B', and constraints Ω'; and at the same time, it establishes new associations between them, see Box 4.*

System Extension

Definition 25. *The extension of a closed system $\widehat{S_2}$ from the parent system $\widehat{S_1}$, denoted by $\overset{+}{\Rightarrow}$, is a special*

Box 3.

$$\begin{aligned}&\widehat{S_1}(C_1, R_1, B_1, \Omega_1) \bar{\Rightarrow} \widehat{S_2}(C_2, R_2, B_2, \Omega_2)\\ &\triangleq \widehat{S_2}(C_2, R_2, B_2, \Omega_2 \mid C_2 = C_1 \setminus C', {R_2}^c = {R_1}^c \setminus \{C_1 \times C'\}\\ &\qquad B_2 = B_1 \setminus B', \Omega_2 = \Omega_1 \setminus \Omega')\end{aligned} \tag{40}$$

Box 4.

$$\begin{aligned}&S_1(C_1, {R_1}^c, {R_1}^i, {R_1}^o, B_1, \Omega_1, \Theta_1) \bar{\Rightarrow} S_2(C_2, {R_2}^c, {R_2}^i, {R_2}^o, B_2, \Omega_2, \Theta_2)\\ &\triangleq S_2(C_2, {R_2}^c, {R_2}^i, {R_2}^o, B_2, \Omega_2, \Theta_2 \mid C_2 = C_1 \setminus C', {R_2}^c = {R_1}^c \setminus \{C_1 \times C'\},\\ &\qquad {R^i}_2 = {R^i}_1 \cup \{C_1 \times C_2\}, {R^o}_2 = {R^o}_1 \cup \{C_2 \times C_1\},\\ &\qquad B_2 = B_1 \setminus B', \Omega_2 = \Omega_1 \setminus \Omega', \Theta_2 = \Theta_1)\\ &\mid\mid S_1(C_1, {R_1}^c, {R_1}^{i'}, {R_1}^{o'}, B_1, \Omega_1, {\Theta'}_1 \mid {R^{i'}}_1 = {R^i}_1 \cup \{C_2 \times C_1\},\\ &\qquad {R^{o'}}_1 = {R^o}_1 \cup \{C_1 \times C_2\}, {\Theta'}_1 = \Theta_1 \cup C_2)\end{aligned} \tag{41}$$

system inheritance that creates the new system $\widehat{S_2}$ based $\widehat{S_1}$ with additional subsets of components C′, behaviors B′, and constraints Ω′, see Box 5.

Similarly, the extension of open systems can be defined as follows.

Definition 26. *The extension of an open system S_2 from the parent system S_1, denoted by $\overset{+}{\Rightarrow}$, is a special system inheritance that creates the new system S_2 based S_1 with additional subsets of components C′, behaviors B′, and constraints Ω′; and at the same time, it establishes new associations between the two systems, see Box 6.*

System Substitution

Definition 27. *The substitute of a closed system $\widehat{S_2}$ from the parent system $\widehat{S_1}$, denoted by $\tilde{\Rightarrow}$, is a flexible system inheritance that creates the new system $\widehat{S_2}$ based on $\widehat{S_1}$ with the new subsets of components C'_{c2}, behaviors B'_{c2}, and constraints Ω'_{c2} to replace the corresponding inherited ones C'_{c1}, B'_{c1}, and Ω'_{c2} that share the same identifiers, see Box 7. Where $C'_{S1} \subset C_1 \wedge C'_{S2} \subset C_2 \wedge \#C'_{S1} = \#C'_{S2}$; $B'_{S1} \subset B_1 \wedge B'_{S2} \subset B_2 \wedge \#B'_{S1} = \#B'_{S2}$; and $\Omega'_{S1} \subset \Omega_1 \wedge \Omega'_{S2} \subset \Omega_2 \wedge \#\Omega'_{S1} = \#\Omega'_{S2}$. Similarly, the substitute of open systems can be defined as follows.*

Box 5.

$$\begin{aligned}
&\widehat{S_1}(C_1, R_1, B_1, \Omega_1) \overset{+}{\Rightarrow} \widehat{S_2}(C_2, R_2, B_2, \Omega_2) \\
&\triangleq \widehat{S_2}(C_2, R_2, B_2, \Omega_2 \mid C_2 = C_1 \cup C', {R_2}^c = {R_1}^c \cup \{C_1 \times C'\} \\
&\quad B_2 = B_1 \cup B', \Omega_2 = \Omega_1 \cup \Omega')
\end{aligned} \tag{42}$$

Box 6.

$$\begin{aligned}
&S_1(C_1, {R_1}^c, {R_1}^i, {R_1}^o, B_1, \Omega_1, \Theta_1) \overset{+}{\Rightarrow} (S_2\ C_2, {R_2}^c, {R_2}^i, {R_2}^o, B_2, \Omega_2, \Theta_2) \\
&\triangleq\ S_2(C_2, {R_2}^c, {R_2}^i, {R_2}^o, B_2, \Omega_2, \Theta_2 \mid C_2 = C_1 \cup C', {R_2}^c = {R_1}^c \cup \{C_1 \times C'\} \\
&\quad {R^i}_2 = {R^i}_1 \cup \{C_1 \times C_2\}, {R^o}_2 = {R^o}_1 \cup \{C_2 \times C_1\}, \\
&\quad B_2 = B_1 \cup B', \Omega_2 = \Omega_1 \cup \Omega', \Theta_2 = \Theta_1) \\
&\|\ S_1(C_1, {R_1}^c, {R_1}^{i'}, {R_1}^{o'}, B_1, \Omega_1, {\Theta'}_1 \mid {R^{i'}}_1 = {R^i}_1 \cup \{C_2 \times C_1\}, \\
&\quad {R^{o'}}_1 = {R^o}_1 \cup \{C_1 \times C_2\}, {\Theta'}_1 = \Theta_1 \cup C_2)
\end{aligned} \tag{43}$$

Definition 28. *The substitute of an open system S_2 from the parent system S_1, denoted by $\tilde{\Rightarrow}$, is a flexible system inheritance that creates the new system S_2 based on S_1 with the new subsets of components C'_{c2}, behaviors B'_{c2}, and constraints attributes Ω'_{c2} to replace the corresponding inherited ones C'_{c1}, B'_{c1}, and Ω'_{c2} that share the same identifiers; and at the same time, it establishes new associations between the two concepts, see Box 8. Where $C'_{S1} \subset C_1 \wedge C'_{S2} \subset C_2 \wedge \#C'_{S1} = \#C'_{S2}$; $B'_{S1} \subset B_1 \wedge B'_{S2} \subset B_2 \wedge \#B'_{S1} = \#B'_{S2}$; and $\Omega'_{S1} \subset \Omega_1 \wedge \Omega'_{S2} \subset \Omega_2 \wedge \#\Omega'_{S1} = \#\Omega'_{S2}$.*

Binary tailoring, extension, and substitution can also be extended to corresponding *n*-nary operations, similar to that of inheritance as given in Definitions 22.

System Composition

As a preparation to describe the important property of system relations, the mathematical calculus of incremental union between sets of relations is introduced below (Wang, 2006c, 2007c).

Definition 29. *An incremental union of two sets of relations R_1 and R_2, denoted by $\boxplus$, are a union of R_1 and R_2 plus a newly generated incremental set of relations ΔR_{12}, i.e.:*

$$R_1 \boxplus R_2 \triangleq R_1 \cup R_2 \cup \Delta R_{12} \tag{46}$$

where

$\Delta R_{12} \not\subseteq R_1 \wedge \Delta R_{12} \not\subseteq R_2$, *but* $\Delta R_{12} \subseteq R_1 \boxplus R_2$.

Box 7.

$$\begin{aligned}
&\widehat{S}_1(C_1, R_1, B_1, \Omega_1) \tilde{\Rightarrow} \widehat{S}_2(C_2, R_2, B_2, \Omega_2) \\
&\triangleq \widehat{S}_2(C_2, R_2, B_2, \Omega_2 \mid C_2 = (C_1 \setminus C'_{S_1}) \cup C'_{S_2}, R_2^c = (R_1^c \setminus (C_1 \times C'_{S_1}))\ (\cup\ C_1 \times C'_{S_2}), \\
&\qquad (B_2 = B_1 \setminus B'_{S_1}) \cup B'_{S_2}, \Omega_2 = (\Omega_1 \setminus \Omega'_{S_1}) \cup \Omega'_{S_2})
\end{aligned} \tag{44}$$

Box 8.

$$\begin{aligned}
&S_1(C_1, R_1^c, R_1^i, R_1^o, B_1, \Omega_1, \Theta_1) \tilde{\Rightarrow} S_2(C_2, R_2^c, R_2^i, R_2^o, B_2, \Omega_2, \Theta_2) \\
&\triangleq S_2(C_2, R_2^c, R_2^i, R_2^o, B_2, \Omega_2, \Theta_2 \mid C_2 = (C_1 \setminus C'_{S_1}) \cup C'_{S_2}, \\
&\qquad R_2^c = (R_1^c \setminus \{C_1 \times C'_{S_1}\})\ \cup \{C_1 \times C'_{S_2}\}, R^i{}_2 = R^i{}_1 \cup \{C_1 \times C_2\}, \\
&\qquad R^o{}_2 = R^o{}_1 \cup \{C_2 \times C_1\}, B_2 = (B_1 \setminus B'_{S_1}) \cup B'_{S_2}, \Omega_2 = (\Omega_1 \setminus \Omega'_{S_1}) \cup \Omega'_{S_2}, \Theta_2 = \Theta_1) \\
&\mid\mid S_1(C_1, R_1^c, R_1^{i'}, R_1^{o'}, B_1, \Omega_1, \Theta'_1 \mid R^{i'}{}_1 = R^i{}_1 \cup \{C_2 \times C_1\}, R^{o'}{}_1 = R^o{}_1 \cup \{C_1 \times C_2\}, \\
&\qquad \Theta'_1 = \Theta_1 \cup C_2)
\end{aligned} \tag{45}$$

The number of the incremental relations ΔR_{12} generated in the incremental union can be determined as stated in the following theorem.

Theorem 3. *The maximum number of newly gained relations ΔR_{12} obtained during the incremental union of two sets of relations is a product of the numbers of elements of the two sets $\#C_1$ and $\#C_2$, i.e.:*

$$\Delta R_{12} = 2(\#C_1 \bullet \#C_2) = 2n_{c_1} n_{c_2}) \tag{47}$$

Proof: *Because ΔR_{12} is the difference between the relations of the newly generated entire system $\#R$ and those of the independent systems $\#R_1$ and $\#R_2$, according to Corollaries 1 and 2, Theorem 3 is proved by the following inference process:*

$$\begin{aligned}\Delta R_{12} &= \#R - (\#R_1 + \#R_2) \\ &= (n_{c_1} + n_{c_2})^2 - ({n_{c_1}}^2 + {n_{c_2}}^2) \\ &= ({n_{c_1}}^2 + 2n_{c_1} n_{c_2} + {n_{c_2}}^2) - ({n_{c_1}}^2 + {n_{c_2}}^2) \\ &= 2n_{c_1} n_{c_2}\end{aligned} \tag{48}$$

The incremental union of relations reveals an important property of systems, which indicates that the merge of two systems results in new relations, behaviors, functions, and/or constraints that are not belong to any original individual subsystems. Theorem 3 can be used to predict the maximum numbers of newly established relations, behaviors, and/or constraints in a composition of two systems. According to Theorem 3, the maximum *incremental system gain* equals to the number of by-directly interconnection between all components in both S_1 and S_2, i.e., $2(\#C_1 \bullet \#C_2)$.

Definition 29 can be extended to *n*-nary incremental unions for multiple sets of relations.

Definition 30. *The n-nary incremental union for multiple sets of relations,*

$$\biguplus_{i=1}^{n} R_i,$$

is a series of cumulative binary incremental unions as in Box 9.

Based on the calculus of incremental union of sets of relations, system compositions can be defined as follows.

Definition 31. *The composition of two closed systems $\widehat{S_1}$ and $\widehat{S_2}$, denoted by $\uplus$, results in a super system $\widehat{S}$ that is formed by union of sets of components and environments, as well as incremental union of sets of relations, behaviors, and constraints, respectively, see Box 10.*

Theorem 4. *The system fusion principle states that new relations ΔR_{12}, new behaviors (functions) ΔB_{12}, and new constraints $\Delta\Omega_{12}$, generated in system compositions are solely a property of the new super system $\widehat{S}$, but not belong to any of the independent subsystems, i.e.:*

Box 9.

$$\begin{aligned}\biguplus_{i=1}^{n} R_i &\triangleq \mathop{\mathbf{R}}_{i=1}^{n-1}(R_i \cup R_j \cup \Delta R_{ij}),\ j = i+1 \\ &= (...((R_1 \cup R_2 \cup \Delta R_{12}) \cup R_3 \cup \Delta R_{2'3})\ \cup ...) \cup R_n \cup \Delta R_{n-1',n}\end{aligned} \tag{49}$$

Box 10.

$$\begin{aligned}
&\widehat{S_1}(C_1, R_1, B_1, \Omega_1) \uplus \widehat{S_2}(C_2, R_2, B_2, \Omega_2) \\
&\triangleq \widehat{S}(C, R, B, \Omega \mid C = C_1 \cup C_2, R = R_1 \boxplus R_2, B = B_1 \boxplus B_2, \Omega = \Omega_1 \boxplus \Omega_2) \\
&= \widehat{S}(C, R, B, \Omega \mid C = C_1 \cup C_2, R = R_1 \cup R_2 \cup \Delta R_{12}, \\
&\qquad\qquad B = B_1 \cup B_2 \cup \Delta B_{12},\ \Omega = \Omega_1 \cup \Omega_2 \cup \Delta\Omega_{12})
\end{aligned} \tag{50}$$

$$\Delta R_{12} \in \widehat{S} \wedge (\Delta R_{12} \notin \widehat{S_1} \wedge \Delta R_{12} \notin \widehat{S_2}) \tag{51.a}$$

$$\Delta B_{12} \in \widehat{S} \wedge (\Delta B_{12} \notin \widehat{S_1} \wedge \Delta B_{12} \notin \widehat{S_2}) \tag{51.b}$$

$$\Delta\Omega_{12} \in \widehat{S} \wedge (\Delta\Omega_{12} \notin \widehat{S_1} \wedge \Delta\Omega_{12} \notin \widehat{S_2}) \tag{51.c}$$

where E denote a membership relation of a given set in a system.

The discovery in Theorems 3 and 4 reveal that the nature of system utilities can be rigorously explained as the newly gained relations ΔR_{12}, as well as behaviors ΔB_{12} and constraints $\Delta\Omega_{12}$, during the composition of two or more systems. The empirical awareness of this key system property has been intuitively or qualitatively described in the literature of system science (Ellis & Fred, 1962; G. J. Klir, 1992). However, Theorems 3 and 4 are the first mathematical explanation of the mechanism of system gains during system compositions (Wang, 2006b, 2007c).

More generally, Definition 31 and Theorem 4 can be extended to open systems.

Definition 32. *The composition of two open systems S_1 and S_2, denoted by $\uplus$, results in a super system S that is formed by simple conjunctions both of sets of components and environments, as well as incremental unions of sets of relations, behaviors, and constraints, respectively, see Box 11.*

The operation of open system composition is illustrated in Figure 4, where the generation of the new relations ΔR^c_1 and ΔR^c_2 in S after the composition of S_1 and S_2 can be observed.

System compositions as modeled in Definitions 31 and 32 can be extended to *n*-nary compositions as follows.

Definition 33. *The composition of multiple open systems, denoted by*

$$\biguplus_{i=1}^{n} S_i,$$

is an iterative integration of a pair of systems, which cumulatively creates the new supersystem S, see Box 12.

The composition of multiple closed systems is similar to Definition 33, which can be tailored from Equation 53.

System composition at the top level is a complicated algebraic operation that integrates two or

Box 11.

\end{aligned}
\tag{53}
$$

Figure 5. Basic types of system structural relations in system compositions

No.	Type of composition	Syntax	Example
1	Parallel	$S_1 \parallel S_2$	$S \triangleq S_1 \parallel S_2 \parallel \ldots \parallel S_n$ 2	Serial	$S_1 \rightarrow S_2$	$S \triangleq S_1 \rightarrow S_2 \rightarrow \ldots \rightarrow S_n$ 
3	Nested	$S_1 \rightarrowtail S_2$	$S \triangleq S_1 \rightarrowtail S_2 \rightarrowtail \ldots \rightarrowtail S_n$ 
more systems into a supersystem with a hierarchical architecture. There are three basic types of system structural relations in system composition known as *parallel* (||), *serial* (→), and *nested* (↣) as shown in Figure 5. Complex system compositions can be represented by a combination of these three meta-architectural relations between subsystems. The syntaxes and semantics of these three system relations in system compositions can be referred to related definitions in RTPA (Wang, 2002, 2003, 2006c, 2007c, 2008a, 2008d).

According to Definition 33, a system can be integrated from the bottom up by a series of compositions, level-by-level, in a system hierarchy.

Example 3. *A composed system S(C, R, B, Ω ,Θ) as given in Figure 6 can be formally described as follows:*

$$S(C, R, B, \Omega\ \Theta) \triangleq S_1 \parallel S_2 \parallel \ldots \parallel S_x$$

in which the subsystems of S can be refined as in Box 13.

System Difference

Definition 34. *The difference between a closed systems $\widehat{S}$ and its subsystem $\widehat{S_1}$, denoted by ⊟, results in a closed subsystem $\widehat{S_2}$ that is formed by the difference of sets of components (C_1), and the differences of the internal relations, behaviors, and constraints (R_1, B_1, Ω_1) with their incremental counterparts (ΔR_{12}, ΔB_{12}, $\Delta\Omega_{12}$), see Box 14.*

According to Definition 34, a difference of a subsystem from a system $\widehat{S}$, will result in the removal of not only the given subsystem but also all

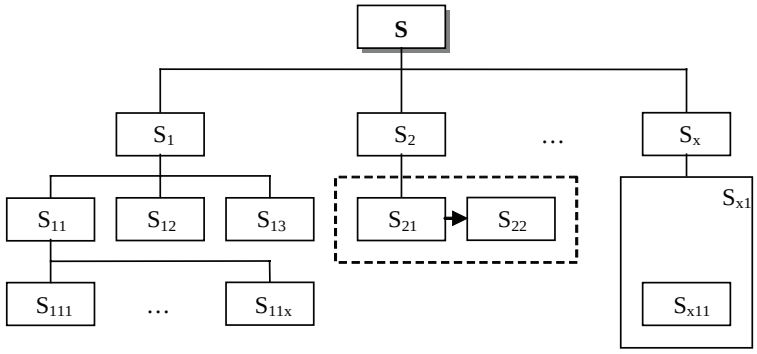
Box 13.

$$S_1(C_1, R_1, B_1, \Omega_1, \Theta_1) \triangleq S_{11} \| S_{12} \| S_{13} = (S_{111} \| .. \| S_{11x}) \| S_{12} \| S_{13}$$

$$S_2(C_2, R_2, B_2, \Omega_2, \Theta_2) \triangleq S_{21} \rightarrow S_{22}$$

$$S_x(C_x, R_x, B_x, \Omega_x, \Theta_x) \triangleq S_{x1} \rightarrowtail S_{x11}$$

Figure 6. The hierarchical structure of system compositions



Box 14.

$$\begin{aligned}&\widehat{S}(C, R, B, \Omega) \boxminus \widehat{S_1}(C_1, R_1, B_1, \Omega_1)\\ &\triangleq \widehat{S_2}(C_2, R_2, B_2, \Omega_2 \mid C_2 = C \setminus C_1, R_2 = R \setminus (R_1 \cup \Delta R_{12}),\\ &\qquad B_2 = B \setminus (B_1 \cup \Delta B_{12}), \Omega_2 = \Omega \setminus (\Omega_1 \cup \Delta \Omega_{12}))\end{aligned} \tag{54}$$

interrelations and incremental behaviors between the subsystem and other subsystem in it.

Similarly, the difference of open systems can be defined as follows.

Definition 35. *The difference between an open systems S and its subsystem S_1, denoted by ⊟, results in an open subsystem S_2 that is formed by the difference of sets of components and I/O relations*

(C_1, R^i_1, R^o_1), and the differences of the internal relations, behaviors, and constraints (R^c_1, B_1, Ω_1) with their incremental counterparts (ΔR^c_{12}, ΔB_{12}, $\Delta\Omega_{12}$), see Box 15.

The operation of open system difference can also be illustrated by Figure 4, where S_1 and all related I/O relations should be removed in the operation $S_2 = S \boxminus S_1$,.

System Decomposition

A system decomposition is an inverse operation of system composition that breaks up a system into two or more subsystems. System decomposition can be described based on the concept of system difference, which is an inversed operation of the incremental union of sets.

Definition 36. *The decomposition of an open systems S, denoted by* $\pitchfork$*, is to break up S into two or more subsystems at a given level of the system hierarchy by one of the compositional relations* $R_c = \{||, \rightarrow, \rightarrowtail\}$*, see Box16.*

As specified in Definition 36, the decomposition operation results in the removal of all internal relations $\Delta R_{ij}{}^c = C_i \times C_j, 1 \le i, j \le n$ that are no longer belong to any of its subsystems.

Box 15.

$$
\begin{aligned}
&S(C, R^c, R^i, R^o, B, \Omega, \Theta) \boxminus S_1(C_1, R_1{}^c, R_1{}^i, R_1{}^o, B_1, \Omega_1, \Theta_1) \\
&\triangleq S_2(C_2, R_2{}^c, R_2{}^i, R_2{}^o, B_2, \Omega_2, \Theta_2 \mid C_2 = C \setminus C_1, R_2{}^c = R^c \setminus (R_1{}^c \cup \Delta R_{12}{}^c), \\
&\quad R_2{}^i = R^i \setminus R_1{}^i, R_2{}^o = R^o \setminus R_1{}^o, B_2 = B \setminus (B_1 \cup \Delta B_{12}), \\
&\quad \Omega_2 = \Omega \setminus (\Omega_1 \cup \Delta\Omega_{12}), \Theta_2 = \Theta_1)
\end{aligned}
\tag{55}
$$

Box 16.

$$
\begin{aligned}
&S(C, R^c, R^i, R^o, B, \Omega, \Theta) \pitchfork_{i=1}^{n} \S_i \ C_i, R_i{}^c, R_i{}^i, R_i{}^o, B_i, \Omega_i, \Theta_i) \\
&\triangleq \mathop{\mathrm{R}}_{i=1}^{n} \{ \ S_i(C_i, R^c{}_i, R^{i'}{}_i, R^{o'}{}_i, B_i, \Omega_i, \Theta'{}_i \mid R^{i'}{}_i = R^i{}_i \cup \{C \times C_i\}, \\
&\qquad R^{o'}{}_i = R^o{}_i \cup \{C_i \times C\}, \Theta'{}_i = \Theta_i \cup C) \\
&\quad \| \ S(C, R^c, R^i, R^o, B, \Omega, \Theta) \boxminus S_i(C_i, R_i{}^c, R_i{}^i, R_i{}^o, B_i, \Omega_i, \Theta_i) \\
&\quad \}
\end{aligned}
\tag{56}
$$

Similarly, the decomposition of a closed system into multiple subsystems can be defined as follows.

Definition 37. *The decomposition of a closed system $\widehat{S}$, denoted by $\pitchfork$, is to break up $\widehat{S}$ into two or more subsystems at a given level of the system hierarchy by one of the compositional relations $R_c = \{||, \rightarrow, \rightarrowtail\}$, see Box17.*

Definitions 36 and 37 indicate that either an open or a closed system can be resolved from the top down by a series of decompositions, level-by-level, in the system hierarchy. It is noteworthy that both open and closed system decompositions result in a set of open subsystems.

System Aggregation

Definition 38. *The aggregation of a closed system $\widehat{S}$ from a set of n peer systems $\widehat{S}_i$, $1 \le i \le n$, denoted by $\Leftarrow$, is an aggregation of $\widehat{S}$ with the elicitation of interested subsets of components C'_i, behaviors B'_i, and constraints Ω'_i, see Box 18. Similarly, the aggregation of open systems can be defined as follows.*

Definition 39. *The aggregation of an open system S from a set of n peer systems S_i, $1 \le i \le n$, denoted by $\Leftarrow$, is an aggregation of S with the elicitation of interested subsets of components C'_i, behaviors B'_i, and constraints Ω'_i; and at the same time, it establishes new associations among all aggregated*

Box 17.

$$\begin{aligned}
&\hat{S}(C,R,B,\Omega) \pitchfork_{i=1}^{n} \widehat{S}_i(C_i,R_i,B_i,\Omega_i) \\
&\triangleq \mathop{R}_{i=1}^{n}\{\ S_i(C_i,R^c{}_i,R^i{}_i,R^o{}_i,B_i,\Omega_i,\Theta_i \mid R^i{}_i = (C\times C_i), R^o{}_i = (C_i\times C), \Theta_i = C) \\
&\quad \| \ \hat{S}(C,R,B,\Omega) \boxminus \widehat{S}_i(C_i,R_i,B_i,\Omega_i) \\
&\quad \}
\end{aligned} \tag{57}$$

Box 18.

$$\begin{aligned}
&S(C,R,B,\Omega) \Leftarrow \mathop{R}_{i=1}^{n}(S_i\ C_i,R_i,B_i,\Omega_i) \\
&\triangleq S(C,R,B,\Omega \mid C = \bigcup_{i=1}^{n} C'_i \subseteq C_i, R = C\times C, \\
&\qquad\qquad B = \bigcup_{i=1}^{n} B_i \subseteq B_i,\ \Omega = \bigcup_{i=1}^{n} C'_i \subseteq C_i)
\end{aligned} \tag{58}$$

Box 19.

$$S(C, R^c, R^i, R^o, B, \Omega, \Theta) \Leftarrow \mathop{R}_{i=1}^{n} S_i(C_i, R_i^c, R_i^i, R_i^o, B_i, \Omega_i, \Theta_i)$$

$$\hat{=} S(C, R^c, R^i, R^o, B, \Omega, \Theta \mid C = \bigcup_{i=1}^{n} C'_i \subseteq C_i, R^c = \{C \times C\},$$

$$R^i = \bigcup_{i=1}^{n} (R^i_i \cup \{C_i \times C\}), R^o = \bigcup_{i=1}^{n} (R^o_i \cup \{C \times C_i\}),$$

$$B = \bigcup_{i=1}^{n} B'_i \subseteq B_i,\ \Omega = \bigcup_{i=1}^{n} C'_i \subseteq C_i,\ \Theta \subseteq C_\Theta \cup \bigcup_{i=1}^{n} \Theta_i)$$

$$|| \mathop{R}_{i=1}^{n} S_i(C_i, R_i^c, R_i^{i'}, R_i^{o'}, B_i, \Omega_i, \Theta'_i \mid R^{i'}_i = R^i_i \cup \{C \times C_i\},$$

$$R^{o'}_i = R^o_i \cup \{C_i \times C\}, \Theta'_i = \Theta_i \cup C) \quad (59)$$

systems, see Box 19. System aggregation is also known as system elicitation.

According to Definitions 32 and 39, the difference between system composition and aggregation is that the former constructs a new system by integrating a set of entire systems as subsystems while the latter constructs a new system by eliciting interested subsets of components, behaviors, and/or constraints from a set of individual and independent systems.

System Specification

A system specification is an inverse operation of system aggregation. System specification is usually operated in a series of refinements.

Definition 40. *The specification of a closed system $\widehat{S}_0$ by a set of n refined systems $\widehat{S}_i$, $1 \le i \le n$, denoted by $\vdash$, is a specification of $\widehat{S}_0$ with a total order of a series of refinements by increasingly specific and detailed components C_i, behaviors B_i, and constraints Ω_i, see Box 20.*

Similarly, the specification of open systems can be defined as follows.

Definition 41. *The specification of an open system S_0 by a set of n refined systems S_i, $1 \le i \le n$, denoted by $\vdash$, is a specification of S_0 with a total order of a series of refinements by increasingly specific and detailed components C_i, behaviors B_i, and constraints Ω_{ij}; and at the same time, it establishes new associations among all refining systems, see Box 21.*

System specification is a refinement process where more specific and detailed components, behaviors, and constraints are developed in a consistent and coherent top-down hierarchy. The major tasks of system specifications are system architecture (component) and behavior specifications, which can be further refined by the Com-

Box 20.

&\triangleq S_0(C_0, R_0^c, R_0^i, R_0^o, B_0, \Omega_0, \Theta_0 \mid C_0 = \overset{n}{\underset{i=1}{R}}(C_{i-1} \subset C_i), R_0^c = \{C_0 \times C_0\}, \\
&\quad R_0^i = \bigcup_{i=1}^{n}(R^i{}_i \cup \{C_i \times C_0\}), R_0^o = \bigcup_{i=1}^{n}(R^o{}_i \cup \{C_0 \times C_i\}), \\
&\quad B_0 = \overset{n}{\underset{i=1}{R}}(B_{i-1} \subset B_i),\ \Omega_0 = \overset{n}{\underset{i=1}{R}}(B_{i-1} \subset B_i),\ \Theta_0 = \Theta_1 = \Theta_2 = .. = \Theta_n) \\
&\mid\mid \overset{n}{\underset{i=1}{R}} S_i(C_i, R_i^c, R_i^{i'}, R_i^{o'}, B_i, \Omega_i, \Theta'_i \mid R_i^{i'} = R_i^i \cup \{C_0 \times C_i\}, \\
&\quad R_i^{o'} = R_i^o \cup \{C_i \times C_o\}, \Theta'_i = \Theta_i \cup C_0))
\end{aligned}
\tag{61}
$$

ponent Logical Models (CLMs) and processes as provided in RTPA (Wang, 2002, 2003, 2006a, 2006c, 2007c, 2008a, 2008d).

CONCLUSION

A new mathematical structure of abstract systems has been presented as the most complicated mathematical entities beyond sets, functions, concepts, and processes. A formal and rigorous treatment of abstract systems as well as their taxonomy and properties has been described. System algebra has been introduced as a set of relational and compositional operations for manipulating abstract systems and their composing rules. The former have been elicited as the algebraic operations of *independent*, *related*, *overlapped*, *equivalent*,

subsystem, and *supersystem*. The latter have been identified as the algebraic operations of *inheritance*, *tailoring*, *extension*, *substitute*, *difference*, *composition*, *decomposition*, *aggregation*, and *specification*. A wide range of applications of system algebra has been recognized in cognitive informatics, system science, system engineering, computing, and software engineering. System algebra has formed a fundamental theory for denoting the rigorous semantics of conventional object-oriented design notations and methodologies such as UML in software and intelligent system engineering.

Chapter 7.27
A Cognitive Informatics Reference Model of Autonomous Agent Systems (AAS)

Yingxu Wang
University of Calgary, Canada

ABSTRACT

Despite the fact that the origin of software agent systems has been rooted in autonomous artificial intelligence and cognitive psychology, their implementations are still based on conventional imperative computing techniques rather than autonomous computational intelligence. This paper presents a cognitive informatics perspective on autonomous agent systems (AAS's). A hierarchical reference model of AAS's is developed, which reveals that an autonomous agent possesses intelligent behaviors at three layers known as those of imperative, autonomic, and autonomous from the bottom up. The theoretical framework of AAS's is described from the facets of cognitive informatics, computational intelligence, and denotational mathematics. According to Wang's abstract intelligence theory, an autonomous software agent is supposed to be called as an intelligent-ware, shortly, an intelware, parallel to hardware and software in computing, information science, and artificial intelligence.

INTRODUCTION

A *software agent* is an intelligent software system that autonomously carries out robotic and interactive applications based on goal-driven cognitive mechanisms. The studies on software agent are rooted in the essences of computing science and cognitive science such as automata theory (von Neumann, 1946, 1958, 1963, 1966; Shannon, 1956), Turing machines (Turing, 1950), cognitive psychology (Newell, 1990; Sternberg, 1997; Anderson and Rosenfeld, 1998; Matlin, 1998), artificial intelligence (*McCarthy,* 1955,

1963; McCulloch, 1943, 1965; Barr and Feigenbaum, 1981), computational intelligence (Poole et al., 1997; Wang, 2008a), and decision theories (Wald, 1950; Newell and Simon, 1972; Berger et al., 1990; Bronson and Naadimuthu, 1997; Wang and Ruhe, 2007; Wang, 2008b).

The history towards software agents may be traced back to the work as early as in the 1940s. J. *McCarthy*, W. McCulloch, *M.L. Minsky, N. Rochester, and C.E. Shannon* proposed the term *Artificial Intelligence* (AI) (*McCarthy,* 1955, 1963; McCulloch, 1943, 1965). S.C. Kleene analyzed the relations of *automata* and nerve nets (Kleene, 1956). Then, Bernard Widrow developed the technology of *artificial neural networks* in the 1950s (Widrow and Lehr, 1990). The concepts of *robotics* (Brooks, 1970) and *expert systems* (Giarrantans and Riley, 1989) were developed in the 1970s and 1980s, respectively. In 1992, the notion of *genetic algorithms* was proposed by J.H. Holland (Holland, 1992). Then, *distributed artificial intelligence* and *intelligent system* technologies emerged since late 1980s (Bond and Gasser, 1988; Kurzweil, 1990; Chaib-Draa et al., 1992; Meystel and Albus, 2002, Meystel and Albus, 2002).

The origin of the term *autonomous agent* is based on Carl Hewitt and his colleagues' *artificial intelligence actor models* proposed in 1973 (Hewitt et al., 1973, 1991). Then, as a novel approach of artificial intelligence, agent technologies have been proliferated since the early 1990s (Foner, 1993; Genesereth and Ketchpel, 1994; Hayes-Roth, 1995; Axelrod, 1997; Huhns and Singh, 1997; Wooldridge and Jenings, 1995; Wooldridge, 2002, Wang, 2003b). Pattie Maes perceived that a software agent is a process that lives in the world of computers and networks and that can operate autonomously to fulfill a set of tasks (Maes, 1991). Dimitris N. Chorafas described a software agent as a new software paradigm of things that think (Chorafas, 1998). Software agents are characterized by knowledge, learning, reasoning, and adaptation, which are rational to the extent that their behaviors are predictable by given goals and the solution environment (Russell and Norvig 1995; Poole, Mackworth, and Goebel 1997; Nilsson 1998).

Multi-agent systems are proposed in (Wittig, 1992; Wellman, 1999) as distributed intelligent systems (Bond and Gasser, 1988) in which each node is an autonomous software agent. The key technology of autonomous agent systems is how a variety of heterogeneous agents allocate their roles, coordinate their behaviors, share their resources, and communicate their information, beliefs, and needs (Maes, 1991). The interaction mechanisms of multi-agent systems, such as cooperation, negotiation, belief reconciliation, information sharing, and distributed decision making, are identified as important issues in the design and implementation of multi-agent systems.

Autonomic computing is one of the fundamental technologies of software agents, which is a mimicry and simulation of the natural intelligence possessed by the brain using general computers. Autonomic computing was first proposed by IBM in 2001, where it is perceived that "Autonomic computing is an approach to self-managed computing systems with a minimum of human interference. The term derives from the body's autonomous nervous system, which controls key functions without conscious awareness or involvement (IBM, 2006)." Various studies on autonomic computing have been reported following the IBM initiative (Kephart and Chess, 2003; Murch, 2004; Wang, 2004).

According to Wang's *abstract intelligence* theory (Wang, 2008a, 2009), software agents are a paradigm of abstract and computational intelligence, which is a subset of or an application-specific virtual brain. Behaviors of a software agent are mirrored human behaviors. Therefore, a software agent may be more accurately named as an *intelligent-ware*, shortly, an *intelware*, parallel to hardware and software in computing,

information science, and artificial intelligence. In this notion, intelware will be treated as a synonym of an autonomous agent system.

This paper presents a coherent theoretical framework of autonomous agent systems (AAS's) or *intelware* from the facets of cognitive informatics, computational intelligence, and denotational mathematics. The nature of software agents and intelware is elaborated. A reference model of AAS with intelligent behaviors at three layers known as those of imperative, autonomic, and autonomous is developed from the bottom up. The theoretical framework of AAS's/intelware is presented on the basis of cognitive informatics and computational intelligence theories. A set of denotational mathematics is introduced in order to provide a fundamental mathematical means for formally and rigorously dealing with the highly complicated architectures and intricate behaviors of AAS's and intelware.

THE NATURE OF SOFTWARE AGENTS AND INTELWARE

Definition 1. *A software agent, or more actually an intelware, is an intelligent software system that autonomously carries out robotistic and interactive applications based on goal-driven cognitive mechanisms.*

On the basis of Definition 1, an autonomous agent is a software agent that possesses high-level autonomous ability and behaviors beyond conventional imperative computing technologies.

Definition 2. *An Autonomous Agent System (AAS) is a composition of distributed agents that possesses autonomous computing and decision making abilities as well as interactive communication capability to peers and the environment.*

The classification of agent/intelware technologies can be described in Table 1, where *I* and *O* denote the inputs/outputs of a given AAS. When both input event (I) and output behavior (O) are constant, it denotes a *routine* intelware; while when both *I/O* are variable, it represents the most complicated *autonomous* intelware. Otherwise, the combinations of variable event/constant behavior and constant event/variable behaviors indicate an *algorithmic* or *autonomic* intelware, respectively.

In Table 1, the routine and algorithmic AAS's may be implemented by computational imperative behaviors. However, the autonomic AAS's should be implemented by autonomic computing, as that of the autonomous AAS's by autonomous mechanisms and behaviors.

Table 1. Classification of intelware / AAS's

		Behavior (O)	
		Constant	Variable
Event (I)	Constant	*Routine*	*Autonomic*
	Variable	*Algorithmic*	*Autonomous*

THE REFERENCE MODEL OF INTELWARE/AUTONOMOUS AGENT SYSTEMS

The reference model of intelware/AAS's is a hierarchical model with three layers known as those of imperative, autonomic, and autonomous behaviors. This section elaborates the mathematical models of the imperative and intelligent behaviors of intelware/AAS's in the layered reference model of agent intelligence.

The Hierarchical Behavioral Model of Intelware/AAS's

Behaviorism is a doctrine of psychology and cognitive informatics that describes the association between a given stimulus and an observed response of human brains and AAS's. Cognitive informatics reveals that human and AAS behaviors may be classified into four categories known as the *perceptive*, *cognitive*, *instructive*, and *reflective* behaviors (Wang, 2007b).

The reference model of AAS's (RMAAS) is a hierarchical behavioral model of agent intelligence as illustrated in Figure 1. In the RMAAS model, the hierarchy of agent behaviors can be divided into the imperative, autonomic, and autonomous layers. Conventional computing machines are implemented only by imperative behaviors. However, the autonomic computing systems and AAS's are implemented by advanced cognitive behaviors. *Imperative computing* is an enclosure of instructive and passive behaviors. The *autonomic computing* is an enclosure of internally motivated behaviors beyond those of the imperative space. The *autonomous computing* is an enclosure of perceptive- and inference-driven behaviors beyond those of both imperative and autonomic computing. More formal descriptions of the three types of behaviors of AAS's will be presented in the following subsections.

The Imperative Behavioral Layer of Intelware/AAS's

According to the RMAAS model as illustrated in Figure 1, the imperative behavioral intelligence of intelware and AAS's can be formally modeled and elaborated in this subsection.

Definition 3. *The imperative behavioral layer of AAS's, B_I, is a set of instruction-based behaviors such as the event-driven behaviors (B_e), time-driven behaviors (B_t), and interrupt-driven behaviors (B_{int}), i.e.:*

$$B_I \triangleq \{B_e, B_t, B_{int}\} \quad (1)$$

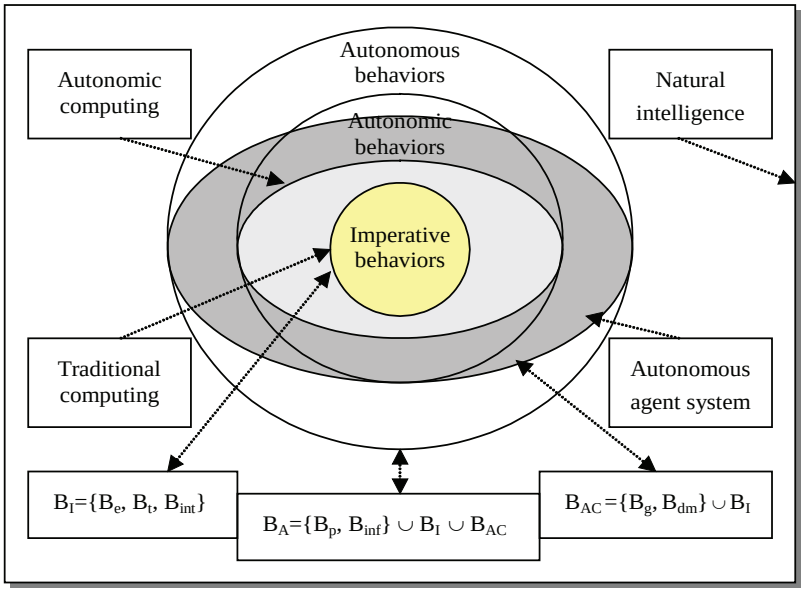
An imperative system implemented with B_I may do nothing unless a specific program is loaded, in which the stored program transfers a general-purpose computer to a specific intelligent application. The imperative system is a passive system that implements deterministic, context-free, and stored-program controlled behaviors.

Definition 4. *An event is an abstract variable that represents an external stimulus to a system or the occurring of an internal change of status, such as an action of users, an updating of the environment, and a change of the value of a control variable.*

The types of events that may trigger a behavior can be classified into operational (@*e*S), time (@*t*TM), and interrupt (@*int*⦿) events, where @ is the *event prefix*, and S, TM, and □ the type suffixes, respectively. The *interrupt event* is a kind of special event that models the interruption of an executing process, the temporal handover of controls to an Interrupt Service Routine (ISR), and the return of control after its completion.

Definition 5. *An interrupt, denoted by ↯, is a parallel process relation in which a running process*

Figure 1. The hierarchical reference model of autonomous agent systems (RMAAS)



P is temporarily held by another higher priority process Q via an interrupt event @int⊙ at the interrupt point ⊙, and the interrupted process will be resumed when the high priority process has been completed, i.e.:

$$P \lightning Q \triangleq P \,||\, (@int\odot \nearrow Q \searrow \odot) \qquad (2)$$

where ↗ and ↘ denote an interrupt service and an interrupt return, respectively.

In general, all types of events, including the operational events, timing events, and interrupt events, are captured by the system in order to dispatch a designated behavior.

Definition 6. *An event-driven behavior B_e, denoted by $\hookrightarrow_e$, is an imperative process in which the ith behavior in term of a designated process P_i is triggered by a predefined event $@e_i$S, i.e.:*

$$B_e \triangleq \mathop{\mathrm{R}}_{i=1}^{n} (@e_i\mathrm{S} \hookrightarrow_e P_i) \qquad (3)$$

where the big-R notation is a mathematical calculus that denotes a sequence of repetitive/iterative behaviors or a set of recurring structures (Wang, 2007a).

Definition 7. *A time-driven behavior B_t, denoted by $\hookrightarrow_t$, is an imperative process in which the ith behavior in term of process P_i is triggered by a predefined point of time $@t_i$TM, i.e.:*

$$B_t \triangleq \mathop{\mathrm{R}}_{i=1}^{n} (@t_i\mathrm{TM} \hookrightarrow_t P_i) \qquad (4)$$

where $@t_i$TM may be a system timing or external timing event.

Definition 8. *An interrupt-driven behavior B_{int}, denoted by $\hookrightarrow_{int}$, is an imperative process in which the ith behavior in term of process P_i is triggered by a predefined system interrupt $@int_i\odot$, i.e.:*

$$B_{int} \triangleq \mathop{\mathrm{R}}_{i=1}^{n}(@int_i \odot \hookrightarrow_{int} P_i) \quad (5)$$

As a summary, an imperative computing system can be described as follows.

Definition 9. *An Imperative Computing (IC) system is a passive system that implements deterministic, context-free, and stored-program controlled behaviors.*

The Autonomic Behavioral Layer of Intelware/AAS's

According to the RMAAS model as illustrated in Figure 1, the autonomic behavioral intelligence of intelware and AAS's can be formally modeled and elaborated in this subsection.

Definition 10. *The autonomic behavioral layer of AAS's, B_C, is a set of internally motivated and self- generated behaviors such as the goal-driven behaviors (B_g) and decision-driven behaviors (B_d) on the basis of the imperative layer B_I , i.e.:*

$$B_C \triangleq \{B_g, B_d\} \cup B_I = \{B_e, B_r, B_{int}, B_g, B_d\} \quad (6)$$

Definition 11. *A goal-driven behavior B_g, denoted by $\hookrightarrow_g$, is an autonomic process in which the ith behavior in term of process P_i is generated by the system itself, rather than be given, corresponding to the goal $@g_i$ST, i.e.:*

$$B_g \triangleq \mathop{\mathrm{R}}_{i=1}^{n}(@g_i\mathrm{ST} \hookrightarrow_{\mathrm{g}} P_i) \quad (7)$$

*where the goal, denoted by g*ST*, is a triple, i.e.:*

$$g\mathrm{ST} = (P, \Omega, \Theta) \quad (8)$$

in which that $P = \{p_1, p_2, \ldots, p_n\}$ is a finite nonempty set of purposes or motivations, Ω is a finite set of constraints for the goal, and Θ is the environment of the goal.

Definition 12. *A decision-driven behavior B_d, denoted by $\hookrightarrow_d$, is an autonomic process in which the ith behavior in term of process P_i is generated by a given decision $@d_i$ST, i.e.:*

$$B_d \triangleq \mathop{\mathrm{R}}_{i=1}^{n}(@\mathrm{d}_i\mathrm{ST} \hookrightarrow_{\mathrm{d}} P_i) \quad (9)$$

*where the decision, denoted by d*ST*, is a selected alternative $a \in \mathcal{A}$ from a nonempty set of alternatives $\mathcal{A}$, based on a given set of criteria C, i.e.:*

$$d = f(\mathcal{A}, C) = f: \mathcal{A} \times C \to \mathcal{A}, \ \mathcal{A} \neq \varnothing \quad (10)$$

Definition 13. *An Autonomic Computing (AC) system is an intelligent system that implements nondeterministic, context-dependent, and adaptive behaviors based on goal- and decision-driven mechanisms.*

The autonomic systems do not rely on instructive and procedural information, but are dependent on internal status and willingness that formed by long-term historical events and current rational or emotional goals (Wang, 2007d).

The Autonomous Behavioral Layer of Intelware/AAS's

According to the RMAAS model as illustrated in Figure 1, the autonomous behavioral intelligence of intelware and AAS's can be formally modeled and elaborated in this subsection.

Definition 14. *The autonomous behavioral layer of AAS's, B_A, is a set of autonomously generated*

behaviors by internal cognitive processes such as the perception-driven behaviors (B_p) and inference-driven behaviors (B_{inf}) on the basis of the imperative space B_I and the autonomic space B_C, i.e.:

$$B_A \triangleq \{B_p, B_{inf}\} \cup B_I \cup B_C = \{B_e, B_t, B_{int}, B_g, B_d, B_p, B_{inf}\} \quad (11)$$

The new forms of behaviors covered in the autonomous layer can be elaborated as follows.

Definition 15. *A perception-driven behavior B_p, denoted by $\hookrightarrow_p$, is a cognitive process in which the ith behavior in term of process P_i is generated by the result of a perceptive process $@p_i$PC, i.e.:*

$$B_p \triangleq \mathop{\mathrm{R}}_{i=1}^{n}(@p_i\mathrm{PC} \hookrightarrow_p P_i) \quad (12)$$

where PC *stands for a type of process, and the perception result* pPC *is an outcome of the cognitive process of perception that an AAS may generate.*

Inferences are cognitive processes that reason about a possible causality from given premises based on known causal relations between a pair of cause and effect proven true by empirical arguments, theoretical inferences, or statistical regulations.

Definition 16. *An inference-driven behavior B_{inf}, denoted by $\hookrightarrow_{inf}$, is a cognitive process in which the ith behavior in term of process P_i is generated by the result of an inference process $@inf_i$PC, i.e.:*

$$B_{inf} \triangleq \mathop{\mathrm{R}}_{i=1}^{n}(@inf_i\mathrm{PC} \hookrightarrow_{inf} P_i) \quad (13)$$

where formal inferences can be classified into the deductive, inductive, abductive, and analogical categories, as well as modal, probabilistic, and belief theories (Wang, 2007e).

As shown in Definition 16 and Figure 1, an AAS implemented on B_A extends the conventional behaviors B_I and B_C to more powerful and intelligent behaviors, which are generated by internal and autonomous processes such as the perception and inference processes. With the possession of all the seven forms of intelligent behaviors in B_A, the AAS may advance closer to the intelligent power of human brains.

Relationships between the Agent Behaviors of Intelware/AAS's at the Three Layers of RMAAS

Contrasting Definitions 3, 10, and 14, the following relationships among the three-layer agent intelligent behaviors can be established on the basis of the RMAAS model as illustrated in Figure 1.

Theorem 1. *The relationships of the imperative behaviors B_I, autonomic behaviors B_C, and cognitive behaviors B_A of intelware or AAS's are hierarchical and inclusive, i.e.:*

$$B_I \subseteq B_C \subseteq B_A \quad (14)$$

Theorem 1 and Definition 14 indicate that any lower layer behavior of an intelware or AAS is a subset of those of a higher layer. In other words, any higher layer behavior is a natural extension of those of lower layers as shown in Figure 1. Therefore, the *necessary and sufficient conditions of AAS's, C_{AAS}*, are the possession of all behaviors at the three layers.

Corollary 1. *The behavioral model of intelware or* AAS, *§*AASST, *can be logically modeled by a set of parallel processes that encompasses the imperative behaviors B_I, autonomic behaviors B_C, and autonomous behaviors B_A from the bottom-up, i.e.:*

$$
\begin{aligned}
\S AASST &\triangleq (B_I, B_C, B_A) \\
&= \{ (\ B_e, B_t, B_{int}) && // B_I \\
&\quad || (B_e, B_t, B_{int}, B_g, B_d) && // B_C \\
&\quad || (B_e, B_t, B_{int}, B_g, B_d, B_p, B_{\inf}) && // B_A \\
&\quad \}
\end{aligned} \tag{15}
$$

where || denotes a parallel relation in RTPA.

THEORETICAL FOUNDATIONS OF INTELWARE/AAS'S

Recent research reveals that the foundations of agent technologies root in cognitive informatics, denotational mathematics, and computational intelligence (Wang, 2002a, 2003b, 2008a). Along with the latest advances in cognitive informatics, non-imperative autonomous agent systems known as *intelware* and *cognitive computers* are emerging. This section explores the theoretical foundations of AAS's and intelware. The latest development of fundamental theories and technologies underpinning AAS's and intelware are highlighted.

Denotational Mathematics for AAS's

Applied mathematics can be classified into two categories known as *analytic* and *denotational* mathematics (Wang, 2002b, 2007a, 2008a, 2008c). The former are mathematical structures that deal with functions of variables as well as their operations and behaviors; while the latter are mathematical structures that formalize rigorous expressions and inferences of system architectures and behaviors with abstract concepts, complex relations, and dynamic processes. The denotational and expressive needs in cognitive informatics, computational intelligence, software engineering, and knowledge engineering have led to new forms of mathematics collectively known as denotational mathematics.

Definition 17. *Denotational mathematics is a category of expressive mathematical structures that deals with high-level mathematical entities beyond numbers and simple sets, such as abstract objects, complex relations, behavioral information, concepts, knowledge, processes, intelligence, and systems.*

The term denotational mathematics is first introduced by Yingxu Wang in the emerging discipline of cognitive informatics (Wang, 2002a, 2007a, 2008c). Typical paradigms of denotational mathematics are comparatively presented in Table 1, where their structures, mathematical entities, algebraic operations, and usages are contrasted. The paradigms of denotational mathematics as shown in Table 1 are *concept algebra* (Wang, 2008d), *system algebra* (Wang, 2008e), and *Real-Time Process Algebra* (RTPA) (Wang, 2002b, 2008f).

The emergence of denotational mathematics is driven by the practical needs in cognitive informatics, computational intelligence, computing science, software science, and knowledge engineering, because all these modern disciplines study complex human and machine behaviors and their rigorous treatments. Among the new forms of denotational mathematics, *concept algebra* is designed to deal with the abstract mathematical structure of concepts and their representation and manipulation in knowledge engineering. *System algebra* is created to the rigorous treatment of abstract systems and their algebraic relations and operations. RTPA is developed to deal with series of behavioral processes and architectures of human and systems.

Denotational mathematics provides a powerful mathematical means for modeling and formalizing AAS's. Not only the architectures of AAS's, but also their dynamic behaviors can be rigorously and systematically manipulated by denotational mathematics. Applications of denotational mathe-

2	System algebra	$SA \triangleq (\mathcal{C}, OP, \Theta) = (\{C, R^c, R^i, R^o, B, \Omega\}, \{\bullet_r, \bullet_c\}, \Theta)$	$S \triangleq (\mathcal{C}, R^c, R^i, R^o, B, \Omega, \Theta)$	$\bullet_r \triangleq \{\nleftrightarrow, \leftrightarrow, \prod, =, \sqsubseteq, \sqsupseteq\}$ $\bullet_c \triangleq \{\Rightarrow, \overset{-}{\Rightarrow}, \overset{+}{\Rightarrow}, \overset{\sim}{\Rightarrow}, \sqcup, \uplus, \Cap, \Lsh, \vdash\}$	Algebraic manipulations on abstract systems
3	Real-time process algebra (RTPA)	$RTPA \triangleq (\mathfrak{T}, \mathfrak{P}, \mathfrak{R})$	$\mathfrak{P} \triangleq \{:=, \blacklozenge, \Rightarrow, \Leftarrow, \nRightarrow, \gg, \ll, \mid \gg, \mid \ll, @, \triangleq, \uparrow, \downarrow, !, \otimes, \boxtimes, \S\}$ $\mathfrak{T} \triangleq \{$N, Z, R, S, BL, B, H, P, TI, D, DT, RT, ST, @*eS*, @*tTM*, @*int*$\odot$, @*sBL*$\}$	$\mathfrak{R} \triangleq \{\mapsto, \curvearrowright, \mid, \mid, \ldots, \mid, \ldots \mid \ldots, R^*, R^+, R^i, R^i, \circlearrowleft, \rightarrowtail, \mid\mid, \Cap, \gg, \lightning, \hookrightarrow, \hookrightarrow, \hookrightarrow, \hookrightarrow, \hookrightarrow, \hookrightarrow\}$	Algebraic manipulations on abstract processes

matics in cognitive informatics and computational intelligence have been elaborated with a wide range of real-world case studies (Wang, 2008a, 2008c), which demonstrate that denotational mathematics is an ideal mathematical means for dealing with concepts, knowledge, behavioral processes, and human/machine intelligence in ASS's and intelware.

Cognitive Informatics Theories of AAS's

Cognitive informatics is the transdisciplinary enquiry of cognitive and information sciences that investigates into the internal information processing mechanisms and processes of the brain and natural intelligence, and their engineering applications via an interdisciplinary approach (Wang, 2002a, 2003a , 2003b, 2006, 2007a, 2007b, 2007c, 2007d). According to the abstract intelligence theory (Wang, 2008a, 2009), because cognitive informatics investigates the internal information processing mechanisms and processes of the brain and natural intelligence, its research results underlie the engineering applications of AAS's. Cognitive informatics reveals that artificial intelligence (AI) is a subset of natural intelligence (NI) (Wang, 2007a, 2007b). Therefore, AAS's may be referred to the natural intelligence and behavioral mechanisms of human beings.

A Layered Reference Model of the Brain (LRMB) is developed (Wang, et al., 2006) that reveals the logical model of NI and a coherent set of cognitive mechanisms. LRMB presents a systematical view toward the formal description and modeling of architectures and behaviors of AAS's, which are created to extend human capability, reachability, and/or memory capacity. The LRMB model explains the functional mechanisms and cognitive processes of the natural intelligence with 39 cognitive processes at seven layers known as the *sensation*, *memory*, *perception*, *action*, *meta-cognitive*, *meta-inference*, and *higher cognitive layers* from the bottom up. LRMB elicits the core and highly repetitive recurrent cognitive processes from a huge variety of life functions, which may shed light on the study of the fundamental mechanisms and interactions of complicated mental processes as well as AAS's, particularly the relationships and interactions between the inherited and the acquired life functions as well as those of the subconscious and conscious cognitive processes. The cognitive model of the brain can be used as a reference model for goal- and inference-driven technologies in AAS's.

Definition 18. *The cognitive model of the kernel of an AAS or intelware, AAS_k, can be described as a real-time intelligent system with an inherited Agent Operating System AOS and a set of Agent Intelligent Behaviors AIB in parallel, i.e.:*

$$AAS_k \triangleq AOS \,||\, AIB \tag{16}$$

Definition 19. *The Cognitive Models of Memory (CMM) states that the architecture of human memory is parallel configured by the Sensory Buffer Memory (SBM), Short-Term Memory (STM), Long-Term Memory (LTM), Conscious Status Memory (CSM), and Action-Buffer Memory (ABM), i.e.:*

$$\begin{aligned} CMM \triangleq (\ & LTM \\ & ||\, STM \\ & ||\, CSM \\ & ||\, SBM \\ & ||\, ABM \\ &) \end{aligned} \tag{17}$$

The CMM model provides a neural informatics foundation of natural intelligence. With the CMM model, the broad sense of an AAS, AAS', can be described by mimicking the abstract architecture and mechanisms of the brain.

Definition 20. *The cognitive model of AAS's, AAS, is represented by a real-time intelligent system that encompasses the intelware and the CMM as well as their interactions, i.e.:*

$$
\begin{aligned}
AAS &\triangleq Intelware \\
&\;||\, CMM \\
&= (\; AOS \\
&\quad ||\, AIB \\
&\quad) \\
&\;||\, (\; LTM \\
&\quad ||\, STM \\
&\quad ||\, CSM \\
&\quad ||\, SBM \\
&\quad ||\, ABM \\
&\quad)
\end{aligned}
\tag{18}
$$

Eq. 18 indicates that although *intelware* is considered the center of AAS's, the memories are essential to enable it to properly function, and to keep temporary and permanent results physiologically retained and retrievable.

Computational Intelligence Theories of AAS's

According to the abstract intelligence theory (Wang, 2008a, 2009), intelligence is perceived as the driving force or the ability to acquire and use knowledge and skills, or to reason in problem solving. It was conventionally perceived that only human beings possess higher-level intelligence. However, the development of computers, robots, intelligent systems, and AAS's indicates that intelligence may also be created or implemented by machines and man-made systems.

Definition 21. *Intelligence, in the narrow sense, is a human or a system ability that transforms information into behaviors; and in a broad sense, it is any human or system ability that autonomously transfers the forms of abstract information between data, information, knowledge, and behaviors in the brain.*

Definition 22. *The Generic Abstract Intelligence Model (GAIM), as shown in Figure 2, represents abstract intelligence in four forms known as the perceptive, cognitive, instructive, and reflective intelligence, corresponding to the specific forms of cognitive information and their memories.*

The GAIM indicates that different forms of intelligence are the driving force that transfers between a pair of abstract objects in the brain such as *data* (*D*), *information* (*I*), *knowledge* (*K*), and *behavior* (*B*). It is noteworthy that each abstract object is physiologically retained in a particular type of memories as given in the CMM model. This is the neural informatics foundation of natural intelligence, and the physiological evidences of why natural intelligence can be classified into four forms as shown in Figure 2.

According to Definitions 21 and 22, *computational intelligence* is a paradigm of abstract

intelligence. Computational intelligence models human intelligence by computational methodologies and cognitively inspired models.

Definition 23. *The computational intelligence model of AAS's and intelware, §AAS*ST*, is a parallel structure represented by the Agent Operating System (AOS*ST*) and a set of agent intelligence represented by the Agent Intelligent Behaviors (AIB*ST*), as shown in Figure 3.*

The GAIM and §AASST model reveal that NI and AI share the same cognitive informatics foundations on the basis of abstract intelligence. The *compatible intelligent capability* states that NI, AI, AAS's, and intelware are compatible by sharing the same mechanisms of intelligent capability and behaviors. In other words, at the logical level, NI of the brain shares the same mechanisms as those of AI and computational intelligence. The differences between NI and AI are only distinguishable by the means of implementation and the extent of intelligent ability. Therefore, the studies on NI and AI in general, and intelware and AAS's in particular, may be unified into a coherent framework based on cognitive informatics and computational intelligence, which are formalized by denotational mathematics.

CONCLUSION

This paper has presented a coherent theoretical framework of Autonomous Agent Systems (AAS), known as *intelware*, from the facets of cognitive informatics, computational intelligence, and denotational mathematics. A reference model of AAS has been developed with three-layer intelligent behaviors known as the imperative, autonomic, and autonomous agent intelligence from the bottom up. It has been recognized that the characteristics of an AAS is its perception-driven and inference-driven behaviors beyond the imperative and autonomic ones as provided by conventional imperative and autonomic computing.

In order to formally and rigorously deal with the highly complicated architectures and intricate behaviors of intelware and AAS's, a new mathematical means known as denotational mathematics has been developed. Typical paradigms of denotational mathematics have been introduced such as concept algebra, system algebra, and RTPA. The findings of this work, particularly the necessary and sufficient conditions of imperative and autonomous computing, and the abstract intelligence model of natural and artificial intelligence, have formed a solid foundation for explaining and developing advanced autonomous computing systems and their engineering applications.

ACKNOWLEDGMENT

The author would like to acknowledge the support of the Natural Sciences and Engineering Research Council of Canada (NSERC) to this work. The author would like to thank the valuable comments and suggestions of the reviewers and colleagues.

ABSTRACT

Reconfigurability is an important requirement in many application systems. Many approaches have been proposed to achieve static/dynamic reconfigurability. Service-oriented architecture offers a certain degree of reconfigurability due to its support in dynamic composition. When system requirements change, new composition of services can be determined to satisfy the new requirements. However, analysis, especially QoS based analysis, is generally required to make appropriate service selections and service configurations. In this chapter, we discuss the development of QoS-based composition analysis techniques and propose a QoS specification model. The specification model facilitates QoS-based specification of the properties of the Web services and the requirements of the application systems. The composition analysis techniques can be used to analyze QoS tradeoffs and determine the best selections and configurations of the Web services. We develop a composition analysis framework and use the genetic algorithm in the framework for composition decision making. The framework currently supports SOA performance

analysis. The details of the genetic algorithm for the framework and the performance analysis techniques are discussed in this chapter.

INTRODUCTION

Reconfigurability is an important feature that is required in many modern application systems (Aksit & Choukair, 2003). For example, avionics systems, intelligent vehicle control systems, and remote monitoring systems frequently require dynamic adaptability so that the system can adapt to changes due to the failure of system components, reduced power level, unexpected operating conditions, and so forth. Also, some systems are multiple-mission and mission-specific, that is, they have to handle a class of missions that have similar system requirements but they also require adaptations to satisfy mission-specific needs.

Service-oriented architecture (SOA) is an ideal vehicle for achieving reconfigurability (Tsai, Song, Paul, Cao, & Huang, 2004). Desired functionalities can be achieved in SOA by dynamically composing appropriate services. Many research works focus on Web service composition (BEA et al., 2002; Hamadi & Benatallah, 2003; Sirin, Parsia, & Hendler, 2004). Most of these investigate various language issues. Business process execution language (BPEL) is an XML-based language for specifying the business processes and interaction protocols. Web services are then composed together to meet the specified functional requirements. The concept of semantic Webs extends the current Web with well-defined meanings for each Web service to facilitate their compositions. Based on semantic Webs, Sirin et al. (2004) have proposed a service composition tool including two main modules, namely, a composer and an inference engine. A user can interact with the composer to generate the composition and filter the results. The inference engine is a Web ontology language (OWL; W3C, 2004a) reasoner. The OWL reasoner searches the related services for the generated composition. Petri net-based algebra has also been used to help the composition by modeling the control flow. These composition methods can be used for adapting a system to new functional requirements (by composing a new set of services to achieve the modified functionalities).

Service composition generally focuses on composition of Web services to achieve some desired functionality. To achieve reconfiguration, new compositions can be derived for the modified functionalities. Actually, many adaptive systems require reconfigurability in terms of quality of service (QoS) behaviors. For example, some unmanned systems allow degraded QoS when some system failures occur. Many systems tradeoff the quality of their outputs versus the execution time to cope with periods of heavy loads or contentions for resources. In SOA-based systems, QoS reconfiguration can be achieved by, for example, selecting different services among those providing the same functionalities but, perhaps, having different QoS behaviors. Thus, systems can be dynamically assembled to fit the changing functional as well as QoS requirements.

Though SOA provides a convenient framework for reconfigurability, advanced techniques are still required to achieve actual adaptation (dynamic or static). For example, when the functional requirements of a system are modified, it is necessary to decompose the new requirements and then find the matching services in order to compose the new system. Similarly, when the QoS requirements of a system are modified due to changes in the execution environment, it is necessary to reconfigure the current services or choose new services to satisfy the new QoS requirements. To determine the correct service selections and configurations, it is necessary to analyze the QoS behaviors of the composed system.

The focus of this chapter is on QoS-based system reconfiguration. The goal is to develop analysis techniques and tools to facilitate static and dynamic system QoS behavior analysis such

that correct decisions regarding service selections and configurations can be made. The next section, *SOA Background*, introduces the SOA concept. The *QoS Specification Model* section presents the QoS specification model, and the *Analysis of Adaptive SOA Systems* section describes the analysis process of adaptive SOA systems. Then the composition analysis framework and genetic algorithm-based decision support are presented in the *Composition Analysis Framework* and the *Genetic-Algorithm-Based Decision Support* sections, respectively. And, the associated performance analysis method for SOA system is introduced the *Performance Analysis* section. The next section after that is *Case Study*, and finally, the *Conclusion* section summarizes this chapter.

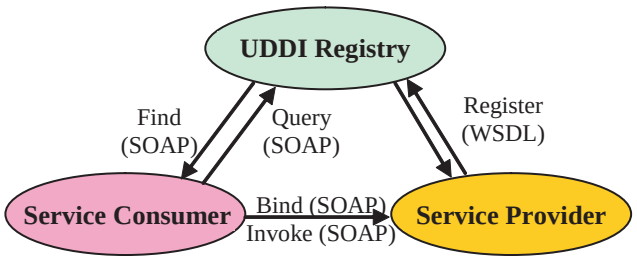
SOA BACKGROUND

The SOA concept is probably one of the most significant software engineering concepts after the currently widely adopted object-oriented technologies. The SOA term expresses the software architectural concept and essentially a collection of services. In SOA, each service encapsulates certain information and data to implement the functionality, and such service can then be consumed by clients in other applications through the exposed interfaces. These services communicate with each other to achieve the system requirements. SOA is an architecture style which is distributed, loosely coupling, highly interoperable between the services, hence, will maximize system flexibility and independent evolvability. Also, due to the potential of reuse and dynamic composition of core services, SOA offers high system reusability and reconfigurability. Legacy systems can be wrapped and reused without significant changes, while new applications can be incorporated into the architecture easily.

Web service-based SOA is a specialized realization of SOA (W3C, 2002). In this specific SOA, Web service (WS) takes the concept of the service and delivers the service over the Web using the technologies such as XML, simple object access protocol (SOAP), Web services description language (WSDL), and universal description, discovery, and integration (UDDI). SOAP provides a way to communicate between the services which are implemented in different programming languages, different technologies, and run on different operating systems. WSDL provides a standard format to describe the Web services by using XML. UDDI is a repository which stores the information of the Web services and facilitates publishing and finding of the Web services.

Web service-based SOA adopts register-find-bind-invoke paradigm which is shown in Figure 1. In this paradigm, service provider registers the

Figure 1. Web services system model



Web services in the public UDDI registry and publishs the Web services. Service consumer searches in the public UDDI registry and finds the desired Web services, then binds and invokes it.

Web service composition enable user to rapidly build a system or create a process by assembling individual Web services. Through specifying some details of the composition, such as when to invoke the appropriate Web services, the calling sequence of the Web services, the developer can implement the needed tasks. To facilitate the composition, several Web service composition languages are proposed, including business process execution language for Web services (BPEL4WS, also called BPEL; BEA Systems et al., 2002) and OWL-based Web Service Ontology (OWL-S; W3C, 2004b).

BPEL provides an abstract business protocol to facilitate the specification of compositions. A BPEL process specifies a set of partners and their interactions and invocation sequence. Each partner is a unit in the process and it is linked to the process via a partner link. The BPEL process coordinates with all involved clients and Web services and interacts with them, coordinates the execution sequence to achieve the desired goal. The process specification is kept at the abstract level, and it only specifies the relations and exchanged messages between partners without considering the internal details of the partner. With certain extensions, the BPEL process can be used to flexibly specify service composition and allows each partner to be associated with alternate Web services.

OWL-S provides a set of markup language constructs for describing the properties and capabilities of the Web services. It facilitates the automated Web service discovery, composition, and execution. It supports similar features as BPEL does for composition specification. OWL-S is widely used in semantic Web community while BPEL is used commonly in business sectors.

QOS SPECIFICATION MODEL

The QoS behavior of a WS-based system can be adapted due to three factors, including: (1) resource allocation, (2) selection of different services that offer the same functionalities, and (3) tuning QoS control parameters within the services. First, for resource allocation, we consider allocating available physical platforms to involved services. Services with higher access rates in the system may be replicated on multiple platforms while multiple services with lower access rates may share a single platform. Second, different services implementing the same functionality may yield different QoS tradeoffs. Thus, appropriate selection of the services can help with achieving the QoS goals of the applications. Third, each service may be reconfigurable in terms of its QoS behavior. Some QoS control parameters within a service unit can be tuned to control the tradeoffs of the QoS behavior. For example, a search program may obtain better results when given more time and the tradeoffs between time and output quality can be controlled by certain parameters within the program. Here, all three types of adaptivity for QoS analysis and reconfiguration in SOA systems are considered.

The goal of QoS-based composition analysis for reconfigurable SOA systems is to determine the best configuration for the system based on system QoS requirements. The configuration should consider the three adaptation factors, resource allocation, Web service selection, and QoS control parameter determination. To achieve QoS-based composition analysis, it is necessary to first establish the model for QoS related specifications. For example, the QoS behavior of the application system is derived from the QoS behavior of individual Web services. Thus, QoS behavior of the Web services to be considered for composing the application systems should be known a priori to facilitate the analysis. Also, it is necessary to specify the QoS requirements of

the application systems and based on which the satisfatory system configuration can be determined. In this section, we step-by-step introduce the model for QoS specification.

QoS Attribute Vector

To support all QoS-related specifications, the first step is to define the set of QoS attributes that need to be measured. Some standard QoS attributes include time and resource consumption metrics. Some application-specific QoS attributes include, for example, picture quality for image compression algorithms, precision of a relaxation based computation, and so forth. Consider a system S. Let $Q_S = (q_1, q_2, ..., q_N)$ denote the quality attribute vector of S, where Q_S includes N quality attributes. For different Web services, different quality attribute vectors may be considered. When specifying the QoS requirements of S, Q_S should be defined first. Note that the quality attribute vectors of the Web services that compose S may not have exactly the same elements, and they may be different from Q_S. When performing composition analysis, the quality attributes that are of interests are the overall system quality attributes (which is Q_S). If a Web service has additional quality attributes, they can simply be ignored. If a Web service does not contribute to a certain quality attribute in Q_S, then, a *null* value can be assigned to it.

System QoS Requirements

Let Γ_S denote the system QoS requirements for system S. Γ_S is defined on Q_S. Generally, system QoS requirements can be in the form of constraints that has to be satisfied and/or objectives that should be optimized. Let $\Gamma_S = (O, R)$, where $O = (o_1, o_2, \ldots)$ is the set of objectives, and $R = (r_1, r_2, \ldots)$ is the set of constraints. An objective o_i is an optimization function defined on one or more QoS attributes in Q_S. For example, maximize(q_1) and minimize ($aq_2 + bq_3$) are possible QoS objectives. A constraint r_i specifies a specific QoS constraint that need to be satisfied, and it is also defined on one or more QoS attributes in Q_S. For example, r_i may specify that the power consumption of the system should be within 100 walts per unit time, denoted as r_i: $q_3 \leq 100$ walts/sec, where q_3 is the power consumption quality attribute.

The goal of the system is to satisfy all the QoS constraints while obtaining optimal solutions in terms of the QoS objectives. Since there may be multiple objectives, the Pareto-optimal solutions can be considered.

Service Composition

The application system S is composed of Web services. We can use BPEL to specify the composition of services. In order to specify the functional requirements and associated candidate Web services of the partner, we extend the definition of the "partner" in BPEL by adding the tags "functional_req" and "associated_ws" respectively. Let Ω_S denote the composition specification for system S. Ω_S consists of a set of partners, $\{\omega_i \mid 1 \leq i \leq M\}$. The functionality of each partner ω_i is specified using the "functional_req" tag. From the functional specification, the actual Web services can be selected to instantiate a partner. Partner ω_i can be instantiated by m_i Web services, $ws_{i,j} \mid 1 \leq j \leq m_i$, which are included in the "associated_ws" tag of ω_i.

QoS Properties of the Individual Web Services

To facilitate QoS analysis and system configuration decision making, it is necessary to know the QoS properties of individual Web services and how to compose them to derive the QoS behavior of the composed system. The QoS property of a Web service is generally a function of the input and the operation environment parameters. For a reconfigurable Web service, the control parameters

in the Web service program also impact its QoS property. Consider the candidate Web services, $ws_{i,j}$, for all i and j, for composing the system S. Let $I_{i,j}^{ws}$ denote the set of input parameters, $E_{i,j}^{ws}$ denote the set of operation environment parameters, and $X_{i,j}^{ws}$ denote the set of configurable parameters for $ws_{i,j}$. $I_{i,j}^{ws}$ is specified by the parameters in client requests. $E_{i,j}^{ws}$ can be, for example, the platform capability. For a given set of $I_{i,j}^{ws}$, $E_{i,j}^{ws}$, and $X_{i,j}^{ws}$ values, the properties of $ws_{i,j}$ in terms of quality attribute q_i can be measured. Let ${}^{*}V_{i,j}^{ws} = ({}^{1}V_{i,j}^{ws}, {}^{2}V_{i,j}^{ws}, \ldots, {}^{N}V_{i,j}^{ws})$ denote the QoS properties of $ws_{i,j}$, where ${}^{k}V_{i,j}^{ws}$ is the QoS property of $ws_{i,j}$ in terms quality attribute q_k. ${}^{k}V_{i,j}^{ws}$ is a function of $I_{i,j}^{ws}$, $E_{i,j}^{ws}$, and $X_{i,j}^{ws}$, i.e., ${}^{k}V_{i,j}^{ws}$ can be expressed as ${}^{k}V_{i,j}^{ws}(I_{i,j}^{ws}, E_{i,j}^{ws}, X_{i,j}^{ws})$. ${}^{k}V_{i,j}^{ws}$ is actually a set of QoS measurement data collected based on various $I_{i,j}^{ws}$, $E_{i,j}^{ws}$, and $X_{i,j}^{ws}$ or a function representing the QoS measurement data. In this chapter, we assume that the measurement data can be fitted to a function.

A configurable parameter is a parameter in a Web service that, when adjusted, can impact the measurements of one or more of the QoS attributes. Different QoS properties of a Web service and the composed system can be obtained by tuning the configurable parameters. For example, the iteration number in a relaxation algorithm can be the control parameter to balance the tradeoffs between execution time and computation precision. The set of configurable parameters $X_{i,j} = (x_{i,j}^{1}, x_{i,j}^{2}, \ldots)$ is the tunable parameters for Web service $ws_{i,j}$ and it includes $\chi_{i,j}$ parameters.

QoS Property Composition

As discussed earlier, how to compose QoS properties of the individual Web services to derive QoS behavior of the composed system is also a necessary entity in QoS-based composition analysis and service configuration decision making. However, the model for QoS property composition depends on the quality attributes and a specific property composition algorithm needs to be defined for each individual quality attribute. The details regarding the QoS property composition algorithms will be discussed in details in the *Genetic Algorithm-Based Decision Support* section.

Resource Specification

Resource allocation can have a significant impact on QoS behavior of the system. QoS properties of each Web service depends on the operation environment $E_{i,j}^{ws}$, which, in turn, depends on the resources allocated to the Web service. In this chapter, the resource allocation problem only considers the allocation of Web services to hardware platforms. Also, heterogeneous platforms are assumed. Multiple platforms may be allocated to a heavily loaded Web service. Let $RS = \{rs_1, rs_2, \ldots, rs_L\}$ denote the set of L resources (platforms) in the system. The configuration decision maker needs to allocate the L platforms to the M Web services that are selected for the M partners.

ANALYSIS OF ADAPTIVE SOA SYSTEMS

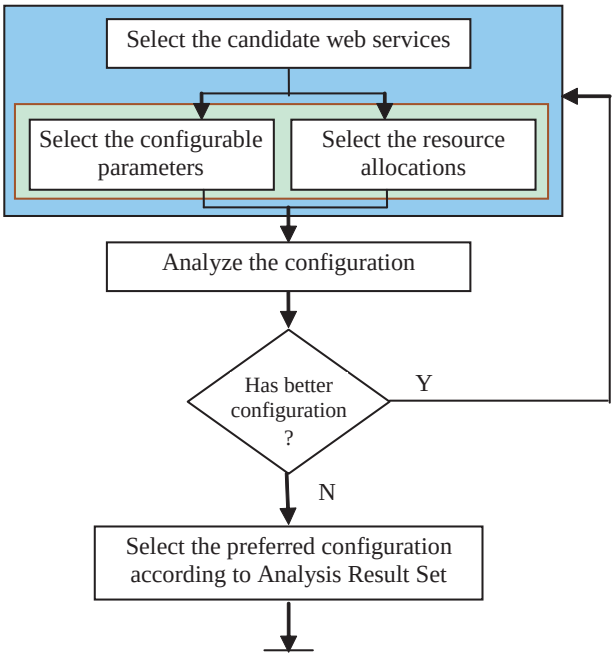
The major goal for QoS-based composition analysis process is to determine the best composition of Web services, their configurations, and mapping of the services to hardware platforms. A general analysis process is illustrated in Figure 2.

In this QoS-based composition analysis process, the candidate configuration is first determined and then analyzed. After analysis, either some potentially better configurations are further considered or the best candidate configuration is selected. More details of each of the steps is given in the following.

Select the Candidate Web Services

Each partner ω_i may be instantiated by multiple candidate Web services $ws_{i,j}$, $1 \le j \le m_i$. In this

Figure 2. QoS analysis process for adaptive SOA systems



step, one of the Web services need to be selected for each partner in the system.

Select the Configurable Parameters

Some of the Web services $ws_{i,j}$ may be reconfigurable and has a set of configurable parameters $X_{i,j}^{ws} = (x_{i,j}^{1}, x_{i,j}^{2}, \ldots)$. Each configurable parameter has a value range. In this step, a specific value in the value range is selected for each configurable parameter.

Select the Resource Allocations

In this step, a specific resource allocation that maps the Web services to the platfoms in *RS* is determined.

Analyze the Configuration

After selecting the specific Web services for each partner, setting each of the configurable parameters, and allocating of the platforms to Web services, the configuration of the system is fixed. Based on the configuration and the component properties of the selected Web services, a QoS property composition algorithm is applied to derive the overall system behavior. The result is then evaluated to determine whether it is satisfatory.

Select the Preferred Configurations

If the QoS behavior of the composed system is not satisfactory, then new configurations are

generated and evaluated repeatedly. The process terminates either after a number of iterations or after a satisfactory solution is selected. The final solution is then used for system configuration.

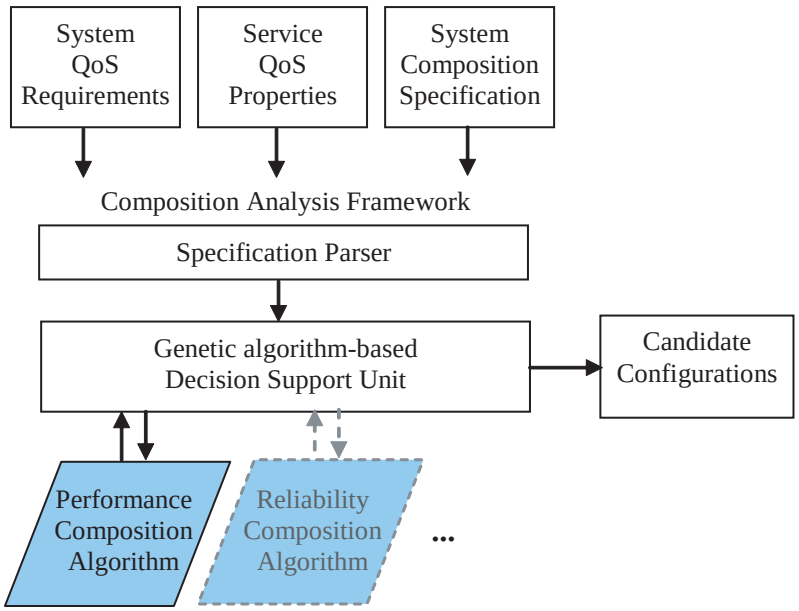
THE COMPOSITION ANALYSIS FRAMEWORK

The goal of the composition analysis process is to find Pareto-optimal configurations for the given SOA system specifications. A composition analysis framework has been developed to realize the QoS analysis process. The architecture of the framework is shown in Figure 3. The framework includes a specfication parser, a genetic-algorithm based decision support unit, and various composition analysis algorithms. The specification parser parses the "system composition specification", "system QoS requirements", and "service QoS properties". The parsed information is integrated and sent to the genetic-algorithm based decision support unit. The genetic-algorithm based decision support unit provides efficient composition decision making.

The genetic algorithm-based decision support unit is responsible for configuration selection, including the steps "select the candidate Web services", "select the configurable parameters", and "select the resource allocations". The selected configurations are passed to the framework. Then the framework invokes the appropriate QoS composition analysis algorithm and pass the selected configuration to it for analysis. The analysis results are then passed back to the decision support unit and the decision support unit either continues to generate new candidate configurations or selects the configuration as the final decision.

QoS composition analysis process may involve the analysis of various QoS attributes, such as

Figure 3. The architecture of the composition analysis framework

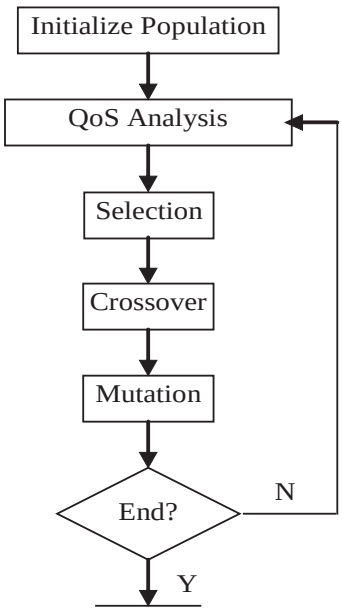


performance, reliability, and so forth. Since the analysis of different QoS attributes requires different methods and the QoS analysis algorithms are highly application-dependent, the composition analysis framework provides a registry table to allow users to plug-in application-specific analysis algorithms. The user can register a QoS property composition algorithm to the framework through the publicly exposed interface. Currently, the algorithm for performance analysis of the SOA is available.

GENETIC ALGORITHM-BASED DECISION SUPPORT

We use a genetic algorithm-based process for the decision support unit in the composition analysis framework. The genetic algorithm is responsible for candidate configuration generation and optimal decision making. An outline of the genetic algorithms is shown in Figure 4. It begins with the initialization phase which randomly selects a set of individuals to form the initial population. An individual represents a solution or, for our specific problem, a configuration. A population, in turn, is a group of individuals. Each individual is composed of a sequence of genes. For our problem, the genes can represent a configurable parameter, selection of a Web service for a partner, and a specific allocation of platforms. The initial population is called the first generation. The individuals in the population are evaluated using a fitness function. For example, in the model discussed in the *QoS Specification Model* section, the performance and/or other quality attributes are measured to evaluate the fitness of the configurations. Based on the evaluation results, the generic "selection" operator is used to select the better individuals as parents. From the parents,

Figure 4. Genetic algorithm outline



the "crossover" and "mutation" operators are applied to generate a new generation of population. The process is repeated until a satisfactory set of solutions are obtained.

In the next sub-section, we introduce the background for multi-objective evolutionary algorithms. The mapping of the composition analysis process to the evolutionary algorithm paradigm is discussed in the *Mapping the Composition Analysis Problem to the Genetic Algorithm* sub-section. The detailed algorithms are discussed in the *Genetic Algorithm for Composition Analysis* sub-section.

Multi-Objective Evolutionary Algorithms (MOEA)

The composition analysis process has some difficulties, including the conflicting objectives, the exponential search space, and a mix of continuous and discrete configurable parameters of the Web services. The classical search algorithms, such as linear programming and gradient search, are not efficient for the multi-objective problems (Deb, 1995). Randomized algorithm can be used to deal with the problem such as local minimal trap but it is very inefficient. The genetic algorithm is a partly randomized exploratory procedure based on biological evolution. Specifically, the multi-objective evolutionary algorithms (MOEA) is a specialized genetic algorithm commonly used to find the Pareto-optimal solutions.

The main objective of the MOEAs is to quickly converge to the true Pareto-optimal front with a widely spread solution set. Initial ones, such as MOGA (Fonseca & Fleming, 1993), non-dominated sorting genetic algorithm (NSGA) (Srinivas & Deb, 1994), and niched Pareto genetic algorithm (NPGA) (Hamadi et al., 2003) realize this objective using non-dominated sorting along with a niching mechanism. These algorithms have shown some successes in finding Pareto optimal solutions. In Zitzler, Deb, and Thiele (2000), the elitism concept is introduced and has been shown to have significant impact on performance improvement. Elitism is a strategy to preserve the better solutions for new population generation. Many subsequent algorithms, for example, NSGA-II (Deb, Pratap, Agarwal, & Meyarivan, 2002), Pareto envelope-based selection (PESA) (Corne, Knowles, & Oates, 2000), and strength Pareto evolutionary algorithm 2 (SPEA2) (Zitzler, Laumanns, & Thiele, 2002) apply the elitism strategy and demonstrate substantial performance improvements.

In Deb et al. (2002), an elitism-based algorithm, NSGA-II, along with improvements in diversity preservation and constraint handling, has been proposed. It has been shown that the algorithm outperforms Pareto archived evolution strategy (PAES) and SPEA (Zitzler & Thiele, 1999) in terms of finding a diverse set of solutions and converging toward the true Pareto-optimal set. Khare, Yao, and Deb (2003) compared the scalability of NSGA-II, PESA, and SPEA2 with respect to the number of objectives (2 to 8). PESA was shown to be the best in terms of converging to the Pareto-optimal front, but it does not have good diversity maintenance. Both SPEA2 and NSGA-II have good performance in terms of convergence and diversity maintenance, but NSGA-II runs much faster than SPEA2. Thus, NSGA-II is chosen to be the algorithm for the composition analysis process, more specifically, to generate and select promising system configurations. Some modifications are made to adapt NSGA-II to the composition analysis problem and to achieve problem-specific improvements.

Mapping the Composition Analysis Problem to the Genetic Algorithm

To map the composition analysis problem to the genetic algorithm flow, it is necessary to first determine the individuals and genes. In the *Genes and Individuals for Configuration Representation* sub-section, the design of individuals and genes for the composition analysis problem is given. To evaluate the individuals, the fitness function

should be defined next. The fitness function is discussed in the *QoS Analysis Algorithms* subsection.

Genes and Individuals for Configuration Representation

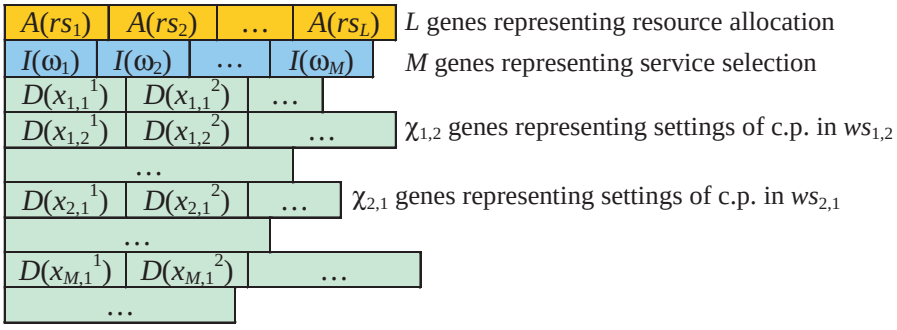
QoS-based SOA composition process supports adaptation in terms of resource allocation, Web service selection, and configurable parameter configuration within services. Thus, each individual includes three types of genes: one represents resource allocation, one represents service selection, and one represents configurable parameter setting. Figure 5 illustrates the different types of genes.

One individual includes L genes which comprise the allocation representations for the L resources in RS. Each gene represents the allocation of a resource rs_i, denoted as $A(rs_i)$. $A(rs_i)$ is an integer value from 1 to M. $A(rs_i) = k$ denotes that rs_i is allocated to the Web service instantiating partner ω_k. It is assumed that resources are independent of the Web services and assumed that these resources can be allocated to any Web services, that is, Web services are not resource dependent. Also, it is assumed that each resource can only be allocated to a single Web service. Hence, the number of resource, L, is greater than or equal to the number of partners, M.

For each partner, a gene is used to represent the selection of the instantiating Web service and there are a total of M such genes. Let $I(\omega_i)$ denote the gene for service selection. Since ω_i can be instantiated by Web services $ws_{i,j}$, $1 \le j \le m_i$, $I(\omega_i)$ is the index of the Web service selected for instantiating ω_i and its value range is from 1 to m_i. In other words, if $I(\omega_i) = j$, then $ws_{i,j}$ is selected to realize ω_i.

For the configurable parameters within individual services, each gene, denoted as $D(x_{i,j}^{k})$, represents a setting of the corresponding configurable parameter $x_{i,j}^{k}$, where $x_{i,j}^{k}$ is a tunable parameter in Web service $ws_{i,j}$. For $ws_{i,j}$, there are $\chi_{i,j}$ configurable parameters. Thus, there are a total of $\sum_{i,j} \chi_{i,j}$ genes representing configurable parameter settings. Each $D(x_{i,j}^{k})$ has its own data type and value range. The data type and value range definitions for $x_{i,j}^{k}$ are defined in the Web service QoS property specification and can be retrieved to define $D(x_{i,j}^{k})$.

Figure 5. Mapping of the system configurations



QoS Analysis Algorithms

The individuals in a population are evaluated using the fitness functions. The fitness functions are defined and realized by QoS analysis algorithms. Essentially, each individual represents a specific configuration of the system (selection and configuration of the Web services and resource allocation for them). Based on the configuration, the overall system properties, such as performance, reliability, and so forth, are determined. In this chapter, we use performance metric as an example to illustrate the QoS Analysis. The performance analysis for the SOA systems is discussed later in the *Performance Analysis* section.

Genetic Algorithm for Composition Analysis

In this section, we discuss the detailed algorithms in the GA paradigm. The overall genetic algorithm is discussed in the *NSGAII-CAA* sub-section. The GA operations, including selection, crossover, and mutation, are discussed in *Selection Operator*, *Mutation Operator*, and *Crossover Operator* sub-sections, respectively.

NSGAII-CAA

The algorithm NSGAII-CAA (non-dominated sorting genetic algorithm II – composition analysis algorithm) is a modified version of NSGA-II. It is specifically adapted for the composition analysis process with some performance improvement features. The algorithm is shown in the following.

Algorithm 1 follows closely the general genetic algorithm flow. In the following sub-sections, the major steps specifically designed for the composition analysis process are discussed.

Algorithm 1.

Algorithm NSGAII-CAA

Input: N_s: population and initial elite set size
D: generation number
Output: Pr: result non-dominated set

1 Initialize population P_0
2 QoS analysis on P_0
3 Create empty elite set P_0'
4 $d := 0$
5 while ($d < D$) do
6 generate a new elite set $P_{d+1}' :=$ NSGAII-crowding-pick (P_d, P_d', N_s)
7 generate the new population $P_{d+1} :=$ Mutation(Recombination(BTS(N_s, P_{d+1}')))
8 QoS analysis on P_{d+1}
9 $d := d + 1$
10 end while
11 $Pr :=$ non-dominated-set (P_d')

Selection Operator

For selecting promising configurations in a population, a comparision standard has to be provided. NSGA-II uses the crowding pick approach (NSGAII-crowding-pick). First, each individual is assigned a priority using non-dominated sort. Then, the individuals are further sorted using the crowding distance sort. Non-dominated sort first identifies the non-dominated solutions and gives them the highest priority and, after priority assignment, moves them out of the set. Then the non-dominated solutions of the remaining individuals are identified and given the second highest priority. This process continues until priorities are assigned to all the individuals. Based on each objective, the crowding distance computation first sorts the individuals with the same priority according to their values. The distances are normalized cross objectives by equalizing the maximum distances (between the highest and lowest values) of the objectives and proportionately adjusting the distances of all pairs of adjacent individuals. For each individual, the distances for all the objectives are summed together. The individual with a larger distance value gets a higher priority.

Based on the priorities, the best individuals can be picked to form the elite set, which stores a fixed number of best individuals ever generated and serves as the mating pool for next generation. Initially, the elite set is empty. For every generation, the population and the elite set from the previous generation are merged into one set. N_s individuals with the highest priorities are picked from the set to form the new elite set, where N_s is the population size. For a J-objective problem with population size N_s, NSGA-II has a storage requirement of $O(N_s^2)$ and time complexity of $O(J N_s^2)$.

The NSGAII-CAA algorithm uses a binary tournament selection (BTS) algorithm to select N_s individuals from the elite set to generate a new set, from which the new generation can be

Algorithm 2.

Algorithm BTS

Input: N_s: population size
P: elite set
Output: P': result new population

```
1    i := 0
2    while (i < N_s) do
3        randomly pick up two configurations s_1, s_2 from P
4        if s_1 has higher priority
5                put s_1 in P'
6        else
7                put s_2 in P'
8         i := i + 1
9    end while
```

produced by recombination and mutation. Each time two individuals are randomly picked from the elite set and one individual with the higher priority is selected. It continues till N_s individuals are selected. The complete BTS algorithm (Algorithm 2) is shown as follows.

Mutation Operator

In a mutation process, a new individual is generated from a randomly picked configuration by slightly modifying it. The probability of mutation of one individual is controlled by a mutation rate, which is normally set as $1/N_s$ where N_s is the population size. In the case study to be discussed later, the mutation rate is set as 0.01. For the individual to be mutated, the mutation point is chosen randomly and the gene of the mutation point is modified. For our specific problem, a random value in a pre-determined range of the chosen gene is used to replace the existing value. Each configurable parameter should have a fixed range so that a random value can be selected for the corresponding gene.

Crossover Operator

While mutation generates a new individual from one parent, crossover process exchanges the genes of one or more parents to reproduce new individuals. We use one-point recombination due to its effectiveness and simplicity. Similar to the mutation process, the crossover point for recombination of two individuals is generated randomly. The one-point recombination process exchanges the genes of two parents on and after the crossover point to reproduce two offsprings.

PERFORMANCE ANALYSIS

We use the Markov chain model to assess the performance for the SOA-based system (Bose, 2001). The SOA-based system consists of multiple Web services that may invoke one another (assume that there is no cyclic invocation). So the system is modeled as a multi-tier client-server system, which include multiple levels of client-server subsystems. In the following sub-sections, we first review the Markov model for performance analysis in the *Markov Model for Performance Analysis* sub-section. Then, in the *Performance Analysis for SOA Systems* sub-section, the method used for performance analysis for SOA system is introduced. Finally, in *A Performance Analysis Example* sub-section, an example is given to illustrate the performance analysis method.

Markov Model for Performance Analysis

Consider a simple client-server system. Let q denote the server queue. Assume that the server has service time t_s and request arrival rate λ. Also, let n denote the average population at the server. From the Markov model, we have (Bose, 2001):

$$\text{Utilization: } \rho = \lambda \cdot t_s,$$
$$\text{Average response time: } t = \frac{t_s}{(1-\rho)},$$
$$\text{Average population: } n = \frac{\rho}{(1-\rho)}. \quad (1)$$

If the load on the server is very high, the server may become a bottleneck. To deal with this problem, a server may be replicated, that is, multiple resources are allocated to that server. In this case, we use the *M*/*M*/*m* queuing model to compute the system performance, which has the following performance characteristics (Bose, 2001).

$$\text{Utilization: } \rho' = \frac{\lambda \cdot t_s}{m},$$
$$\text{Average response time: } t' = t_s + \frac{P_Q}{(m/t_s - \lambda)}, \quad (2)$$

where P_Q denotes the probability that all m servers are busy and $p(0)$ denotes the probability that the queue length is 0. We have

$$P_Q = (m \cdot \rho')^m \frac{p(0)}{m!} \cdot \frac{1}{1-\rho'},$$

$$p(0) = \left[\frac{(m \cdot \rho')^m}{m! \cdot (1-\rho')} + \left(\sum_{i=0}^{m-1} \frac{(m \cdot \rho')^i}{i!} \right) \right]^{-1}$$

Average population: $n' = P_Q \cdot \frac{\rho'}{(1-\rho')}$

Performance Analysis for SOA Systems

In the *Markov Model for Performance Analysis* sub-section, it is assumed that the arrival rates for the input ports of each Web service are known. When one Web service uses services provided by other Web services, it forms the client-server relationship. A Web service $ws_{1,1}$, for some requests, may invoke another Web service $ws_{2,1}$, but for some other requests, may invoke Web service $ws_{3,1}$, and for yet some other requests, may simply serve them locally. Also, a request may be propagated through several layers of service invocation. Thus, each request has a service path. To facilitate performance analysis, it is necessary to compute the effective arrival rate for each Web service in the system, and the computation is based on the invocation paths and the arrival rates from the real clients.

The SOA composition specification specifies the service architecture, including the partners and the links. The QoS specification for the individual services includes several essential parts: (1) for each partner, the arrival rates for its input ports should be specified if it takes input from real clients; (2) for each partner, the distribution of client requests that are forwarded to each of the output ports should also be specified; and (3) for each Web service, the service rate should be specified.

We assume that the client arrival rates follows a Poisson distribution. Also, we assume that the service rate of each Web service has an exponential distribution or is constant. In addition, assume that the arrival rate λ_i for partner ω_i is less than the service rate $1/t_{i,j}$ of the Web service $ws_{i,j}$ which instantiates ω_i. Thus, the output from each partner follows a Poisson distribution with rate λ_i. We also assume that if ω_i, after processing the requests, forwards the requests to other partners, then the probability for the requests going to different partners follows a uniform random distribution. Consider the case that partner ω_i has a request arrival rate λ_i and the probability that ω_i forwards a request to ω_j is $p_{i,j}$. Then, the effective arrival rate for partner ω_j has a Possion distribution with average arrival rate $\lambda_i * p_{i,j}$. From the effective arrival rate, the response time for each Web service can be computed based on the Markov model discussed in the *Markov Model for Performance Analysis* sub-section.

To compute the response time of client requests in terms of the overall system, we need to consider the individual paths of the requests flowing through the service hierarchy. First, according to the effective arrival rate, the response time for each service can be computed. For each path, the response time of the requests can be computed by adding together the response times of the multiple tiers that a request has to go through. The average response time of the overall system is the expected value of the response times of all the paths in the service architecture. The algorithm of computing the average response time is shown in Algorithms 3 and 4.

In the SOA based system, the link delay also affects the performance of the system. A link can be viewed as a network service unit. In the QoS property specifications of the individual services, the link delay can be specified either as a fixed latency or a specific distribution.

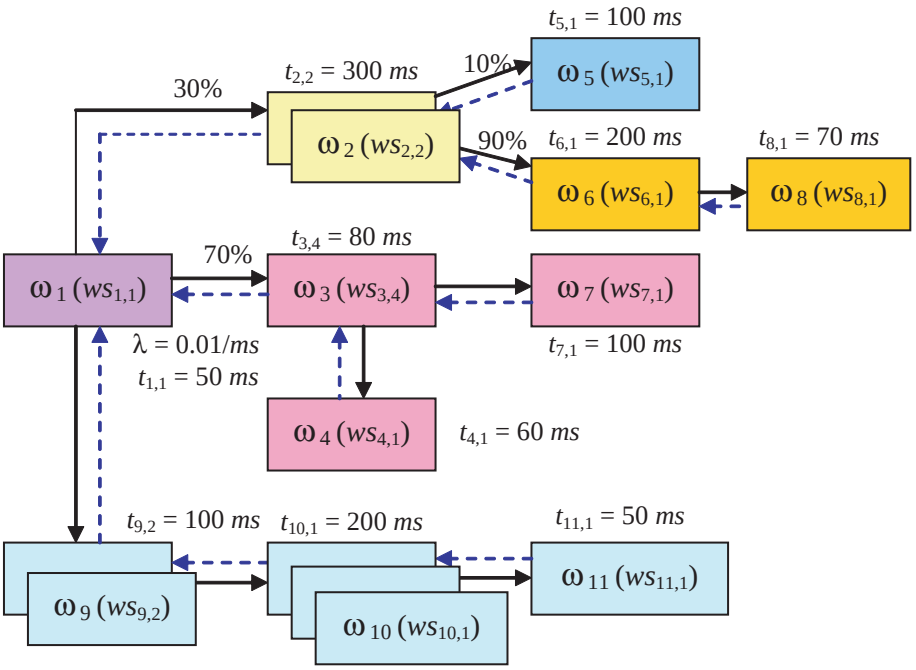
A Performance Analysis Example

Here, an example is given to illustrate the performance analysis algorithm.

The example system is shown in Figure 6. The performance analysis is based on a given system configuration, thus, each partner in the system has been instantiated by certain Web service which is specified in Figure 6, such as ω_1 is instantiated by $ws_{1,1}$. The specification for each Web service, partner, and link are also given in Figure 6. For example, the arrival rate λ

Figure 6. An example system for performance analysis



of partner ω_1 is 0.01/*ms* and the service time $t_{1,1}$ for Web service $ws_{1,1}$ (instantiates ω_1) is 50 *ms*. Also, from Figure 6, we can see that the service flow is initiated at ω_1. Requests from partner ω_1 are forwarded to different partners, where 70% are forwarded to partner ω_3 and 30% to ω_2. After receiving the responses from partner ω_2 and ω_3, partner ω_1 sends the requests to partner ω_9 .The possible paths for the requests include ω_1-ω_2-ω_5-ω_9-ω_{10}-ω_{11}, ω_1-ω_2-ω_6-ω_8-ω_9-ω_{10}-ω_{11}, etc. Here, we assume that the transmission time of the requests and responses between any two partners is a constant value, namely, 20 *ms*.

First, we compute the response time for path ω_1-ω_3-ω_7-ω_4. From the properties of partner ω_1 and partner ω_3 in Figure 6, the effective arrival rate of partner ω_3 from partner ω_1 can be computed as 0.7*λ. The requests are processed by Web service $ws_{3,4}$ (instantiates ω_3) with the service time $t_{3,4}$ = 80 *ms*. Then requests from partner ω_3 are forwarded to partner ω_7 and gets processed by Web service $ws_{7,1}$ (instantiates ω_7). Because the requests from partner ω_3 are all forwarded to partner ω_7, the effective arrival rate is the same as partner ω_3, namely, 0.7*λ. After receiving the responses from partner ω_7, partner ω_3 sends the requests to partner ω_4. Similarly, the effective arrival rate of partner ω_4 is 0.7*λ. Based on the effective arrival rate, the response time of Web service $ws_{3,4}$ is computed as 182 *ms*. Similarly, the response times of Web service $ws_{7,1}$ and $ws_{4,1}$ are 333 *ms* and 103 *ms*, respectively.

Then look at path ω_1-ω_2-ω_5 and ω_1-ω_2-ω_6-ω_8. As can be seen, Web service $ws_{2,2}$ (instantiates

ω_2) is replicated. It has an arrival rate 0.3*λ and the service time $t_{3,2}$ for Web service $ws_{2,2}$ is 300 *ms*. Since Web service $ws_{2,2}$ is replicated by 2, we compute the response time of Web service $ws_{2,2}$ using *M*/*M*/*m* (here *m* = 2) queuing model. Then, 10% of the requests from partner ω_2 are forwarded to partner ω_5 and 90% to partner ω_6. So the effective arrival rates of partners ω_5 and ω_6 are 0.1*0.3*λ and 0.9*0.3*λ. The requests forwarded to partner ω_6 are processed further by Web service $ws_{8,1}$ (instantiates ω_8). Thus, the response times of all Web services ($ws_{2,2}$, $ws_{5,1}$, $ws_{6,1}$, $ws_{8,1}$) are computed and they are 423 *ms*, 103 *ms*, 435 *ms*, and 86 *ms* respectively.

After receiving the responses from partner ω_2 or partner ω_3, partner ω_1 sends the requests to partner ω_9. Since partner ω_1 receives all the responses from partner ω_2 and partner ω_3 and all the responses follow Poisson distribution, the effective arrival rate of the responses for partner ω_1 is λ. The requests from partner ω_1 get processed by Web service $ws_{9,2}$ (instantiates ω_9). We compute the response time of Web service $ws_{9,2}$ using *M*/*M*/*m* (here *m* = 2) queuing model due to the replication of Web service $ws_{9,2}$ by 2. Then requests from partner ω_9 are forwarded to partner ω_{10} and gets processed by Web service $ws_{10,1}$ (instantiates ω_{10}). Web service $ws_{10,1}$ is replicated by 3, so the response time of Web service $ws_{10,1}$ is computed using *M*/*M*/*m* (here *m* = 3) queuing model. Finally the requests are forwarded to partner ω_{11} and are processed by Web service $ws_{11,1}$ (instantiates ω_{11}). Thus, the response times of all Web services ($ws_{9,2}$, $ws_{10,1}$, $ws_{11,1}$) are computed and they are 150 *ms*, 333 *ms*, 100 *ms*, respectively.

Note that the possible paths for the requests include ω_1-ω_2-ω_5-ω_9-ω_{10}-ω_{11}, ω_1-ω_2-ω_6-ω_8-ω_9-ω_{10}-ω_{11}, ω_1-ω_3-ω_7-ω_4-ω_9-ω_{10}-ω_{11}. The average response time for path ω_1-ω_2-ω_5-ω_9-ω_{10}-ω_{11} is computed as 100+423+103+150+333+100+10*20 = 1509 *ms*. Similarly, the average response time for path ω_1-ω_2-ω_6-ω_8-ω_9-ω_{10}-ω_{11} is computed as 100+423+435+86+150+333+100+12*20 = 1867*ms* and the average response time for path ω_1-ω_3-ω_7-ω_4-ω_9-ω_{10}-ω_{11} is computed as 100+182+333+103+150+333+100+12*20 = 1541 *ms*. Thus, the average response time of the overall system is 0.3*0.1*1509 + 0.3*0.9*1867 + 0.7*1541 = 1625 *ms*.

CASE STUDY

We use the example system shown in Figure 6 as a case study to illustrate the composition analysis approach. Let *S* denote the example system.

System QoS Specification

In the example system *S*, the QoS attribute vector $Q_S = (q_1, q_2)$, where q_1 represents time and q_2 represents accuracy. The system QoS requirements include the objectives $O = (o_1, o_2)$ and $R = \phi$, where o_1 is "*minimize* (q_1)" and o_2 is "*maximize* (q_2)". Here, q_1 represents response time. For composition specification, we have $\Omega_S = \{\omega_i \mid 1 \le i \le 11\}$. The set of Web services for each partner is shown in Table 1. For example, Web service $ws_{1,1}$ is associated with partner ω_1, Web services $ws_{2,1}$, $ws_{2,2}$ are associated with partner ω_2, Web services $ws_{3,1}$, $ws_{3,2}$, $ws_{3,3}$, $ws_{3,4}$ are associated with partner ω_3, and so forth.

For simplicity, we do not consider the execution environment $E_{i,j}^{ws}$ for Web services $ws_{i,j}$ and the input parameter set $I_{i,j}^{ws}$, for all *i*, *j*, in the example system *S*. The configurable parameter set $X_{i,j}^{ws}$ of each involved Web services $ws_{i,j}$ are specified in Table 2. For example, Web service $ws_{1,1}$ has two configurable parameters $x_{1,1}^{1}$, $x_{1,1}^{2}$, Web service $ws_{2,1}$ has one configurable parameter $x_{2,1}^{1}$, Web service $ws_{3,2}$ doesn't have configurable parameters, and so forth.

The QoS property functions of the Web services are shown in Table 3. Since we have quality attributes q_1 and q_2, correspondingly, we have QoS property functions ${}^1V_{i,j}^{ws}$ and ${}^2V_{i,j}^{ws}$, where ${}^1V_{i,j}^{ws}$ represents the time property function and ${}^2V_{i,j}^{ws}$ represents the accuracy property function. Note that ${}^1V_{i,j}^{ws}$ and ${}^2V_{i,j}^{ws}$ are functions of the

ω_1	$ws_{1,1}$	$X_{1,1}^{ws} = (x_{1,1}^{1}, x_{1,1}^{2})$	ω_6	$ws_{6,1}$	$X_{6,1}^{ws} = \phi$
ω_2	$ws_{2,1}$	$X_{2,1}^{ws} = (x_{2,1}^{1})$	ω_7	$ws_{7,1}$	$X_{7,1}^{ws} = \phi$
	$ws_{2,2}$	$X_{2,2}^{ws} = (x_{2,2}^{1})$		$ws_{7,2}$	$X_{7,2}^{ws} = (x_{7,1}^{1}, x_{7,2}^{2})$
ω_3	$ws_{3,1}$	$X_{3,1}^{ws} = (x_{3,1}^{1})$	ω_8	$ws_{8,1}$	$X_{8,1}^{ws} = \phi$
	$ws_{3,2}$	$X_{3,2}^{ws} = \phi$	ω_9	$ws_{9,1}$	$X_{9,1}^{ws} = \phi$
	$ws_{3,3}$	$X_{3,3}^{ws} = \phi$		$ws_{9,2}$	$X_{9,2}^{ws} = (x_{9,2}^{1})$
	$ws_{3,4}$	$X_{3,4}^{ws} = (x_{3,4}^{1}, x_{3,4}^{2}, x_{3,4}^{3})$	ω_{10}	$ws_{10,1}$	$X_{10,1}^{ws} = (x_{10,1}^{1}, x_{10,1}^{2})$
ω_4	$ws_{4,1}$	$X_{4,1}^{ws} = \phi$		$ws_{10,2}$	$X_{10,2}^{ws} = \phi$
ω_5	$ws_{5,1}$	$X_{5,1}^{ws} = (x_{5,1}^{1})$	ω_{11}	$ws_{11,1}$	$X_{11,1}^{ws} = \phi$
	$ws_{5,2}$	$X_{5,2}^{ws} = \phi$			
	$ws_{5,3}$	$X_{5,3}^{ws} = (x_{5,3}^{1}, x_{5,3}^{2})$			

configurable parameters $X_{i,j}^{ws}$ (it is assumed that the impacts of $I_{i,j}^{ws}$ and $E_{i,j}^{ws}$ are not considered). Since the service time of the Web services follows the exponential distribution, we have

$$ {}^{1}V_{i,j}^{ws}\left(t, X_{i,j}^{ws}\right) = 1 - \frac{1}{\mu_{i,j}\left(X_{i,j}^{ws}\right)} \times e^{-\frac{1}{\mu_{i,j}\left(X_{i,j}^{ws}\right)} \times t} . $$

Note that $\mu_{i,j}(X_{i,j}^{ws})$ denotes the service rate of $ws_{i,j}$,

$$\mu_{i,j}\left(X_{i,j}^{ws}\right)=\frac{1}{t_{i,j}\left(\mu_{i,j}\left(X_{i,j}^{ws}\right)\right)},$$

and here we assume that the configurable parameters in $X_{i,j}^{ws}$ impacts the average service rate. In Table 3, $\mu_{i,j}(X_{i,j}^{ws})$ for each Web service $ws_{i,j}$ is given. Property functions ${}^2V_{i,j}^{ws}$ for all Web services $ws_{i,j}$ are also given in Table 3. It is also a function of the configurable parameters in $X_{i,j}^{ws}$. Here, the value range of the configurable parameters in $X_{i,j}^{ws}$ is 0 to 10.

Consider the Web services $ws_{2,1}$ as an example. The property functions of $ws_{2,1}$ are

$${}^1V_{2,1}^{ws}(t)=1-\left(\frac{1}{\left(2*x_{2,1}^{1}+280\right)}\times e^{-\left(\frac{1}{\left(2*x_{2,1}^{1}+280\right)}\right)\times t}\right)$$

and

$${}^2V_{2,1}^{ws}(t)=0.31*(x_{2,1}^{2})^{0.5}.$$

Table 3. QoS properties of individual Web service specification

Partner	Web Service	$\mu_{i,j}(X_{i,j}^{ws})$	${}^2V_{i,j}^{ws}$

	$ws_{10,2}$	170	0.93
ω_{11}	$ws_{11,1}$	50	0.97

The resources in the example system S is $RS = \{rs_1, rs_2, \ldots, rs_{15}\}$, including 15 platforms. We assume that all the platforms have the same computation power.

Configuration and Gene Mapping

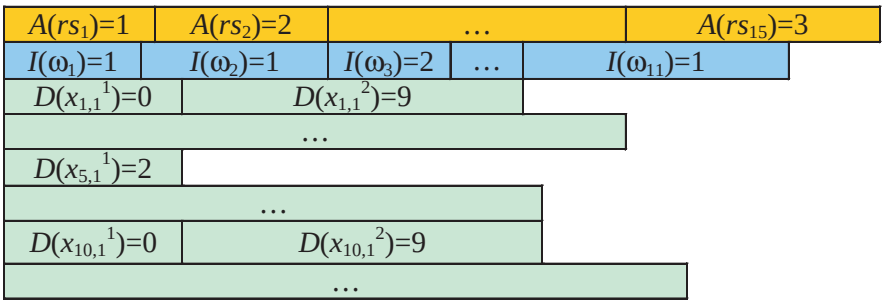
We map the specification for S given in the *System QoS Specification* sub-section to the genetic algorithm paradigm. An example individual for S is given in Figure 7. The genes for selection of Web services are given in the second line. For example, $I(\omega_1) = 1$ represents that $ws_{1,1}$ instantiates ω_1. The genes for resource allocation are given in the first line. We can see that, for example, rs_1 hosts Web service $ws_{1,1}$ since $A(rs_1) = 1$ and $I(\omega_1) = 1$. The remaining genes are for the configurable parameter settings, one line per partner (actually, the Web service that instantiates the partner). For example, $x_{1,1}^{\ 2} = 9$, it means the first configurable parameter $x_{1,1}^{\ 2}$ of the Web service $ws_{1,1}$ is set to 9.

Some other parameters for the genetic algorithm are as follows. The population size N_s and elite set size P are set to 100. The number of generations D is set to 60. These settings are determined based on the convergence speed and output quality we observed.

Performance Analysis

Each system configuration is analyzed by the performance composition algorithm. For the system configuration shown in Figure 7, the service time and accuracy of each Web service, which instantiates the corresponding partner in the example system, are computed according to the configuration mapping and QoS properties of individual Web service specification shown in Table 3. For example, Web service $ws_{1,1}$ is selected to instantiate partner ω_1. The service time and accuracy of $ws_{1,1}$ are 0.5*0 + 3*9 + 10 = 37 *ms* and $0.63*(9)^{0.2} = 0.98$, here $x_{1,1}^{\ 1} = 0$, $x_{1,1}^{\ 2} = 9$. Similarly, Web service $ws_{11,1}$ is selected to instantiate partner ω_{11}. Since Web service $ws_{11,1}$ doesn't have configurable parameters, the service time and accuracy of $ws_{11,1}$ are fixed, namely, 50 *ms* and 0.97, respectively. The average response time of this example system with the given configuration is then computed according to the algorithm "computeTotalAverageResponseTime" presented in the *Performance Analysis for SOA Systems* sub-section and the result is 1412 *ms*. To compute the accuracy of client requests in terms of the overall system, we consider the individual paths of the requests flowing through

Figure 7. Mapping of the system configurations

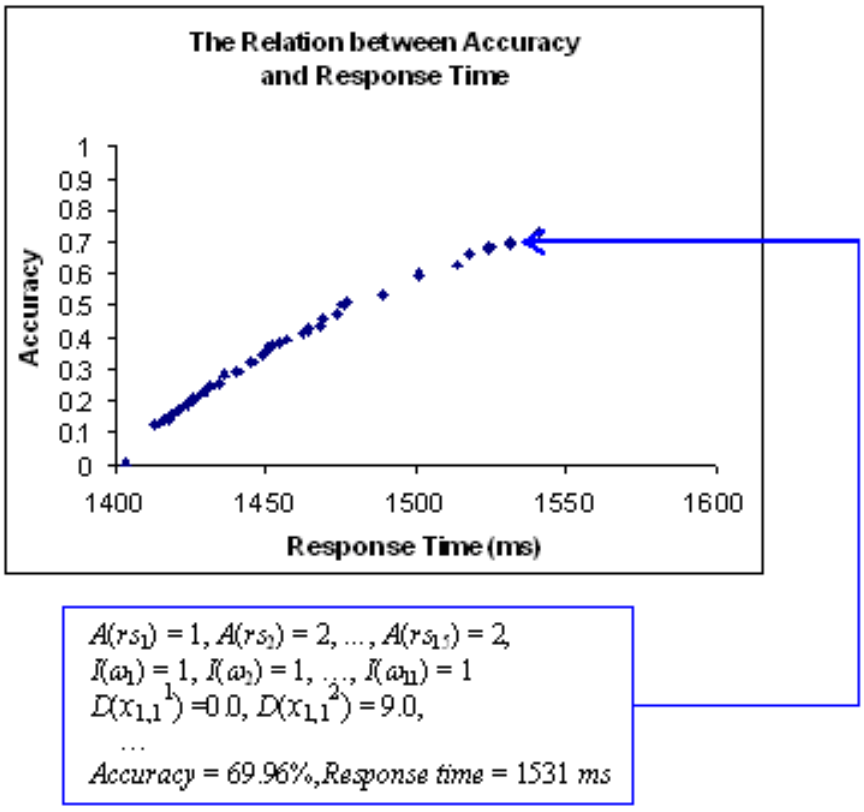


the service hierarchy. For each path, the accuracy of the requests can be computed by multiplying together the accuracy of the multiple tiers that a request has to go through. The accuracy of the overall system is the summation of the accuracy of all the paths in the service architecture. The accuracy of the example system with the given configuration is 0.12.

Analysis Results

For the example system, we consider the tradeoffs of the two QoS objectives—response time and accuracy. Figure 8 shows the Pareto front for the two objectives. There are many possible configurations to meet the functional and QoS requirements of the system *S* and the Pareto front are the configurations that are better than the eliminated solutions in at least one of the objectives. As we can see, in order to obtain higher accuracy, we need longer execution time. Each point in Figure 8 corresponds to a configuration. For example, the configuration corresponding to the point pointed by the arrow in Figure 8 is given in the corresponding box. In this configuration, the configurable parameters for the Web service $ws_{1,1}$ are set to: $x_{1,1}^{1} = 0.0$, $x_{1,2}^{2} = 9.0$, etc. The *average response time* of the system *S* is 1531 millisecond and *accuracy* of the system *S* is 69.96%.

Figure 8. The relationship between accuracy and response time



Based on the analysis results, the system can be adapted statically and/or dynamically according to the modified QoS requirements. When the execution environment or operation condition changes, the system simply searches for the configuration(s) that satisfy the new requirements and constraints. From the case study, we can see that the framework can be used to effectively analyze QoS tradeoffs. The GA algorithm generally converges very fast and, hence, can be used for efficient adaptation decision making.

CONCLUSION

In this chapter, we have presented the QoS analysis process to facilitate dynamic reconfiguration in SOA-based systems. We consider the selections and configurations of Web services to compose a system. We also consider the resource allocation for Web services. The goal is to find the best configurations that satisfy the changing QoS requirements. A case study is used to validate the feasibility of our QoS-based composition analysis techniques and tools.

There are many research directions that can be explored further. The most important direction is to further develop techniques and tools for general QoS behavior analysis. For example, reliability, availability, and so forth, are also important QoS attributes. Currently, we are developing compositional analysis techniques to compute system reliability based on the reliability of individual services. Other QoS attributes will also be considered. Though some quality attributes are very difficult to assess and/or to compose, we plan to investigate these attributes and develop some common mechanisms for thorough analysis.

Dynamic reconfiguration requires the analysis process to be performed in real time so that the adaptation can be completed in a timely way. For the case study discussed in this chapter, the configuration analysis takes close to one second. For large-scale systems, the analysis process may take longer. Thus, it is necessary to investigate mechanisms for achieving real-time performance. For example, special composition analysis service sites can be offered and analysis can be done off-line and results can be provided efficiently to the clients.

We also plan to extend the toolset and develop a complete suite of tools to facilitate QoS analysis of SOA-based systems. We will consider more complicated service architectures and various composition mechanisms. Also, analysis algorithms for various QoS attributes will be incorporated.

Chapter 7.29
Fuzzy Logic Classifiers and Models in Quantitative Software Engineering

Witold Pedrycz

Giancarlo Succi
Free University of Bolzano, Italy

ABSTRACT

The learning abilities and high transparency are the two important and highly desirable features of any model of software quality. The transparency and user-centricity of quantitative models of software engineering are of paramount relevancy as they help us gain a better and more comprehensive insight into the revealed relationships characteristic to software quality and software processes. In this study, we are concerned with logic-driven architectures of logic models based on fuzzy multiplexers (fMUXs). Those constructs exhibit a clear and modular topology whose interpretation gives rise to a collection of straightforward logic expressions. The design of the logic models is based on the genetic optimization and genetic algorithms, in particular. Through the prudent usage of this optimization framework, we address the issues of structural and parametric optimization of the logic models. Experimental studies exploit software data that relates software metrics (measures) to the number of modifications made to software modules.

INTRODUCTION: MODELING SOFTWARE PRODUCTS AND PROCESSES

The important objectives of quantitative software engineering revolve around building models that help express software quality in terms of some software metrics (measures) (Canfora, García, Piattini, Ruiz, & Visaggio, 2005; Cant, Jeffery, & Henderson-Sellers, 1995; Chhabra, Aggarwal, & Singh, 2004; Lanubile & Visaggio, 1997; Lee, 1993; Offutt, Harrold, & Kolte, 1993; Poels &

Dedene, 2000). There have been numerous approaches to such modeling pursuits. In addition to some "standard" linear and non-linear regression models, we can witness other techniques exploiting neural networks, machine learning, neural networks and fuzzy sets (Ebert, 1994, 1996; Mantere & Alander, 2005; Pedrycz, Han, Peters, Ramanna, & Zhai, 2001; Pedrycz & Succi, 2005; Pedrycz, Succi, Musílek, & Bai, 2001; Reformat, Pedrycz, & Pizzi, 2003; Thwin & Quah, 2005).

There are several compelling reasons behind studying different approaches to modeling software processes and software products.

- Typically, the available software data are quite limited yet they may involve a significant number of variables; in this sense, their sparse character requires careful attention.
- As the models produce results to be presented to the user (designers, managers, testers, etc.), it is highly advisable to assure high transparency (user-centricity) of the overall modeling process. In particular, this feature supports an interpretation of results and reveals relationships between software metrics and software quality.
- Software processes are human-oriented and not governed by any laws of physics. This strongly suggests considering modeling practices realized at some abstract levels engaging logic constructs.
- It is highly advisable to develop models in such a way that they could accommodate heterogeneous input information not necessarily being confined to numeric data.
- The models should be endowed with a significant level of flexibility and learning mechanisms to accommodate commonly encountered non-linear relationships and potential variability of the individual projects and software products.

Being aware of these main objectives, we may conclude that ideally the modeling framework should support the development of models in such a way that they combine a high degree of plasticity and learning abilities with an evident transparency and a significant level of interpretability. Interestingly enough, we could state without any exaggeration that the fundamentals of such modeling are inherently rooted in the world of multi-valued or fuzzy logic. The underlying logic nature of the models makes them transparent, and this transparency contributes to a highly interpretative insight into experimental data. The agenda of fuzzy modeling is inherently associated with the transparency of fuzzy models. While this facet of modeling has already started to gain visibility and properly balance the otherwise accuracy-driven fuzzy models, there are still a number of fundamental issues as to the definition of interpretability itself, granularity of models vis-à-vis the characteristics of experimental data, and assessment of the readability of the structure of the model itself (Reformat et al., 2003).

Two-valued logic forms a well-known boundary case of the fuzzy logic. The design of digital systems comes with a diversity of well-established, highly efficient, and scalable architectures and related development algorithms. By acknowledging a point of view that the two-valued logic is just a special case of fuzzy logic, we are then somewhat tempted to generalize or reformulate the already existing architectures and design practices of digital systems and cast them in the framework of fuzzy logic. This point of view is the crux of this approach to the development of fuzzy logic models. We focus on a certain standard technique of implementation of combinational systems by means of multiplexers (the approach which results in an array of multiplexers implementing any Boolean function); see McCluskey (1986) and generalize this concept to the world of fuzzy logic. In essence, we are concerned with the three main phases: (1) building a generic

structure of a fuzzy multiplexers; (2) developing models (networks) exploiting fuzzy multiplexers as their building components (we will be referring to them as networks of fuzzy multiplexers); and (3) designing such networks with the aid of methods of structural and parametric optimization.

As emphasized, the embedding principle (where fuzzy logic subsumes two-values logic and inherits from its fundamental constructs), makes that this starting point of view becomes especially justifiable and appealing considering that multiplexers have been commonly used in the design of digital systems and come with a well-developed design methodology (Ciletti, 1999).

The organization of the material is structured in a way that reflects the research agenda outlined earlier. First, we introduce a basic processing module of a fuzzy multiplexer (fMUX) and discuss its characteristics (the *Fuzzy Multiplexer as a Generic Processing Unit* section). This naturally leads us to the networks formed by fuzzy multiplexers, *A Realization of the Network of fMUXs* section, relates their structure to the expansion theorem by Shannon, and emphasizes the nature of the function decomposition completed in this manner. *The General Development Environment of the Network-Interfaces Issues* section is concerned with the general development of fMUX networks and serves as a pre-requisite to the comprehensive discussion on the design of the networks. *The Development of the fMUX Networks* section concentrates on the genetic optimization of the networks using which we address an issue of their structural optimization (concerned with a selection of an optimal subset of input variables) and parametric learning. The discussion covers architectural considerations of GAs as well as presents the underlying genetic operators pertinent to the optimization realized here. Experimental results dealing with synthetic and software data are included in the *Experimental Studies* section.

The terminology used here adheres to the standards encountered in two-valued logic, digital systems, and fuzzy logic. The logic operators are modeled via t- and t-conorms. If not stated otherwise, we use two standard realizations of t- and t-conorms coming in the form of a product and probabilistic sum. An overbar denotes a complement treated in a usual way encountered in logic (that is $\overline{x} = 1\text{-}x$).

FUZZY MULTIPLEXER AS A GENERIC PROCESSING UNIT

We are concerned with the development of logic-based models of data in the unit hypercube. More precisely, such models realize logic transformations that map the unit hypercubes (say $[0,1]^n$) into [0,1] and come with some well-defined semantics. We require that such mapping is made modular meaning that it is formed on a basis of a collection of some generic processing units (nodes). The basic processing node, referred to as a fuzzy multiplexer (fMUX), realizes a mapping from $[0,1]^2$ into [0,1] that comes in the following form

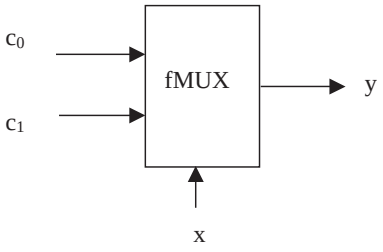
$$y = c_0 * \overline{x} + c_1 * x \qquad (1)$$

where the logic operations (* and +) are implemented using some t- and t-conorms. For the sake of completeness of the presentation, let us recall that by a t-norm we mean a two argument function t: $[0,1]^2$ –>[01,] such that it is monotonic, associative, distributive, and satisfies two boundary conditions of the form 0tx =0 and 1tx =x for all x in [0,1]. For any t-conorm all these conditions hold true while the boundary condition reads as 0sx =x and 1sx =1. Given these t- and t-conorm realizations, (1) is governed by the expression

$$y = (c_0 t\overline{x})\, s\, (c_1 t x) \qquad (2)$$

The structure of (1) can be schematically illustrated as visualized in Figure 1. The variable (x) standing in the earlier-mentioned expression plays a role of a *switching* (selection or select)

Figure 1. A schematic view of the fuzzy multiplexer with one select input (x) and two fixed information inputs (c_0 and c_1)



variable that allows two fixed *information* inputs (c_0 or c_1) to affect the output. The degree to which the produced result depends on these fixed information values is controlled by the select variable. To emphasize the role played by all these signals, we use a concise notation y = fMUX(x, **c**) where **c** (=[c_0 c_1]) denotes a vector of the information inputs. In the two boundary conditions the select variable may assume, we produce a binary switch (as being used in digital systems). It means that if x =1 then y = c_1. Likewise the value of x set up to 0 leads to the output being equal to c_0 meaning that the value of c_0 is transferred to the output of the device.

Figure 2 includes a series of plots of the characteristics of the fuzzy multiplexer being treated as a function of x; noticeable is a fact that different configurations of the values of the information inputs (c_0 and c_1) give rise to different non-linear input-output relationships of the device. By choosing a certain value of the select input, we logically "blend" the two constant logic values present at the information inputs. The detailed non-linear form of the relationship depends on the use of the t-norms and t-conorms. In the specific example illustrated in Figure 2, the t-norm is realized as a product operator that is atb = ab while the t-conorm is treated as the probabilistic sum, asb = a + b – ab, a,b ∈ [0,1].

Using fuzzy multiplexers, we can easily form cascade structures (networks) as commonly

Figure 2. Input-output characteristics of the fuzzy multiplexer for selected values of c_0 and c_1, y = fMUX(x,c_1,c_0):

a - c_0=0.9 c_1=0.8
b- c_0=0.2, c_1=0.8
c – c_0=1.0, c_1=0.0
d- c_0=0.6, c_1=0.3

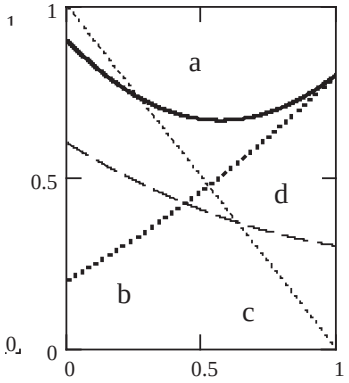


Figure 3. A two-layer network of fuzzy multiplexers

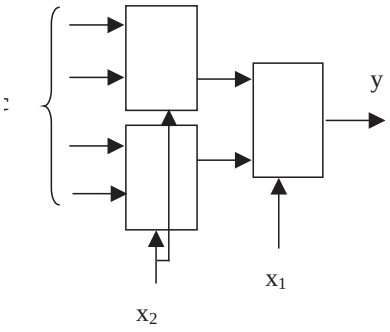

encountered in the two-valued logic constructs (digital systems). An example of a two-layer structure, a network of fMUXs is displayed in Figure 3. The input-output characteristics of the network that are regarded as a function of the select signals x_1 and x_2 are shown in Figure 4. Depending upon the numeric values in the vector of the information inputs (**c**), we encounter various types of non-linearities. Figure 5 includes the corresponding characteristics for the minimum and maximum operations; it becomes apparent that the piece-wise character of the relationships becomes predominant. Regarding the notation,

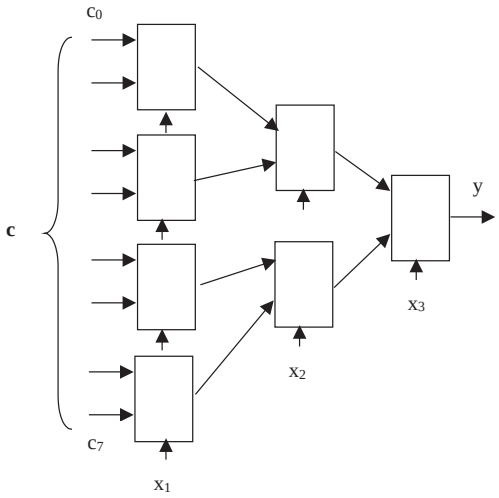
A REALIZATION OF THE NETWORK OF FMUXS

The functional module of the fuzzy multiplexer introduced earlier is a generic building block that can be efficiently used to construct larger structures. Its functionality is minimal (in the sense we have here only a single switching variable, that is x). If we are dealing with more variables (x_1, x_2, …,x_n), the resulting structure is formed as a regular multi-level architecture composed of the basic fMUXs as visualized in Figure 6. Noticeably at each level of the network, we assign a single selection variable. Moreover at each level of the network, the number of multiplexers doubles; the output layer comprises one multiplexer, the

Figure 6. Network architecture built with the use of the basic functional modules of fuzzy multiplexers; for illustrative purposes, shown are only three layers of the network



layer next to it two multiplexers, the next one four units, and so forth. With the substantial number of select variables, we can envision some scalability problems (and these have to be addressed at the design phase).

The fMUX network comes with an interesting motivation and exhibits a clear interpretation. As functionality is concerned, it is instructive to go back to the two-valued logic which clearly reveals a rationale behind the use of such networks of multiplexers (Kohavi, 1970). Consider a two-variable Boolean function $f(x_1, x_2)$. According to the classic Shannon expansion theorem, the function can be written down as a sum of products, that is

$$y = f(x_1, x_2) = \overline{x}_2 f(x_1,0) + x_2 f(x_1,1)$$
$$= \overline{x}_2[\overline{x}_1 f(0,0) + x_1 f(1,0)] + x_2[\overline{x}_1 f(0,1) + x_1 f(1,1)] \quad (3)$$

In essence **c** = [f(0,0) f(1,0) f(0,1) f(1,1)] becomes a vector of constant information inputs here; these numeric values uniquely define the given Boolean function.

This successive expansion of the Boolean function maps directly on the two-level structure of the multiplexers; the information inputs to the multiplexer are the functions of one variable, namely $f(x_1,0)$ and $f(x_1,1)$, which are realized by the two multiplexers in the first layer of the network. Here, f(0,0), f(1,0), and so forth, are the information inputs to these multiplexers. The network of the fuzzy multiplexers is just a generalization of this fundamental result to fuzzy functions defined in the unit interval.

When it comes to the interpretation, the network exhibits several interesting properties. We start with the input layer. The outputs of these fMUXs are just logic expressions of a single

input (select) variable (being more specific, the variable and its complement). In the sense of involving only one variable, they are general. There are also a lot of them (especially if we are dealing with the multi-player network). In this sense, what becomes realized at the first layer is just a list of partial realizations of the function, and the outputs there can be treated as generalized variables. In the subsequent layers, these are specialized (by involving another variable), and their number becomes reduced.

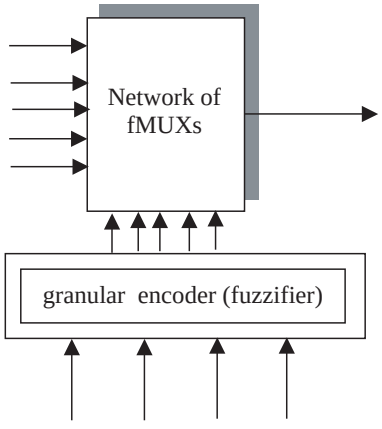
THE GENERAL DEVELOPMENT ENVIRONMENT OF THE NETWORK-INTERFACES ISSUES

The fuzzy multiplexer completes a logic-based processing of input variables and realizes a certain logic-driven mapping between input and output spaces. As they interact with a physical world whose manifestation does not arise at the level of logic (multi-valued) signals, it becomes apparent that there is a need for some interface of the model. Such interfaces are well known in fuzzy modeling. They commonly arise under a name of fuzzifiers (granular coders) and defuzzifiers (granular decoders). The role of the coder is to convert a numeric input coming from the external environment into the internal format of logic membership grades associated with each input variable. This can be shown in the form outlined in Figure 7.

The choice of the fuzzy sets coming as the components of the interfaces is essential to the performance of the fuzzy models. In particular, this concerns: (1) the number of fuzzy sets and (2) their membership functions. The number of fuzzy sets implies a certain level of granularity of the model while the form of the membership function could help in further parametric optimization of the model.

In this study, we consider one of the simplest scenarios. While being quite straightforward, this design alternative exhibits interesting properties, supports computational simplicity and implies a significant level of the interpretability of the model.

Figure 7. A general-layered structure of fuzzy modeling; the granular decoder is used in case of several networks of fuzzy multiplexers



For an input variable that assumes values in the range of [a, b], let us consider two fuzzy sets with triangular membership functions defined as

$$A_1(x) = (x-a)/(b-a) \quad (4)$$

and

$$A_2(x) = 1- (x-a)/(b-a) \quad (5)$$

Evidently, the family $\{A_1, A_2\}$ forms a fuzzy partition of the space as $A_1(x) + A_2(x) = 1$. These two fuzzy sets overlap at the level of 0.5. The linear model of membership is quite common and simple to interpret. It is also highly legitimate in all those cases where we do not have any additional knowledge about the problem at hand. We can look at these membership functions from a different standpoint. The linear normalization of the input variable from the interval of [a, b] to the unit interval [0,1] is just expressed by (4) so in essence A_1 is a result of such normalization. A_2 complements A_1. A_1 is monotonically (linearly) increasing while A_2 is monotonically (linearly) decreasing.

THE DEVELOPMENT OF THE FMUX NETWORKS

In this section, we discuss some general design scenarios and envision their suitability in the development of the fMUX networks.

Selecting Among General Design Scenarios

The development of the fMUX networks entails two fundamental design scenarios:

1. If we consider all input variables (x_1, x_2, …, x_n) to be used in the development of the system then the values of the entries of the vector $\mathbf{c}=[c_0\ c_1\ c_2\ c_k\ldots]$ have to be estimated
2. If the number of the input variables is high (and this implies a high dimensionality of **c** along with all drawbacks of learning we envision under such circumstances), the design of the network has to involve a selection of an optimal subset of the variables and a simultaneous estimation of the pertinent vector of constants (**c**).

In the first scenario, we can use a standard gradient-based learning. It is straightforward; for a given structure (that is the variables being specified in advance along with their arrangement within the network), a detailed form of a performance index to be minimized (Q), specific models of t- and t-conorms, the gradient of Q taken with respect to **c** navigates the optimization process realized throughout the search space,

$$\mathbf{c}(\text{iter}+1) = \mathbf{c}(\text{iter}) - ?\nabla_{\mathbf{c}} Q \quad (6)$$

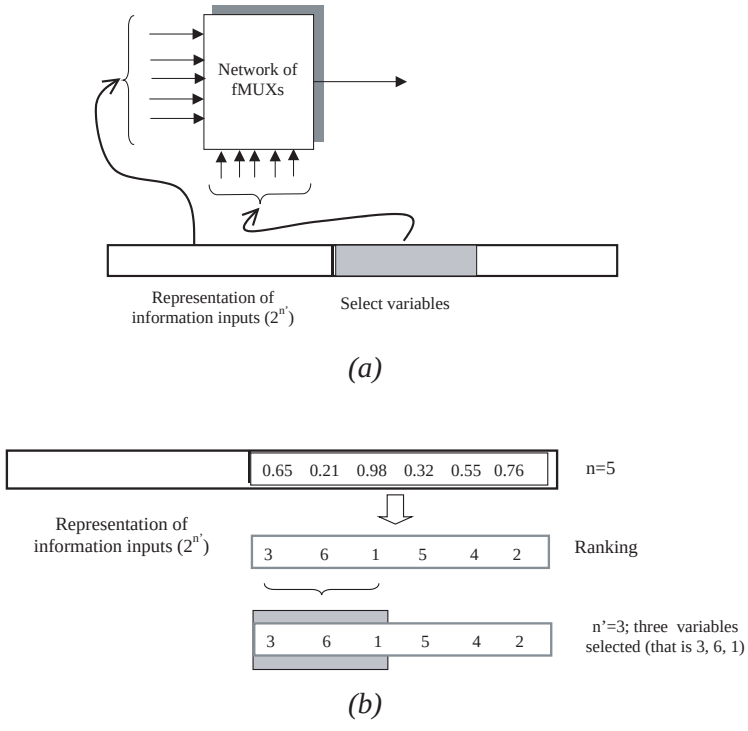
where **c**(iter) denotes the values of the input constants at a certain iteration step (iter); $\beta > 0$ is a learning factor implying an intensity of adjustments of the values of **c**. The gradient of Q can be easily determined. In spite of that, there could be some potential shortcomings of this learning scheme. The most profound one comes with a high dimensionality of the network. If there are a significant number of the variables in the problem, the computed gradient assumes low values. As a result, the learning becomes very inefficient. Note also that the dimensionality of the input vector is equal to 2^n and this expression gives rise to a prohibitively high dimensionality quite quickly even for relatively small values of "n". In light of these, it is very likely that the gradient-based methods will come with a limited applicability and we have to proceed with caution when dealing with the increased problem dimensionality.

The second design scenario involves an optimization of the structure (selection of variables) that helps handle the dimensionality problem in an efficient manner. The parametric optimization concerning the vector of the co-efficients in some reduced format becomes then more efficient. We may also envision frequent situations in which not all variables become essential to the design of the logic mapping (the same holds in pattern recognition where a stage of feature selection becomes a necessity). With the structural and parametric optimization at hand, we have to confine ourselves to some techniques of global and structural optimization. An appealing way to follow is to consider genetic algorithms (GAs).

Genetic Development of the fMUX Networks

Having recognized the primary design objectives, we now concentrate on the details of the underlying genetic optimization. GAs (Goldberg, 1989; Michalewicz, 1996) are well-documented in the literature including a long list of their numerous applications to neuro-fuzzy systems. Bearing this in mind, we elaborate on the fundamental architecture of the GA, its parameters, and discuss some implementation details.

Figure 8. The structure of the fMUX network and its genetic representation (a) and details of the coding of the subset of the input variables (b) through ranking and using the first n' entries of the sub-string



Genotype Representation

The proposed genotype is a direct reflection of the structure of the fMUX network. We consider a floating point coding as this results in compact chromosomes. Let us assume that the number of input variables to be used in the network is given in advance and equal to n' where n' < n. The chromosome consists of two sub-strings of real numbers. The first block (sub-string) contains $2^{n'}$ values of the information inputs, vector. The second block (with n inputs) deals with the subset of the variables to be used in the design. The details are schematically visualized in Figure 8.

As far as the structure of network is concerned, it is instructive to discuss a way in which the select variables are coded in the second block of the chromosome. The second portion of the chromosome corresponds to the subset of the original inputs that are chosen as select variables and requires some processing before being used to identify the structure of the network. As the entries of the chromosome are real-coded, the likelihood of encountering two identical entries is zero (to be on the safe side, we can always break a tie randomly). With the pre-defined number of the inputs (n'), we then use only the first n' entries of the chromosome, and this produces the sequence of the input variables. The entries are ranked (in the increasing order), and the first n' entries of the sub-string are used to choose among all variables. This ordering is directly mapped onto the network where the first variable is the one switching the first layer of the network.

N.B. One could easily optimize the number of the subset of the input variables (n') instead of supplying it externally yet this does not to seem to be very attractive. It is perhaps more justifiable to do a systematic search by sweeping n' from 1 to n. In essence, this systematic search helps us assess approximation and generalization abilities of the networks and get a better sense as to the plausible subset of the variables.

When it comes to the *selection process*, we use an elitist ranking selection (Michalewicz, 1996). This selection mechanism means that individuals to be selected for the next generation are based on their relative rank in the population, as determined by the fitness function. The best individual from each generation is always carried over to the next generation (elitist mechanism) meaning that the solution found so far during the genetic optimization is guaranteed to never disappear.

The *mutation* operator is a standard construct encountered in a number of genetic algorithms, cf. . 0. Given an individual string $\mathbf{a} = [a_1, a_2, \ldots, a_{2n}]$, we generate a new string $\mathbf{a}' = [a_1', a_2', \ldots, a_{2n}']$ where a_i', i=1, 2,…,2n, is a random number confined in the range of [0,1] and subject to the following replacement (mutation) rule: a_i is mutated that is replaced by a_i' with some probability of mutation (p_m) otherwise the entry of the chromosome is left intact, that is $a_i' = a_i$.

The *crossover* operation is realized as the BLX-0.5 crossover operator (Baker, 1985; Eshelman & Schaffer, 1993; Goldberg, 1991; Herrera, Lozano, & Verdegay, 1998) which is carried out as follows. Given are two individuals $\mathbf{a} = [a_1, a_2, \ldots, a_{2n}]$ and $\mathbf{b} = [b_1, b_2, \ldots, b_{2n}]$. The resulting offsprings are formed in the form $\mathbf{a}' = [a_1', a_2', \ldots, a_{2n}']$ and $\mathbf{b}' = [b_1', b_2', \ldots, b_{2n}']$, where a_i', b_i', i=1,2,…,2n, are random numbers located in the range $[\max(0, \min_i - 0.5I), \min(1, \max_i + 0.5I)]$. Here, $\min_i = \min(a_i, b_i)$, $\max_i = \max(a_i, b_i)$, and $I = \max_i - \min_i$. This particular crossover operation provides a good balance between using the information of the parents and avoiding premature convergence. The crossover operator ensures that all values of the generated offspring are confined to the unit interval [0, 1]. The operator is employed with probability of crossover, p_c, otherwise the individuals are left unchanged $\mathbf{a}' = \mathbf{a}$ and $\mathbf{b}' = \mathbf{b}$.

Fitness Function

The fitness function quantifies how the network approximates the data and is taken as

$$1 - \frac{Q}{Q + \varepsilon}$$

with Q being a sum of squared errors between the target values (experimental output data) and the corresponding outputs of the network. The other option is the standard root mean squared error (RMSE). A small positive constant ε standing in the denominator of the earlier expression assures that the fitness function remains meaningful even for Q = 0 (which in practice never occurs).

EXPERIMENTAL STUDIES

In the experimental part of the study, we start with some illustrative material dealing with Boolean expressions and then move on to the software data.

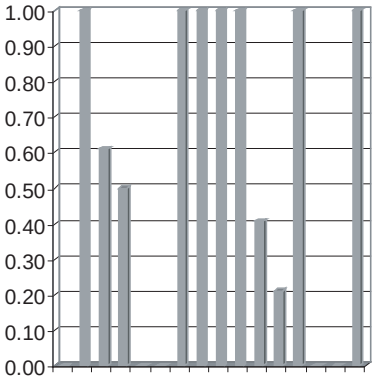
Realization of Boolean Functions

In this experiment, we are concerned with Boolean data; this helps us compare the result produced

Table 1. Structure of the multiplexer network and associated errors; by the classification error, we mean the number of mismatches between the binary (that is subjected to some threshold) output of the network and the data

Number of variables	1	2	3	4	5
Order of variables	x_3	x_5, x_3	x_3, x_5, x_2	x_4, x_3, x_2, x_5	x_4, x_1, x_2,x_5,x_3
MSE	0.478	0.408	0.354	$1.29*10^{-4}$	$2.09*10^{-5}$
Classification error	3	2	4	0	0

Figure 9. Values of the information inputs; observe that their distribution is highly bimodal with the values of information inputs being close to 1 or 0 with a very few exceptions



by the fuzzy multiplexer with the solutions obtained using standard techniques used to design digital systems. The data set comprises of 12 input-output pairs of binary data with 5 inputs and a single output,

(**x**(k)-y(k)): ([1 0 0 0 0] 0), ([1 0 0 0 1] 1), ([1 0 0 1 0] 1), ([1 0 0 1 1] 1), ([1 1 1 0 0] 1),
([1 1 1 0 1] 0), ([1 1 1 1 0] 1), ([1 1 1 1 1] 1), ([1 1 0 0 0] 0), ([1 1 0 0 1] 1),
([1 1 0 1 0] 0), ([1 1 0 1 1] 0)

The development of the network is completed for a varying number of inputs starting from one variable and ending up with all the variables. The results are summarized in Table 1.

From this table (based on the values of the classification error), it becomes obvious that four variables are optimal for the problem. The resulting inputs are shown in Figure 9. With the threshold value of 0.5, we are left with eight significant inputs. Noticeably, all those very close to 1 identify the min terms existing in the data. The one extra here with the value equal to 0.61 (and still deemed relevant) corresponds to the combination of the inputs equal to 0100 (that is $\overline{x}_4 x_3 \overline{x}_2 \overline{x}_5$), and it is subsumed by the remaining sum of the minterms. Alluding to the problem variables being identified by the genetic algorithm, it is interesting to note that x1 has been eliminated. It is not surprising at all noting that it fixed at 1 and thus becomes redundant in the problem. For this optimal number of the inputs, Figure 10 shows how GA performs in terms of the optimization; evidently most learning occurs at the beginning of the process, and this becomes evident for the best individual as well as the average fitness in the population.

The second example is shown here to visualize the effectiveness of the genetic optimization. The binary data describe a three-dimensional XOR problem. With the population of 50 chromosomes, 50 generations, the mutation rate of 0.05, and crossover rate equal to 0.8, the ideal result is obtained after a few initial generations. As expected, the information inputs are either close to 1 or become practically equal to zero (Figure 11).

Experiments with Software Data

In the ensuing comprehensive suite of experiments, we consider a well-documented MIS data

Figure 10. Fitness function (average and best individual) in successive generations

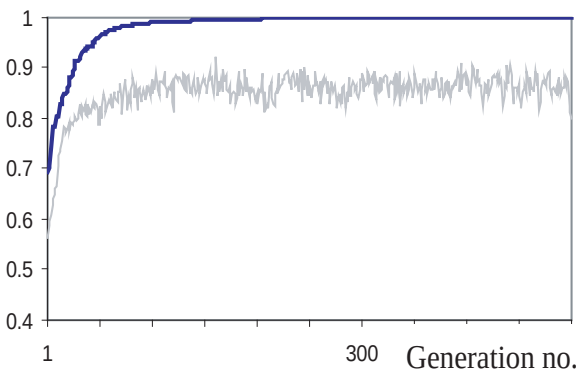


Figure 11. Information inputs of the network of fuzzy multiplexers

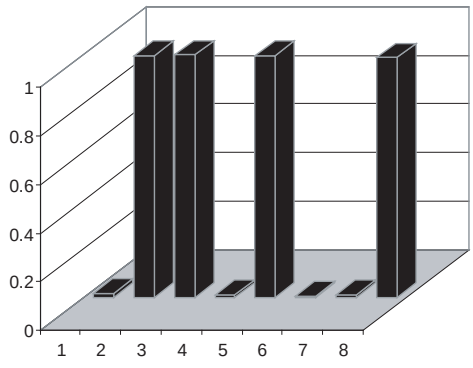


set (Munson & Khoshgoftaar, 1996) which has already been used in other experimentation with models of quantitative software engineering. The dataset includes software modules described by a collection of typical software metrics and associated number of changes made to the corresponding module. For the purpose of this experimentation, we focused only on the selected software measures leaving some others out (such as, e.g., number of characters, number of code characters, number of comments); refer to Table 2.

For further experimentation, we eliminated one data point for which the number of changes was overly high (98) in comparison to the rest of the data and which could easily skew up the entire picture. Note that the average number of changes was 7.25. In the learning process, we use 60% of randomly selected data. The rest (40%) is left for testing purposes. The t- and t-conorm are implemented as the product and probabilistic sum.

As discussed in *The General Development Environment of the Network-Interfaces Issues* section, the software measures were linearly normalized to the unit interval. The evolutionary optimization was realized with the following parameters of the GA whose values are quite typical and quite similar to those found in the literature, namely

size of population –300,
number of generations – 500,
mutation rate – 0.05,
crossover rate – 0.8

As a matter of fact, it is worth noting that those parameters could be fine-tuned, however the process might be quite tedious and geared only towards a specific dataset.

In the series of experiments, we modified the number of allowed input variables starting from a single software metrics and moving on to the entire set. The results are reported in terms of the performance index (RMSE) for the training and testing set as well as the corresponding subsets of the variables (see Table 3).

We observe that the performance index on the training set achieves the minimum for two and three variables. With the increase of the dimensionality, there is some increase in the values of the performance index. Given this, we may regard the two software metrics, that is, the number of lines of code, and the estimated program length

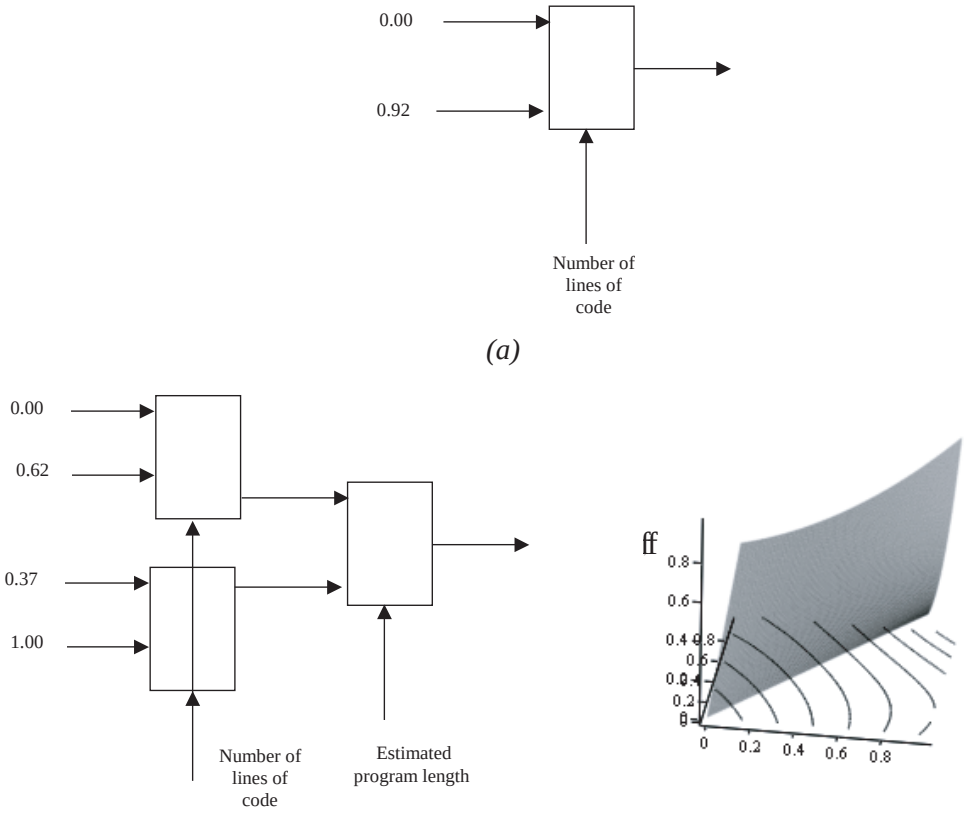
Table 2. A collection of software metrics (measures) used in the experiments

	Software metrics	notes
x_1	Number of lines of code, including comments	
x_2	Program length	N = N1 + N2; N1- the total number of operators, N2-total number of operands
x_3	Estimated program length	$n_1 \log_2 n_1 + n_2 \log_2 n_2$ n_1-the number of unique operators, n_2 – the number of unique operators
x_4	Jensen's estimator of program length	$(\log_2 n_1)! + (\log_2 n_2)!$
x_5	McCabe cyclomatic complexity number	number of decision nodes +1
x_6	Belady's bandwidth metric	average level of nesting

Table 3. Results of genetic optimization of the logic model of the network of fuzzy multiplexers (the switching variables are listed starting from the first layer of the fuzzy multiplexers in the overall architecture)

Number of input variables	1	2	3	4	5	6
Software metrics and their arrangement	x_1	x_1 x_3	x_1 x_5 x_3	x_1 x_4 x_3 x_5	x_3 x_1 x_4 x_6 x_5	x_4 x_1 x_3 x_5 x_6 x_2
Performance index (training data)	5.42	**5.37**	5.37	5.41	5.53	5.76

Figure 12. The detailed architecture of the network with the values of the inputs to the fuzzy multiplexers; shown are also the input-output characteristics of the networks for the two software metrics



to form a suitable subset of software metrics. By adding the third metrics, that is, McCabe cyclomatic complexity, we are not witnessing any improvement (the performance index stays the same). As a matter of act, the performance index on the testing set reaches 8.09 for two metrics and 5.37 for the suite of the three metrics. The topologies of the networks with a single input and two inputs along with their characteristics are visualized in Figure 12.

The findings are intuitively appealing as far as the specific software metrics are concerned and their occurrence in the overall expression. In the case of the single input, the number of lines of code is a fairly compelling indicator of possible changes. The logic expression identifies a direct relationship between the increase in the values of this metrics and the resulting increase in the number of changes made to the software module. This observation is drawn from the logic expression; see Figure 12, $y = 0.92\ t\ x_1 = 0.92\ x_1$ (as the t-norm has been implemented as the product operator). This relationship is linear as illustrated in Figure 12. Given the underlying logic of the fuzzy multiplexer, one could infer that the increase of the number of lines of code leads to the increase of the number of changes in the code. With the two inputs, we observe that the x1 is the first switching variable and the results produced at the first layer are combined by the fuzzy multiplexer guided by x_3 (estimated program length). The logic expression governing the relationships is intuitively appealing: roughly speaking, the increase in the number of changes occurs when both the number of lines and the estimated program length are increasing or at least one of them with the more significant impact caused by the high number of lines. This slightly asymmetric behavior is also reflected in Figure 12.

CONCLUSIONS

We have introduced a logic-driven architecture of fuzzy models based on a concept of fuzzy multiplexers (fMUXs). fMUXs are direct generalizations of fundamental building blocks encountered in two-valued (digital) logic and being used in a design process therein. The design of the fMUX networks has been carried in the framework of genetic optimization. The GA is effectively used at the level of structural and parametric optimization. It is worth stressing that the structural optimization becomes indispensable in case of multi-variable problems. The selected (optimized) subset of input variables leads to an efficient dimensionality reduction of the problem and helps concentrate on the most significant variables. With this regard, the resulting transparency of the model is also worth emphasizing. Given the topology of the network itself and the processing therein, its structure becomes highly interpretable. Any fMUXs construct is translated into a coherent logical description of the experimental data being used in its development. Taking full advantage of this aspect, we were able to reveal and quantify immediate links between some software metrics and the quality of the software product (in our case, it related to the number of changes that were made to the software modules). We emphasize that the network of fMUXs translates into a logic description of experimental software data we used in their development. Given the form of the input interface that linked the data with the logic processing realized through two linear membership functions, we came up with an interesting and highly readable semantics of the relationships conveyed by the logic model. In essence, the logic model endowed with this type of interface expresses "gradual" dependencies between the inputs (software metrics) and some ensuing effects (the number of changes) and quantifies the strength of these relationships

(which is done with the use of the numeric values of the data inputs of the fMUXs positioned at the input layer of the network).

ABSTRACT

Real-time database-management systems provide efficient support for applications with data and transactions that have temporal constraints, such as industrial automation, aviation, and sensor networks, among others. Many issues in real-time databases have brought interest to research in this area, such as: concurrence control mechanisms, scheduling policy, and quality of services management. However, considering the complexity of these applications, it is of fundamental importance to conceive formal verification and validation techniques for real-time database systems. This chapter presents a formal verification and validation method for real-time databases. Such a method can be applied to database systems developed for computer integrated manufacturing, stock exchange, network-management, and command-and-control applications and multimedia systems. In this chapter, we describe a case study that considers sensor networks.

INTRODUCTION

Nowadays, the heterogeneity of platforms, distributed execution, real-time constraints, and other features are increasingly making software development a more complex activity. Besides, the amount of data to be managed is increasing as well. Taken together, complexity and data management are causing both risk and cost of software projects to get higher.

Database management systems are used to manage and store large amounts of data efficiently. However, when both data and transactions have timing restrictions, real-time databases (RTDB) are required to deal with real-time constraints (Ribeiro-Neto, Perkusich, & Perkusich, 2004). For an RTDB, the goal is to complete transactions on time, while maintaining logical and temporal consistency of the data. For real-time systems, correct system functionality depends on logical as well as on temporal correctness. Static analysis alone is not sufficient to verify the temporal behavior of real-time systems. To satisfy logical and temporal consistency, concurrency control techniques and time-cognizant transactions processing can be used, respectively. The last occurs by tailoring transaction management techniques to explicitly deal with time.

The real-time ability defines nonfunctional requirements of the system that must be considered during the software development. The quality assurance of real-time systems is necessary to assure that the real-time ability has been correctly specified. Imprecise computation is used as a technique for real-time systems where precise outputs are traded off for timely responses to system events. For that, formal models can be created to verify the requirement specifications, including the real-time specifications (Ribeiro-Neto, Perkusich, & Perkusich, 2003).

Validation as well as verification can be carried out by simulation model. With the simulation model, a random sample will be selected from the input domain of the test object, which is then simulated with these chosen input values. After that, the results obtained by this execution are compared with the expected values. Thus, a simulation model is as a dynamic technique, that is a technique that contains the execution of the test object. One major objective of simulation models is error detection (Herrmann, 2001).

The main motivation for this research is the fact that methods to describe conceptual models of conventional database systems cannot be directly applied to describe models of real-time database systems. It occurs because these models do not provide mechanisms to represent temporal restrictions that are inherent to real-time systems. Also, most of the available models focus on the representation of static properties of the data. On the other hand, complex systems, such as real-time databases, also require the modeling of dynamic properties for data and information. Therefore, the development of methods to design real-time databases with support for both static and dynamic modeling is an important issue.

In the literature, there are few works for real-time database modeling that allow a formal analysis, considering verification and validation characteristics. The existing tools for supporting modeling process especially do not present simulation capacity. The unified modeling language (UML) approach presents a number of favorable characteristics for modeling complex real-time systems, as described in Selic and Rumbaugh (1998) and Douglass (2004). UML also is used for modeling object-oriented database systems. However, the existing tools for UML modeling do not present simulation capacity.

This chapter describes a formal approach to verify and validate real-time database systems. The approach consists of the application of the five steps: (1) building an object model; (2) building a process model; (3) generating an occurrence graph; (4) generating a message-sequence chart; and (5) generating a timing diagram. The two first steps include static and dynamic analysis, respectively. The following steps allow the user

to validate the model. Hierarchical coloured Petri nets (HCPNs) are used as the formal language to describe RTDB models (Jensen, 1998). The proposed approach can be applied to different domains, such as computer-integrated manufacturing, stock exchanges, network management, command-and-control applications, multimedia systems, sensor networks, and navigation systems. In this chapter, we describe a case study considering sensor networks. Sensor networks are used to control and to monitor the physical environment and sensor nodes may have different physical sensors and can be used for different application scenarios.

The remainder of this chapter is presented as follows. First, a background is presented, to ease the comprehension of approach. Concepts about RTDB, quality of services and HCPNs are defined. Second, the formal verification and validation approach for real-time databases is described as well as a sensor network case study. Third, future trends are presented. Finally, conclusions are presented.

BACKGROUND

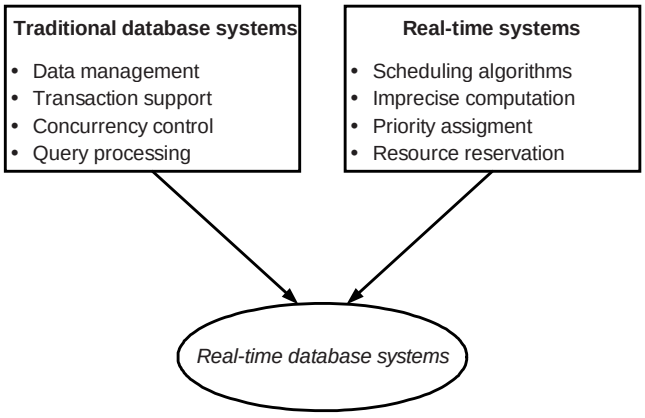
Real-Time Databases (RTDB)

The real-time database-management systems must provide the characteristics of conventional databases besides assuring that the real-time constraints are imposed on both the data and transactions. These constraints arise in applications where the transactions must meet deadlines.

The amount of applications that benefit from the utilization of RTDB is increasing as well. This increase is a consequence of the proliferation of embedded systems that includes both systems that are similar to those present in personal computers and smaller systems with a minimal memory and calculator capacity, such as those present in mobile devices.

An RTDB is required when: The volume of data is large; responses depend on multiple values; responses to aperiodic events are required; and there are constrained timing requirements. The correctness in real-time databases implies: sat-

Figure 1. Real-time database systems



isfying all usual consistency constraints; executing transactions within timing constraints; and satisfying temporal consistency of the data. The real-time data and transactions are also defined. The data items reflect the state of the environment. The transactions are classified with respect to their deadlines, such as hard, soft, or firm; arrival-pattern — periodic, aperiodic, sporadic; and data-access-pattern — read-only, write-only and update. In Figure 1, a schema illustrating the properties of the RTDB is shown.

Data Properties

The data correctness in RTDB is assured by logical and temporal consistency. The real-time data can be classified into static and dynamic. The correctness of static data is guaranteed by the logical consistency, since is has not become outdated. The dynamic data may change continuously to reflect the real-world state, such as object positions, physic measure, stock market, and so on. Each dynamic datum has a timestamp of the latest update and the data can be divided into base data and derived data. A derived datum can be derived from various base data (Kang, 2001).

The external consistency of dynamic data is defined using validity intervals to assure the consistency between the state represented by the database content and the actual state of environment. The validity intervals are of two types as follows (Kang, 2001):

- **Absolute validity interval (*avi*)** is defined between the environment state and the value reflected in the database. The data *x* is considered temporally inconsistent if (*now* - *timestamp*(*x*) > *avi*(*x*)), where *now* is the actual time of system, *timestamp* is the time of the latest update of data.
- **Relative validity interval (*rvi*)** is defined among the data used to derive other data. Consider a data item *y* is derived from a data set $R=\{x_1,x_2,...,x_k\}$. *y* is temporally consistent if the if the data in *R* that the compose are temporally valid and the $|timestamp(x_i \in R) - timestamp(x_j\ 0\ R)| \leq rvi(y)$. This measure arises to produce derived data from data with the approximate time.

The dynamic data are represented by *x*:(*value*,*avi*,*timestamp*) and will be temporally consistent. If both absolute and relative validity interval are satisfied. Consider the example where a data item *t*, with *avi*(*t*)=5, reflect the current temperature and the data item p represent the pressure with *avi*(*p*)=10. The data item y is derived from data set *R*={*t*,*p*} and have relative validity interval *rvi*(*y*)=2. If the actual time is 50, then (a) *t*:(25,5,45) and *p*:(40,10,47) are temporally consistent because as absolute validity interval as relative validity interval is valid. But, (b) *t*:(*25,5,45*) and *p*:(*40,10,42*) are not temporally consistent, because only the absolute validity interval is assured.

Transaction Properties

The real-time transactions are characterized along three dimensions based on the nature of transactions in real-time database systems: the nature of real-time constraints, the arrival pattern, and the data-access type.

- **Real-time constraints:** The real-time constraints of transactions are related to the effect of missing its deadline and can be categorized in hard, firm and soft. Hard deadlines are those that may result in a catastrophe if the deadline is missed. These are typically critical systems, such as a command delayed to stop a train causing a collision.
  To complete a transaction with a soft deadline after its time constraint is undesirable. However, soft deadlines missed can commit

the system performance. The transactions with firm deadline will be aborted if its temporal constraints are lost.

- **Arrival pattern of transactions:** The arrival pattern of transactions refers to time interval of execution. Generally, the transactions are periodically executed in real-time databases, since they are used to record the device reading associated to the environment or to manipulate system events. The arrival pattern can be aperiodic, where there is not a regular time interval between the executions of transactions. The transactions also can execute in random time. However, there is a minimal time interval between the executions of transactions.
- **Data access type:** In relation to data access, the transactions are categorized as: write transactions (or sensors), update transactions, and read transactions. The *write transactions* obtain the state of the environment and write into the database. The *update transactions* derive new data and store them in the database. Finally, the read transactions read data from database and send them.

In the database, it is necessary to guarantee the same views, of the same data item, for different transactions. This property is called *internal consistency* and is assured by the ACID properties. ACID is an acronym for atomicity, consistency, isolation, and durability. These properties are defined for a real-time database as follows:

- **Atomicity:** Is applied for subtransactions, where a subtransaction must be whole executed or neither step must be considered of them.
- **Consistency:** The transaction execution must always change the consistent state of a database in another consistent state. An imprecision limited in the internal consistency can be permitted in order to meet the temporal constraints of transactions.
- **Isolation:** The actions of a transaction can be visible by other transactions before it commits.
- **Durability:** The actions of a transaction need not be persistent, since both data and transactions have temporal validity.

Concurrency Control

The negotiation between logical and temporal consistency, a concurrency-control technique should be capable of using knowledge about the application to determine which transactions can be executed concurrently. Such a technique, named semantic concurrency control, allows increasing the concurrent execution of transactions (method invocation). Based on the knowledge of the application the designer must define which transactions may be concurrently executed and when. Defining compatibilities between the executions of the transactions does this. Therefore, this technique allows relaxing the ACID properties.

Transactions in real-time do not need to be serialized, especially updated transactions that record information from the environment. However, the consequence of relaxing serialization is that some imprecision can be accumulated in the database, and in the vision of the database.

An object-oriented semantic concurrency control technique, described in DiPippo (1995), named *semantic-lock technique*, allows logical and temporal consistency of the data and transactions and allows the negotiation among them. The technique also allows the control of the imprecision resulting from the negotiation. The concurrency control is distributed among the objects, and a compatibility function, says C*F* for short, is defined for each pair of methods for database objects. *CF* is defined as follows:

$$CF(m_{ati}, m_{inv}) = Boolean\ Expression \rightarrow IA$$

where m_{ati} represents the method that is being executed and, m_{inv} represents the method that was invoked. The *Boolean Expression* can be defined based on predicates involving values of the arguments of the methods, the database attributes, and the system in general. *IA* is defined by an expression that evaluates the accumulated imprecision for the attributes of the database object and for the arguments of the methods.

The consequence of using such a concurrency control is that more flexible scheduling for transactions can be determined than those allowed by serialization. Besides, that technique can specify and limit some imprecision that may appear in the system due to relax of the serialization.

Quality of Service (QoS) Management

In a real-time database, the QoS management can help to verify both the correctness and performance of a system, through functions and performance metrics. This is necessary, since the real-time transactions have temporal constraints. Therefore, we consider transactions correct only if they finish within their deadlines using valid data.

The functions defined are the functions of *specification, mapping, negotiation,* and *monitoring.* The function specification defines which QoS parameters are available and determines their syntax and semantics. The mapping function has to be provided to translate the QoS requirements expressed.

The role of a QoS negotiation mechanism is to determine an agreement for the required values of the QoS parameters between the system and the users or applications. A QoS negotiation protocol is executed, every time a new user or application joins an active session, to verify whether the system has enough resources to accept the new user or application request without compromising the current performance. This function usually employs several QoS mechanisms to fulfill its task, such as: *admission control* is used to determine whether a new user can be served, while *resource reservation* has to be called as soon as the user is admitted, in order to guarantee the requested service quality. The negotiation function has the role of the compability function, described above.

We define two performance metrics to guarantee the RTDB performance. These metrics are shown as follows:

1. **Number of transactions that miss the deadline in relation to the amount of transactions that finish with success (*Pt*):** This metric set up the rate of missed deadline of transactions that can be allowed during a time interval. The metric is defined as:

$$Pt = 100 * \left(\frac{MissedDeadline}{FinishTransactions} \right)$$

   where *Pt* is the amount of transactions that miss the deadline (*MissedDeadline*) in relation to the amount of transactions that finish with success (*FinishTransactions*).
2. **Upper imprecision of data (*Impr*):** Is the threshold of imprecision admitted in the data item for it to be considered logically valid. *Impr* is defined as:

$$Impr = CurrentValue * \left(\frac{Imp}{100} \right)$$

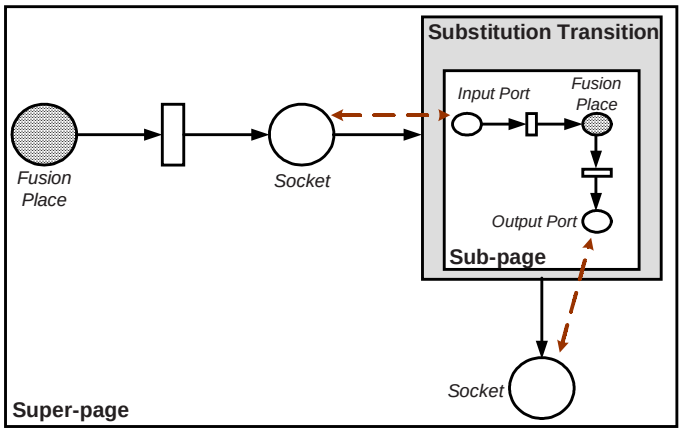
   where *CurrentValue* is the value of data item stored in database and *Imp* is the index of amount of imprecision admitted.

HCPN-Based Modeling

Hierarchical Coloured Petri Nets

Hierarchical coloured Petri nets (HCPNs) are an extension of coloured Petri nets (CPNs) (Jensen, 1998) and are a suitable modeling language for verifying systems, as they can express concurrency, parallelism, nondeterminism, and different levels of abstraction.

Figure 2. Coloured Petri net



In Figure 2, a Petri net is illustrated, where hierarchical levels are allowed. These hierarchical levels are possible due to the inclusion of two mechanisms: substitution transitions and fusion places. A substitution transition is a transition that will be replaced by a CPN page. The page to which the substitution transition belongs is called a superpage and the page represented by the transition is called the subpage. The association between subpages and superpages is performed by means of sockets and ports.

Sockets are all the input and output places of the transition in the superpage. Ports are the places in the subpage associated to the sockets. The ports can be input, output, or input-output. For simulation and state, space-generation sockets and ports are glued together and the resulting model is a flat CPN model. The fusion places are physically different but logically only one forming a fusion set. Therefore, all the places belonging to a fusion set have always the same marking. A marking of a place is the set of tokens in that place in a given moment. The marking of a net is the set of markings of all places in the net at a given moment (Jensen, 1998).

Indeed, these two additional mechanisms, substitution transitions and fusion places, are only graphical, helping in the organization and visualization of a CPN model. They favor the modeling of larger and more complex systems by giving the designer the ability to model by abstraction, specialization, or both.

Design/CPN Tools

Design/CPN (Jensen et al.,1999) is a tool package supporting the use of HCPN. The Design/CPN tool has four integrated parts:

1. The **CPN editor** supports construction, modification, and syntax check of CPN models.
2. The **CPN simulator** supports interactive and automatic simulation of CPN models.
3. The **occurrence graph tool** supports construction and analysis of occurrence graphs

for CPN models (also known as state spaces or reachability graphs/trees).

4. The **perfomance tool** supports simulation=based performance analysis of CPN models.

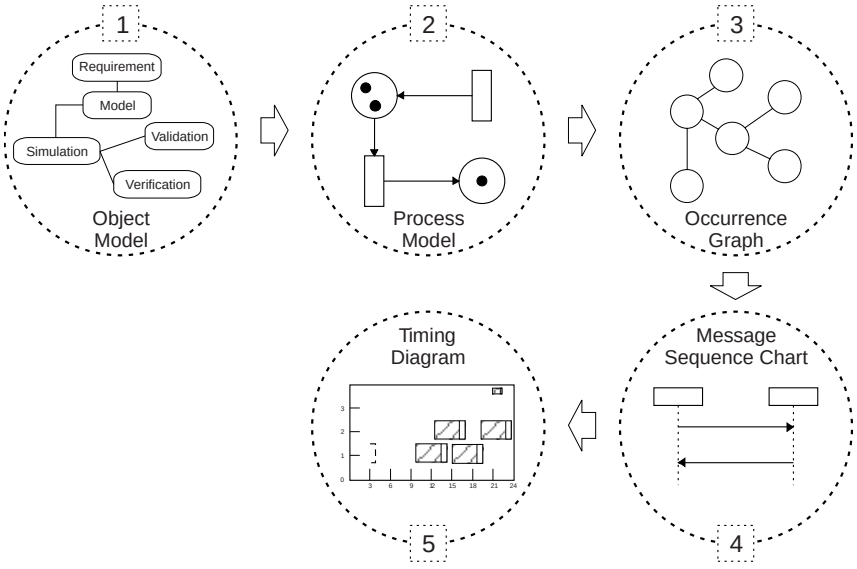
The design/CPN package is one of the most used Petri net tools. Design/CPN supports CPN models with complex data types (colour sets) and complex data manipulations (arc expressions and guards), both specified in the functional programming language Standard ML(Jensen et al., 1999).

REAL-TIME DATABASE VERIFICATION AND VALIDATION METHOD

The formal verification and validation method for real-time database systems consists of the application of the following steps, as illustrated in Figure 3, which are detailed in this section:

1. **Build an object model:** It is used to specify the requirements and identify the main components of the system. It is also used to model static properties of objects, such as attributes, operations, and logical and timing constraints. In any way, the object model defines the discourse universe to the process model.
2. **Build a process model:** It is used to model both functional and dynamic properties of objects. The functional properties define the object operations, while the dynamic property represents the temporal interactions of objects and its answers to the events. The process model is composed of the operations identified in the *object model.*
3. **Generate an occurrence graph:** It is a representation of the state space of the HCPN model.
4. **Generate a message sequence chart:** They are generated for each scenario, considering a possible execution sequence.

Figure 3. Real-time database verification and validation method



5. **Generate a timing diagram:** It is a diagram to show the timing constraints in time sample.

Build an Object Model

In the object model each *object* is a unique entity. Objects with the same data structure (attributes) and behavior (operations), in the context of the particular application environment are grouped into an object *class.* Classes can be grouped in a hierarchical structure. Classes may have attributes; the attributes are structural properties of classes that can have both logical and temporal constraints; the *relationships* are the links between the classes; the *operations* are functions or procedures applicable to the class attributes, and the *method* is the implementation of an *operation* (Rumbaugh, Blaha, Premerlani, Eddy, & Lorensen, 1991).

The object model consists of a set of: *class diagram*, *object diagram*, and *data dictionary.* The *class diagrams* have shown the general description of the system, while the *object diagrams* shown object instances. The data *dictionary* defines whole entities modeled (class, associations, attributes, operations).

The object model begins with the problem declaration analysis and has the following steps:

1. **Identification of the objects:** The external actors and objects that interact with the system are identified as the problem context. Elements of the object model that emerge from the analysis of the real problem are directly mapped into logical objects. Each instance of an object is assumed to be unique. The objects in an object class have a unique identity that separates and identifies them from all other object instances.
2. **Identification of relationships among objects:** A conceptual relationship among instances of classes. Associations have *cardinality* including one-to-one, one-to-many, and many-to-many. Most object-oriented texts do not address the *nature* of an association (i.e., mandatory or optional), except in the definition of the object behavior.
3. **Addition of attributes to objects:** a data value that can be held by the objects in a class. Attributes may be assigned to different data types (e.g., integer).
4. **Use of generalizations to observe similarities and differences:** the essential characteristics of an object or class, ignoring irrelevant features, providing crisply defined conceptual boundaries. This maintains a focus upon identifying common characteristics among what may initially appear to be different objects. Abstraction enhances reusability and inheritance.
5. **Identification of operations:** the direct manipulation of an object, categorized as: *Constructor:* create an object and/or initialize. *Destructor:* free the state of an object and/or destroy the object. *Modifier:* alter the state of the object. *Selector:* access and read the state of an object. *Iterator:* access all parts of an object in a well-defined order.
6. **Identification of concurrent operations:** In this step, the designer analyzes the system to discover which operations need to be executed concurrently and in that condition this occurs. In follow, it is defined the function that details the situations which the operations can be executed concurrently.
7. **Identification of both logical and temporal constraints:** The designer must declare both logical and temporal constraints to objects. These constraints define the correct states of each object. Thus, the constraints are defined as predicates that include the attributes value, time, and so on. For instance, the absolute validity interval defined to real-time data, in the Background section, expresses a temporal constraint to data objects.

Build a Process Model

The process model captures both functional and dynamic properties of objects. This model is used in the analysis, design, and implementation phases of the software-development life cycle. These phases can be tackled concurrently, using hierarchical coloured Petri nets. HCPNs are used to analyze the system behavior. In this model, the objects are described through HCPN modules (or pages) that are defined from object models. Then, for each object that contains operations identified in the model, a HCPN module is created, where the correspondent operations are modeled. We use the design/CPN tool package (Jensen et al., 1999) for HCPN modeling. For that, the following steps must be performed:

1. **Identification of the objects in HCPN:** In this step, all of the objects in the object model are identified, and for each object identified an HCPN module is constructed.
2. **Identification of functions for each object:** The operations that must be executed by each object are identified. What each object must execute is analyzed without considering its implementation.
3. **Definition of the interface for each object:** The interface of each object is declared, indicating the methods with its respective argument of input and output, the constraints defined to the classes, besides functions that describe the compatibility between methods.
4. **Definition of the internal structure of each object:** The methods detailed in the interface of objects are described, satisfying the requisites identified in the phase of identification of the objects.

Occurrence Graph (OG)

The occurrence graph tool is closely integrated with the design/CPN tool package (Jensen et al., 1999). The basic idea behind occurrence graphs is to make a directed graph with a node for each reachable marking and an arc for each occurring binding element. OGs are directed graphs that have a node for each reachable marking and an arc for each binding element. An arc binding the marking node that the binding element associated occurs at each marking node resultant of occurrence (Jensen, 1998).

The OG has a large number of built-in standard queries, such as *Reachable*, which determines whether there is an occurrence sequence between two specified markings, and *AllReachable*, which determines whether all the reachable markings are reachable from each other. These queries can be used to investigate all the standard properties of a HCPN. In addition to the standard queries, there are a number of powerful search facilities allowing formulating nonstandard queries. The standard queries require no programming at all. The nonstandard queries usually require that 2-5 programming lines of quite straightforward ML code.

Through an occurrence graph, it is possible to verify the properties inherent to the model. The occurrence graph tool allows obtaining reports with general properties about the model. These reports contain information about the graph and metaproperties that are utilities for comprehension of model behavior in HCPN. For instance: *boundness properties*, which supply the upper and lower limit of tokens that each net place can contain, besides marking limits for each place; *liveness properties*, which shown the markings and transitions that are dead (not precede none other marking) and which transitions are live (appear in some occurrence sequence started of the initial marking of the net). Occurrence graphs can be constructed with or without considering time or code segments.

When an occurrence graph has been constructed using the design/CPN it can be analyzed in different ways. The easiest approach is to use the *Save Report* command to generate a standard

report providing information about all standard CPN properties:

- **Statistics:** Size of occurrence graph
- **Boundedness properties:** Integer and multiset bounds for place instances
- **Home properties:** Home markings
- **Liveness properties:** Dead markings, dead/live transition instances
- **Fairness properties:** Impartial/fair/just transition instances

To use the OG tool, the user simply enters the simulator and invokes the Enter Occ Graph command (in the file menu of design/CPN). This has a similar effect as Enter Simulator. It creates the occurrence graph code, that is, the ML code necessary to calculate, analyze, and draw occurrence graphs. Moreover, it creates a new menu, called Occ. This menu contains all the commands which are used to perform the calculation and drawing of occurrence graphs.

Generate a Message Sequence Chart (MSC)

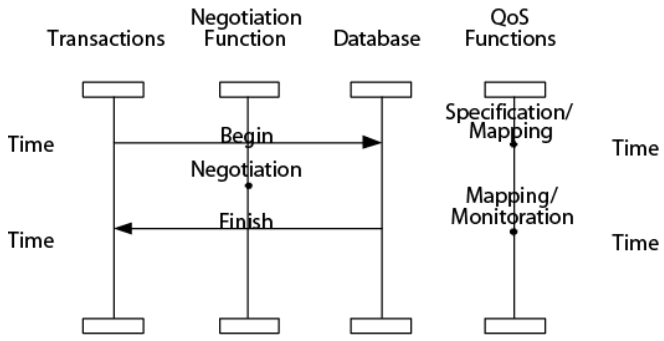
MSC is a graphical and textual language for the description and specification of the interactions between system components. Message sequence charts may be used for requirement specification, simulation and validation, test-case specification and documentation of real-time systems.

As illustrated in Figure 4, the MSC comprises the QoS functions, the transactions with its operations, and the RTDB. In this method, the use of MSC is primordial, since it is possible to verify the properties of real-time database by representing the transactions properties and data properties, both with temporal constraints. Also, it is possible to validate the behavior of objects, its relationships, and the situations where concurrent access to the RTDB occurs through the object operations. To generate the MSC, we use the "*smc.sml*" library of the design/CPN tool package.

Generate a Timing Diagram (TD)

The design/CPN performance tool for facilitating simulation-based performance analysis of HCPN generates the timing diagram. In this context, performance analysis is based on the analysis of data extracted from a HCPN model during simulation. The Performance tool provides random number generators for a variety of probability distributions and high-level support for both data collection and for generating simulation output.

Figure 4. Description of message sequence chart



The random number generators can be used to create more accurate models by modeling certain probability distribution aspects of a system, while the data collection facilities can extract relevant data from a CPN model.

Before data can be collected from a HCPN model, it is necessary to generate the *performance code*, that is, the ML code that is used to extract data from the HCPN model. The design/CPN performance tool can then be used to generate performance reports as a time diagram.

Case Study: Real-Time Database for Sensor Networks

Case Study Overview

A sensor network is considered as application domain to the case study, where the method proposed is applied. For this case study, a scenario where the environment monitored must have a steady temperature is described. The upper and lower bound for temperature is defined. Sensors are placed in the environment with the objective of acquiring and storing the temperature values.

Periodically, data stored in the sensors are sent to a real-time database server, through sensors transactions. The data obtained has temporal validity and the transactions have a deadline. The server is updated in order to allow historical queries. The architecture of the case study is illustrated in Figure 5.

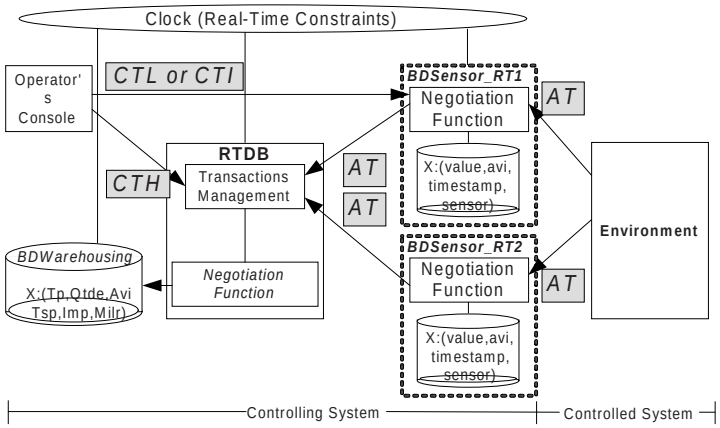
Applying the Proposed Method

Building the Object Model

According to the steps defined to obtain the object model, we have:

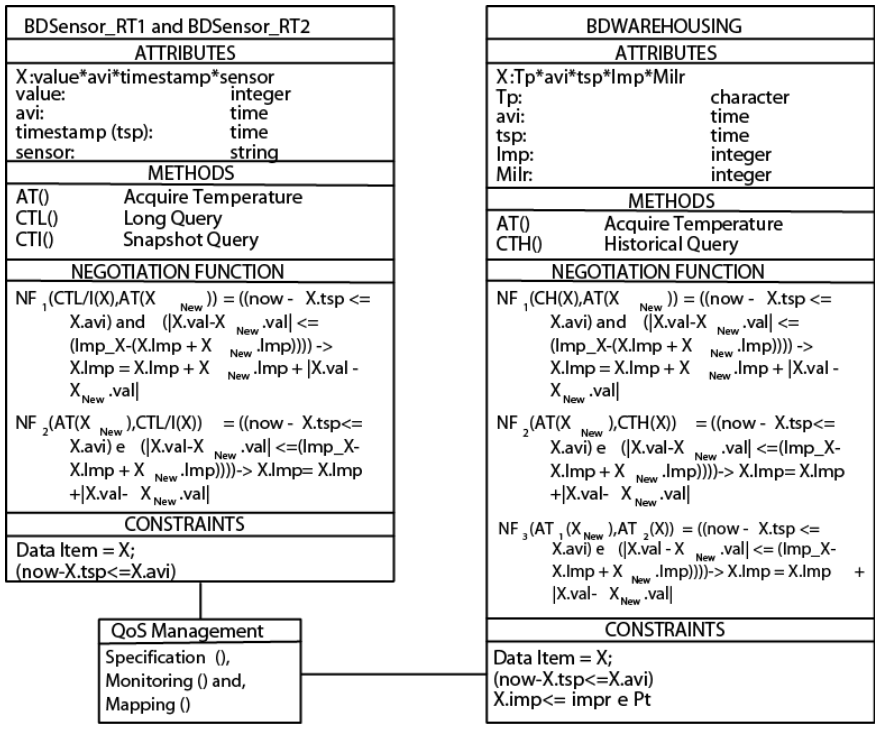
1. **Identification of the objects:** The objects identified in the model are the sensors *BDSensor_RT1 and BDSensor_RT2*, and the real-time database server, called *BDWarehousing.*
2. **Identification of relationships among objects:** The sensors send data to the server through transactions. Each sensor updates the server, while the server is updated by various sensors.

Figure 5. Architecture of the sensor network case study



3. **Addition of attributes to objects:** The data item *X* acquired by the sensor is composed of the following attributes: *Value* is the content of data item; *avi* is the absolute validate interval; *timestamp* is the late update time; and *sensor* identifies which sensor acquired the data. The attributes of the data item stored in the real-time database server has the fields: *Tp*, which is the data item processed; *Qtde*, which is the value that will be updated in the server; *Avi*, which is the absolute validate interval; *Tsp*, which is the late update time; *sensor*, which identifies the sensor that acquired the data; *Imp*, which is the accumulated imprecision; and *Milr*, which is the limit of *Imp*.
4. **Use of generalization to observe similarities and differences:** This step is unnecessary for this model, due to existence of only two objects.
5. **Identification of operations:** The sensors aim at acquiring data of the external environment (method *AT*) and these data can be read by long and snapshot queries (method *CTL* and method *CTI*, respectively). Long queries are performed in a time interval, and snapshot queries are performed in an absolute time. The real-time database server has historical data obtained by sensors (method *AT*), and allows one to query this historical data (method *CTH*).
6. **Identification of concurrent operations:** The *BDSensor_RT1 and BDSensor_RT2* object has two negotiation functions that represent two different types of concurrency. The first situation is observed when

Figure 6. Object model



the data item is being acquired and a query is invocated. The second situation of concurrency is possible when a query is running and an acquisition operation begins. In the *BDWarehousing*, three negotiation functions define the concurrence between the transactions. Besides the situations defined to the sensors, it is possible that two update operations try to access the same data item, where the sensor is updating the item and an applicative program is changing this data.

7. **Identification of both logical and temporal constraints:** In the sensor, the constraints defined to the data are: The type and the absolute validity interval of them. The constraints defined to the server are: the type of data item and the performance metrics *Pt* and *Impr*, described in this chapter.

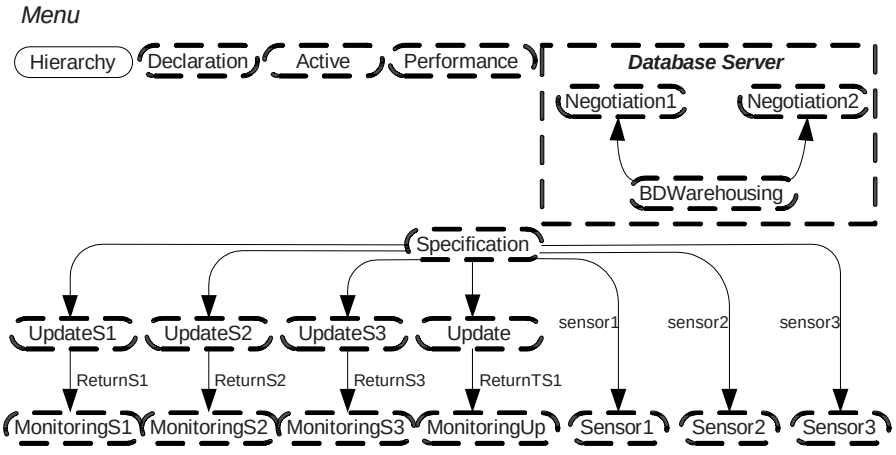
The QoS management is performed by the functions: specification, mapping, and monitoring, in addition to the negotiation function defined for the objects. Figure 6 illustrates the object model for the case study.

Building the Process Model

According to the steps defined to obtain the process model, we have:

1. **Identification of the objects in HCPN:** In this first step, the objects are identified from the object model for the the HCPN modules.
2. **Identification of functions for each object:** The sensor object implements the mechanisms of acquisition and stored data, besides reading the content stored. The real-time database server object implements the update and reading of the database.
3. **Definition of interface for each object:** In the HCPN module of sensor, the interface is defined by the methods: *AT*, *CTL*, and *CTI* and by attribute *X* that represents a record. The interface of the HCPN module to the server object indicates the methods *AT* and *CTH* and the attribute *DB* that represent a record with the fields defined to the data item stored in the server.

Figure 7. Process model



4. **Definition of internal structure for each object:** The internal structure is a hierarchical coloured Petri net to model the methods declared in the interface of the object.

The overview of the process model is illustrated in Figure 7. The HCPN modules are:

- **Declaration:** This represents the declarations, that is, the functions, types, and so on.
- **BDWarehousing:** It is the database server.
- **Negotiation1 and Negotiation:** This represents the negotiation functions.
- **Specification:** It is the module where the temporal parameters are specified.
- **Sensor1, Sensor2, and Sensor3:** This represents the modules for sensors.
- **UpdateS1, UpdateS2, and UpdateS3:** These are the sensors' transactions that update the server.
- **MonitoringS1, MonitoringS2, and MonitoringS3:** They are the monitoring functions related to each sensor transaction.
- **Update and MonitoringUp:** These modules are for the update transaction (only read) and the monitoring function defined for it.
- **Active and Performance:** These are control modules.

Generating the Occurrence Graph

For the real-time database modeled, the full standard report follows. According to the report, we have the full generation in 47 seconds, with 6,713 nodes and 22,867 arcs (see Box 1).

Some places are shown in the *boundedness properties*. The place ObjetoBD'ObjetoBDP represents the repository of data and it has the limit of 1 token. Two different combinations to the token in this place are represented in report (see Box 2).

Box 1.

```
Statistics
------------------------------------------------------------------------
Occurrence Graph
  Nodes:  6,713
  Arcs:   22,867
  Secs:   47
  Status: Full
```

Box 2.

```
Boundedness Properties
------------------------------------------------------------------------
Best Integers                    Bounds  Upper   Lower
ObjetoBD'ObjetoBDP                1       1       1

Best Upper Multi-set Bounds
ObjetoBD'ObjetoBDP               1  1`{nr = t1,vrr = 10,avir = 10,tsr = 33,impr = 1,milr =
8}++ 1`{nr = t1,vrr = 10,avir = 10,tsr = 39,impr = 1,milr = 8}
```

Box 3.

Liveness Properties

Dead Markings: 24 [6713,6712,6711,6710,6703,...]
Dead Transitions Instances: FCObjetoBDLeAt'AvaliaFCLeAt 1

In *liveness properties*, we have 24 dead markings, that is, there are 24 different ways to the net stopping. In relation to dead transition, there is only one FCObjetoBDLeAt'AvaliaFCLeAt. This transition is dead, since neither conflict occurred when a read transaction was executing and a write transaction was invocated (see Box 3).

Generating the Message Sequence Chart

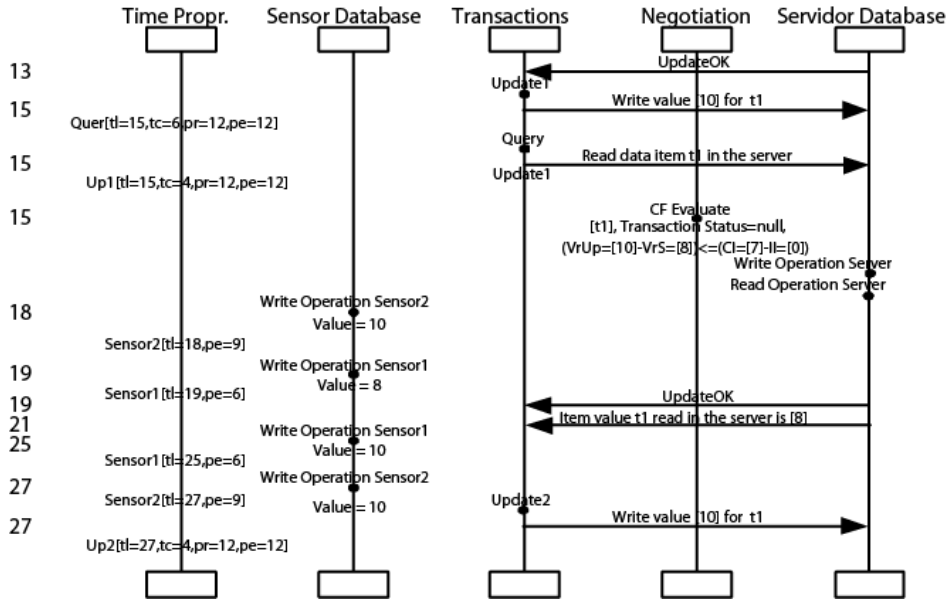
In Figure 8, we have the MSC generated considering the scenario with two sensors acquiring the same data item.

- **Sensor1:** writes periodically in the local database, the release time is 1 time unit (t.u.) and the period is 3 t.u.
- **Sensor2:** writes periodically in the local database, the release time is 9 t.u., and the period is 9 t.u.

Moreover, there are two write transactions and one read transaction.

- **Update 1:** Periodically updates the database server object with respect to the data in *Sensor1.* The release time is 3 t.u., the

Figure 8. Message sequence chart



computational time is 2 t.u., the deadline is 12 t.u., and the period is 12 t.u.

- **Update 2:** Periodically updates the database server object for sensor2. The release time is 9 t.u., the computational time is 4 t.u., the deadline is 18 t.u., and the period is 18 t.u.
- **Query:** Periodically queries the real-time database-server application. The release time is 3 t.u., the computational time is 6 t.u., the deadline is 12 t.u., and the period is 12 t.u.

The release time is the moment when all the necessary resources to the execution of the transaction and sensors are available. Starting from this moment the transaction will be ready to be executed. The computation time is the processing time necessary to execute it. The deadline defines the maximum transaction execution period. Finally, the period defines the periodicity of the transaction and sensor.

In the MSC, it is also possible to verify the QoS functions, where the negotiation between transactions conflicting and the time properties are visible during whole lifetime of a system.

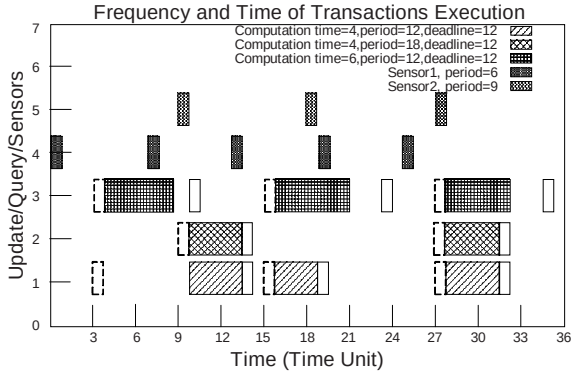
Generating the Timing Diagram

In Figure 9, the timing diagram for the execution of transactions and sensors is presented. In this figure, it is possible to see a representation of the timing model execution for both transactions and sensors, where the execution is represented by rectangles.

In the vertical axis, the transactions and the sensors are represented. In the horizontal axis the release time and the periods for both, transactions and sensors, and computational times and deadline for transactions are represented. For each transaction, we consider three states: start; processing, and committing. The start of the execution of a transaction is illustrated by a dotted line rectangle. The processing is represented by a filled rectangle, and the committing by a continuous line rectangle. For the sensor, we only show the state processing.

In the vertical axis, the *Update 1* transaction is represented in 1. The *Update 2* transaction is represented in 2. The *Query* transaction is represented in 3. The *sensor1* is represented in 4, and the *sensor2* in 5.

Figure 9. Timing diagram



FUTURE TRENDS

As for future trends, we believe that our method should be applied to other application domains. Also, the method can be expanded in order to add more functionality and graphs. Depending on the application domain, the method could be customized and its phases adapted according to the domain features.

Moreover, automatic code generation could be considered. It would be useful to ensure that the programming code for the software is according to the verified and validated model. In this context, we are currently developing an automatic code generator from HCPN model to the Java programming language.

CONCLUSION

In this chapter we presented a method for real-time database verification and validation. The main objective of this method is to make possible the identification of whole components of a system for modeling, analyzing, verifying, and validating them.

The method is based on a model developed using hierarchical coloured Petri nets. The computational tool used to generate the model, verifying the properties and generating graphs for validation by users was the design/CPN tool package.

Using the proposed method, a real system can be studied without the danger, expense, or inconvenience of the manipulation of its elements. It is performed through the analysis of the system's conceptual model and the application of guidelines which drive the developer in the validation and verification activity.

When dealing with complex systems, the process of analysis, verification, and validation needs to be automated. However, the utilization of mathematical models is primordial, which allows automatic verification and validation. It makes it possible to identify various potential deficiencies in the conceptual model, such as contradictions, ambiguity, redundancy, so forth.

Section VIII
Emerging Trends

This section highlights research potential within the field of software applications while exploring uncharted areas of study for the advancement of the discipline. Chapters within this section highlight evolutions in social software, state-of-the-art agile software methods, and modeling large software systems. These contributions, which conclude this exhaustive, multi-volume set, provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Chapter 8.1
Social Software Trends in Business: Introduction

Peter Burkhardt
IBM, USA

ABSTRACT

Social networking and Web 2.0 are the hottest words in technology right now; but is there more than just hype? This chapter will define and describe social software and Web 2.0, separate their true concepts from the marketing and buzz, and follow by identifying what might be next for this dynamic technology space. After establishing the social software and Web 2.0 concepts, this chapter identifies the value that they can bring to a company when used in a business context and the shortcomings or pitfalls. This chapter will set the foundation for subsequent discussions of social software and Web 2.0 for specific industry applications.

INTRODUCTION

Social software is the hottest topic in the technology space right now. It is nearly impossible to avoid hearing about Web 2.0 and social networking in mainstream media publications and broadcast news—and it is not just technology magazines or TV shows either. For example, just about every recent issue of *Time* magazine has had an article on Web 2.0, social networking, or something related to those buzzwords.

It is not just the mainstream media that are picking up on this hot topic. The technology itself is being used to tout both its unmatched potential and its less-often-mentioned shortcomings. Web 2.0 is providing the ability for evangelists and skeptics across the globe to weigh in and have equal voice on the very platform they are using to deliver their opinions and thoughts. For those not in the know, this seems like an opportunity that can only be missed at one's own peril.

Every new Web site is clamoring to be known as a Web 2.0 or social networking site and be the next big buzz. Gone are the days when it was good enough to provide a store front on the Internet and generate millions of dollars in sales. These days, you have to have the ability to connect people, provide consumer ratings systems, and allow ev-

erything to be tagged and commented on. Users have become more fickle and will quickly move on to another Web site that enlists more Web 2.0 feel and functionality. Casual Internet users have evolved and do not want to just browse for information; they want to project themselves, get connected to others, and interact or collaborate.

Likewise, traditional corporations are clamoring to put Web 2.0 and social software to work for their own benefit as well. Many managers and executives have said that they need to implement Web 2.0 and social software to have a competitive advantage and not be left behind by the competition. However, many will also admit that they are not quite sure what Web 2.0 really is or what social software really does for their business.

As a result of all this recent press and the amazing amount of hype surrounding Web 2.0 and social software, there are many who believe that these are new concepts (which they use interchangeably), have only recently come to fruition, and have been made available in the last few years. However, like most things, the application of social networking in software is just a new application of a concept that has existed for quite some time. Web 2.0 has been more of a gradual evolution than the instantaneous explosion that the hype would have one believe.

To help one understand where the social software market trend is going, it is extremely important to remove the hype and understand its underlying concepts and history. Only after understanding the foundation concepts of social software can one truly define its value in the marketplace and what social software means to a corporation. The remainder of this chapter will answer the question "What is social software?" and discuss its value to businesses. Subsequent chapters will proceed to examine the relevance of social software and its value as applied in the context of specific business and educational applications.

BACKGROUND

One of the most common issues that leads to confusion in this space and obfuscates the ability to see the value in social software is the interchangeable usage of terms. Just about everyone who talks and writes about this technology space freely and openly substitutes terms such as *Web 2.0*, *social networking*, and *collaboration* as though they all mean the same thing. This only serves to make this market space appear more nebulous than it needs to be and confuses those who are not already knowledgeable on the topic.

Perhaps all of this confusion should be an indicator that there is more marketing hype than substance in the social software trend. However, there are also examples and data to substantiate the validity of the use of social software for the benefit of business. The reality of the situation is that it is quite a bit of both. While there is true business value to be derived from social software, it takes the ability to see through the "buzzword bingo" that regularly occurs.

This is not to say that all terms have been clearly defined to date either. There are many experts in this space who still cannot seem to reach agreement on what certain terms, such as *Web 2.0*, really mean. Therefore, it is important to establish some definitions in order to build our social software foundation of understanding and to see the business benefits of social software.

Social Networking

Contrary to recent technology hype, social networking is a sociology concept that has evolved from sociology studies in the late 1800s and continues to mature even today. While the first studies of social networks may not have been deemed as such, the coining of the term *social network* and the analysis thereof became more mainstream and evolved rapidly within the sociology field in the 1950s to 1970s.

A social network is a grouping of personal relationships that each of us establishes. As opposed to other types of networks, the value of a social network is not in the nodes on the network, which in this case are people, but are in the relationships themselves. Social networking, therefore, is the act of building one's social network. People rely heavily on these relationships to help them with everyday tasks, such as making decisions, forming opinions, and/or finding information:

Our heavy reliance on other people for information and learning is one of the most consistent and robust findings in the social sciences. It also matches our intuition and lived experience in organizations: other people are critical to our ability to find information, learn how to do our work, and develop professionally. (Cross, Abrams, & Parker, 2004, p. 152)

As a result, one of the many uses of a social network is in conjunction with, and as a precursor to, collaboration. Leveraging one's social network vastly improves the ability to collect the right people and information upon which to collaborate toward a common goal. While social networking is a strong precursor for collaboration, the same cannot be said for the relationship when examined in the inverse order.

Social Software

Building upon this definition then, social software is about using technology, and more specifically computer software, to support the process of social networking. It is important to note that the software itself is not performing the activity of social networking. The software is simply being leveraged to support and facilitate the creation and maturation of relationships between individuals, otherwise known as social networking.

The value of social software lies in its ability to do two things. First, it helps to cross traditional barriers that keep individuals from creating relationships. In a corporate environment this could be departmental organization, where people in different departments do not normally talk to each other. The purpose of the software is not to overcome the department structure, but to acknowledge the boundaries and then cross them in order to connect people.

Second, social software assists people to better leverage their existing relationships in order to find knowledge. By exposing contextual relationships between individuals, it can assist in helping to streamline the process of identifying who should be included in a collaborative effort or who knows where to find the knowledge that is being sought. Many people easily confuse this area of value with expertise management. In reality, this may lead to someone eventually locating an expert; however, it is not expertise location in itself because the determination of the expert qualifications is inferred, at best, in social software.

Social Network Analysis

Social network analysis (SNA) is a way of identifying and understanding social linkages and relationships between people. Through the understanding of these relationships, we can then assess information flows and communication breakdowns in a social network. When applied to a business, this information can then be leveraged to identify where talent and expertise could be better applied, how work gets done in a company, and where bottlenecks exist for processes, decision making, and information flow.

SNA starts with gathering relationship information through a series of interviews, questionnaires, and company communication data. After the information has been gathered, it is analyzed to uncover the relationships that exist within an organization. More specifically, the analysis examines the nodes or actors that are in the network, the relationships between the actors, and the attributes that may be affecting those relationships. As a result of the analysis, an organization will

have a better understanding of how things happen and can take actions to increase productivity, efficiency, and/or innovation. Corporate mergers and acquisitions are a prime example of how SNA can benefit a business. After performing an SNA, the two businesses can be organized and melded together in a way that takes advantage of the most efficient processes and people in each business.

Collaboration

Collaboration is defined by Merriam-Webster's Online Dictionary ("Collaboration," n.d.) as "to work jointly with others or together especially in an intellectual endeavor." Collaboration is about more than one person (a team, a group, etc.) working together toward a common goal. There have been many types of software in the past that support collaboration, mainly in the business environment. However, the fault of these applications was that they assumed that the identification of the people being brought together to collaborate had already been conducted. While the tools facilitated the collaboration, they did not ensure that the teams had the right people involved in the collaboration or all of the most appropriate information to collaborate upon. Recent increased focus on social networks has demonstrated their importance as a precursor to collaboration and helped to exponentially increase the value of collaboration.

While collaboration software has been available in the corporate or enterprise space for quite some time (e.g., Lotus Notes, Domino), it has not been prevalent in the public domain and available to end users independent of organizational affiliation. As a result, individuals have had a tough time leveraging the Internet for collaboration in the public domain. That trend is starting to change as new technologies like wikis provide individuals with the ability to organize and collaborate toward a common goal in the public domain. The impact of domains is discussed in greater detail later in this chapter.

Web 2.0

Web 2.0 is the most commonly heard term in the social software trend and the most confusing. Even the experts disagree on the definition. O'Reilly Media is accredited with the creation of the term *Web 2.0* during a conference brainstorming session in 2004 between O'Reilly Media and MediaLive International (O'Reilly, 2005).

In short, Tim O'Reilly (2006, p.1) states, "Web 2.0 is the business revolution in the computer industry caused by the move to the internet as platform, and an attempt to understand the rules for success on that new platform." It is meant to refer to the second generation of the Internet and is composed of seven core principles.

1. The Web as a platform
2. Harnessing collective intelligence
3. Data as the next Intel Inside
4. End of the software release cycle
5. Lightweight programming models
6. Software above the level of a single device
7. Rich user experiences

Web 2.0 has, without a doubt, become the hottest buzzword today in the technology space and has just about every company and Web site clamoring to claim that they are or use Web 2.0. However, there is also a great deal of misunderstanding, or lack of understanding, as to what Web 2.0 really means when you start to boil down the term.

Critics have stated that Web 2.0 is merely a buzzword, skips over important evolutionary changes to the Web by declaring itself the second generation, does not really have much substance to it, and has yet to produce any meaningful or truly important results. One important critic is Tim Berners-Lee, the inventor of the World Wide Web. In an interview in July 2006, Berners-Lee was asked if it was fair to say that "Web 1.0 was about connecting computers and making information

available; and Web 2 is about connecting people and facilitating new kinds of collaboration." His response was

Totally not. Web 1.0 was all about connecting people. It was an interactive space, and I think Web 2.0 is of course a piece of jargon, nobody even knows what it means. If Web 2.0 for you is blogs and wikis, then that is people to people. But that was what the Web was supposed to be all along. And in fact, you know, this Web 2.0, quote, it means using the standards which have been produced by all these people working on Web 1.0. (Laningham, 2006, p. 1)

In clarifying the definition of Web 2.0, Tim O'Reilly (2006, p. 1) subsequently had this to say: "Ironically, Tim Berners-Lee's original Web 1.0 is one of the most 'Web 2.0' systems out there—it completely harnesses the power of user contribution, collective intelligence, and network effects." So, to summarize the attempts at Web 2.0 definition, O'Reilly coins the concept of Web 2.0 as the next generation of the Internet, gets challenged on that statement, and then clarifies it by saying that the first generation of the Internet is the perfect example of the second generation of the Internet. If that does not confuse people, nothing will.

While there may never be a solid definition for this nebulous concept, for the sake of argument, I will define how Web 2.0 fits into the Internet today in order to discuss it in the context of business. Web 2.0 is a technology concept, unlike social networking (which is a sociology concept). Web 2.0 refers to a style or method for combining existing technologies to empower people. A list of the technologies commonly combined under the Web 2.0 banner is discussed in the next section of this chapter.

The idea is to make the usage of software applications and Web sites faster, easier, and more intuitive for users. This is accomplished through three general thrusts. First, Web 2.0 leverages the power of end users' computers to improve the responsiveness of the user interface (UI) of Web applications. As opposed to previous Web application architecture, where all layers of an application were combined on centralized servers, Web 2.0 moves some of the application logic and management of the UI to the client on the end user's computer. Second, by separating the content from the UI design, users can focus on the publishing and exchange of information without having to know the UI programming required to publish the information. Third, by improving the UI to be more dynamic and responsive, users' attention is drawn to the application and their experience is greatly improved.

These improvements to software applications and Web sites did not happen overnight, though. Many software applications use numbers to indicate versions of the software, with newer versions meant to replace older versions through an installation process. This is where Web 2.0 is very misleading. By using the *2.0* nomenclature associated with software product releases, one might think that Web 2.0 is meant to replace Web 1.0 or is the next version of the Web. This could not be further from the truth. There have been many significant milestones in the evolution of the Web since its inception. The Web continues to change on a regular basis as a result of new ways for combining technologies and concepts, not in a disjointed, iterative manner, but in a smooth evolution.

In reality, Web 2.0 is really nothing new. It is simply a way of recombining and repackaging existing technologies that have been around for quite some time. There are no truly fundamental differences between the technologies used in Web 1.0 and Web 2.0. A brief examination of the most common technologies that are associated with the Web 2.0 banner is included below.

Technologies within Web 2.0

The hypertext markup language (HTML) has been around since the creation of the Internet.

This language is used to create and format the content that is included on Web pages.

The extensible markup language (XML) is a programming language that allows a developer to define content and specific tags that surround the content. Like HTML, the content can be formatted through the use of tags. However, XML also allows the programmer to create his or her own tags and then find and manipulate content through the tags that are associated with the content.

Cascading style sheets (CSS) are used to describe the presentation of a document written in HTML or XML. For each style that is defined in the markup language, CSS tells the client how to display that style. For example, CSS would define that the Header style should be displayed in a bold 12-point font.

JavaScript is a cross-platform scripting language that can be used in a server or client environment to manipulate data and objects. It is most commonly used for client-side Web development to create a more dynamic user experience with a Web page.

Asynchronous JavaScript and XML (AJAX) is a development technique used on Web sites that combines the use of JavaScript and XML to create a more interactive user experience. The concept is to separate the user interface from data in order to be able to exchange data with the server without having to refresh the entire user interface. As a result, the Web page becomes more responsive. AJAX is a key part of Web 2.0 because of its ability to greatly improve the user interface of applications and make them more dynamic.

Really simple syndication (RSS) is a method for publishing information in a structured feed format (usually in XML). This allows clients and other software applications to subscribe to and receive timely information updates. Many people use feed readers to subscribe to a number of Web sites and have the updates aggregated into a single interface. RSS is part of Web 2.0 because of its ability to exchange data in a structured but easily consumable manner between applications.

ATOM is another publishing format that is similar to RSS, but is more robust and flexible. It is based on XML and, while not as widely used as RSS, is gaining market adoption. Like RSS, ATOM is part of Web 2.0 because of its ability to exchange data in a structured but easily consumable manner between applications.

JavaScript object notation (JSON) is a lightweight computer data interchange format. It is a subset of the JavaScript programming language and is commonly used within AJAX as an alternative to using XML.

Tags are keywords that users of a particular application can associate with a piece of content in that application. For example, if a user is posting a blog entry about what he or she ate for breakfast, that entry might be tagged with the keywords *orange juice*, *toast*, *breakfast*, and *eggs* so that other users searching on those keywords will find the blog entry. Users can also tag content created by others.

A folksonomy is a taxonomy where the tags and categorization of data are created and updated in a dynamic way by the consumers of the content. Folksonomies are part of Web 2.0 because they give the responsibility of creating the tags and associating them with the content to the users of the system.

A weblog (blog) is a Web site that is essentially a journal posted on the Web. The most common uses for the journal are either personal publishing, or commentary or news on a particular topic. Blogs are part of Web 2.0 because they enable common users to publish their thoughts and have their voices heard without the need to know how to program Web pages.

Wikis are server software that allows for one or more users to work together to create and edit content. Many wikis serve as a place for multiple people or communities to come together to collaborate on a particular topic. Wikis are part of Web 2.0 because of their ability to facilitate collaboration between users.

A podcast is a radio-style broadcast that is recorded and made available for users to download onto their computers, iPods, or MP3 players. Users generally find and subscribe to podcasts from Web sites as a method to keep up with the information being disseminated on the site. Podcasts are a very valuable tool to both mobile and office workers because they provide the ability to access audio information (e.g., presentations) at the convenience of the listener. Podcasts are part of Web 2.0 because of their ability to be easily created and disseminated by users without costly equipment or extensive experience.

Mashups are Web sites or applications that take multiple data sources and bring them together to provide specialized or situational value. Mashups are part of Web 2.0 because of their ability to let regular users create valuable situational applications without having to perform extensive application development.

Enterprise 2.0

Enterprise 2.0 is a recently identified term that is used to refer to the application of Web 2.0 and social networking concepts in an enterprise business context. First coined by Andrew McAfee (2006b, p. 1), "Enterprise 2.0 is the use of emergent social software platforms within companies, or between companies and their partners or customers."

McAfee (2006a) opines that these new Web 2.0 and social software may replace traditional communications methods in companies because of their ability to make tacit knowledge available to more employees. While it is still too early to tell if this will come to pass, there are some businesses that have taken advantage of them in addition to traditional communications methods.

Anything 2.0

In perpetuating the Web 2.0 moniker, many have started taking the *2.0* label and using it on the end of anything that they wish to express as exciting, new, and/or cutting edge (i.e., Media 2.0, Manufacturing 2.0, etc.). Due to the Web 2.0 buzz, this tactic certainly brings attention where desired. However, like Web 2.0, it does still leave people wondering what the differences from the previous version are and what is so new and great. In a way, this also detracts from the Web 2.0 concept itself because it further reinforces the notion that anything *2.0* is more hype than results.

DO YOU BELIEVE THE HYPE?

With all of the excitement surrounding the Web 2.0 and social software phenomenon, many businesses are in the position of deciding whether they should jump on the Web 2.0 and social software bandwagon or sit this one out. It is not an easy choice when you are a business. The stakes are high and a gamble in the technology space that does not pay off can have quite an effect on the company's bottom line. On the other side of the coin, if the company decides to sit it out and then its competitors can leverage the trend, the company is at a competitive disadvantage in the marketplace and could be equally penalized on the bottom line of the fiscal reports. So, what is a company to do? Should it buy into the hype and take the risk? Is there really something to this social software trend or is this just an example of the emperor's new clothes?

Social software is not a panacea or silver bullet. It will not solve all problems that a business entity has and instantly make things run smoothly while adding millions of dollars to the company's bottom line. It will not instantly resolve tensions in the organization between groups or make people instantly start talking to everyone that they should be talking to. It will not unravel issues with a supply chain or instantly create a distribution network for a product, and it will not result in all of the corporate knowledge being made available online so the company can do more with less people.

Social software can be used to help surface innovative ideas, respond to customers more dynamically, and cross departmental and organizational boundaries where appropriate to get things accomplished. It can assist in rapid growth, the hiring of new talent, and employee retention. It can reduce the loss of tacit corporate knowledge through natural attrition and retirement. It can also improve productivity and allow employees, partners, and customers to do more, faster.

Interestingly enough, there are some teams sometimes found in businesses that may seem like they would be ripe to quickly adopt social software and leverage its capabilities. Contrary to what one might assume, these teams may have the hardest time accepting and adjusting to social software. Two examples of this situation might be with the research and development (R&D) and knowledge management (KM) teams.

Research and development teams have been the staple of innovation in many organizations for the last century. Business entities hire the brightest and most creative minds and give them the funding and freedom to come up with the next set of great innovations that will make the company a success. It is probably not surprising that when the opportunity is created to have others provide innovation and exercise their creativity, R&D may feel a bit like its mission is threatened. However, this is not really the case as experience has shown that R&D is still greatly needed, but its role might slightly change. Instead of being the source of all innovation, it may now participate in the innovation instead of lead, and take on the greater importance by proving the innovation.

Likewise, a knowledge management team may also feel a bit threatened by social software. The reason for this is that the KM team has a wealth of experience in organizing and managing corporate knowledge. Members probably have a rich background in working with knowledge management and collaborative software, and lots of experience in creating information taxonomies. So, the concept of folksonomies may seem to go against everything on which they have worked for the past decade. Again, social software does not make the team obsolete, though; it simply changes the team's role. Social software will allow users to connect and leverage relationships, but it is not a replacement for knowledge management and does not address important aspects of knowledge management, such as the storage and availability of information. Instead, it is a compliment to knowledge management.

Social software is currently in the peak-of-inflated-expectations phase of its hype cycle (*Understanding Hype Cycles*, n.d.). It is not the be-all, end-all in the technology space that some make it out to be. However, it can bring very real results to a business. A business will most likely not use it in all of the ways that it is being used on the social networking Internet sites. If a business takes the time to understand the fundamental concepts behind Web 2.0 and social software, the underlying value propositions associated with each, and select the ones that are appropriate, it can put them to work for the business.

While the benefits are undeniable, many will struggle with measuring those benefits. Most businesses today use objective numbers to measure success. Companies look at things such as revenue, profit, and expenses at the macro level, and sales quotas, wages, product volume delivered, hours worked, and other measurements at the micro level to measure and track progress. In the case of social software, though, the focus is the human element, not finances or output measured.

The problem with measuring the value of social software and social networking is the extreme difficulty of putting an objective measure on a subjective topic. It is just not possible to put a direct measurement on human elements, like relationships or tacit knowledge. For example, a company may deploy a social software environment to help with recruiting new employees. The system will help new employees to grow their network more quickly, which they can, in turn, use to locate knowledge faster. But how

does the company measure that? Any attempt to quantify that value into a dollar amount will need to include a number of assumptions and mostly fictional, best-guess estimates. Inevitably, this is an inaccurate method of measurement, at best, and is usually fraught with skewed data and meaningless results.

Social software may have a direct effect on the company's bottom line, but the direct correlation between social software and items in the general ledger may never be numerically established. Social networking is about personal relationships and personal relationships are about people. In order to make the investment in social software, a company has to value their employees, partners, and customers and be ready to make an investment in people.

FINDING AND APPLYING THE VALUE OF SOCIAL SOFTWARE FOR BUSINESS

It is a good first step to identify that there is value in using social software to support daily interactions and relationships between individuals working at or with a business. However, that is not quite enough to harness that value and put it to work for the business. Not all aspects or implementation methods of social software are appropriate for a business. Likewise, not all existing social networking applications that are available on the Internet are appropriate for use in a business environment. Some sites like LinkedIn (http://www.linkedin.com) offer some value to employees by allowing them to make contacts in other businesses for sales or marketing reasons. Others require more examination and may not necessarily be appropriate.

The very first area of examination must be the concept of, for lack of a better word, what I will call *domains*. In this area of examination, the individual's use of the Internet will be referred to as the public domain; the business IT environment, including use of the Internet to work with customers and partners, will be the enterprise domain. It is extremely important to understand the differences between these domains, the nuances of each domain, and the behavior and motivation of users in each domain. These differences and characteristics will have a profound impact on leveraging social software in a business.

The public domain can largely be characterized as having recreational users with minimal affiliations. Most users will be independent individuals using the Internet for personal use. While many voluntarily identify themselves appropriately, anonymity is entirely possible and is leveraged by some. Their purpose for use will most likely be associated with serving self-interests. This is the domain where many of the most popular social networking sites are currently active. Sites like MySpace (http://www.myspace.com), Facebook (http://www.facebook.com), Flickr (http://www.flickr.com), and others are focused on serving the self-interests of individuals by providing services to connect with each other on an independent, individual level.

The enterprise domain can be characterized as having professional users associated or affiliated with businesses or professional organizations. This association of user with business or professional organization is usually readily indicated in the identity that is used online. The purpose of use will most likely be associated with serving either the associate business or the professional life (e.g., career) of the user and is expected to be used in a professional manner. This is the domain where the traditional business IT communications, financial, sales, marketing, and similar systems are located. Applications such as company e-mail, financial software, collaboration software, portals, supply chain management, and intercompany applications are focused on providing value to the business by facilitating business functions.

The purpose of social software remains the same independent of domain, but the way that social software is valued and, as a result, leveraged

is quite different in each domain. Public-domain users value social software for its ability to facilitate relationships that are self-interest focused. Businesses value social software for its ability to facilitate relationships that benefit the needs of the business. Therefore, businesses do not see a lot of value in having users join MySpace to create a profile and keep up with people's hobbies, likes, and dislikes, but public-domain users do. However, businesses do see a lot of value in using this same concept to provide profiles of their employees that identify their skills, professional affiliations, areas of expertise, and tags for the purpose of locating people with particular skills or knowledge.

To get the most value from social software, businesses should not try to duplicate the most popular Web sites that exist in the public domain and bring them into the enterprise domain. Instead, businesses need to examine the social software and Web sites in the public domain, understand why they are popular and what functions they offer that could be useful to the business, and then implement those functions in areas of their business that will provide the greatest benefit.

For example, podcasting got its start as a way for an audio blog to be taken off line and listened to on personal media devices. This was quickly adopted by the media industry and leveraged to provide audio files such as radio broadcasts and audio journalistic articles for subscribers to listen to on their personal media devices while disconnected. Since then, many businesses have taken a close look at the concept of podcasting as a way to use audio and sometimes video files to deliver information in a quick and asynchronous way to users. As a result, businesses have been able to leverage the concept to accommodate increasingly time-constrained employees, partners, and customers with important presentations, training, recorded meetings, and even sales and marketing materials that are available when they want, where they want. It is even being used to overcome language and cultural barriers by allowing people the ability to pause and listen multiple times to a recording that may be in a second language to them. This greatly increases comprehension and the effectiveness of the information being delivered.

Most importantly, businesses need to understand that all of the individual added value social software brings to the table roll up under one umbrella. The social software trend is about empowering people. Through this empowerment, a business achieves the maximum potential from social software. Freeing people from traditional business control of information and organization and giving them tools that they need to make their voices, thoughts, and ideas heard while transcending boundaries is the value that social software brings to the table.

If a business is satisfied with its current business process and thinks there is no room for improvement, social software is not for it. If it is not interested in improving customer services and does not care about suggestions for cutting operating costs, social software is not for it. If a business is not concerned about employee morale or overcoming communication and cultural barriers, it need not examine social software for its business. If it has all of the innovation that it needs and does not want to find new sources of ideas or better know what its customers need, social software is unnecessary.

However, if a business does care about all of these things, and arguably every business should, then social software brings a great deal of value to the initiatives, not by traditional formal programs or structured initiatives, but through unstructured approaches to tapping into normally unheard ideas. Every company has employees with ideas about how to refine processes that they work with on a daily basis to be more efficient or how to cut wasteful spending. There are plenty of customers and business partners that are willing, and even anxious, to tell a business exactly what they need, how to improve a product, or even become involved with the design and innovation process in

order to contribute their experience and requirements. It is through empowering the people and letting their contributions be heard that the great advances are made.

Fostering innovation in a company is one of the most highly touted uses for social software in business. Empowerment through social software can have a profound effect: "Research and development projects fail more often than they succeed. In fact, out of every 10 R&D projects, five are flops, three are abandoned and only two ultimately become commercial successes" (Rizova, 2006, p. 49). Traditional business approaches to R&D put the source and responsibility for innovation squarely on the shoulders of a single structured department. The brightest minds would be hired to work in this department—people with master's and doctorate degrees and a history of researching, being innovative, and capturing their results in academic papers and prototypes.

Does it not seem that there is something fundamentally wrong with this approach? It is not reasonable to assume that only the people who work in the R&D department can be creative or should be allowed to be creative. Most businesses would agree that there are other people in a company or who work for business partners and customers who are creative. In the overwhelming majority of cases, most businesses do not have the capacity, tools, or methods in place to hear and capture the innovation from those additional sources. That is where social software can support the process. As a rudimentary example, if a business were to implement blogs for their employees and allow them to start expressing their thoughts, frustrations, wishes, ideas, and more, there is plenty of innovation that could be harvested from the blogs and ultimately turned into valuable business assets.

Another major area of benefit under the empowerment umbrella is the ability to provide easier access for users to find, use, and integrate data sources. For example providing RSS or ATOM feeds to key business systems allows a user to aggregate that information to a place that is easy to scan and keep up with (much like scanning the headlines of a newspaper). This makes users more aware and knowledgeable about the business as a whole and makes them more effective in their tasks relating to the business. It also increases their efficiency because what once took an hour of time to seek out multiple data sources and review or interact with them now takes a fraction of the time because they are summarized in a single location. Another example would be to provide users with the ability to create a mashup so that they can generate reports or create situational applications that are context sensitive and specific to their task at hand. By putting this capability in the users' hands, a business removes the shackles of having to request and wait for the IT department to create the needed application or reports.

Additionally, many of the Web 2.0 technology aspects of social software trends provide for a more interactive and responsive user experience in working with data. By improving the user experience of interacting with the data, two things occur. First, users are comfortable using the software and prone to use it more extensively. Second, as power users leverage the software more, additional users will be drawn into using the software through both necessity and word of mouth. This is known as "viral" adoption of the social software system because usage spreads like a virus instead of through traditional IT mandate or formal marketing.

CONCERNS ABOUT SOCIAL SOFTWARE IN THE ENTERPRISE

By removing the traditional business structure and empowering people through such an open solution, most businesses will be legitimately concerned about corporate information security. This is yet another aspect of social software in the enterprise domain that is not an issue or consideration in the public domain. The very thought

of accidentally exposing internal confidential information is something that will immediately send business IT security departments into a full panic. Realistically, there is a balance to be struck between providing openness and ensuring that truly confidential information does not wind up freely available to all.

This balance is struck by understanding which boundaries are going to be crossed by using social software, recognizing the implications of crossing each boundary, and putting the proper guidance and security in place for each. Most businesses already have corporate information guidelines that can be easily extended to cover social software. For example, users should understand that there are different conduct guidelines that apply to blogs only available on a business's internal network vs. blogs available on the company's public Web site. On the internal blog location, the boundaries being crossed are internal (e.g., between departments), with users having the same association (the business) and therefore needing less rigorous guidelines because all users are business employees and working toward the same general business goal. Users should be able to post almost any content with a few exceptions (i.e., no customer names, no personal attacks, etc.). As a result, there may be plenty of blog entries that complain about business processes or strategy, share ideas for new products or solutions, and share personal information.

However, this type of content would not be appropriate to be posted on the business' public Web site. Externally available social software crosses the boundaries between the business and partners, customers, and the general public. As a result, there are additional guidelines that should be applied to address the different associations and affiliations of users of the social software. In this situation, blogs or wikis might be used to publicize new or little-known information about products or solutions and work together with customers and partners on advancing nonconfidential business ideas. Additionally, guidelines will need to be established to deal with information posted by those with negative intentions. These guidelines do not include constructive criticism, but instead are directed toward malicious content and spam.

Most users will intuitively realize what content is appropriate to be posted in social software based on the boundaries that are being crossed. This does not mean that there is no need for a business to deal with exceptions. For example, what happens when someone creates a blog entry that negatively talks about another department in the organization? That is probably not so bad if it is an individual's blog and is expressing the thoughts of the individual. It helps bring an issue to the surface so that it can be addressed and resolved, and everyone can move on. However, what happens if this same entry were to appear in a group or team blog? The author's name posting the entry is explicit, but how does this reflect on the entire team that owns the blog? Members might not all feel this way about the other department, but now these negative thoughts are projected as coming from the entire team. Perhaps in this situation, it is not appropriate and the author should move the entry to his or her personal blog or remove the posting altogether. There is no right answer to these types of scenarios, but some guidelines for working with these situations should be established and publicized to the users of the social software.

Social software also raises privacy concerns in the enterprise domain, but not in the public domain. Most social software solutions work based on a voluntary participation basis, empowering the user to contribute, but not mandating participation in the usage of the software. While this type of opt-in participation does eliminate many of the privacy issues that might be associated, there are some social software (more specifically, social network analysis) tools that analyze corporate communications data to extract social relationship data and make that available. Some would consider this an invasion of privacy

and even have the feeling of the business's "big brother" watching.

However, there is another perspective that data in corporate communications tools belongs to the corporation and not the individual. Additionally, most of these types of social software will analyze only cursory information in the communications data (e.g., e-mail headers, but not the body) and store or transmit only the analysis itself, not the data being analyzed. Businesses have to comply with national employee privacy laws that address the types of employee data that can be made available and used by the business. It is important to always make sure that the business is in full compliance with these laws.

In many businesses, social software is viewed by some as a way for employees to waste time. Initially, some do not see the inherent value in social software, but instead think that it will make the company less productive because users will spend all their time working on things of no value to the business. Those same people are starting to have a realization that they need to use this technology, but are not quite sure just what should be done about it.

This is nothing more than a case of history repeating itself. This same opinion was voiced by many when e-mail first emerged as a new communication tool. It was often viewed by many as a way for people to waste their time sending each other frivolous messages. This same opinion was then applied to the Internet, where users would presumably while away their hours surfing the Internet. Most recently, this same approach has been applied to instant messaging. Many view it as a kid's toy and a way for people to waste time chatting with their friends about nothing in particular. In each of these cases, the naysayers have been proved wrong and each technology has become an integral part of the way business is done on a daily basis. In fact, all of the previous technologies mentioned here have moved into the critical path for businesses and many do not know how they ever operated without them. Social software is destined to follow this same path and become an integral part of doing business.

FUTURE TRENDS

Is there a Web 3.0? Will Web 2.0 one day go the way of Web 1.0? The real question is not whether Web 2.0 will be usurped, as it is only natural that the evolution of the Web continues. The real question is what will be next. At this point, there are two concepts that look to be the most promising and are gaining a large amount of interest. However, they are only conceptual at this point and there has not yet been any real traction in making the concepts into a reality.

The Semantic Web refers to a vision for the Web to become a medium for machines to be able to understand, relate, and compile information without human intervention: "It is envisaged to smoothly interconnect personal information management, enterprise application integration, and the global sharing of commercial, scientific and cultural data" (W3C [World Wide Web Consortium] Advisory Committee, 2007, p. 1). The current configuration of the Web supports the linking and interaction of Web sites, but requires human interaction to interpret the data that is on the Web site. In the Semantic Web, individual pieces of data that are available on the Web are surrounded by descriptive tags that allow computers to understand relationships between pieces of data, as well as the properties of those pieces of data.

By making individual pieces of data readable and understandable to computers, the Semantic Web will truly transition the Web as we know it today from a collection of interacting Web sites to an unbelievable mass of data that is free to be combined and integrated. Allowing machines the ability to combine individual pieces of data will lead to the ability for machines to begin to perform tasks on behalf of humans. For example, a human currently has to submit a query on Google and

then review the results to find the result that best fits the context with which they are interested. In the Semantic Web, a machine would be able to query and review the results for the appropriate context to return to the human.

While the Semantic Web has been discussed as early as 1999, critics have cited that there has not been a great amount of progress made on the Semantic Web coming to fruition over the past 9 years. Also, concerns of privacy and censorship would have been raised because of the ability for machines to understand the data that they are communicating. If this understanding were in place, computers could be made to more rigidly filter or display that data without human approval.

Another direction for the future centers on opening up the individualized social networking Web sites. Many sites now require users to register and then maintain their connections to others within the site. This causes a lot of frustration and extra work when users move to a different social networking site and have to reenter all of their information and connections to friends. Not to mention that their friends might not even be part of the new site; then they have to convince their friends to move over as well. This is a very Web site focused approach to social networking and only a fraction of how true social networking works outside of computers.

To address this issue, there has been much discussion about the Social Graph. The Social Graph refers to a visual mapping of all of our social interactions and connections as human beings. As opposed to having connections to others maintained on a Web-site-by-Web-site basis, it has been proposed that there be one open Social Graph created to manage connections between anyone and everyone. The Social Graph would also take care of maintaining a single identity for a user. The identity and connections could then be mapped to and leveraged by any Web site without having to recreate and store this information in a proprietary way.

This Social Graph further evolves the Internet from a space of interconnected Web sites to a space for interconnected people. After all, users may care about information or knowledge in a contextual and periodic nature (for business use, for personal use, etc.), but care about relationships to others (family, friends, colleagues, etc.) on a constant basis.

In both the Semantic Web and the Social Graph, it is proposed that the Internet move away from a set of connected Web pages and documents and focus connections more on people and data. This shift in direction will prove to be another powerful evolution because it will expose data and relationships at a much more granular level, thereby paving the way for a new level of contextual application. It would not be surprising to see some combination of these two notions in the future.

CONCLUSION

Social software and Web 2.0 are the hottest topics on the Internet. As they continue to draw an incredible amount of attention through the media and online traffic, there is also a great amount of confusion being perpetuated. The intermixing and interchangeable use of terms is, at best, confusing people and leaving others thinking that the social software trend is all smoke and mirrors. While some of the hype surrounding Web 2.0 and social software is just that, there is value in the concepts that underlie the trend.

Just like the value of the social network lies in the relationship between people, instead of the people themselves, the value of defining the terms associated with the social software trend lies in their relationships. Social networking is about the relationships between people. It is about bringing people and knowledge together and better leveraging what you know about who you know. Collaboration is about formalizing the group established through a social network into

a team to work toward a common goal. Web 2.0 is the technology that is being used to empower and facilitate the social networking and, in some cases, the ensuing collaboration.

Many businesses are starting to examine the social software and Web 2.0 trend in order to see how it can add value to their business:

Much like late 1997, when technology specialists were getting asked by senior executives "What is the Internet, exactly, why is it a big deal, and what's our Internet strategy?" The question now is "What's Web 2.0/Enterprise 2.0/social media, exactly, why is it a big deal, and what's our W2.0/E2.0/social media strategy?" (McAfee, 2007, p. 1)

Social software is about relationships and relationships are about people. In order to fully leverage the social software trend, a company needs to value its human resources and be prepared to invest in people. There may never be a direct correlation between the deployment of social software and the bottom line of the ledger sheet (without a few bits of creatively fictional logic), but the company will surely see the value reflected in subjective measures, like customers' satisfaction, increased productivity, enhanced cost cutting, improved employee morale, and more. All of these factors will translate to an improved financial bottom line.

Businesses will need to apply the concepts behind the social software trend to areas of their business where they can be effectively used to unlock and open up the business and provide a voice to users. By empowering users, social software will allow for new sources of innovation and collaboration. According to a 2006 IBM Global CEO study (IBM Global Services, 2006), only 17% of CEOs ranked internal R&D as a source for new ideas. This means that overwhelmingly, businesses will be looking to customers, partners, and other company sources for the ideas and innovation that will power the future of their business.

Unlocking all of this value will not come without some challenges. It is encouraging, however, to know that those challenges can be overcome. Issues of security, privacy, and adoption of social software will emerge within businesses. Nevertheless, these issues have emerged with previous technologies, such as e-mail or the Internet itself, and have been addressed accordingly.

Now that we have had a look at how social software trends can impact businesses, subsequent chapters will examine how elements of social software are being adopted by businesses in different industry segments.

Chapter 8.2
Social Software and Language Acquisition

Sarah Guth
Università degli studi di Padova, Italy

Corrado Petrucco
Università degli studi di Padova, Italy

ABSTRACT

This chapter describes how the social software tools that characterize Web 2.0, such as wikis and blogs, can be used as a valid substitute for more traditional Learning Management Systems in the context of e-learning and blended learning language courses. First, we will give a brief overview of how the educational arena is changing and the role social software can play in promoting these changes. Then we will describe two experimental courses carried out at the University of Padova using social software. The chapter ends with a discussion of the role of these tools in formal education. The aim of the chapter is to show how these tools allow language educators to take network-based language teaching beyond the limits of planned classroom activities, offering students new opportunities to access and produce real language in real situations.

INTRODUCTION

The evolution of e-learning and computer-assisted language learning (CALL) is inherently connected to the evolution of technology and theories on language learning pedagogy intertwined with ways in which society changes. The advent of the Internet in the 1990s led to a shift toward a focus on authentic communication, task-based learning, and network-based language teaching (NBLT) using sociocognitive approaches. NBLT involves a shift from learners' interaction *with* computers to interaction with other humans *via* the computer (Kern & Warschauer, 2000). Whereas the Internet was initially a place where information and knowledge were delivered by "experts" and information was simply retrieved, toward the end of the 1990s, the Web started to become a place where users, everyday people, *produced* and *shared* content in ever-growing global communities. Contrary to the dominant epistemology of Western culture according to

which knowledge is created and transmitted by experts, the new way of using the Internet was based on the concept of the "wisdom of the crowds" (Surowiecki, 2005). In 2003, Tim O'Reilly and Dale Dougherty dubbed this new revolution "Web 2.0" (O'Reilly, 2005).

Web 2.0 is characterized by what can generically be called "social software": different types of software that enable people to collaborate and create and join online communities. What is particularly interesting is the widespread use these tools have achieved in a very short time, especially among young people, the so-called Digital Natives (Prensky, 2001) or Net Generation (Oblinger & Oblinger, 2005). Whether people are using these tools to express their creativity (YouTube, Flickr), to share their thoughts (MySpace, blogs), or to share their knowledge (Wikipedia), they are creating and participating in online social networks in a way that was not imaginable just a few years ago.

The aim of this chapter is to argue that not only can language educators not ignore this revolution, but they should embrace it. The benefits of using social software for language learning go beyond simply providing new tools students can use to communicate. They promote social networking on a global scale and knowledge sharing and creation beyond the classroom, thereby giving students opportunities to access, use, and produce authentic language in real-world contexts. In this chapter, we will first provide a brief overview of the implications of Web 2.0 and social software for education in a general context. This information served as the foundation for an action research project that was started at the University of Padova in the spring semester, 2006. We will then describe the second stage of the project, which involved the use of wikis, Skype, blogs, and other Web 2.0 tools in an advanced English as a Foreign Language (EFL) course. Though the research is not yet complete, the initial results are positive and confirm results from other studies. Finally, the chapter ends with a discussion of the future of these tools in education.

WEB 2.0 AND SOCIAL SOFTWARE FOR EDUCATIONAL PURPOSES

The educational arena today is finding it necessary to react and adapt to the shift from an industrial to a knowledge-based economy. We are now living in an information society where the way knowledge is created and organized and the very nature of knowledge have changed. The ways knowledge is represented have always been strongly influenced by the tools used to express it. Today it is impossible to think of knowledge without associating it with tools such as search engines, Web sites, repositories of learning objects, and more recently, social software tools such as blogs and wikis. Today's students need to learn how to operate effectively in today's information overload and, at the same time, how to become creators of knowledge. Upon graduation, they will find themselves looking for work in a global knowledge-based, networked economy where they will need to be skilled in collaborative and creative project-based work and critical thinking (Bruns & Humphreys, 2005). At the same time, we must also help students develop "the resources and skills necessary to engage with social and technical change, and to continue learning throughout the rest of their lives" (Owen et al., 2006, p. 3). Language acquisition especially is a lifelong process that cannot end with traditional education, but rather must be cultivated throughout life.

The advent and success of Web 2.0 technologies have led many to speak of e-learning 2.0. Much of the focus during the first decade of e-learning was on the tools, or learning management systems (LMS), through which material could be delivered while less focus was given to the actual pedagogy to be used. We can distinguish between two approaches to information and communications technology (ICT): a technology-centered

approach and a learner-centered approach (Mayer, 2005). The former generally fails to lead to lasting improvements in education. A learner-centered approach, on the other hand, can help students and teachers learn and teach through the aid of technology with a focus on how ICT can be used as an aid to human cognition helping students solve complex tasks and deal with today's information overload. Not only has the quantity and kind of information students access today expanded exponentially in the last few years, but the way they interact with the information and the global communities creating it has changed dramatically as well.

As suggested by Bonaiuti (2007), this change has two specific characteristics: a shift from formal learning to informal learning and a shift from content-based learning to collaborative learning. Pedagogy based on a social-constructivist approach and supported by tools readily available online and part of the everyday lives of students can help create an active learning environment in which students and instructors work together to solve problems contextualized in the real world. What's more, in this context, the collaboration does not stop outside the classroom, but rather flows over into personal lives and develops through the use of social software tools such as blogs, wikis, and forums. To do this, an effort must be made to try to integrate formal and informal learning (Cross, 2006). This is certainly not a new idea (Dewey, 1965), but it is one that is worth experimenting with through the social interactions mediated through the Web, which thus becomes a powerful *zone of proximal development* able to organize knowledge in multiple and flexible contexts (Spiro et al., 1991). It is a model that follows a participative approach to knowledge creation (Sfard, 1998) and is closely tied to social constructivism (Brown, Collins & Duguid, 1989; Jonassen, 2000) by which learning is above all an active process that is socially situated and aimed at solving real problems. Rather than refer to this new trend as e-learning 2.0, Futurelab[1] proposes the term "c-learning," which could be intended as "community learning, communicative learning or collaborative learning, [because] at its heart learning is a social process" (Owen et al., 2006, p. 11).

Social software follows the c-learning trend. The use of social software in education focuses on activities rather than applications (i.e., all those activities that involve sharing knowledge [blogs], collaboratively creating knowledge [wikis], and managing knowledge [social bookmarking]). In education, adopting social software has several advantages with respect to other computer-mediated communication tools.

1. **Enabling communication among many people beyond the classroom:** Unlike many closed LMSs, social software tools give students the opportunity to interact with experts and novices alike on a global scale beyond planned classroom activities.
2. **Providing new ways to share and create content:** These tools provide ways to share and create content in systematic, organized ways (e.g., blogs, photo sharing on Flickr at http://www.flickr.com/, and video sharing on YouTube at http://www.youtube.com/). They also offer students the opportunity to share knowledge beyond the classroom through, for example, public wikis. The process of sharing knowledge often involves the process of transforming tacit knowledge into explicit knowledge, which is where true learning takes place.

   Some social software tools make it possible to collaboratively collect and index information in such a way that not only is it easier for users to access their own resources, but it is also possible to share them with others in the community and exploit other users' online searches. In this way, they function as a filter for the information overload on the Web (e.g., social bookmarking on http://del.icio.us and social annotation on http://www.

diigo.com). This is what Giger (2006) has called "participation literacy" (i.e., it is no longer the individual that filters information, but the collectivity). Another useful tool for filtering information is feed aggregators; syndication makes it possible for information to come to you rather than you going to it. Some tools offer remote hosting (e.g., Bloglines at http://www.bloglines.com/), which means users can access their feeds from any computer, while others are installed locally on a user's computer (e.g., Sage, an extension for Mozilla Firefox at http://sage.mozdev.org/).

4. **Integrating many types of media (audio, video, images):** With the growing number of free tools to create multimedia, the increase in the number of sites dedicated to sharing these resources, and the spread of broadband, students now have the possibility to better express their ideas and creativity by integrating audio, video, and images into the contents they create online.

When several social software tools are used together, students learn how to learn by (1) taking on responsibility for managing the social software tools; (2) working cooperatively and learning from each other; and (3) developing online research skills (Mejias, 2006). All of these activities enhance a student's sense of responsibility and collaboration, both of which can help foster autonomy. If students learn how to exploit the Web for their autonomous language learning in the context of online communities, they will be able to continue the language acquisition process in their informal learning as well. Social software tools take the practice of NBLT beyond the limits of the language learning classroom into the global communities of Web 2.0.

In the next section, we will describe how these tools were aggregated and used in an advanced EFL course at the University of Padova.

BLENDED EFL COURSES USING SOCIAL SOFTWARE

In spring of 2006, an action research project was set up to study the potential of social software to effectively teach blended learning courses for English as a Foreign Language (EFL). The first stage involved an experimental course that was held at the Faculty of Engineering using blogs and a wiki to conduct an upper-intermediate EFL course. Overall, students proved to be highly motivated by using these tools, participated actively, and were satisfied with the course. A careful study of the empirical data corpus led to a redesigning of the course for 28 second-year EFL students in a graduate course in International Communications Studies as the second stage in the project. The year-long course was divided into two semester-long courses: TulanePadovaXchange, a telecollaboration project (Belz, 2005; O'Dowd, 2005) with Italian language students at Tulane University in the United States and EFL students at the University of Padova, and BloggingEnglish, a course aimed at exploring the potential of Web 2.0 tools for autonomous and collaborative language learning in the other semester. In order to work more effectively, students were divided into two groups of 14. One group did the exchange in the first semester, while the other did the blogging course; the groups switched courses in the second semester.

Various data sources were used in the research study, including the following: participant observation (teacher's field notes), posts in students' personal blogs, transcripts of students' online correspondence on the wiki and recordings of their Skype conversations, informal interviews, comparison of students' writing at various points throughout the course, and end-of-course questionnaires. As the courses were blended and students were asked to reflect weekly on their learning process in their personal blogs, it was possible to read students' impressions and then discuss them in class as the courses progressed.

In this way, the instructor was able to check her interpretations of the data with students.

In the following paragraphs, we will describe each course's structure, language learning aims, and preliminary results. This is followed by a brief description of how assessment was carried out.

Padova-Tulane Exchange: Telecollaboration on a Wiki

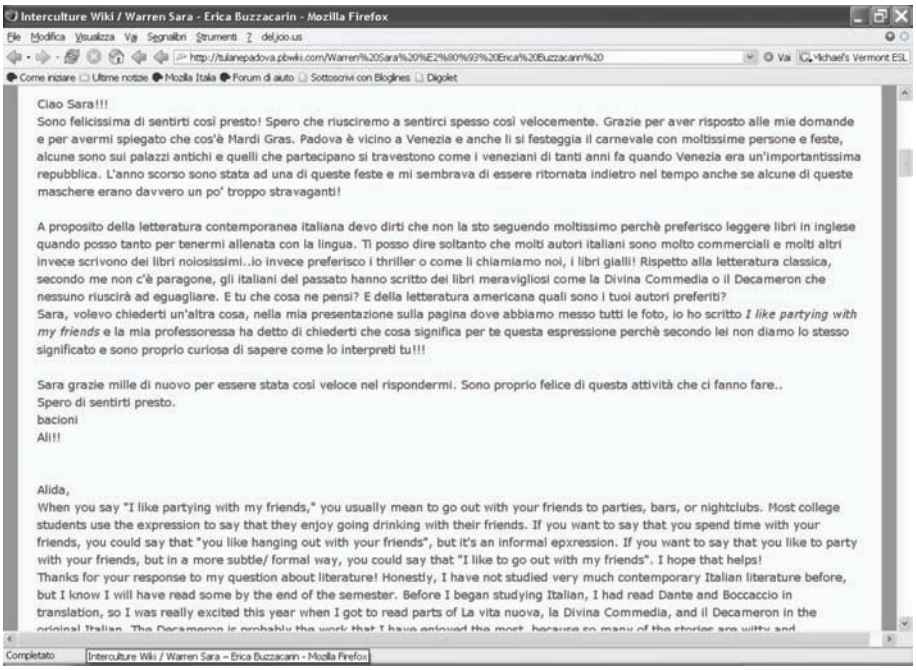
Telecollaboration projects have been carried out in recent years using many tools, from simple e-mail exchanges to specifically designed software (e.g., *Cultura*) (Furstenberg et al., 2001). Regardless of the tool chosen, "the underlying rationale is to provide the members of each parallel class with cost-effective access to and engagement with age peers who are expert speakers of the language under study in an effort to increase intercultural awareness as well as linguistic proficiency, to increase the authentication of foreign language use in the tutored setting, and to broaden the range of discourse options and subject positions available to classroom learners of language" (Belz, 2005, p. 1). Using a wiki as a platform offers advantages that other tools do not. A wiki offers the possibility to create an ever-growing repository of cultural knowledge that can be used and re-used by students in various learning contexts over time (Godwin-Jones, 2004). Furthermore, writing on a wiki involves collective authoring, which by its very nature requires significant amounts of reading and peer correction. Students can also use the revision history function available on most wikis to keep track of changes in a piece of writing over time, promoting close reading, revision, and tracking of drafts in order to focus on writing as a process rather than a product (Lamb, 2004). Therefore, a telecollaboration project called TulanePadovaXchange was set up between the University of Padova and Tulane University using a wiki (http://tulanepadova.pbwiki.com/) and Skype to add an oral component to the course. The course was blended; students had one two-hour face-to-face lesson a week for 10 weeks (one semester) and were expected to do four to six hours online per week.

The Exchange

During the first semester, students spent several weeks exchanging messages on the wiki based on the outcomes of tasks proposed by the *Cultura* model. Each group of two or three peers had a page they used as one might use a discussion thread in a forum (see Figure 1). Two advantages, however, to using the wiki were (1) all of the information exchanged was present on the same page and, therefore, easier to access for reflection and (2) all of the students could see the other groups' exchange pages so they could learn not only from their own peers but from the other exchanges as well. Due to scheduling difficulties, the Skype exchanges took place outside of class time and, at most, students had three 15-minute conversations.

In the second semester, the teachers in the United States and Italy managed to organize one hour a week in the respective language labs when students could meet online so that rather than carrying out the exchanges on partner wiki pages, all exchanges took place orally via Skype interviews. The sixth and final meeting was a videoconference between the two groups carried out using Skype. A significant increase in involvement and motivation took place on both sides of the Atlantic in the second semester. Although students communicated frequently on the wiki in the first semester, the focus of their exchanges seemed to lack purpose leading to a decrease in motivation throughout the course. The exchange was not an integral part of the American students' grade or coursework, but rather an additional activity. During the second semester, the teachers in the United States and Italy chose three topics students were to explore (recycling, alternative energy resources, and water resources) and integrated the exchange into both course syl-

Figure 1. Example of a wiki page for peer exchanges; two Italian students and one American student exchange messages in their native languages



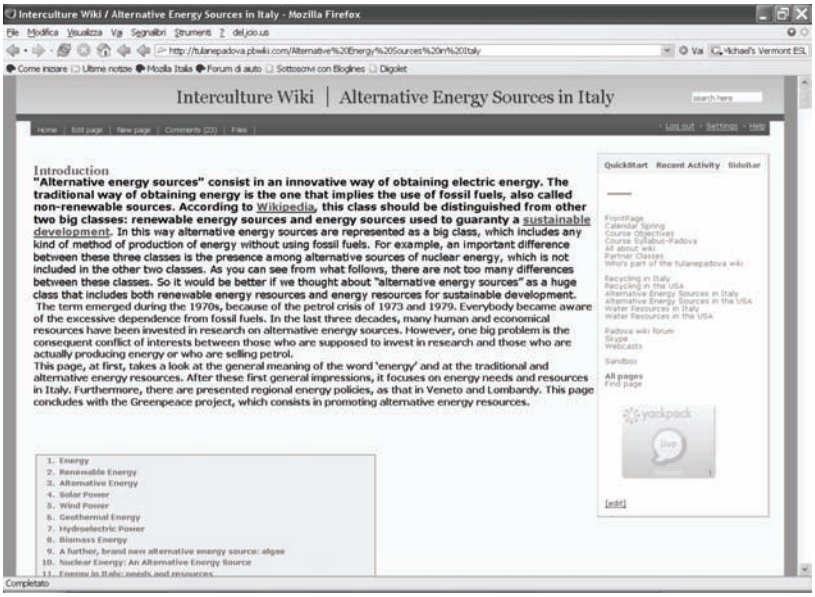
labi. The regular use of Skype in the language lab also increased motivation since students in the two institutions had previously been given very few opportunities to speak in the target language and even fewer to speak with native speakers. All the peer conversations were placed online after each exchange in both streaming format and as downloadable MP3 files offering students on both sides of the Atlantic the opportunity to listen not only to their own conversations but to their peers' as well, as was the case with the wiki pages in the first semester. In her blog, one student noted that "one of the most positive aspects of Skype exchanges is that we can all benefit from every single conversation, that is, not only from the exchange with our American conversation partner, but also from the other exchanges: each of us can learn from the experience made by other students. Therefore… the more we listen and talk to our peers, the more we learn…!" Finally, as O'Dowd (2007) found, the students realized the benefits of telecollaboration with respect to traditional culture learning materials: "[T]he online exchanges provided learners with a different type of knowledge. … As opposed to objective factual information, the accounts which students received from their partners were of a subjective and personalized nature" (p. 146).

The Interculture Wiki Pages

The culture pages in the wiki were developed exclusively by the Italian students in English as the writing component in the course.

During the first semester, the Italian students were given the freedom to create and develop wiki pages on a topic of interest to them based on issues that came up during the asynchronous exchanges with their American peers. Once pages had been created, students were then encouraged, and eventually forced, to read and edit each other's pages. When students create their own pages,

Figure 2. Example of a wiki page before the final edit; each page had the same structure: introduction, table of contents, contents



they maintain a strong sense of ownership. In Lund and Smordal's (2006) wiki experience, the authors state, "[L]earners did not immediately embrace any notion of collective ownership or epistemology but continued a practice where the institutionally cultivated individual ownership persisted" (p. 41). Indeed, writing collectively did not come naturally, and students had to be guided through the process. Collective authoring gives students an opportunity to focus on the writing process (e.g., from collecting information to organizing, rereading, and doing a final edit. They eventually learn that it is actually easier to correct a peer's work and find where meaning is unclear (Berg, 1999) rather than correct their own contributions. The comment function in the wiki allowed students to asynchronously negotiate content and structure.

An attempt was made in the second semester to encourage collective authoring by creating the following six wiki pages for the students to develop: Recycling in Italy/the USA, Alternative Energy Resources in Italy/the USA, and Water Resources in Italy/the USA. The Italian students had to collectively develop the Italian page as preparation for the Skype exchanges (see Figure 2) and then, based on the information exchanged with their American partners, had to develop the American page. An analysis of the six wiki pages shows significant improvements in their ability to collaborate and write collectively with this organization. For example, they learned to propose structure before writing and discuss which part of that structure each individual student was interested in developing. The benefit of working asynchronously is that students must critically read what has been written by others before contributing. As one student commented, "Thanks to this task I was obliged to search some news and first of all … **READ, READ, READ**! My colleagues had already written some generic aspects and so I could begin my discovery from that." In the second semester, there was much more knowledge sharing as students were developing only six pages and developing them together. Nonetheless, they still felt strong ownership for

their personal contributions and had difficulty editing each other's work, as was the case in the first semester. The overall feeling toward the end of the experience was, however, positive. As one student commented, "Developing our six wiki pages and conversing every week with my American peer made me understand the importance of 'learning-by-doing', co-operation and negotiation and, most importantly, made me reflect on the close, triple connection existing between the communicative function of language, the use of technology and the process of creating and sharing knowledge."

Finally, one of the main aims of the project proved successful during the shift from the first to the second semester: creating a repository of shared knowledge. Students during the second semester continued to contribute to the wiki created during the first semester. Rather than being a hindrance to production (i.e., "let's copy what they've done"), reading what other students had written and experienced proved to be motivating for students during the second semester. It is the intention of the authors that the wiki continue to grow with future semesters in such a way that students continue to learn from their peers' experience, avoid some of the pitfalls encountered, and help the repository of intercultural knowledge grow and improve.

Language Learning

The three linguistic aims established at the beginning of the course were:

- To improve students' reading skills and vocabulary in the target language by reading messages written by native speakers of the target language.[2]
- To improve students' written accuracy in the target language via production of contents in a wiki in the target language.
- To develop students' speaking fluency in the target language via interviews in Skype.

During the first semester, students were asked to carry out their asynchronous text exchanges in their native language in order to provide each other with accurate, authentic language and to have the freedom to fully express their ideas regarding their culture. The most commonly cited benefit was the opportunity to learn "real" language, new idioms, slang words, and so forth, which students then reproduced when developing their wiki pages.

The questionnaires and focus groups (self-assessment) and a careful analysis of the corpus of written (wiki) and spoken (Skype recordings) text confirmed that the second two aims were achieved in both semesters. The second aim involves improving reading skills as well, since before you add a contribution to a wiki, you must first carefully read what others have already written. As one student commented, "Collaborative writing is a very stimulating activity, it fosters multi-steps collaboration (reading, writing-integrating) between wiki-contributors." Furthermore, given the nature of the tasks, students had to do a significant amount of searching and reading online to develop the factual contents of their wiki pages. During the second semester, as they developed three pages about Italy, they had to practice their abilities to read in Italian and then produce new knowledge in English. One student commented, "Finding pages in Italian is not only a translation exercise but it involves many other skills, such as reading, summarizing, writing, thinking in a critical way, etc." Finally, accuracy regards not only linguistic accuracy, but also issues such as structure, content, and plagiarism. An analysis of the development of the wiki pages throughout the second semester course shows that with each new page (of the total six), students' abilities to structure the pages, organize the information, and provide references improved. Final feedback on linguistic accuracy was provided by the teacher. In groups, students then had to make a final edit of assigned pages.

There is no doubt that the opportunity to speak on Skype improved students' confidence in speaking in English and ability to express themselves in English. They learned how to deal with uncomfortable pauses, ask for clarification when they did not understand, and, in the process, learn new words and expressions. As one student wrote in her blog, "Skyping pushes me to enrich my vocabulary because, at first, my aim was that of speaking with a native in order to improve my English; now, I want to communicate, convey ideas and for doing so, I must express myself in a more appropriate way." What is more interesting, however, is that this process also helped them learn how to communicate more effectively with non-native speakers of Italian, as students conversed in both languages. Italian students are not accustomed to speaking to non-native speakers of Italian who are trying to communicate in Italian. At first, many found it frustrating, but they became much more aware of the importance of the role of the native speaker when communicating with non-native speakers. For example, they learned to speak more slowly, how to piece together the disjointed sentences their American peers were producing, and understand the American students' pronunciations in Italian. Given the growing number of immigrants in Italy, this can be considered a particularly important social skill.

BloggingEnglish: Reflecting on Social Software and Language Learning

Many blended language courses are carried out using forums or other tools in traditional, closed LMSs to promote communication. However, if current language learning aims to offer students authentic opportunities for accessing and producing language, we asked ourselves if blogs and other Web 2.0 tools were not more suitable. According to Ferdig and Trammell (2004), "[K]nowledge construction is discursive, relational and conversational in nature. Therefore, as students appropriate and transform knowledge, they must have authentic opportunities for publication of knowledge" (p. 1). Blogs do just this if they are public, which means they can be read by anyone on the Web. This gives students a real audience for their writing, beyond the teacher and the classroom, which in turn increases students' sense of ownership and responsibility for what they write (Godwin-Jones, 2004). Furthermore, the journal-like nature of blogs and the fact that posts are archived and can be retrieved promote reflective analysis of their writing (Bryant, 2006; Ferdig & Trammell, 2004). Finally, though at first blogs may appear to be all about writing, they are first and foremost about reading. Therefore, an advanced ESL course, called BloggingEnglish (http://www.bloggingenglish1.blogspot.com/) was designed using a blog and e-tivities (Salmon, 2002) that focus on familiarization with Web 2.0 tools.

The Course

The course was blended, and students had one two-hour face-to-face lesson a week for 10 weeks (one semester) and were expected to do four to six hours online per week. The course blog was used as a substitute for the forums found on traditional LMSs, and students developed their own personal blogs as a place where they could reflect on their learning experience, express their own creativity, and interact with their classmates. This was believed to be important because, as Godwin-Jones (2006) states, "[I]t is possible to create a more student-centred learning environment using blogs, particularly if students create blogs that they control and whose content they own" (p. 13). Throughout the 10-week course, students were given weekly e-tivities to complete, either on the course blog or on their own personal blogs.

The course had three main objectives:

- Students will develop competency in the use of blogs, wikis, social bookmarking, Web

syndication, and other Web 2.0 tools, and explore their potential for language learning.
- Students will improve their written communicative fluency in English and their reflective and critical thinking skills by publishing their thoughts, opinions, and reactions on a course blog and on a personal blog.
- Students will develop their practical research skills using online information networks as they look for, find, and share online resources.

Each week students were faced with a new Web 2.0 tool with the aim of helping them improve their information literacy skills and participation literacy skills (Giger, 2006) (i.e., how to exploit the knowledge of other Web users and share their knowledge in global communities) (see Table 1). They were encouraged to find blogs where the blogger regularly posted useful information and resources with regard to language learning or their future professions (e.g., as translators or tourism professionals) and podcasts containing regularly updated audio files useful for developing listening skills. Students learned how to use a feed aggregator to have updated information from blogs and other Web sites come to them rather than having to regularly check all the sites they had found. They learned how to participate in social bookmarking (i.e., to exploit the Web sites other members of the community had already found and add their own contributions). They discovered how to effectively use sites like YouTube to practice their listening skills in an interesting, personalized way by choosing topics of particular interest to them (see Figure 3 for the e-tivity on YouTube and Figure 4 for a student's post on her personal blog and a peer's comment). Toward the end of the course, two e-tivities were dedicated to contributing to an existing public wiki. These tasks helped students understand not only that they could gain from other people sharing knowledge but that they too had knowledge to share. As one student commented at the end of the tasks, "We are given the great opportunity to 'tell the world' what we've learned so far during the English course." In other words, students learned to create knowledge, share knowledge, and benefit from the sharing of knowledge of other Web 2.0 users.

Table 1. Weekly e-tivities in the second semester

e-tivity 1	Let's get started	To become familiarized with the course blog; introductions
e-tivity 2	Exploring the blogosphere	To learn how to exploit the blogosphere as a source of information
e-tivity 3	Developing your own blog	To develop a space to express your own creativity and opinions
e-tivity 4	Social bookmarking	To learn how to save all the resources you find on the Web and exploit those found by others
e-tivity 5	Feeds and feed aggregators	To learn how to have selected updated information come to you
e-tivity 6	YouTube	To learn how to exploit video online for language learning and discussion
e-tivity 7	Let's wiki on a public wiki	To experiment with writing on a public wiki
e-tivity 8	Cleaning up the wiki	
e-tivity 9	PLEs	To develop a mindmap of your personal learning environment

The final e-tivity aimed to have students stop and reflect on what they had done and learned by individually developing a mindmap (using the open source software FreeMind) of their own personal learning environment (PLE) and publishing it on their personal blogs. A PLE is "a combination of the formal and informal tools and processes we use to gather information, reflect on it, and do something with it, which is essentially what we mean when we talk about learning" (Martin, 2007). This seemed an appropriate way to end a course on social software as these tools are flexible and can be personalized, and as such allow students to develop their own platforms for their informal learning.

Students found that being faced with a new tool each week was challenging. The general reaction was initially frustration and a sense of not being able to accomplish the task. These 24-year-old Italian students are not, in fact, Digital Natives, and there was no overlap with what they did in the classroom and their personal lives, as most had never seen a blog and none had ever used a wiki, social bookmarking, or feed aggregators. This initial frustration, however, inevitably turned into appreciation for what the new tools had to

Figure 3. Example of an e-tivity based on Salmon's model (2002): spark, purpose, task, respond, timeline. The figure shows e-tivity 6 on exploring YouTube. All students completed the optional part of the task (3)

YouTube
This week we're going to explore (no panic!) YouTube. YouTube is the largest online video sharing tool. It is probably the fastest-growing tool on Web 2.0. According to Wikipedia (http://en.wikipedia.org/wiki/Youtube), "the company was named *TIME* magazine's "Invention of the Year" for 2006.[2] In October 2006, Google Inc. announced that it had reached a deal to acquire the company for US$1.65 billion in Google's stock." In other words, it was something special if Google was willing to invest that much money. You might be asking yourselves, as you often have in this course, 'cosa c'entra con l'inglese?' Well, let's see if you can figure out how it may be useful for your language learning, or blogging, or anything else!
Sarah

Purpose: To start reflecting on the potential of YouTube for language learning and Web filtering.

Task:
1 – **Go to the group I have created for us on YouTube. (http://www.youtube.com/group/bloggingenglish)**. There you will find three videos and three discussions. I have invited you to participate, though the invitation should not be necessary. Should you have problems accessing, send a comment to this post. Before clicking on the videos, click on each discussion and read my message first.

2 – **Complete the tasks in the discussions in YouTube.** As indicated in my comments, please complete the tasks on YouTube by adding your own comments.

3 – **Find a video for your blog.** This part of the e–tivity is optional. If you so desire, search for a video on YouTube that says something about you and add it to your blog. How do you do this? When you click on a video, on the right you should see information about the video including 'embed'. Copy the html, go to blogger, click on new post, click on html and paste the html there. Post the message and the video should appear. Again, if you've got questions, feel free to ask via the comment function here! Note: the videos I've put here so far have been from YouTube and I'm no expert so it can't be hard!

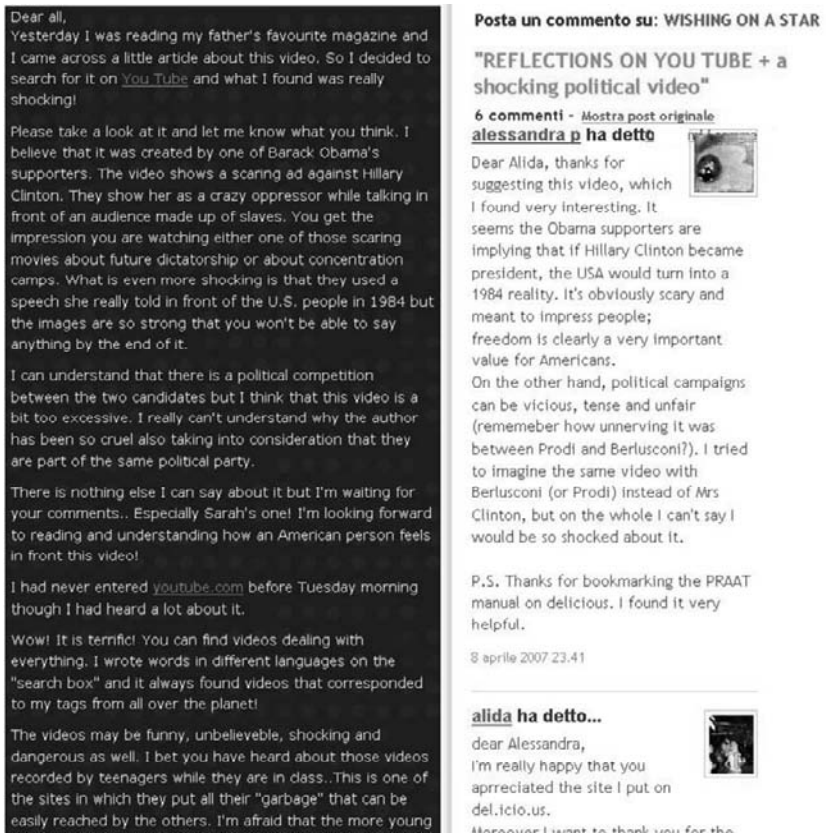
4 – **Reflect**. What do you think are the consequences of this tool? Do you think it has been / can be useful for your English language learning? And for other purposes? Make a blog post reflecting on your YouTube experience.

Respond: Go to each other's blogs (using bloglines!) and read your peers' reflections. Have they said things similar to what you thought? Different? What does this mean? Add comments that help develop the debate on the potential or non-potential of these tools in language learning. Remember, what you contribute may help future students! You've got two weeks to complete this one, so take all the time you need to reflect!

Happy Easter!!!

Timeline: Wednesday, April 11 (task), Tuesday, April 17 (respond).

Figure 4. Example of a student post following an e-tivity and peer comments using the comment function; in this screenshot, the student is responding to e-tivity 6 (see Figure 3); the comment exchange demonstrates how the students are developing a community of learners



offer and an understanding that they were not so difficult to use. A typical entry in students' personal blogs was one student's reaction to learning how to use the feed aggregator: "As has already happened with the previous e-tivities, when we were asked to learn to use new tools, this time I had little problems at first as well. Anyway, after hesitating and being a bit 'angry,' I'm now able to use another tool, and this thanks to my English teacher and e-tivities."

Language Learning

A typical reaction of students at the beginning of the course was "What does this have to do with language learning?" An analysis of the data proves that it can have much to do with language learning, especially reading and writing. As Will Richardson (2004) states in his blog on educational blogging, "Blogging starts with reading. … blogging, at base, is writing down what you think when you read others. … The tool requires writing. The act requires reading. Without reading, you're just writing, not blogging." They developed their reading skills through searching on the Internet to complete the tasks ("I've never read so much!" was one comment) and reading each other's posts before commenting on the course blog or each other's personal blogs. Furthermore, although "writing a weblog appears in the first

instance to be a form of publishing, … as time goes by, blogging resembles more and more a conversation" (Downes, 2004, p. 24). Not only did students send comments to each other's posts in their personal blogs and on the course blogs, engaging them in asynchronous conversation, but comments were also received from strangers on all the personal blogs. Receiving comments from the outside helped students become aware of the fact that they were not only writing for their peers and teacher, but for a global audience as well. Students felt more responsible for what they were writing when they realized anybody could read what they were writing.

Blogging is also, of course, about writing. Students had to write regularly during the course in the form of blog posts and comments. The teacher provided feedback on the language used in the blog posts, and improvements in accuracy took place throughout the course as a result of the feedback. Based on a genre analysis of blogs and online publishing in general, students learned how to be concise and clear and effectively organize their blog posts into small, well-structured readable pieces of information. In their questionnaires, students also mentioned having improved their ability to use different registers (blog, peer feedback, public wiki) and to write more quickly under time pressure. Since blogging involves connecting information to the rest of the Web, students learned to create links to other pages and cite sources of information or images they found on the Web. In this process, they became aware of the importance of attribution and respecting copyright or copyleft, as is the case of Creative Commons, a series of licenses from which an author of any artistic work can choose to allow others to use their work in various ways. Finally, whereas writing on their blogs entailed using relatively informal language, writing on a public wiki where anyone could read or edit their contributions required students to use more formal language and respect sound academic practice. The wiki used, EduTech Wiki (http://edutechwiki.unige.ch/en/Main_Page), is a wiki on educational technologies hosted at the University of Geneva. It is beyond the scope of this chapter to compare the differences in student writing on the TulanePadova wiki and the public EduTech Wiki[3]. However, it is worth pointing out that by being able to compare the two experiences, students came to the overall conclusion that although more challenging, having a real audience makes them take their writing more seriously. As one second-semester student wrote:

[C]ontributing to EduTech Wiki is a good way to make students more responsible and aware of what they're writing. Here anyone can access the pages and contribute to them, while last semester this didn't happen. Writing for a public audience helps us improving our languages, our style and—as in this case—our content (in the sense that maybe we are more careful in looking for sources, links, and information, and in deciding which of them are more reliable than the other ones).

In other words, the change in audience from peers and teacher to any potential Web user influences student writing.

Finally, it is important to point out that four students have continued blogging in English since the end of the course. They have changed the names of their blogs but continue to explore the potential of Web 2.0 and participate in discussions with each other and other bloggers through comments. These students have successfully integrated what they learned in the course into their postgraduation, informal language learning process.

ASSESSMENT

In a context where students are encouraged to work in groups, collaboration must be taken into consideration in assessment. According to Johnson and Johnson (in Swan, Shen & Hiltz, 2006),

"The key to successful cooperative learning is maintaining both individual accountability, in which students are held responsible for their own learning, and positive interdependence, in which students reach their goals if and only if the other students in the learning group also reach theirs" (p. 47). In other words, not only do activities have to be developed in such a way so as to promote group work and responsibility, but also, at least in a formal academic context where students place a lot of importance on grades, collective work must be assessed. Therefore, both courses used continuous assessment and weekly feedback that considered both individual and collective work as well as a final project. Based on the work by Meijas (2006), different percentages were assigned to the various aspects to be assessed. At the start of the course, the grading scheme and rubrics were demonstrated and discussed with the students so they knew what was expected of them.

For the wiki course, the percentages were as follows:

1. *Participation* (individual grade – exchanges with American peers): 25%
2. *Participation* (individual grade – wiki contributions and editing): 25%
3. *Editing the wiki* (collective grade – accuracy): 25%
4. *Final paper/presentation* (individual grade – accuracy): 25%

As can be seen, 75% of the final grade is individual, as this is still considered of primary importance at the university. Nonetheless, the grids used to weekly assess the two participation grades take into consideration collaboration skills (e.g., whether or not the contents of their exchanges and wiki pages responded to what their peers had said or done). Both communicative fluency and linguistic accuracy were taken into consideration. In other words, attempts were made to find a balance between individual and collective grades and between assessment of fluency and accuracy.

For the blogging course, the percentages aimed at encouraging active participation in knowledge creation and sharing.

1. *Distributed research* (links posted to del.icio.us): 10%
2. *Individual analysis (reflection and content–communicative fluency)*: 40%
3. *Final paper (individual grade–accuracy)*: 25%
4. *Comments to classmates' posts (quality of peer assessment)*: 10%
5. *Editing the public wiki (collective grade–accuracy)*: 15%

Here, 20% of the final grade was based on students' abilities to share, collaborate, and do peer review (e.g., distributed research, comments); 40% on their individual abilities to effectively carry out the activities and reflect on their learning experience (e.g., blog posts); and 25% on their individual performances and 15% on group work (e.g., editing the public wiki). Accuracy was considered in only 40% of the grade, while 60% focused on fluency. This choice was based on the fact that throughout their studies, Italian students focus mainly on accuracy and very little on communicative fluency. Many students commented on how much they appreciated the opportunity to be able to just communicate in English. Furthermore, the instructor expected students to emulate the communicative techniques used in the tools they were exploring as part of the course.

In order to keep track of student participation during both courses, grids were used that included task achievement, quality (on a scale of 1 to 10 based on predefined rubrics), and any additional comments. This allowed the instructor to provide weekly qualitative feedback and mid-term feedback as well as to easily calculate the final grade.

DISCUSSION

Numerous studies on network-based language teaching (Kern & Warschauer, 2000) have begun to show the benefits of using networked technologies in the foreign language classroom to connect humans to other humans. As new technologies have developed and Web 2.0 has taken hold, the use of social software in promoting these practices is simply the next step. Never before have language learners had similar opportunities not only to access authentic language but also to participate in the creation of authentic language in real contexts. Given the fact that many of these tools are free, offer remote hosting, and are easy to use, experimenting with them becomes plausible for any language teacher. In the context of the projects discussed in this chapter, for example, the teacher developed both courses without the assistance of a technician or the use of institutional servers. Furthermore, students can develop personal collaborative learning environments (e.g., through blogging and social bookmarking) that they can continue to exploit after courses are finished. In other words, rather than being contained within a closed institutional environment, students can create their own personal learning environments (Attwell, 2007; Wilson, 2006) suited to their own specific language learning styles and needs, and transferable to informal learning.

There are, however, institutional hurdles to overcome. Up until now, many institutions have integrated social software tools into their closed Learning Management Systems (LMS) or installed them on closed university servers. In many ways, this seems to imply simply using social software tools to do what can already be done with other tools in LMSs. An LMS is a centralized environment controlled by an administrator and most often accessible to a limited community of users where the learning process takes place in times and ways that have been established by an instructor. This paradigm tends to promote traditional transmissive pedagogy where the learner has a relatively passive role and cannot take control over his or her own learning. However, today most educators recognize the need for students to become more autonomous and responsible for organizing their own learning. This replication of social software in closed environments works against the very potential of social software, which reaches its full potential when there is a large user base. As has already been stated, combining various tools not only encourages students to take responsibility for their own learning, but also, if these tools are open, to continue using them once their formal education is complete.

Another issue, which seems particularly relevant in Anglo-Saxon contexts where copying and cheating have serious consequences, is destigmatizing collaboration: "[I]t is no longer cheating to find out from or gain the advice of other people or to use information sources not already in your head" (Owen et al., 2006, p. 49). If resource sharing and peer assessment are encouraged and an emphasis is placed on developing skills to learn how to judge resources, paraphrase, and reference electronic sources, then students can gather knowledge from different sources, even their peers, and produce valid academic content. In this way, students learn to learn from one another and the larger Web 2.0 community, thereby developing their participation literacy.

CONCLUSION

This chapter has attempted to offer an introduction to the use of social software in language acquisition. First, we considered the changes that are currently taking place in education toward more collaboration, responsibility, and autonomy for students in both formal and informal learning contexts. We discussed ways in which social software can help meet these new needs. Then we described two blended learning courses carried out at the University of Padova with advanced EFL students, one involving the use of a wiki and Skype in a

telecollaboration project with Tulane University in the United States, and the other involving the use of blogs and other social software tools to help promote autonomous language learning. The initial results, which are quite positive, and a description of how assessment was carried out were presented. Finally, the challenges of using social software in formal education were discussed. In order to achieve the true benefits of using social software in education, institutions and teachers will have to shift from a focus on individual work within the boundaries of a classroom or course to a focus on collective and collaborative work beyond institutional confines.

KEY TERMS

Blog: Simply defined, a blog, or weblog is a sort of online journal organized in reverse chronological order, where a person writes about his or her thoughts and interests, including providing links to relevant resources on the Web. Most blogs allow readers to leave comments. There are many types of blogs, from very personal journals to educational blogs. Various types of media, from audio to video to images, can often be integrated into a text blog.

Feed Aggregators: A client software that allows users to receive syndicated Web content from any type of Web site that uses feeds such as newspaper Web sites, blogs, podcasts, and so forth. In other words, rather than having to regularly check Web sites for updated information through the use of feeds (RSS, XML RSD, XML Atom), updated information is sent to the feed aggregator so users have only one place to check for updated content. Users can decide how much of the updated information they would like to receive in the aggregator (e.g., a few lines or the entire text) and whether or not to receive just text or other media as well. Users can also go directly to the Web sites from the aggregator. Feed aggregators provide a useful tool for managing the information overload on the Internet.

Informal Learning: Learning that takes place outside of institutionally defined contexts; for example, learning on the job and in one's personal life. It can be associated with other concepts such as lifelong and continuous learning, both of which are becoming more important in today's information society.

Network-Based Language Teaching (NBLT): NBLT involves teaching languages through the use of computers that are connected to one another in either local or global networks. NBLT allows students to interact with speakers of the target language without having to physically meet with them. In NBLT, the main focus is on authentic communication via the computer and the Internet. Social software offers new opportunities for NBLT.

Participation Literacy: Whereas information literacy refers to a person's ability to effectively manage information, participation refers to the competences required to effectively participate in Web 2.0 environments. In other words, participation literacy involves learning the social skills needed to take part in online communities.

Social Bookmarking: Social bookmarking Web sites allow users to store, classify, share, and search their own Internet bookmarks as well as those of other community members by using tags (folksonomies). Most services offer remote hosting so that users can access their bookmarks from any computer. Social bookmarking can serve as a filter for the information overload on the Internet. When users search on these Web sites, they are not searching the entire Web using an algorithm, as is the case on most search engines, but rather they are viewing Web sites that other users have found to be useful and taken the time to save and describe, and for which they have chosen semantically classified tags.

Social Software: A generic term used to describe various types of software that enable people to collaborate and create, and join online communities. The tools can promote various types of communication: synchronous one-to-one (instant messaging), synchronous one-to-many (Skypecasts), asynchronous one-to-many (blogs), asynchronous many-to-many (wikis), or asynchronous many-to-one (feed aggregators). These tools allow users to share and create content, collaboratively create and edit content and/or manage content.

Web 2.0: A term used to contrast the World Wide Web in the 1990s as a collection of Web sites produced by experts, institutions, and companies (the read-only Web) with the changes that took place starting with the 21st century where Web applications allow end users to create and share content on the Web (the read-write Web).

Wiki: A software application that allows the creation and development of interlinked Web pages; any user can create new pages and edit existing pages. Wikis, therefore, are an effective tool for collaborative authoring, collective learning, and project-based work.

ENDNOTES

1 Futurelab is a not-for-profit organization researching innovation in education, incubating new ideas, communicating thinking and practice, etc. and can be found at http://www.futurelab.org.uk/

2 There was no informal written communication in the second semester so the first aim only applied to the first semester.

Chapter 8.3
Activity-Oriented Computing

ABSTRACT

This chapter introduces a new way of thinking about software systems for supporting the activities of end-users. In this approach, models of user activities are promoted to first class entities, and software systems are assembled and configured dynamically based on activity models. This constitutes a fundamental change of perspective over traditional applications; activities take the main stage and may be long-lived, whereas the agents that carry them out are plentiful and interchangeable. The core of the chapter describes a closed-loop control design that enables activity-oriented systems to become self-aware and self-configurable, and to adapt to dynamic changes both in the requirements of user activities and in the environment resources. The chapter discusses how that design addresses challenges such as user mobility, resolving conflicts in accessing scarce resources, and robustness in the broad sense of responding adequately to user expectations, even in unpredictable situations, such as random failures, erroneous user input, and continuously changing resources. The chapter further summarizes challenges and ongoing work related to managing activities where humans and automated agents collaborate, human-computer interactions for managing activities, and privacy and security aspects.

INTRODUCTION

Over the past few years, considerable effort has been put into developing networking and middle-

ware infrastructures for ubiquitous computing, as well as in novel human-computer interfaces based on speech, vision, and gesture. These efforts tackle ubiquitous computing from two different perspectives—systems research and HCI research—hoping to converge and result in software that can support a rich variety of successful ubiquitous computing applications. However, although examples of successful applications exist, a good understanding of frameworks for designing ubiquitous computing applications is still largely missing.

A key reason for the lack of a broadly applicable framework is that many research efforts are based on an obsolete application model. This model assumes that ubiquitous computing applications can support user activities by packaging, at design time, a set of related functionalities within a specific domain, such as spatial navigation, finding information on the Web, or online chatting. However, user **activities** may require much diverse functionality, often spanning different domains. Which functionalities are required to support an activity can only be determined at runtime, depending on the user needs, and may need to evolve in response to changes in those needs. Examples of user activities targeted by ubiquitous computing are navigating spaces such as museums, assisting debilitated people in their daily living, activities at the office such as producing reports, as well as activities in the home such as watching a TV show, answering the doorbell, or enhancing house security.

This chapter introduces activity-oriented computing (AoC) as a basis for developing more comprehensive and dynamic applications for ubiquitous computing. Activity-oriented computing brings user activities to the foreground by promoting models of such activities to first class primitives in computing systems.

In the remainder of this chapter, the section on background presents our vision for activity-oriented computing and compares it with related work. Next we discuss the main challenges of this approach to ubiquitous computing. Specifically, we discuss user mobility (as opposed to mobile computing), conflict resolution and robustness, mixed-initiative control, human-computer interaction, and security and privacy.

The main body of the chapter presents our work towards a solution. Specifically, we discuss software architectures for activity-oriented computing and how to address the challenges of mobility and robustness, as well as the options to model user activities. The chapter ends with a discussion of future directions concerning human-computer interactions, and the tradeoff between ubiquity and security and privacy.

BACKGROUND

The vision of AoC is to make the computing environment aware of *user **activities*** so that resources can be autonomously managed to optimally assist the user. Activities are everyday actions that users wish to accomplish and that may be assisted in various ways by computing resources in the environment. Done right, AoC will allow users to focus on pursuing their activities rather than on configuring and managing the computing environment. For example, an AoC system could reduce overhead by automatically customizing the environment each time the user wishes to resume a previously interrupted long-lived activity, such as preparing a monthly report, or organizing a party.

To help make this vision concrete, the following examples illustrate possible applications of AoC:

- **Elderly care:** Rather than relying on hardcoded solutions, AoC enables domain experts such as doctors and nurses to "write prescriptions" for the activities of monitoring the health of the elderly or outpatients. Such descriptions enable smart homes to take charge of those activities, collaborating

with humans as appropriate. For example, the heart rate of an elderly person may be monitored by a smart home, which takes responsibility to alert family members when alarming measurements are detected. Who gets alerted and the media to convey the alert may depend on contextual rules, such as the seriousness of the situation, as prescribed by the doctor; the elder's preferences of who to contact, who is available, who is closer to the elder's home, whether sending an SMS appropriate, and so forth.

- **Entertainment:** While others have explored the vision that music, radio, or television can follow occupants as they move through the house, activity-oriented computing enables a more general approach. Entertainment can be defined as an activity, allowing preferences and constraints to be specified, and underlying **services** to be shared, such as tracking people, identifying and using devices in various rooms. For example, the same location services used for home security activities can be used for entertainment; the television that can be used for entertainment can also be used for displaying images of a visitor at the front door.
- **Home Security:** Many homes have a security system that uses sensors to detect burglary attempts and fires. They are standalone systems with limited capabilities; for example the system is typically either on or off and control is entirely based on a secret code. If the security system were built as an activity service, it could be an open system with richer functionality. For example:
    - A richer set of control options, for example, based on fingerprint readers or voice recognition. These methods may be more appropriate for children or the elderly.
    - More flexibility (e.g., giving neighbors limited access to water the plants when the homeowners are on vacation, the ability to control and interact with the system remotely, or incorporate cameras that ignore dogs).
    - Remote diagnosis, for example, in response to an alarm, police or fire responders may be able to quickly check for false alarms through cameras.
- **Doorbell:** A very simple activity is responding to somebody ringing the doorbell. Today's solution is broadcast; the doorbell is loud enough to alert everybody in the house and then people decide independently or after coordination (through shouting!) how to respond. In activity-oriented computing, a doorbell activity carried out by the hallway selects a person, based on their current location, current activity, and age. If the visitor can be identified, it might be possible to have the person who is being visited respond. Also, the method of alerting the person can be customized, for example, using a (local) sound, displaying a message on the television screen, or flashing the lights. Finally, if nobody is home, the doorbell service can take a voice message or, if needed, establish a voice or video link to a house occupant who might be available in their office or car. Activities such as answering the phone could be handled in a similar way, that is replace the broadcast ringing by a targeted, context-aware alert.

What is Activity-Oriented Computing

Activity-oriented computing adopts a fundamental change of perspective over traditional applications in that **activities** take the main stage and may be long-lived, whereas the agents that carry them out are plentiful and interchangeable; how activities are best supported will evolve over time, depending on the user's needs and context. In AoC, activities are explicitly represented and manipulated by the computing infrastructure.

Broadly speaking, this has two significant advantages.

First, it enables explicit reasoning about user **activities**: which activities a user may want to carry out in a particular context; what functionality (**services**) is required to support an activity; what are the user preferences relative to quality of service for each different activity; which activities conflict; which have specific privacy or security concerns, and so forth.

Second, it enables reasoning about the optimal way of supporting activities, through the dynamic selection of service suppliers (agents) that implement specific functions relevant to the activity. Thanks to the explicit modeling of the requirements of activities and of the capabilities of agents, the optimality of such assignment may be addressed by quantitative frameworks such as **utility** theory. Also, by raising the level of abstraction above particular applications or implementations, activity models make it easier to target a broad range of concrete implementations of similar services in different devices, in contrast to solutions based on mobile code (more in the Challenges section, below).

Related Work

Early work in ubiquitous computing focused on making certain applications ubiquitously available. For that, it explored OS-level support that included location sensing components to automatically transfer user interfaces to the nearest display. Examples of this are the work on teleporting X Windows desktops (Richardson, Bennet, Mapp, & Hopper, 1994) and Microsoft's Easy Living project (Brumitt, Meyers, Krumm, Kern, & Shafer, 2000). This idea was coupled with the idea of desktop management to treat users' tasks as sets of applications independent of a particular device. Examples of systems that exploit this idea are the Kimura project (MacIntyre et al., 2001), which migrates collections of applications across displays within a smart room, and earlier work in aura that targets migration of user tasks across machines at different locations (Wang & Garlan, 2000). Internet Suspend-Resume (ISR) requires minimal changes to the operating system to migrate the entire virtual memory of one machine to another machine (Kozuch & Satyanarayanan, 2002). These approaches focus on making applications available ubiquitously, but do not have a notion of user activity that encompasses user needs and preferences, and therefore do not scale to environments with heterogeneous machines and varying levels of service.

More recent work seeks to support cooperative tasks in office-like domains, for example ICrafter (Ponnekanti, Lee, Fox, & Hanrahan, 2001) and Gaia (Román et al., 2002); as well as domain-specific tasks, such as healthcare (Christensen & Bardram, 2002) and biology experiments, for example, Labscape (Arnstein, Sigurdsson, & Franza, 2001). This research shares with ours the goal of supporting activities for mobile users, where activities may involve several services in the environment, and environments may contain heterogeneous devices. However, much of this work is predicated on rebuilding, or significantly extending, operating systems and applications to work over custom-built infrastructures. In contrast the work described in this chapter supports user activities with a new software layer on top of existing operating systems, and accommodates integration of legacy applications.

Focusing on being able to suspend and resume existing activities in a ubiquitous environment does not go all the way toward the vision of providing ubiquitous assistance for user activities. Such support can be divided into two categories: 1) helping to guide users in conducting tasks; and 2) performing tasks, or parts of tasks, on behalf of users. An early example of the first category is the Adtranz system (Siewiorek, 1998), which guides technical staff through diagnosing problems in a train system. More recent work concentrates on daily life, often for people with special needs, such as the elderly, or those with debilitated health

(Abowd, Bobick, Essa, Mynatt, & Rogers, 2002; Intille, 2002).

Research on automated agents takes assistance one step further by enabling systems to carry out activities on behalf of users. Examples of this are the RETSINA framework (Sycara, Paolucci, Velsen, & Giampapa, 2003), with applications in domains such as financial portfolio management, e-commerce and military logistics; and more recently the RADAR project (Garlan & Schmerl, 2007), which focuses on the office domain, automating such tasks as processing e-mail, scheduling meetings, and updating Web sites.

Consumer solutions for activities in the home are beginning to emerge, mainly from the increasing complexity of configuring home theater equipment. Universal remote controls, such as those provided by Logitech, allow users to define activities such as "Watch DVD," which choose the input source for the television, output of sound through the home theater system, and choosing the configuration of the DVD player (Logitech). However, in these solutions, activities are bound to particular device and device configurations—the activities themselves must be redefined for different equipment, and it is not possible for the activities to move around different rooms in the home, or to allow different levels of service for the same activity.

In this chapter, we discuss the potential and the challenges of having software systems using activity models at runtime. Specifically, we focus on the benefits of using activity models for enabling users to access their activities ubiquitously, and for delegating responsibility for activities to automated agents.

CHALLENGES

Activity-oriented computing raises a number of challenges that must be addressed by any adequate supporting infrastructure and architecture.

- **User mobility:** As users move from one environment to another—for example, between rooms in a house—activities may need to migrate with the users, tracking their location and adapting themselves to the local situation. A key distinction between user mobility in AoC and previous approaches is that no assumptions are made with respect to the users having to carry mobile devices, or to the availability of a particular kind of platform at every location. Since different environments may have very different resources (devices, services, interfaces, etc.) a critical issue is how best to retarget an activity to a new situation. For example, an activity that involves "watching a TV show" can be changed into "listening" when the user walks through a room that only offers audio support. Solving this problem requires the ability to take advantage of context information (location, resource availability, user state, etc.), as well as knowledge of the activity requirements (which services are required, fidelity tradeoffs, etc.) to provide an optimal use of the environment in support of the activity.
- **Conflict resolution:** Complicating the problem of automated configuration and reconfiguration is the need to support multiple activities—both for a single user and between multiple users. If an individual wants to carry out two activities concurrently that may need to use shared resources, how should these activities simultaneously be supported? For example, if the user is engaged in entertainment, should the doorbell activity interrupt that activity? Similar problems exist when two or more people share an environment. For example, if two users enter the living room hoping to be entertained, but having different ideas of what kind of entertainment they want, how can those conflicts be reconciled? Solving this problem requires (a) the ability to detect

when there may be conflicts, and (b) the ability to apply conflict resolution policies, which may itself require user interaction.

- **Mixed-initiative control:** The ability to accomplish certain kinds of activities requires the active participation of users. For example, the door answering activity, which might be associated with a house, requires occupants of the house to respond to requests from the house to greet a visitor. Since humans exhibit considerably more autonomy and unpredictability than computational elements, it is not clear how one should write the activity control policies and mechanisms to allow for this. Standard solutions to human-based activities (such as work-flow management systems) are likely not to be effective, since they assume users will adhere to predetermined plans to a much higher degree than is typically the case in the kinds of domains targeted by ubiquitous computing.
- **Security and privacy:** Some security and privacy issues can be solved through traditional mechanisms for security, but others are complicated by key features of ubiquity; they include rich context information, and user mobility across public or shared spaces such as a car, or an airport lounge. In a multi-user environment with rich sources of context information (such as a person's location), an important issue is how to permit appropriate access to and sharing of that information. Furthermore, which guarantees can be made to a user that wishes to access personal activities in a shared space? What mechanisms can back such guarantees? Are there deeper issues than the exposure of the information that is accessed in a public space? Is it possible that all of a user's information and identity may be compromised as a consequence of a seemingly innocuous access at a public space?
- **Human-computer interaction:** Many of the activities that a ubiquitous computing environment should support will take place outside of standard computing environment (such as a networked office environment). In such environments, one cannot assume that users will have access to standard displays, keyboards, and pointing devices. How then can the system communicate and interact with users effectively? What should be the role of emerging technologies such as augmented reality and natural interaction modalities such as speech, gesture, and ambient properties such as light and smell?

While the challenges above stem from the problem domain, we now turn to the challenges associated with building a solution for AoC.

- **Activity models**. The first challenge is to define what kinds of knowledge should be imparted in systems to make them aware of user activities. Specifically, what should be the contents and form of activity models? What should be the semantic primitives to compose and decompose activities? At what level of sophistication should activity models be captured? Presumably, the more sophisticated the models, the more a system can do to assist users. For example, to help users with repairing an airplane or with planning a conference, a significant amount of domain knowledge needs to be captured. But obviously, capturing such knowledge demands more from users (or domain experts) than capturing simple models of activities. Is there an optimal level of sophistication to capture activity models—a sweet spot that maximizes the ratio between the benefits of imparting knowledge to systems and the costs of eliciting such knowledge from users? Or is it possible to have flexible solutions that allow incremental levels of sophistication for representing each activity, depending

on the expected benefits and on the user's willingness to train the system?

- **System design**. Systems that support AoC should be capable of dynamic reconfiguration in response to changes in the needs of user activities. Ideally, such systems would also be aware of the availability of resources in the environment and respond to changes in those. The questions then become: What is an appropriate architecture to support activity-oriented computing? What responsibilities should be taken by a common infrastructure (middleware) and which should be activity- or service-specific? What are the relevant parameters to guide service discovery (location, quality of service, etc.) and how should discovery be geographically scoped and coordinated? Can activity models be capitalized to handle the heterogeneity of the environment, self-awareness and dynamic adaptation? Furthermore, what operations might be used to manage activities: suspend and resume, delegate, collaborate, others? What should be the operational semantics of each of these operations?
- **Robustness**. In AoC, robustness is taken in the broad sense of responding adequately to user expectations, even in unpredictable situations, such as random failures, erroneous user input, and continuously changing resources. First of all, should adequacy be a Boolean variable—either the system is adequate or it is not—or can it be quantified and measured? Specifically, are there system capabilities and configurations that are more adequate than others to support a user's activity? If so, can measures of adequacy be used to choose among alternatives in rich environments? For example, is the user better served by carrying out a video conference on a PDA over a wireless link, or on the wall display down the hall?

TOWARDS A SOLUTION

To address the challenges identified above, we decided to start with relatively simple models of activities and address concrete problems where the advantages of AoC could be demonstrated. This section summarizes our experience of about six years at Carnegie Mellon University's project **aura**. Initially, this research targeted the smart office domain, and later extended to the smart home domain (more below).

Designing systems for AoC brings up some hard questions. What makes those questions especially challenging, is that to answer them, we need to reexamine a significant number of assumptions that have been made about software for decades. Not surprisingly, our own understanding of how to answer those questions continues to evolve. This section is organized around the set of solution-related challenges identified above; namely, system design, activity models, and robustness.

System Design

The first research problem we focused on, starting around the year 2000, was user mobility in the smart office domain. Here, activities (or tasks) typically involve several applications and information assets. For instance, for preparing a presentation, a user may edit slides, refer to a couple of papers on the topic, check previous related presentations, and browse the web for new developments. An example of user mobility is that the user may start working on the presentation at his or her office, continue at the office of a collaborator, and pick the task up later at home.

The premise adopted for user mobility is that users should not have to carry a machine around, just as people normally don't carry their own chairs everywhere. If they so desire, users should be able to resume their tasks, on demand, with whatever computing systems are available. This premise is neither incompatible with users carrying mobile devices, nor with mobile code. Ideally, the capa-

bilities of any devices or code that travel with the user contribute to the richness of the environment surrounding the user, and therefore contribute to a better user experience. A discussion of why solutions centered on mobile devices, mobile code, or remote computing (such as PC Anywhere) are not entirely satisfactory to address user mobility can be found in (J.P. Sousa, 2005).

Designing a solution to support user mobility is made harder by the heterogeneity of devices where users may want to resume their activities, and by dynamic variations in the resources and devices available to the user. Even in a fairly restricted office domain, it is common to find different operating systems, offering different suites of applications (e.g., Linux vs. PC vs. Mac). In a broader context, users may want to carry over their activities to devices with a wide range of capabilities, from handhelds to smart rooms. In addition to heterogeneity, mobile devices are subject to wide variations of resources, such as battery and bandwidth. Ideally, software would automatically manage alternative computing strategies based on user requirements and on the availability of resources. Moreover, in heavily networked environments, remote servers may constantly change their response times and even availability. Ideally, users should be shielded as much as possible from dealing with such dynamic variations.

Before describing an architecture for supporting user mobility as outlined above, Table 1 clarifies the terminology used throughout this chapter, since although the terms are in common use, their interpretation is far from universal.

Our starting point for supporting user mobility was to design an infrastructure, the **aura** infrastructure, that exploits knowledge about a user's tasks to automatically configure and reconfigure the environment on behalf of the user. Aura is best explained by a layered view of its infrastructure together with an explanation of the roles of each layer with respect to task suspend-resume and dynamic **adaptation**.

First, the infrastructure needs to know *what* to configure for; that is, what a user needs from

Table 1. Terminology

task	An everyday activity such as preparing a presentation or writing a report. Carrying out a task may require obtaining several *services* from an *environment*, as well as accessing several *materials*.
environment	The set of *suppliers*, *materials* and *resources* accessible to a user at a particular location.
service	Either (a) a service type, such as printing, or (b) the occurrence of a service proper, such as printing a given document. For simplicity, we will let these meanings be inferred from context.
supplier	An application or device offering *services* – for example, a printer.
material	An information asset such as a file or data stream.
capabilities	The set of *services* offered by a *supplier*, or by a whole *environment*.
resources	Are consumed by *suppliers* while providing *services*. Examples are: CPU cycles, memory, battery, bandwidth, and so forth.
context	Set of human-perceived attributes such as physical location, physical activity (sitting, walking…), or social activity (alone, giving a talk…).
user-perceived state of a task	User-observable set of properties in the *environment* that characterize the support for the task. Specifically, the set of *services* supporting the task, the user-level settings (preferences, options) associated with each of those services, the *materials* being worked on, user-interaction parameters (window size, cursors…), and the user's preferences with respect to quality of service tradeoffs.

the environment in order to carry out his or her tasks. Second, the infrastructure needs to know *how* to best configure the environment; it needs mechanisms to optimally match the user's needs to the capabilities and resources in the environment.

In our architecture, each of these two sub-problems is addressed by a distinct software layer: (1) the *Task Management* layer determines *what* the user needs from the environment at a specific time and location; and (2) the *Environment Management* layer determines *how* to best configure the environment to support the user's needs.

Table 2 summarizes the roles of the software layers in the infrastructure. The top layer, *task management* (TM), captures knowledge about user needs and preferences for each activity. Such knowledge is used to coordinate the configuration of the environment upon changes in the user's task or context. For instance, when the user attempts to carry out a task in a new environment, TM coordinates access to all the information related to the user's task, and negotiates task support with environment management (EM). Task Management also monitors explicit indications from the user and events in the physical context surrounding the user. Upon getting indication that the user intends to suspend the current task or resume some other task, TM coordinates saving the user-perceived state of the suspended task and recovers the state of the resumed task, as appropriate.

The *EM layer* maintains abstract models of the environment. These models provide a level of indirection between the user's needs, expressed in environment-independent terms, and the concrete capabilities of each environment.

This indirection is used to address both heterogeneity and dynamic change in the environments. With respect to heterogeneity, when the user needs a service, such as speech recognition, EM will find and configure a supplier for that service among those available in the environment. With respect to dynamic change, the existence of explicit models of the capabilities in the environment enables automatic reasoning when those capabilities change dynamically. The Environment Management adjusts such a mapping automatically in response to changes in the user's needs (adaptation initiated by TM), and changes in the environment's capabilities and resources (adaptation initiated by EM). In both cases adaptation is guided by the maximization of a ***utility*** *function* representing the user's preferences (more in the section on Robustness, below).

Table 2. Summary of the software layers in aura

layer	mission	roles
Task Management	***what*** does the user need	monitor tasks, contexts and preferences
		map tasks to needs for services in an environment
		for complex tasks: decomposition, plans, context dependencies
Environment Management	***how*** to best configure the environment	monitor environment capabilities and resources
		map service needs and user-level state of tasks to available suppliers
		ongoing optimization of the utility of the environment relative to user task
Env.	support the user tasks	monitor relevant resources
		fine grain management of QoS/resource tradeoffs

The *environment layer* comprises the applications and devices that can be configured to support a user's task. Configuration issues aside, these suppliers interact with the user exactly as they would without the presence of the infrastructure. The infrastructure steps in only to automatically configure those suppliers on behalf of the user. The specific capabilities of each supplier are manipulated by EM, which acts as a translator for the environment-independent descriptions of user needs issued by TM. Typically, suppliers are developed by wrapping existing applications. Our experience in wrapping over a dozen applications native to Windows and Linux has shown that it is relatively easy to support setting and retrieving the user-perceived state (Balan, Sousa, & Satyanarayanan, 2003; J.P. Sousa, 2005).

This layering offers a clean separation of concerns between what pertains to user activities and what pertains to the environment. The knowledge about user activities is held by the TM and travels with the user to each environment in which he or she wishes to carry out activities. The knowledge about the environment stays with the EM and can be used to address the needs of many users.

A significant distinction of this approach to user mobility is that it does not require code or devices to travel with the user. A generic piece of code, Prism, in the TM layer *becomes* an **aura** for a user by loading models of user activities. Those models are encoded in XML for convenience of mobility across heterogeneous devices (more in the section on Activity Models, below).

Extending to the Home Environment

Although the layered perspective played an important role in clarifying the separation of concerns and protocols of interaction, it captures only the case where users consume services, and software components provide them.

In the smart home domain, software could take responsibility for activities, and users might be asked to contribute services for those activities. For example, a smart home might take charge of the home's security and ask a human to lock the windows when night falls. Other examples of activities include a user watching a TV show, a user checking on a remote family member, the main hallway facilitating answering the door, and the home keeping a comfortable temperature. These examples prompted us to realize that any domain entity could have an aura, and that an aura might find itself on either the supplying or the consuming side, or both. Specifically, **auras** can be associated with:

- People including individual residents, or groups, such as a resident's parents, or the entire family.
- Spaces, such as the main hallway, living room or the entire home. Spaces of interest are not necessarily disjoint.
- Appliances, such as a TV, phone, table or couch. Appliances have a well-defined purpose and may have a range of automation levels, from fairly sophisticated (a smart refrigerator), to not automated at all (an old couch).
- Software applications, such as a media player, a video conferencing app, or a people locator. Applications run on general purpose devices, and which applications are available on one such device define the purpose that the device may serve.

Figure 1 shows the run-time architectural framework for an activity-oriented system. The boxes correspond to types of components, and the lines to possible connectors between instances of those types.[1] Part (a) shows our initial understanding based on the smart office domain, and part (b) shows the more general framework. Contrasting the two, it is now clear that the TM corresponded to an aura (of users) that consumed services but supplied none; and suppliers corresponded to auras of software that supplied services, but consumed none.

Figure 1. Architectural framework

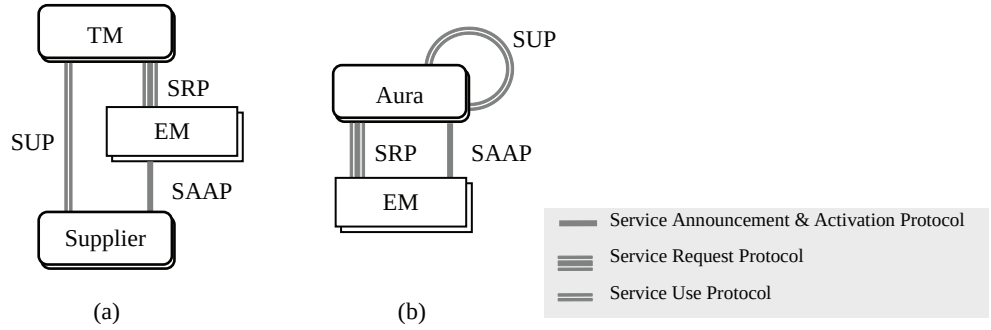

Figure 2. Snapshot of the architecture of one system

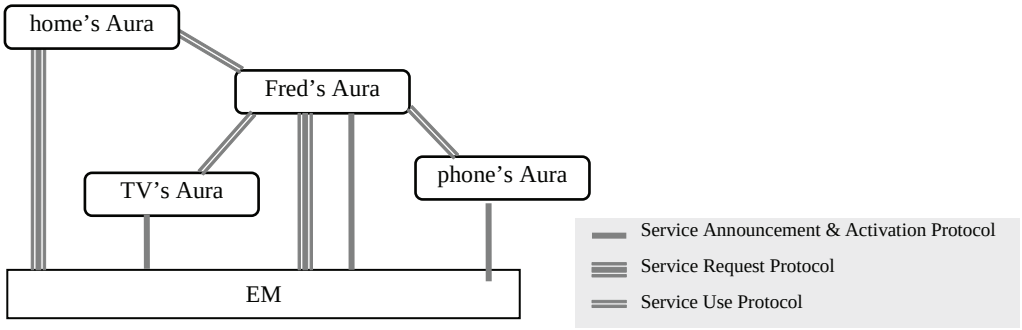

In the new architectural framework, when an aura boots up, it first locates the EM (see the section on Service Discovery, below) and then may engage on the service announcement & activation protocol (SAAP) to announce any services that its entity provides, as well as on the service request protocol (SRP) to discover services that are relevant to support the entity's activities. Once the services in other auras are actually recruited by the EM, using the SAAP, the consumer aura and the supplier auras interact via the service use protocol (SUP) to reconstruct the user-perceived state of the activity.

Figure 2 shows an example of an architecture that was dynamically created to respond to the needs of a user, Fred, at a particular place, Fred's home. The boxes correspond to run time components (autonomous processes that may be deployed in different devices) rather than denoting code packaging, and the lines correspond to connectors, that is, actual communication channels that are established dynamically as the components are created. The diagram represents two kinds of components: auras, with rounded corners, and the EM, and it visually identifies the different kinds of interaction protocols between the components (see Figure 1).

The instance of the architecture in the example is the result of Fred's aura interacting with the EM to recruit two suppliers: the TV and the phone's auras, after interpreting Fred's needs for the desired activity. This architecture may evolve to adapt to changes in Fred's needs, and in the figure, Fred's aura is also shown as being recruited by the home's aura to get Fred to open the front door.

Context Awareness

An important decision is how to enable context awareness in activity-oriented computing. Addressing context awareness can be decomposed into three parts—sensing context, distributing contextual information, and reacting to context. We start by discussing the latter.

Potentially, all domain entities, and therefore their auras, might want to react to context. A user's aura may change the requirements on an activity, or change which activities are being carried out depending on context such as user location, or whether the user is sitting alone at the office, driving a car, or having an important conversation with his or her boss. Suppliers contributing services to an activity may want to change modalities of those services based on context. For example, an application that shows confidential information may hide that information automatically if someone else is detected entering the room; or an application that requires text or command input may switch to speech recognition if the user needs to use his or her hands, say, for driving a vehicle. The EM may change the allocation of suppliers for a given activity based on user location. For example, if the user is watching a TV show while moving around the house, different devices may be allocated: the TV in the living room, the computer monitor at the home office, etc. The upshot of this is that contextual information should be accessible to all the boxes in the architecture.

Initially, we thought that a dedicated part in the infrastructure would be in charge of gathering and distributing contextual information; there would be a Context Management component/layer in each environment, just like there is an Environment Management. However, both the contextual information and the policies for distributing such information are associated with each user and not really with the environment where that user happens to be. Therefore, auras are the hub of knowledge about the entities they represent.

Whenever a component wishes to obtain contextual information about entity X, it will ask X's aura. X's aura itself may use a variety of mechanisms to gather information about X. For example, since physical location of a space is normally a non-varying property, the aura for a home can read the home's location from a configuration file. In contrast, the aura for an application running on a cell phone equipped with GPS might obtain the application's location from the device's GPS. The aura for a person P typically obtains P's contextual information via contextual information services (CIS).

Unlike sensors specific to devices or spaces, CIS's are fairly generic. Specifically, devices such as a thermometer attached to a wall, or a window sensor for detecting whether *that* window is open or closed, are accessed only by the auras of the corresponding physical spaces. In contrast, given a training set with a person's face, a generic face recognizer may be able to track that person's location inside an office building by using cameras spread over rooms and halls.

CISs are integrated into the architecture using the same protocols for discovery and activation as other services, which allows for gracefully handling of activity instantiation in both sensor-rich environments, such as a smart building, and in depleted environments, such as a park.

While CIS components release information based on generic premises such as the rule of law (e.g., only an authenticated aura for X or a law enforcement agent with a warrant can obtain information about X), the auras themselves are responsible for knowing and enforcing their entity's privacy policies regulating whom to release which information. As an example of distribution policy, a user may authorize only a restricted group of friends to obtain his or her current location.

Service Discovery

In the initial architectural framework (Figure 1.a), **service** discovery is coordinated by the environ-

ment management layer. When we expanded the focus of our research to the smart home domain, around the year 2004, we revisited the problem of service discovery. Among the questions that prompted this revisiting are: are there real advantages in brokering discovery? What are the relevant parameters to guide service discovery (location, quality of service, etc.)? How can discovery be geographically scoped? Would some measure of physical distance be enough for such scoping? Can discovery be scoped by geographical areas that are meaningful to the user? We elaborate on these below.

This first question is what should be the strategy for discovery. Many activities in the smart home domain involve entities performing services for other entities, and it is up to auras to find and configure the services required by their entities. For example, for watching a TV show, Fred will need some entity to play the video stream for him. Fred's aura takes care of finding and configuring such an entity in Fred's vicinity (for instance the TV in the living room,) and to change the video stream to other convenient entities whenever Fred moves around the home (a TV in the kitchen, a computer in the office, etc.).

One candidate solution would be to have auras broadcast service availability and/or service requests. However, service discovery in ubiquitous computing involves not just matching service names or capabilities but, ideally, it would find *optimal* services in terms of attributes such as desired levels of quality of service, user preferences, proximity, and so forth. Furthermore, scoping the search would be constrained by network administration policies regarding broadcast (see below). Also, it is hard to establish trust based on broadcast mechanisms.

Because finding the optimal entities to perform services is both a non-trivial problem and common across auras, there are clear engineering advantages in factoring the solution to this problem out of individual auras and into a dedicated piece of the infrastructure. Specifically, the benefits of introducing Environment Managers (EMs) as discovery brokers include:

- **Separation of concerns:** It is up to specialized service brokers to know *how* to find the optimal entities to provide services, while each aura retains the responsibility of knowing *what* services are required by their entity's activities at each moment. By providing a separate locus for optimal discovery in EMs, auras can focus on the task-specific knowledge required to interact with other auras, once they are identified.
- **Efficiency:** EMs can cashe service announcements, thereby improving the latency of processing a service request, and reducing the network traffic required to locate a service, whenever one is requested.

auras register the services offered by the entity they represent with an EM. Each service posting includes the type of service and all attributes of the offering entity that characterize the service. For example, Fred's aura announces that Fred is capable of *answering the door* (service type,) along with Fred's contextual attributes pertaining to his current *location* and whether he is *busy*. Although Fred's aura might know about Fred's blood pressure, that wouldn't be directly relevant for his ability to answer the door. As another example, the aura for a printer announces its ability to *print documents*, along with the printer's *location*, *pages per minute* and *queue length* (contextual and quality of service attributes).

auras may request an EM to find services, as needed by the activities of the entities they represent. Service discovery is guided by optimality criteria in the form of **utility** functions over the attributes of the service suppliers and of the requesting entity. Specifically a service request is of the form:

```
find x : service | y • max u(p_x, p_y)
```

This means: find a set of entities $\underline{x}$, each capable of supplying a `service`, given the requestor entity `y`, such that a utility function `u` over the properties of `y` and of the elements of $\underline{x}$ is maximized. The following are examples with simple utility functions:

Track Fred's location. Upon startup, Fred's aura issues:

```
find x1:people-locating | Fred
```

That is, find x_1 capable of providing a people locating service for Fred.

Follow-me video. When Fred wishes to watch a soccer game while moving around the house, his aura issues:

```
find x1:video-playing | Fred · min x1.location – Fred.location
```

That is, find a video player closest to Fred. In this case, maximizing the utility corresponds to minimizing the physical distance between Fred and the video player.

Doorbell. When the doorbell is pressed by someone, the aura for the main hallway issues:

```
find x1:door-answering, x2:notifying | hallway
· x1.busy = no & min (x1.location – hallway.location
+ x1.location – x2.location)
```

That is, find a notifying mechanism and a door answerer that is not busy and both closest to the hallway and to the notifying mechanism.

Utility functions are quantitative representations of usefulness with respect to each property. Formally, selecting a specific value of a property, such as x_1.busy = no, is encoded as a discrete mapping, specifically:

$$u_{x_1 \cdot busy}(yes) \mapsto 0,\ u_{x_1 \cdot busy}(no) \mapsto 1$$

For properties characterized by numeric values, such as the distance to the hallway, we use utility functions that distinguish two intervals: one where the user considers the quantity to be good enough for his activity, the other where the user considers the quantity to be insufficient. *Sigmoid* functions, which look like smooth step functions, characterize such intervals and provide a smooth interpolation between the limits of those intervals. Sigmoids are easily encoded by just two points; the values corresponding to the knees of the curve that define the limits *good* of the good-enough interval, and *bad* of the inadequate interval. The case of "more-is-better" qualities (e.g., *accuracy*) are as easily captured as "less-is-better" qualities (e.g., *latency*) by flipping the order of the *good* and *bad* values (see (Sousa, Poladian, Garlan, Schmerl, & Shaw, 2006) for the formal underpinnings).

In the case studies evaluated so far, we have found this level of expressiveness for utility functions to be sufficient.

Scoping Service Discovery

The second question is how service discovery can be scoped in a way that is meaningful to the user. Specifically, many searches take place in the user's immediate vicinity, such as the user's home.

However, neither physical distance nor network range are good parameters to scope discovery. For example, if the user's activity asks for a device to display a video, the TV set in the apartment next door should probably not be considered, even though it might be just as close as other candidates within the user's apartment, and be within range of the user's wireless network as well. To be clear, once a set of devices is scoped for discovery, physical distance may be factored in as a parameter for *optimality* (see above).

Furthermore, sometimes users may want to scope discovery across areas that are not contigu-

ous. For example, suppose that Fred is at a coffee shop and wants to print an interesting document he just found while browsing the internet. Fred may be willing to have the document printed either at the coffee shop, or at Fred's office, since Fred is heading there shortly. A printer at a store down the street may not be something that Fred would consider, even though it is physically closer than Fred's office.

The question about scoping service discovery can then be refined into (a) if not by distance or network boundaries, how can the range of one environment be defined? and (b) how to coordinate discovery across non-contiguous environments?

When an aura directs a discovery request to an EM, by default, discovery runs across all services registered with that EM. That is, the range of an environment is defined by the services that registered with its EM. The question then becomes, how does an aura know with which EM it should register its services? For example, how would the aura for the TV set in Fred's living room know to register its services with the EM in Fred's apartment, and not with the neighbor's?

Auras resolve their physical location into the network address of the appropriate EM by using the environment manager binding protocol (EMBP).[2] This service plays a similar role to the domain naming service in the internet, which resolves URI/URLs into the network address of the corresponding internet server. Physical locations are encoded as aura location identifiers (ALIs), with structure and intent similar to universal resource identifiers (URIs) in the internet. Like URIs, ALIs are a hierarchical representation meant to be interpreted by humans and resolved automatically. For example, *ali://pittsburgh.pa.us/zip-15000/main-street/1234/apt-6* might correspond to Fred's apartment; and *ali://aura.cmu.edu/wean-hall/floor-8/8100-corridor* to a particular corridor on the 8th floor of Wean Hall at Carnegie Mellon University.

Requests for discovery across remote and/or multiple environments can be directed to the local EM, which then coordinates discovery with other relevant EMs (more below). The following are examples of such requests. When Fred is at home and wishes to print a document at the office, his aura would issue a request like:

```
find x:printing | Fred • u(…)
    @ ali://aura.cmu.edu/wean-hall/floor-8/8100-
corridor
```

Or, if Fred wanted to consider alternatives either at home or at his office:

```
find x:printing | Fred • u(…)
    @ ali://aura.cmu.edu/wean-hall/floor-8/8100-
corridor,
    ali://pittsburgh.pa.us/zip-15000/main-
street/1234/apt-6
```

Or, if Fred wanted to search a number of adjacent environments, such as all the environments in his office building:

```
find x:printing | Fred • u(…)
    @ ali://aura.cmu.edu/wean-hall
```

Any such requests are directed by the requestor aura to the local EM, which then resolves such requests in three steps:

1. Use the EMBP to identify the EMs that cover the desired region.
2. Obtain from such EMs all the service descriptions that match the requested service types.
3. Run the service selection algorithms over the candidate set of services.

Activity Models

What to include in activity models is ultimately determined by the purpose that those models are

meant to serve. In some applications of activity models the goal is to assist users with learning or with performing complex tasks. Examples of these are applications to automated tutoring, expert systems to help engineers repair complex mechanisms, such as trains and airplanes, and automated assistants to help manage complex activities such as organizing a conference (Garlan & Schmerl, 2007; Siewiorek, 1998). For these kinds of applications, models of activities may include a specification of workflow, as a sequence of steps to be performed, and cognitive models of the user.

In the smart office domain, we experimented with enabling users to suspend their ongoing activities and resume them at a later time and/or at another location, possibly using a disjoint set of devices. For that purpose, the models capture user needs and preferences to carry out each activity. Specifically, such models include of a snapshot of the services and materials being used during the activity, as well as utility theory-based models of user preferences (for details on the latter, see (Sousa et al., 2006)).

Figure 3 shows a grammar for modeling **activities**, or tasks, as a set of possibly interconnected services. This grammar follows a variant of the Backus-Naur Form (BNF, see for instance (ISO, 1996)). To simplify reading the specification, we drop the convention of surrounding non-terminal symbols with angle brackets, and since the task models are built on top of XML syntax, we augment the operators of BNF with the following:

```
E ::= t: A; C
```

defines a type E of XML elements with tag t, attributes A, and children C, where t is a terminal symbol, A is an expression containing only terminals (the attribute names), and C is an expression containing only non-terminals (the child XML elements). In this restricted use of BNF, whether a symbol is a terminal or non-terminal is entirely established by context. So, for instance the rule:

Figure 3. Grammar for specifying task models

```
Task  ::= auraTask: id;
      Prefs {ServiceSnapshot | MaterialSnapshot | Config}

ServiceSnapshot ::= service: id type;
      Settings
MaterialSnapshot ::= material: id;
      State

Config ::= configuration: name weight;
      { Service | Connection }

Service ::= service: id;
      {Uses}
Uses  ::= uses: materialId;

Connection ::= connection; id type;
      Attach QoSPrefs
Attach ::= attach: ;
      From To
From  ::= from: serviceId port;
To    ::= to: serviceId port;
```

```
Book = book: year ISBN; Title {Author}
```

allows the following as a valid element:

```
<book year="2004" ISBN="123">
    <title>...</title>
    <author>...</author>
    <author>...</author>
</book>
```

Specifically, in Figure 3, a task (model) is an XML element with tag `auraTask`, with one `id` attribute, and with one `Prefs` child, followed by an arbitrary number of `ServiceSnapshot`, `MaterialSnapshot`, and `Config` children. A task may be carried out using one of several alternative service configurations of services.

Services stand for concepts such as *edit text*, or *browse the web*, and materials are files and data streams manipulated by the services. A service may manipulate zero or many materials; for instance, text editing can be carried out on an arbitrary number of files simultaneously. That relationship is captured by the `Uses` clauses within the `Service` element.

The snapshot of the user-perceived state of the task is captured in the *`Settings`* and *`State`* elements. The *`Settings`* element captures the state that is specific to a service, and shared by all materials manipulated by that service, while the *`State`* element captures the state that is specific to each material. A detailed discussion of this grammar can be found in (Sousa, 2005).

Figure 4 shows one example of a task model for reviewing a video clip, which formally is a sentence allowed, or generated, by the grammar in Figure 3. This example was captured while running the infrastructure described in the section on System Design. The user defined two alternative configurations for this task: one including both playing the video and taking notes, the other, playing the video alone. Both services use a single material: *play video* uses a video file, with material id 11, and *edit text* uses a text file, with material id 21. The user-perceived state of the task is represented as the current service settings, under each service, and the current state of each material. For instance, the state of the video includes the fact that the video is stopped at the beginning (the cursor is set to 0 time elapsed), and it indicates the position and dimensions of the window showing the video.

Extending to the Home Environment

In the smart home domain, in addition to supporting suspend/resume of activities, we wanted to enable users to delegate responsibility for some activities to **auras**. Examples of the latter activities include managing intrusion detection for the home, finding a person to answer the door for a visitor, or assisting with monitoring elder family members.

The research questions then become: is the services and materials view of activities adequate in the smart home domain? For enabling auras to take responsibility for activities, which concepts should activity models capture?

The usefulness of capturing the services needed for an activity seems to carry over well into the smart home domain. For example, in the case of the doorbell scenario, the activity of answering the door requires finding services such as notification can be supplied by devices such as a telephone, a TV, a buzzer, etc., and *door answerer*, which can be supplied by a qualified person (e.g., not a toddler). Selecting the suppliers for such services is guided by the home owner's preferences encoded in the activity model, which may include things such as the door needs to be answered within a certain time, and that the notification service should be in close proximity to the candidate door answerer.

A prototype of this case study has shown that these models can handle sophisticated policies of configuration (e.g., excluding children from answering the door, or specifying criteria for proximity) and that they trivially accommodate the dynamic addition of new notification devices.

Figure 4. Example task model for reviewing a video clip

```
<auraTask id="34">
  <preferences>
    <service template="default" id="1"/>
    <service template="default" id="2"/>
  </preferences>
  <service type="play Video" id="1">
    <settings mute="true"/>
  </service>
  <material id="11">
    <state>
      <video state="stopped" cursor="0"/>
      <position xpos="645" ypos="441"/>
      <dimension height="684" width="838"/>
    </state>
  </material>
  <service type="edit Text" id="2">
    <settings>
      <format overtype="0"/>
      <language checkLanguage="1"/>
    </settings>
  </service>
  <material id="21">
    <state>
      <cursor position="31510"/>
      <scroll horizontal="0" vertical="7"/>
      <zoom value="140"/>
      <spellchecking enabled="1" language="1033"/>
      <window height="500" xpos="20" width="600" mode="min" ypos="100"/>
    </state>
  </material>
  <configuration name="all" weight="1.0">
    <service id="2">
      <uses materialId="21"/>
    </service>
    <service id="1">
      <uses materialId="11"/>
    </service>
  </configuration>
  <configuration name="only video" weight="0.7">
    <service id="1">
      <uses materialId="11"/>
    </service>
  </configuration>
</auraTask>
```

This prototype also highlighted two fundamental differences between the kinds of activities supported in the smart-office domain and the ones we target in the smart-home domain. The first difference is that, while in the office domain services were only provided by automated agents (software), now people may also be asked to provide services. This has implications on how auras control service supply, since people are much more likely than software to do something totally different than what they are being asked. In the example, after being notified to answer the door, a person may get sidetracked and forget about it. It is up to the responsible aura to monitor whether or not the service is being delivered, and react to a "fault" in a similar way as it would in the case of

faulty software: by seeking a replacement (more in the section on Robustness).

The second difference is that, in the smart home domain, auras may take the responsibility for activities; this is related to the question above of which concepts to capture in activity models to enable that to happen. In the smart office domain, when a fault cannot be handled, for example, if a suitable replacement cannot be found for a faulty supplier, the problem is passed up to the entity responsible for the activity, that is, the user. If an aura is to be truly responsible for an activity, it must be take charge of such situations as well.

One way of addressing a hurdle in one activity, is to carry out another activity that circumvents the hurdle. In the example, if the hallway aura cannot find a person to answer the door, it may take a message from the visitor, or initiate a phone call to the person being visited.

A simple enhancement of activity models to allow this is to support the specification of conditions to automatically resume or suspend activities. Such conditions are expressed as Boolean formulas over observation of contextual information. For example, if everyone left the house, resume the intrusion detection activity.

For these models to cover situations as the one where a person could not be found to answer the door, contextual information needs to be rich enough to include semantic observations, such as "the door could not be open for a visitor."

Another scenario where we tested this approach is the elder care scenario. The aura for Susan, Fred's grandmother, runs a perpetual task that recruits a heart monitor service for her. Susan defined under which conditions her aura should trigger the task of alerting the family. When defining such conditions, Susan takes into consideration her physician's recommendations, but also conditions under which she may desire privacy. Fred's aura runs a perpetual task of monitoring contextual postings by Susan's aura. It is up to John to (a) define that posting such a notification should trigger the task of alerting him, and (b) define the means employed by his aura to carry out such a task. For example, if Fred is at the office, his aura sends an instant message to Fred's computer screen; otherwise, it sends a text message to Fred's cell phone.

While these are simple scenarios, they illustrate the ability to chain activities, and to direct the exact behavior of activities, by capturing conditions on contextual information in the models of activities. Such conditions are associated to the operations of either resuming or suspending activities, and can be monitored by auras to automatically initiate the corresponding operation.

Formally, condition-action primitives can be used to express the same space of solutions than other more sophisticated approaches, such as models of activities based on workflow notations, or on hierarchical decomposition of activities. Which approach would be more suitable for end-users to express and understand such models is an open research problem.

ROBUSTNESS

The term *robustness* in activity-oriented computing is interpreted very broadly: is the system's behavior consistent with the users' expectations, even under unanticipated circumstances. In this section, we first use the examples in the Background section to identify key robustness requirements. We then look at the challenges associated with supporting robust operation, distinguishing between general challenges and challenges that are specific to the home environment. Finally, we summarize some results showing how we support robust tasks in an office environment and discuss how these results can be extended to support activities in the home.

Properties

In daily use, the system should correctly identify the users' intent and should support a wide vari-

ety of activities in a way that is consistent with their preferences and policies. If users observe unexpected behavior, the system should be able to explain its behavior. This will increase the users' confidence in the system and will allow the system to improve over time. For example, by adjusting preferences and policies, either manually by the user or automatically by the system (case-base reasoning) the system's future behavior can be made to better match user intent. Similarly, the system should be able to engage users if input is confusing or unexpected. Ideally, the system would be able to recognize undesirable or unsafe actions, for example, a child opening the door for a stranger.

The above properties must also be maintained as the system evolves and under failure conditions. For example, when new services or devices are added (e.g., camera and face recognition software is added to support the doorbell scenario) or become unavailable (e.g., the license for the face recognition software expired), the system should automatically adapt to the available services.

Challenges

When we looked at how to support user activities and tasks in different environments (e.g., work in an office, daily activities in the home, or guiding visitors in a museum), we found that several key challenges are shared across these environments. These generic challenges include capturing and representing user intent, discovering and managing services and devices (suppliers), and optimizing resources allocation to maximize overall system utility. All these functions should be adaptive, that is, automatically adapt to changes in the computational and physical environment and to changes in the goals and preferences of users.

Each environment also adds its own challenges. For example, activities in homes are device-centric (e.g., displays, sound) or include physical actions that involve people (e.g., opening doors). Managing and allocating such "resources" is very different from an office environment, where tasks are computer-centric and are supported by executing applications that use a variable amount of resources (network bandwidth, CPU, battery power). Similarly, the interactions with users are very different in the home (discreet interface for non-experts) and the office (keyboard/mouse/display used by computer knowledgeable users).

Robustness in an Office Environment

In order to achieve robustness in a smart-office environment, we have designed, implemented and evaluated an infrastructure that uses utility theory to dynamically select the best achievable configuration of services, even in the face of failures and coming online of better alternatives (Sousa et al., 2006).

Robustness is achieved through self-**adaptation** in response to events ranging from faults, to positive changes in the environment, to changes in the user's task. Self-adaptation is realized through a closed-loop control system design that senses, actuates, and controls the runtime state of the environment based on input from the user. Each layer reacts to changes in user tasks and in the environment at a different granularity and time-scale. Task Management acts at a human perceived time-scale (minutes), evaluating the adequacy of sets of services to support the user's task. Environment Management acts at a time-scale of seconds, evaluating the adequacy of the mapping between the requested services and specific suppliers. Adaptive applications (fidelity-aware and context-aware) choose appropriate computation tactics at a time-scale of milliseconds.

Let us illustrate the behavior of the system using the following scenario. Fred is engaged in a conversation that requires real-time speech-to-speech translation. For that task, assume the aura infrastructure has assembled three services: speech recognition, language translation, and speech synthesis. Initially both speech recognition

and synthesis are running on Fred's handheld. To save resources on Fred's handheld, and since language translation is computationally intensive, but has very low demand on data-flow (the text representation of each utterance), the translation service is configured to run on a remote server. We now discuss how the system adapts in response to faults, variability in resource and service availability, and changes in the user's task requirements:

- **Fault tolerance**. Suppose now that there is loss of connectivity to the remote server, or equivalently, that there is a software crash that renders it unavailable. Live monitoring at the EM level detects that the supplier for language translation is lost. The EM looks for an alternative supplier for that service, for example, translation software on Fred's handheld, activates it, and automatically reconfigures the service assembly.
- **Resource and fidelity-awareness**. Computational resources in Fred's handheld are allocated by the EM among the services supporting Fred's task. For computing optimal resource allocation, the EM uses each supplier's spec sheet (relating fidelity levels with resource consumption), live monitoring of the available resources, and the user's preferences with respect to fidelity levels. Resource allocation is adjusted over time. For example, suppose that during the social part of the conversation, Fred is fine with a less accurate translation, but response times should be snappy. The speech recognizer, as the main driver of the overall response time, gets proportionally more resources and uses faster, if less accurate, recognition algorithms (Balan et al., 2003).
- **Adaption.** Adaptation is also needed to deal with changes in resource availability. Each supplier issues periodic reports on the Quality of Service (QoS) actually being provided—in this example, response time and estimated accuracy of recognition/translation. Suppose that at some point during the conversation, Fred brings up his calendar to check his availability for a meeting. The suppliers for the speech-to-speech translation task, already stretched for resources, reduce their QoS below what Fred's preferences state as acceptable. The EM detects this "soft fault," and replaces the speech recognizer by a lightweight component, that although unable to provide as high a QoS as the full-fledged version, performs better under sub-optimal resource availability. Alternatively, suppose that at some point, the language translation supplier running on the remote server (which failed earlier) becomes available again. The EM detects the availability of a new candidate to supply a service required by Fred's task, and compares the estimated utility of the candidate solution against the current one. If there is a clear benefit, the EM automatically reconfigures the service assembly. In calculating the benefit, the EM factors in a cost of change. This mechanism introduces hysteresis in the reconfiguration behavior, thus avoiding oscillation between closely competing solutions.
- **Task requirements change**. Suppose that at some point Fred's conversation enters a technical core for which translation accuracy becomes more important than fast response times. The TM provides the mechanisms to allow Fred to quickly indicate his new preferences; for instance, by choosing among a set of preference templates. The new preferences are distributed by the TM to the EM and all the suppliers supporting Fred's task. Given a new set of constraints, the EM evaluates the current solution against other candidates, reconfigures, if necessary, and determines the new optimal resource allocation. The suppliers that remain in the configuration, upon receiving the new preferences, change

their computation strategies dynamically, for example, by changing to algorithms that offer better accuracy at the expense of response time.

Suppose that after the conversation, Fred wants to resume writing one of his research papers. Again, the TM provides the mechanisms to detect, or for Fred to quickly indicate, his change of task. Once the TM is aware that the conversation is over it coordinates with the suppliers for capturing the user-level state of the current task, if any, and with the EM to deactivate (and release the resources for) the current suppliers. The TM then analyses the description it saved the last time Fred worked on writing the paper, recognizes which services Fred was using and requests those from the EM. After the EM identifies the optimal supplier assignment, the TM interacts with those suppliers to automatically recover the user-level state where Fred left off. See Sousa and Garlan (2003) for a formal specification of such interactions.

Extending to the Home Environment

We are currently enhancing this solution to provide robust support for activities in the home. While the key challenges are the same (e.g., optimizing utility, adapting to changes, etc.), extensions are needed in a number of areas.

First, activities in the home are very different from tasks in the office. For example, since some activities in the home involve physical actions, people must be involved (e.g., to open a door), that is, people become suppliers of services. Moreover, some tasks are not associated with individuals, but with the home itself (e.g., responding to the doorbell or a phone call). This change in roles means that it is even more critical to make appropriate allocations since the cost of mistakes is much higher; for example, people will be much less willing to overlook being personally inconvenienced by a wrong decision, than when a suboptimal application is invoked on their computer.

Second, many activities in the home involve the use of devices that are shared by many people, or involve deciding who should perform a certain action. This means that the Task Manager will typically need to balance the preferences and goals of multiple users. An extreme example is conflicts, for example, when multiple users would like to use the same device. In contrast, tasks in the office typically involve only personal resources (e.g., a handheld) or resources with simple sharing rules (e.g., a server).

Third, the methods for interaction with the system will be much different in the home. Even on a handheld, Fred had access to pull down menus and a keyboard to reliably communicate with the system. For the home environment, we are exploring natural modalities of interaction, which are less intrusive, but more ambiguous (more in the section on Future Research).

Finally, uncertainty will play a more significant role in the home, for example, because of unpredictable behavior when people are asked to perform services, or due to ambiguity caused by primitive I/O devices. Work in progress is extending the utility optimization components to explicitly consider uncertainty.

FUTURE RESEARCH

Some of the challenges identified in this chapter are the topic of undergoing and future work, such as research on the kinds of knowledge to capture in activity models so to support mixed-initiative control, including delegation and collaboration among human and automated agents. Below we summarize our current work on human-computer interaction and on security and privacy for AoC systems.

User Interfaces for Managing Activities

Human-computer interaction in the office domain currently uses one de-facto standard modality,

based on keyboards, pointing devices, and windows-based displays. In a more general ubiquitous computing setting, natural modalities such as speech and gesture may be highly desirable, but they also may lead to ambiguity and misunderstanding. For example, if Fred points at a TV where a soccer game is playing and leaves the room, does that mean that Fred wants to keep watching the game while moving around the house, that the TV should pause the game until Fred returns, or that the TV should be turned off?

Rather than trying to pick a privileged modality of interaction, we take the approach that interactions between humans and auras may have many channels that complement and serve as alternatives to each other. For example, users might indicate their intention to suspend an activity verbally, but might sometimes prefer a graphical interface to express a sophisticated set of contextual conditions for when an activity should be automatically resumed. The research questions then become: what are appropriate modalities for each kind of interaction? Is there a role for explicit interactions, as well as for implicit interactions based on sensing and inference? Can different modalities be coordinated, contributing to disambiguate user intentions? What mechanisms can be used to detect and recover from misunderstandings? What are specific technologies that can be harnessed in the home?

To support explicit interactions, we started exploring technologies such as Everywhere Displays and RFID. The Everywhere Displays technology uses a digital camera to track down the location of a user, and then uses a projector to project an image of the interface onto a surface near the user (Kjeldsen, Levas, & Pinhanez, 2004). The feedback loop through the camera allows the image to be adjusted for certain characteristics of the surface, such as color and tilt. The user interacts with this image by performing hand motions over the image, which are then recognized via the camera. This technology supports a metaphor similar to the point-and-click metaphor, although fewer icons seem to be feasible relative to a computer screen, and a rich set of command primitives, such as double clicking or selecting a group of objects, seems harder to achieve.

RFID technology supports a simple form of tangible interfaces (Greenberg & Boyle, 2002). For example, RFID tags can be used to create tangible widgets for activities. In the example where Fred is watching the game on TV, Fred may bind an activity widget with the show playing on the TV by swiping the widget near the TV. That activity may be activated in other rooms by swiping the activity widget by a reader in the room, or deactivated it by swapping the widget again, once activated (see demo video at (Sousa, Poladian, & Schmerl, 2005)).

Tradeoff between Ubiquity and Security

The big question to be answered is: can ubiquity be reconciled with goals of security and privacy? There seems to be a tradeoff between the openness of ubiquitous computing and security assurances. The very meaning of *ubiquity* implies that users should be enabled to use the services offered by devices embedded in many different places. But how confident can users be that those devices, or the environment where they run, will not take advantage of the access to the user's information to initiate malicious actions?

Rather that taking an absolute view of security and privacy, we argue that there are different requirements for different activities. For example, the computing environment at a coffee shop could be deemed unsafe to carry out online financial transactions, but acceptable for sharing online vacation photos with a friend.

In essence, this is a problem of controlling access; ideally, a ubiquitous computing environment would gain access only to the information pertaining to the activities that a user is willing to carry out in that environment, and none other.

Unfortunately, existing solutions for controlling access are not a good fit to this problem because they make a direct association between identity and access. Specifically, once a user authenticates, he gains access to *all* the information and resources he is entitled to, and so does the computing environment where the user authenticated.

A candidate solution would be to associate access control to the cross-product of users and environments; in the example, user Fred at the coffee shop would get access to a limited set of activities, but user Fred at his office would get access to a wide range (possibly all) of Fred's activities. A serious problem with this solution is that it would require the pre-encoding of all the types of environments where the user might want to access his or her activities.

Another candidate solution would be for users to have multiple identities; Fred at the coffee shop would use an identity that has access to the vacation photos, but not to online banking. This solution has two obvious problems; first, separating the activities and associated information for the different identities may not be clear cut, and may quickly become cumbersome for moderately high numbers of activities. Second, if users are given the freedom to define new identities and the corresponding access controls, does that mean that every user should be given security administration privileges?

We are currently investigating an access control model centered on the notion of *persona*. A user is given one identity and may define multiple personae associated with that identity. The user may freely associate activities with personae in a many-to-many fashion, and may also define which credentials are required to activate each persona. This model has a number of benefits, as follows.

First, it allows users to manage which activities are seen by an arbitrary environment (by authenticating specific personae) while drawing a clear boundary on the administrative privileges of each user.

Second, users may draw on rich forms of authentication to make the overhead of authentication proportionate to the security requirements. For example, for activating Fred's financial persona, Fred may require two forms of id to be presented, such as entering a password *and* scanning an id card, while for his social persona, a weak form of authentication, such as face or voice recognition, will suffice.

Third, the model offers users a coherent view of the personal workspace centered on their identity, while enabling users to expand the set of accessible activities at will, by providing the credentials required to activate the desired personae.

CONCLUSION

The key idea of Activity-oriented Computing (AoC) is to capture models of user activities and have systems interpret those models at run time. By becoming aware of what user activities entail, systems can do a better job at supporting those activities, either by facilitating access to the activities while relieving users from overhead such as configuring devices and software, or by taking responsibility for parts or whole activities.

This chapter described the authors' work on building systems to support AoC. It discussed how those systems may address challenges inherent to the problem domain, such as user mobility and conflict resolution, as well as challenges that are entailed by building the systems themselves. Specifically, (a) defining what to capture in activity models (b) designing systems that do a good job at supporting user activities while addressing the challenges in the problem domain, and (c) making those systems robust, self-aware, self-configurable, and self-adaptable. The chapter dissected those challenges, identified specific research questions, and described how the authors

answered these questions for the past six years, as their understanding of the issues improved.

The main contributions of this work are as follows:

- Pragmatic models of user activities that enable mobile users to instantiate activities in different environments, taking advantage of diverse local capabilities without requiring the use of mobile devices, and retaining the ability to reconstitute the user-perceived state of those activities
- Mechanisms that enable scoping service discovery over geographical boundaries that are meaningful to users, and which can be specific to each activity and be freely defined
- A utility-theoretic framework for service discovery that enables optimization of sophisticated, service-specific models of QoS and context properties
- A robustness framework, based on the same utility-theoretic framework, that departs from the traditional binary notion of fault and uniformly treats as an optimization problem faults, "soft faults" (unresponsiveness to QoS requirements,) and conflicts in accessing scarce resources
- Closed-loop control that enables systems to become self-aware and self-configurable, and to adapt to dynamic changes in both user/activity requirements and environment resources
- A software architecture that harmoniously integrates all the features above, additionally (a) integrating context sensing according to the capabilities of each environment, and (b) coordinating adaptation policies with applications that may contain their own fine-grain mechanisms for adaptation to resource variations

This chapter also summarized ongoing and future work towards addressing other challenges, namely, supporting activities where human and automated agents collaborate (mixed-initiative activities), exploring human-computer interaction modalities for AoC in ubiquitous computing environments, and investigating models for security and privacy.

ENDNOTES

1 For generality, the protocols of interaction were renamed from previous architecture documentation (e.g. Sousa & Garlan, 2003, Sousa, 2005). For instance, the EM—Supplier protocol is now the Service Announcement and Activation Protocol (SAAP). Since these protocols were already based on peer-to-peer asynchronous communication, no changes were implied by the transition to the new perspective of the architectural framework.

2 As discussed in the subsection on context awareness, there is a variety of mechanisms for auras to obtain their physical location, or more precisely, the location of their corresponding entities.

This work was previously published in Advances in Ubiquitous Computing: Future Paradigms and Directions, edited by S. Mostefaoui, Z. Maamar, and G. Giaglis, pp. 280-315, copyright 2008 by IGI Publishing (an imprint of IGI Global).

Chapter 8.4
Integration Concept for Knowledge Processes, Methods, and Software for SMEs

Kerstin Fink
University of Innsbruck, Austria

Christian Ploder
University of Innsbruck, Austria

ABSTRACT

Small and medium-sized enterprises (SMEs) are a vital and growing part of any national economy. Like most large businesses, SMEs have recognized the importance of knowledge management. This Chapter investigates the use of knowledge processes and knowledge methods for SMEs. The learning objectives of this Chapter are to assess the role of knowledge management and knowledge processes in SMEs. Furthermore, the reader should be able to describe major knowledge management programs in SMEs and assess how they provide value for organizations. Empirical studies conducted by the authors show that for SMEs, only four knowledge processes are important: (1) knowledge identification, (2) knowledge acquisition, (3) knowledge distribution and (4) knowledge preservation. Based on the research result of several empirical studies, an integration concept for knowledge processes, knowledge methods, and knowledge software tools for SMEs is introduced and discussed.

INTRODUCTION

The academic literature on knowledge management has become a major research field in different disciplines in the last decade (Davenport & Prusak, 1998). Through knowledge management, organizations are enabled to create, identify and renew the company's knowledge base and to deliver innovative products and services to the customer. Knowledge management is a process of systematically managed and leveraged knowledge in an organization. For Mockler and Dologite (2002, p. 18) knowledge management "refers to the process of identifying and generating, systematically gathering and providing

access to, and putting in use anything and everything which might be useful to know when performing some specified business activity. The knowledge management process is designed to increase profitability and competitive advantage in the marketplace". Before implementing a knowledge integration concept, there must be a common understanding of the term knowledge, its characteristics, and its impact on knowledge management. The multi-faceted nature of the term knowledge is reflected in a variety of definitions (Kakabadse, Kouzmin, & Kakabadse, 2001, p. 138). Davenport and Prusak (1998) use the term *"knowledge in action"* to express the characteristics of the term knowledge management in a way it is valuable for the company and to capture it in words because it resists in the minds of the humans and their action. Davenport and Prusak (1998, pp. 6) identify five key components that describe the term knowledge management:

1. The first component is *experience*. Knowledge develops over time, and it builds on the lifelong learning and training practice of an employee. Experience has a historical perspective, and it is based on the skills the knowledge-worker applies to familiar patterns to make connections between these links.
2. The second component of the term knowledge is *"ground truth"* (Davenport & Prusak, 1998) which is a term used by the U.S. Army's Center for Army Lessons Learned (CALL). CALL used the term "ground truth" to express experiences that come from the ground rather than from theories and generalizations. "Ground truth" refers to the way that the people involved know what works and what does not. CALL experts' take part in real military situations, and they pass their observations to the troops through videotapes or photos. The success of this knowledge management approach lies in "After Action Review" programs which try to cover the gap between what happened during an action and what was supposed to happen. This reflection process helps uncover disparities and differences
3. The third component is *complexity*. The skill to solve complex problems and the ability to know how to deal with uncertainties distinguish an expert from a normal employee.
4. A forth characteristic of knowledge is *judgment*. An expert can judge new situations based on experience gained over time. Furthermore, they have the ability to refine them through reflection. Knowledge, in this sense, is a living system that interacts with the environment.
5. Finally, knowledge is about heuristics and *intuition*. An expert acts based on their intuitive knowledge.

Knowledge is tacit, action-oriented, supported by rules, and it is constantly changing. In a global and interconnected society, it is more difficult for companies to know where the best and most valuable knowledge is, thus it becomes more difficult to know what the knowledge is. A successful implementation of knowledge management only can be achieved in a culture that supports knowledge sharing and transfer. An appropriate organizational culture can empower effective knowledge management. The organizational culture of a company consists of its shared values or norms which are transmitted through common beliefs and feelings, regularities of behavior, and historical processes. Trompenaars and Hampden-Turner (2006, p. 6) define culture as a group of people concerned with problem solving processes and reconciliation dilemmas. Culture itself has three different levels. The first, and highest level, is *national culture* or regional society; the second level describes *organizational culture*, and, finally, *professional culture* focuses on the knowledge of specific groups. A knowledge culture is the most important value for the implementation of knowledge management,

because organizational knowledge resides in the culture, structure and individuals who make up the organization.

Besides culture and networking, the objective for knowledge management technology is the creation of a connected environment for the exchange of knowledge (Mentzas, Apostolou, Young, & Abecker, 2001). These new software products facilitate communication and interaction among people as well as among people and systems. Mentzas et al. (2001, p. 95) discuss two key components that are required to support the sharing of information and knowledge:

- *Collaboration facilities* for knowledge workers are mainly the domain of groupware products. Other technology examples in this group are email systems, workflow automation, discussion groups, document management, shared databases, scheduling and calendar functions.
- *Discovery facilities* are required for searching and retrieval purposes. Knowledge workers are in constant need of finding and accessing information and knowledge from other experts. A wide variety of information sources support the finding of expertise, and they include the Internet, corporate Intranets, legacy systems and corporate local area networks (LANs).

Knowledge management is more than the technological solutions provided to give people access to better and more relevant information (Wang & Plaskoff, 2002, p. 113). It is important that the design of the knowledge management systems reflects the mindset of the knowledge workers and their way of offering highly qualitative knowledge solutions with quick solution processes. An effective knowledge management system must integrate people, processes, technology and the organizational structure.

Historically, knowledge management focused on the domain of larger organizations. Consequently issues of culture, networking, organizational structure and technological infrastructure have been examined upon the implementation of knowledge management initiatives in large multi-national organizations and seem to give little relevance (Delahaye, 2003) to small and medium enterprises (SMEs). However, the success and growth of SMEs depends on how well they manage the knowledge of their knowledge workers. Managers in SMEs have to recognize that the uniqueness and creativity of each knowledge worker will lead to customer satisfaction and the success of the SMEs. Dezouza & Awazu (2006) point out that SMEs have to compete with know-how in order to gain competitive advantages. As SMEs do not have much money to spend on knowledge management initiatives, knowledge must be leveraged so that goals can be achieved in an effective and efficient manner. There are several research articles dealing with knowledge management in SMEs (2001), but only a few empirical studies have been conducted to see the impact of knowledge processes in them. McAdam & Reid (2005) concluded that the time is right for knowledge management within the SME-sector. The results of their comparative study of large organizations and SMEs showed that both have much to gain from the development of knowledge management systems. Salojärvi, Furu & Sveiby (Dunkelberg & Wade, 2007) concluded that SMEs should be able to enhance their performance and competitive advantages by a more conscious and systematic approach to knowledge management.

There are several quantitative (2007, p. 240) and qualitative definitions of the term SME depending on regional and national differences. Street & Cameron (Fink & Ploder, 2007a, 2007b) conducted a literature review from 1990 until 2002 to analyze the current status of SMEs and found a variety of definitions of SMEs with the following clustering: individual characteristics of the entrepreneur, organizational characteristics of the SME, relationship characteristics,

performance characteristics, strategic planning characteristics or relationship characteristics. In 2000, the European Council set the clear strategic goal for the European Union (EU) of becoming "the most competitive and dynamic economy in the world, capable of sustaining economic growth with more and better jobs and greater social cohesion" by the year 2010 (ec.europa.eu/growthandjobs). SMEs are playing a key role in European economic performance because they account for a high proportion of the Gross Domestic Product (GDP) and employ some two thirds of the European workforce. According to the OECD Small and Medium Enterprise Outlook 2005 (www.oecd.org) SMEs are very important for strengthening economic performances. They represent over 95 percent of enterprises in most OECD countries, and generate over half of private sector development. Looking at the European countries of Austria and Switzerland including Liechtenstein a similar SME landscape can be found. According to the Austrian Statistical Year Book (www.statistik.at) and the Austrian Institute for SMEs Research (www.kmuforschung.ac.at) in the year 2006, 99.7 percent of companies in Austria, or 297,800, were SMEs. According to the data from CHSME (www.kmu.admin.ch), 99.7 percent of the companies in Switzerland are SMEs.

In the United States (US), the definition of small business is set by a government department called the Small Business Administration (SBA) Size Standards Office. The SBA uses the term "size standards" to indicate the largest a concern can be in order to still be considered a small business. It must also be independently owned and operated. Unlike the European Union, which has simple definitions applied to all industries, the United States has chosen to set size standards for each individual industry. This distinction is intended to better reflect industry differences. SMEs are also of high importance for in the US Economy. Similar to Europe, more than 97 percent of the firms in the US can be defined as SME.

A comparable influence of SMEs on economic value can be found in the report of the Asia-Pacific Economic Cooperation (www.apec.com), where about 90 percent of enterprises are SMEs. During their 2006 meeting in Beijing the members agreed to strengthen SME´s competitiveness for trade and investment. For example, SMEs account for more than 95 percent of companies in Australia. Of the 624,010 SMEs in Australia, more than two thirds employ between one and four people. A further 180,880 SMEs employ between five and 19 people meaning that 93.5 percent of people employed by SMEs in Australia are employed by what can be described as 'micro-SMEs', namely companies with fewer than 20 employees.

In section two the authors introduce an integration concept for the implementation of knowledge management systems in SMEs by taking the knowledge processes, knowledge methods and supporting knowledge software tools into consideration. Section three discusses future research and describes objectives.

INTEGRATION CONCEPT FOR KNOWLEDGE MANAGEMENT IN SMES

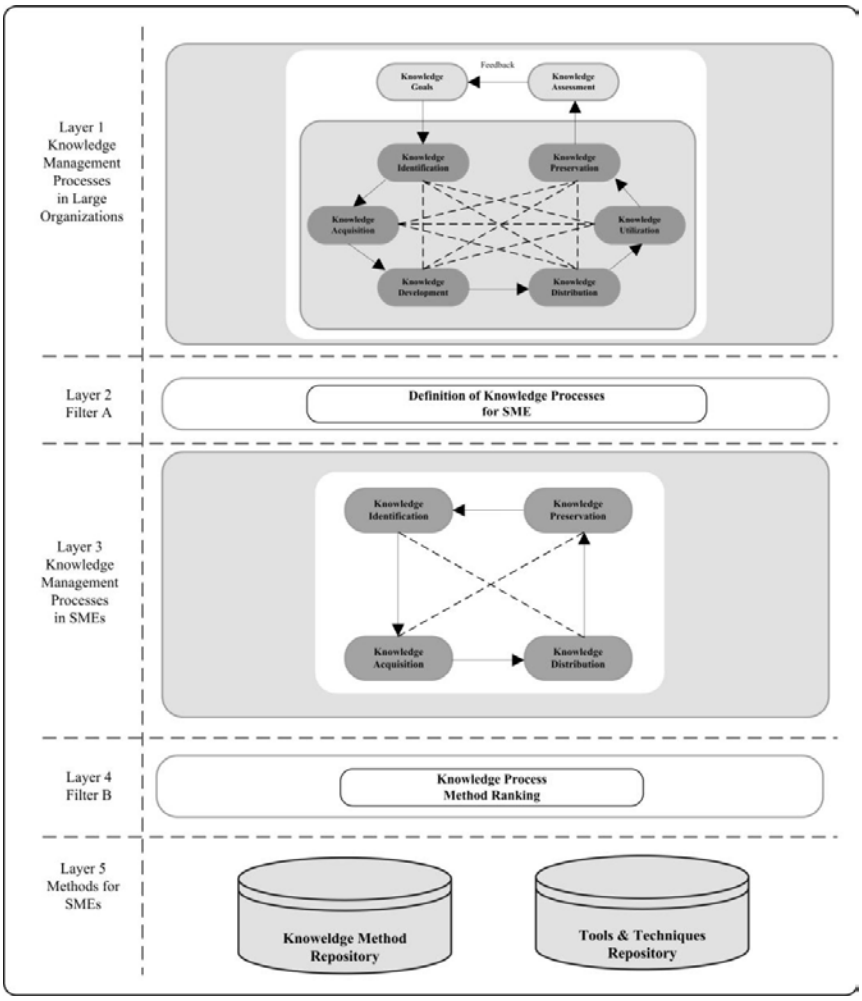
Research Framework and SME Definition

This section focuses on discussing the integration concept for SMEs. Our research findings (2006) indicate that SMEs need only four key knowledge processes (1) Knowledge Identification, (2) Knowledge Acquisition, (3) Knowledge Distribution and (4) Knowledge Preservation and therefore the authors propose a knowledge layer concept designed specifically for implementing knowledge management in SMEs. The empirical studies conducted by the authors combine the concepts of knowledge processes as well as knowledge methods for SMEs in a single study. The key objective of this section is the matching

of knowledge methods to knowledge processes in these companies. Figure 1 illustrates the research process for modeling knowledge processes in SMEs and assigning knowledge methods to each of the four key processes with supporting software tools. The basic research model is the "building block" approach by Probst, Raub & Romhardt (Laudon & Laudon, 2006) with their description of the knowledge processes (Figure 1, layer 1). Involved are eight components that form two cycles, one inner cycle and one outer cycle. Among other knowledge process models (2006), the building block approach of Probst, Raub & Romhardt (Edwards & Kidd, 2003) has the advantage that it is well known in European companies, including SMEs, and furthermore it has a unique and complete design.

The authors use the definition of SMEs of the European Commission 2006 for their research design. The European Commission analyzes SMEs by using the following three characteristics: (1) number of employees, (2) annual turnover and (3) total assets. Characterized through these three factors, the European Commission differentiates between (1) middle enterprises [fewer than 250 employees and less than EURO 50 million

Figure 1. Knowledge integration layer concept for SMEs



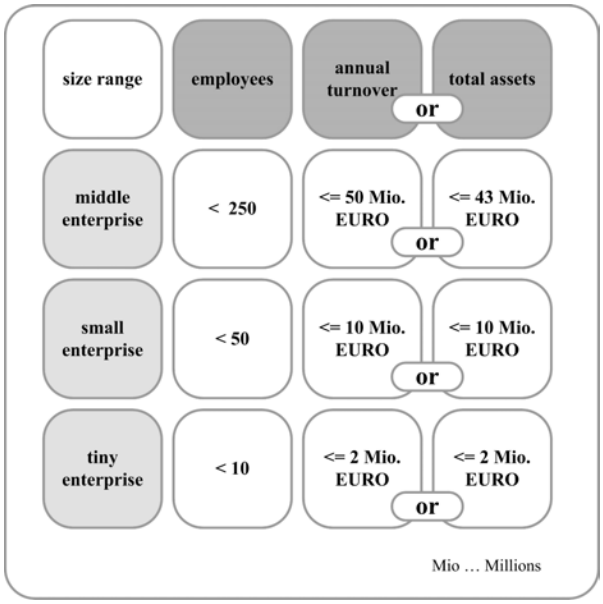
annual turnover or less than EURO 43 million total assets], (2) small enterprises [fewer than 50 employees and less than EURO 10 million annual turnover or less than EURO 10 million total assets] and (3) micro enterprises [fewer than 10 employees and less than EURO 2 million annual turnover or less than EURO 2 million total assets]. Figure 2 illustrates the European Commission's definition of SMEs. Focusing on this definition, the authors follow the research view of a quantitative perspective of SMEs. This means, that all enterprises with fewer than 250 employees and less than EURO 50 million annual turnover or less than EURO 43 million total assets in Austria and Switzerland including Liechtenstein are the target population. In figure 1 layer 2 symbolizes the quantitative view of the SME definition.

Knowledge Processes Approaches (Layer 1)

Business process modeling (Davenport & Prusak, 1998) has become a major research field in the information systems discipline in the last ten years. Davenport sees the term business process as "a structured, measured set of activities designed to produce a specified output from a particular customer or market" (Probst et al., 2006; Rao, 2004). However, in recent years, not only business process management, but also knowledge management has been developing into a new research field (2003, p. 124). The term knowledge process modeling comes from the linking of these two research fields. Key features of knowledge intensive processes can be described as follows: diversity of sources and media, variance and dynamic development of the process organization, plentiful process participants with different expertise, use of creativity, high level of innovation and influence on the area of the decision. Edwards and Kidd (2000) used the following five characteristics to emphasize that knowledge management and business process management should be integrated:

- Knowledge management is important for business if the initiative implies an advantage

Figure 2. SME definition according to the European Commission definition



for the customers. The idea of implementing the customer's requests – may be internal or external – is the basis for including the customer.
- Knowledge doesn't follow business borders. Business processes also model activities carried out by global trading companies and lay the foundations for modeling knowledge intensive processes.
- Knowledge management can only be efficient if it follows a structured model. Business processes are modeled by structured actions and they are necessary to deduce knowledge intensive processes.
- The success of knowledge management depends on the measurement of knowledge. There is a similarity to the measurement of business processes. The measurement of the knowledge potential provides a central position and biases the success.
- Knowledge management is affected by a holistic approach. Every part of the business process modeling is important for success but every aspect should be considered.

In addition, knowledge management and business process modeling initially focused on large companies. The knowledge economy has to shift from focusing on large companies to small and medium-sized enterprises (SME) because of their importance for industrial economies. The main reason behind today's change of focus is that all businesses depend on methods and tools of knowledge management in order to gain competitive advantages and to deal with the knowledge potential of their employees.

The basic research model is the "building block" approach by Probst, Raub & Romhardt (2006) with their description of the knowledge processes (Figure 1, layer 1). Involved are eight components that form two cycles, one inner cycle and the other outer cycle. The inner cycle is composed of six key knowledge processes:

- *Knowledge Identification* is the process of identifying external knowledge for analyzing and describing the company's knowledge environment.
- *Knowledge Acquisition* refers to what forms of expertise the company should acquire from outside through relationships with customers, suppliers, competitors and partners in co-operative ventures.
- *Knowledge Development* is a building block which complements Knowledge Acquisition. It focuses on generating new skills, new products, better ideas and more efficient processes. Knowledge Development includes all management actions consciously aimed at producing capabilities.
- *Knowledge Distribution* is the process of sharing and spreading knowledge which is already present within the organization.
- *Knowledge Utilization* consists of carrying out activities to ensure that the knowledge present in the organization is applied productively for its benefit.
- *Knowledge Preservation* is the process where the selective retention of information, documents and experience required by management takes place.

In addition, there are two other processes in the outer cycle, Knowledge Assessment and Knowledge Goals, which provide the direction to the whole knowledge management cycle:

- *Knowledge Assessment* completes the cycle, providing the essential data for strategic control of knowledge management.
- *Knowledge Goals* determine which capabilities should be built on which level.

Knowledge Processes in SMEs (Layer 2 and 3)

The research method for the identification of knowledge processes in SMEs were expert

interviews or what Gillham (Gillham, 2000, p. 64) referred to as "elite interviewing". This kind of interviewing is chosen to address someone in a special position or an expert. Gillham lists several characteristics of open-ended interviews (Davenport & Prusak, 1998; Ruggels, 1997):

- The respondents will know more about the topic and the setting than the interviewer. Sometimes they can even tell the interviewer what questions to ask.
- By virtue of their authority and experience, they will have their own structuring of their knowledge. They will not allow an interview for which they have to answer a series of questions addressed at them.
- The best thing the interviewer can hope for is a response to a topic raised.
- The experts can be particularly informative about the location of documents, records, or other experts.
- The experts will expect some control over the interviewer, and they also will demand a level of accountability and feedback.

These five characteristics of elite interviews also apply to the interview situation for the knowledge processes in SMEs. The managers or company owners were highly motivated to articulate their view of knowledge processes and wanted to share their personal position about the key knowledge processes. The first interview session was conducted in 2004 and was limited to Austrian SME managers. This study was the proving ground for the future procedure of the empirical studies in 2005/2006/2007. The research hypothesis was:

Hypothesis: SMEs need a simple knowledge process model in order to implement knowledge management successfully.

The second interview session was conducted from December 2005 to February 2006 (Figure 1, layer 2). The research method was the elite interview. The data sample ranged from all industry sectors in which SMEs could be found in Austria at this time with a special focus on enterprises in the of consulting and information technology sector. The survey subjects were CIOs (Chief information officer) and CEOs (Chief executive officer) in Austrian and Swiss SMEs as these are recognized as proficient in answering questions concerning knowledge management (1980, p. 21). The data sample of 36 interviewees was the proving ground for asking open ended questions. The data was analyzed by content analysis defined by Krippendorf (Davenport & Prusak, 1998) as "a research technique for making replicable and valid inferences to the content". The interview sessions lasted approximately one hour and the authors were the interviewers. The result of the Austrian and Swiss research showed clearly that in both countries only four knowledge processes identified in the Probst, Raub & Romhardt (2006) model are ranked as important for the implementation of knowledge management in SMEs (see Figure 1, layer 3):

- **Knowledge identification:** In SMEs it is highly important to identify the key sources of knowledge, experiences and know-how in order to stay competitive on the market.
- **Knowledge Acquisition:** The know-how of SMEs resides in many cases in the head of the experts or knowledge worker.
- **Knowledge distribution:** This process focuses on the sharing of explicit and implicit knowledge between knowledge workers in SMEs. As SMEs are characterized by smaller groups, a knowledge sharing culture which facilitates the exchange of knowledge with other groups and utilizes knowledge tools and mechanisms is especially important.
- **Knowledge preservation:** It is well recognized that the most critical asset of any company are the sum of its collective knowl-

edge and intellectual property (Laudon & Laudon, 2006; Schwartz, 2006). Knowledge preservation and growth of this asset requires effective knowledge management throughout SMEs, so as to make sure that the right information is available to the right people when they need it. In addition, the managers of the SMEs in our study pointed out that the process of *knowledge disposal* is also relevant for SMEs with the objective of not overloading the information flow between the individuals. From the content analysis of the expert interviews with Austrian and Swiss managers, knowledge disposal can be identified as an integrated part of knowledge preservation.

There were no significant differences in the answers given by the managers of SMEs in Austria and Switzerland. In general, it can be stated that SMEs are satisfied with only four knowledge processes instead of the original framework with eight building blocks. This implies that hypothesis 1 is verified. These four key knowledge processes and the basic framework they provide for assigning knowledge methods in SMEs will be part of our future research.

Knowledge Methods (Layer 4)

Based on a literature review (Fink & Ploder, 2007b) a list of existing knowledge methods which support one of the four key knowledge processes was developed (Figure 1, layer 4). The objective of this empirical study was to find out which of the methods are most relevant for SMEs. The data sample of 587 enterprises was stochastically appointed from the target population. It was average allocated across the federal states of Austria, Switzerland to get a representative result. In Austria there are 535,031 SMEs and in Switzerland/Liechtenstein there are 308,819. The online questionnaire was carried out in summer 2006 after a pre-test with 30 respondents. The respondents were divided into seven industry sectors. 60 percent were from the three key industries: industry, information & consulting and trade & handcraft, with the remaining 40 percent dispersed over various other industries. Figure 3 lists the key methods for the four knowledge management

Figure 3. List of knowledge methods

processes, which are stored in the knowledge method repository (Figure 1, layer 5) and can be extended to new knowledge methods.

Knowledge Software-Support (Layer 5)

In a next step, the objective was to match a cost-efficient software product to each knowledge method which is usable in practice. In the research design the focus was on Freeware and Shareware software tools in order to fulfill the presetting of cost-efficient software support. An online research method was used which resulted in a list of evaluated cost-efficient software products. The evaluation of each software product was conducted by applying the ISO/IEC 9126 norm. The Quality Model of the norm is divided into two parts which are important for the evaluation of the software products to support knowledge methods:

- the internal and the external quality of the software as well as
- the quality for use.

The ISO norm (see Figure 4) lists five characteristics to evaluate software products: (1) functionality, (2) reliability, (3) usability, (4) efficiency and (5) assignability. For each characteristic a different number of items were assessed by a likert scale from -2 up to +2. The process used by the authors to make the assessment is shown in the appendix. The data sample of the Quality Model included more than 200 different software products. A key research finding was that some of the software products cannot be used in practice because their quality is inadequate. Finally there were 45 software products which are suitable for use in SMEs.

Table 1 gives an overview of all methods supporting the four knowledge processes for SMEs and the corresponding cost-efficient software tools. Table 1 also lists the absolute number of

each method in the likert scale. The ranking of each method is the calculated value based on the likert scale. The "ISO Ranking" illustrates the assessment of the software based on the Quality Model. The absolute frequency with which the software was named by the respondents can be seen in the last column.

Knowledge Balance (92) was ranked highest among the methods for the first process of the *identification of knowledge*. 56% of SMEs think that this is the best method. Further methods are the Balanced Scorecard (89) and the Skandia Navigator (74). The methods Market-Asset Value-Method (-5) and Tobin`s q (-15) were rated by less than 30% to be of good use in SMEs.

Brainstorming (225) and Knowledge Network (203) are popular methods for the *acquisition of knowledge*. Mind Mapping (195), eMail Systems (134), Scenario Technique (126) and System Simulation (98) are also suitable methods for this knowledge process, while Business Games (91) are also a possibility. The method of "Synektik" was rated very low because of its complexity. The absolute star for the acquisition of knowledge was the Search Engine (232) with over 70% for efficient use in SMEs. In this case the Google Desktop Search Engine was the prior selection software. 60% of the respondents chose eMail-Systems which can be supported by the software Thunderbird1.5. For Brainstorming a good tool is Concept X7, while for Mind Mapping the tools Free Mind (42%) and Think Graph (41%) were rated highly. As support software to a Business Game 64% rated Gamma was well

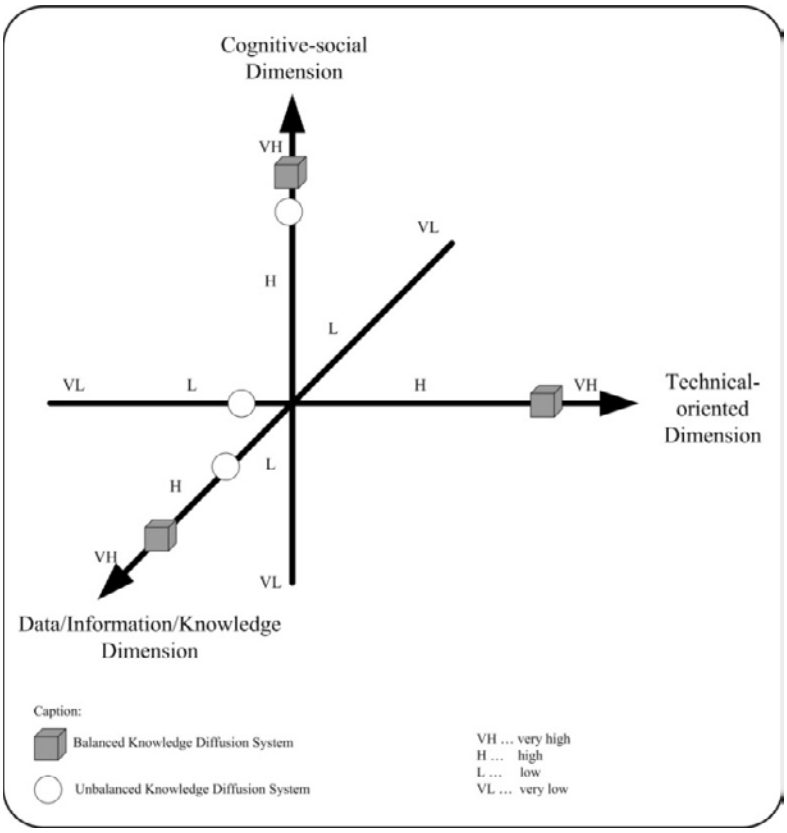
As illustrated in Table 1 the methods eMail-System (185), Handbook FAQs (159), Communities of Practice (152), Groupware (139), Questionnaire (110) and Best Practice (108) are the favorites for the *distribution of knowledge*. It has to be pointed out that the methods Micro Article (2) and Chatroom (29) are rated not as well in the survey. The software products for the methods of transferring knowledge are InfoRapid supporting Knowledge Maps, EasySurvey supporting Questionnaire, Skype and MSN supporting Chatroom, eGroupware1.2 and AlphaAgent1.6.0 supporting Groupware, CUCards 2000 supporting Checklists and Pegasus Mail, Thunderbird1.5 and Amicron Mailoffice 2.0 for the support of eMail-Systems.

Databases (242) are a recognized method of *the knowledge preservation process.* 80% of the SMEs think that they will organize their knowledge with databases. Mind Mapping (200), Document Management System (195) and Checklists (164) are further efficient methods. Content Management Systems (126), Project Review (122), Expert Systems (74) and Conceptualization (40) are methods which can be chosen but are not the favorite choice. Neural Network (-10) is not an adequate method for preserving knowledge in an SME. There were many different software products to support this process. MySQL is the favorite database software followed by the MSDE from Microsoft. Document management can be done by the Office Manager, the UDEX dotNETContact or the QVTutto. There are also software tools for the other methods which are described in Table 1.

CONCLUSION AND SECTION OBJECTIVES

In the future the research area will be expanded from Austria, Germany and Switzerland to other key members of the European Union as well as to the U.S. and Asia-Pacific area. Furthermore, in future research work the authors will focus on knowledge diffusion to the dissemination of explicit knowledge captioned in SMEs from many sources. The diffusion of knowledge through an effective SME website creates benefits not only to the enterprise itself but also to customers and suppliers as well as to new alliances. Empirical studies conducted by Ordanini show that the website is the only solution which has been used by the majority of SMEs, while the adoption of a highly-sophisticated website is a relevant matter for only 10 percent or 20 percent of SMEs. The use of information technology, especially websites, is recognized as a critical success factor for knowledge management initiatives in the SME sector (Wong & Aspinwall, 2005). Wong (2005) sees information technologies as a key enabler for the implementation of knowledge management and considers factors such as the simplicity of technology, ease of use, suitability for users' needs, relevancy of knowledge content, and standardization of a knowledge structure as key factors for knowledge diffusion in the development of a knowledge management systems. Knowledge diffusion through websites is a dominant factor for successful knowledge initiatives. The central research question of this section can be described as follows: How can SMEs spread their knowledge competencies through their websites? For successful knowledge diffusion (Fink & Ploder, 2007a) in SMEs the authors propose a three-dimensional theoretical framework as shown in figure 5: (1)

Figure 5. Three-dimensional framework for knowledge diffusion



Data/Information/Knowledge Dimension, (2) Technical-oriented Dimension and (3) Social-cognitive Dimension.

The major learning objectives of this chapter are:

- Identification and description of contemporary approaches to knowledge management in SMEs.
- Assessing contemporary knowledge processes that are required for successful implementation of knowledge management in SMEs.
- Identification of major knowledge methods supporting the key knowledge processes in SMEs: identification, acquisition, dissemination, preservation referring to the layer concept
- Discussion of the impact of cost-efficient software support for knowledge initiatives.
- Analyzing the relationship of knowledge transfer through SME websites.

In summary, it can be stated that the use of an integration concept can help SMEs leverage their core competencies by promoting the sharing of information and knowledge inside and outside their organization. The impact of cost-efficient software products for knowledge management facilitates business models based on simple knowledge processes. The knowledge process model highlights specific processes in the business where competitive advantages can be achieved and knowledge management systems will have a greater impact. The integration concepts view knowledge management in SMEs as a holistic approach where primary knowledge processes are directly related to knowledge methods and software tools.

KEY TERMS

Enterprise: Considered to be any entity engaged in an economic activity, irrespective of its legal form. This includes, in particular, self-employed persons and family businesses engaged in craft or other activities, along with partnerships or associations regularly engaged in economic activities. The category of micro, small and medium-sized enterprises (SME) is made up of enterprises which employ fewer than 250 persons and which have an annual turnover not exceeding EURO 50 million, and/or an annual balance sheet total not exceeding EURO 43 million. Within the SME category, a small enterprise is defined as an enterprise which employs fewer than 50 persons and whose annual turnover and/or annual balance sheet total does not exceed EURO 10 million. Within the SME category, a micro enterprise is defined as an enterprise which employs fewer than 10 persons and whose annual turnover and/or annual balance sheet total does not exceed EURO 2 million.

Knowledge Distribution: Can be defined as the transfer of knowledge within and across settings, with the expectation that the knowledge will be "used" conceptually (as learning, enlightenment, or the acquisition of new perspectives

or attitudes) or instrumentally (in the form of modified or new practices.). There are those who see distribution as having other legitimate outcomes. Some of these outcomes include: (1) increased awareness; (2) ability to make informed choices among alternatives and (3) the exchange of information, materials or perspectives.

Knowledge Integration Concepts: Aim to customize knowledge processes and knowledge methods for SMEs in a single enterprise solution platform. Enterprise application such as knowledge management systems are designed to support the SME orientation of business and knowledge processes to that the SMEs can operate efficiently.

Knowledge Management: Can be seen as the overall dealing with knowledge. Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of those who know. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices and norms (Davenport & Prusak, 1998).

Knowledge Management Systems: A fast growing area of corporate software investment. Contemporary technologies such as Portals, Content Management Systems, Search engines, ontologies help managers and employees in their daily decisions and processes. At each level of the organization, knowledge management systems support the major knowledge processes of the business.

Knowledge Methods: Support knowledge processes and are designed to add value to these within organizations. Depending on the identification of industry specific knowledge processes, SMEs have to choose from a knowledge method repository the corresponding knowledge method.

Knowledge Processes: Accelerate the company's business processes while ensuring compliance with the knowledge of the employees. Knowledge processes concentrate on the identification, acquisition, dissemination and preservation of knowledge in order to gain competitive advantages and enhance the value of the company. Organizations have to use the ability to incorporate their knowledge into their business processes.

Chapter 8.5
Adaptive Computation Paradigm in Knowledge Representation:
Traditional and Emerging Applications

Marina L. Gavrilova
University of Calgary, Canada

ABSTRACT

The constant demand for complex applications, the ever increasing complexity and size of software systems, and the inherently complicated nature of the information drive the needs for developing radically new approaches for information representation. This drive is leading to creation of new and exciting interdisciplinary fields that investigate convergence of software science and intelligence science, as well as computational sciences and their applications. This survey article discusses the new paradigm of the algorithmic models of intelligence, based on the adaptive hierarchical model of computation, and presents the algorithms and applications utilizing this paradigm in data-intensive, collaborative environment. Examples from the various areas include references to adaptive paradigm in biometric technologies, evolutionary computing, swarm intelligence, robotics, networks, e-learning, knowledge representation and information system design. Special topics related to adaptive models design and geometric computing are also included in the survey.

INTRODUCTION

Adaptive computing focuses on the methodology and implementation of algorithms and systems that can adjust to different situations and circumstances. An adaptive system may change its own behavior depending on the goals, tasks, and other features of individual users and the environment. Adaptivity is important for ubiquitous and pervasive computing, and as it will be shown in this survey, plays an important role in a variety of traditional as well as emerging areas, such as biometric technologies, evolutionary computing, swarm intelligence, robotics, networks, e-learning, knowledge representation and information system design.

The constant demand for complex applications, the ever increasing complexity and size of software systems, and the inherently complicated

nature of the information drive the needs for developing radically new approaches for information representation and processing. This drive is leading to creation of new and exciting interdisciplinary fields that investigate convergence of software science and intelligence science, as well as computational sciences and their applications. As can be seen from the definition, the driving force behind the need for adaptive paradigm is variety of situations, variability in backgrounds and needs of different user groups or applications. This survey article presents the new paradigm of the algorithmic models of intelligence, based on the adaptive hierarchical model of computation, and presents the algorithms and applications utilizing this paradigm in data-intensive, collaborative environment.

ADAPTIVE METHODS IN TERRAIN MODELING

For a long time, researchers were pressed with questions on how to model real-world objects realistically, while at the same time preserving efficiency, quality and operability requirements. The examples from the area of computer graphics and terrain modeling showcase the concept perfectly. Over the past twenty years, a grid, mesh, TIN, k-d trees, and Voronoi based methods for model representation were developed (Bonnefoi and Plemenos 2000, Gold and Dakowicz 2006, Cohen-Or and Levanoni 1996, Duchaineauy et. al. 1997, Franc and Skala 2002, Iglesis 2002, Kolingerová 2002). Most of these were however static methods, not suitable for rendering dynamic scenes or preserving higher level of details (see Figure 1.). In 1997, first methods for dynamic model representation: Real-time Optimally Adapting Mesh (ROAM) and Progressive Mesh (PM), were developed (Duchaineauy 1997). However, even with the further improvements (Li et. a. 2003), these methods were not capable of dealing with large amount of complex data or significantly varied level of details (see Figure 2.). The main difference between terrain visualized using static and adaptive methods is the size and distribution of the triangles – in Figure 1, it is clearly seen that the patches of similar triangles are used throughout the various terrain features, while Figure 2 uses adaptive methods to decide on the most appropriate triangle sizes based on the curvature and distance from the viewer. However, this method is still not sufficient for dealing with all variety of terrain features, nor it is fast enough to be used in real-time.

Recently, the adaptive multi-resolution technique for real-time terrain rendering was developed (Apu and Gavrilova 2005). The method is characterized by the efficient representation of massive underlying terrain, utilizes efficient transition between detail levels, and achieves frame rate constancy ensuring visual continuity. The method is based on the adaptive loop subdivision and recursive split operation (see Figure 3.), implemented with the use of novel S-Queue operations ordering data structure.

Furthermore, a novel approach based on adaptive dynamic viewer-dependent level of details (LOD), utilizing the above strategy, was developed for real-time terrain rendering. The approach uses mesh regularity operator and LOD control parameters to achieve fast recursive seamless patch stitching, ensure geometric regularity, improve rendering quality, provide multi-resolution storage and allow for rendering and transmission of massive data sets (see Figure 4).

More formally, the process can be described as follows. A mesh M can be viewed as a piecewise linear surface. It is defined as a pair (K, V) where $V \subset \mathbb{R}^3$ is the set of vertices and K is a simplicial complex specifying the connectivity of the mesh simplices (the adjacency of the vertices, edges and faces). A combinatorial k-simplex of K is the $(k + 1)$ element subset of K. Therefore the 0-simplices $\{i\} \in K$ are called vertices, the 1-simpices $\{i, j\} \in K$ are called edges, and the 2-simplices $\{i, j, l\} \in K$ are called faces.

Figure 1. A static mesh (40,000 triangles)

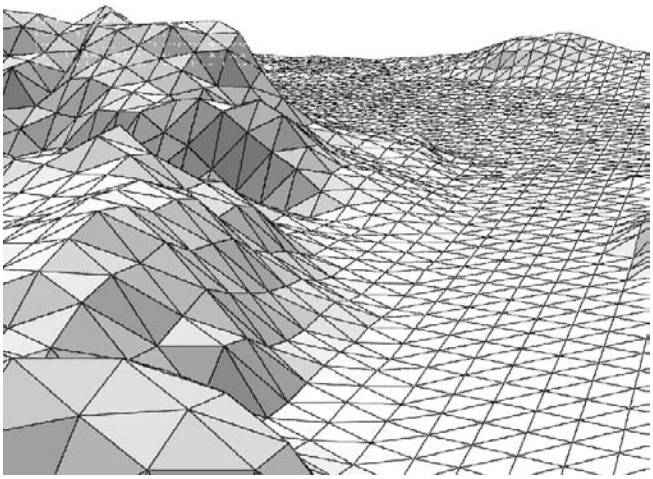

Figure 2. Real-time optimally adaptive mesh (25,000 triangles)

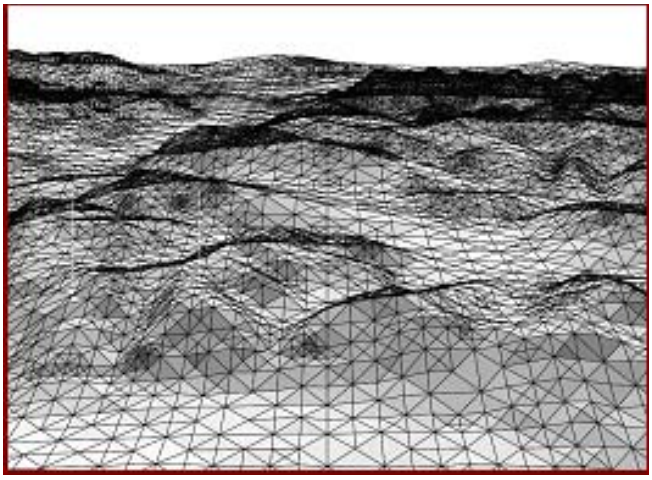

Figure 3. Adaptive loop subdivision and recursive split operations

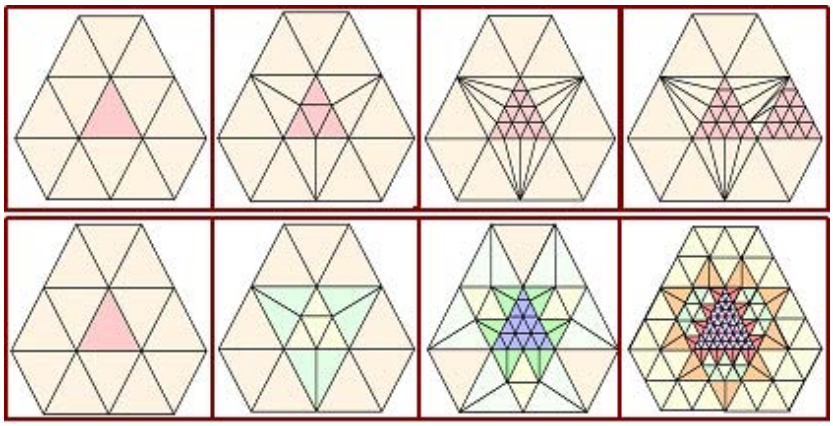

Figure 4. Varied Mesh regularity operator and LOD control parameters

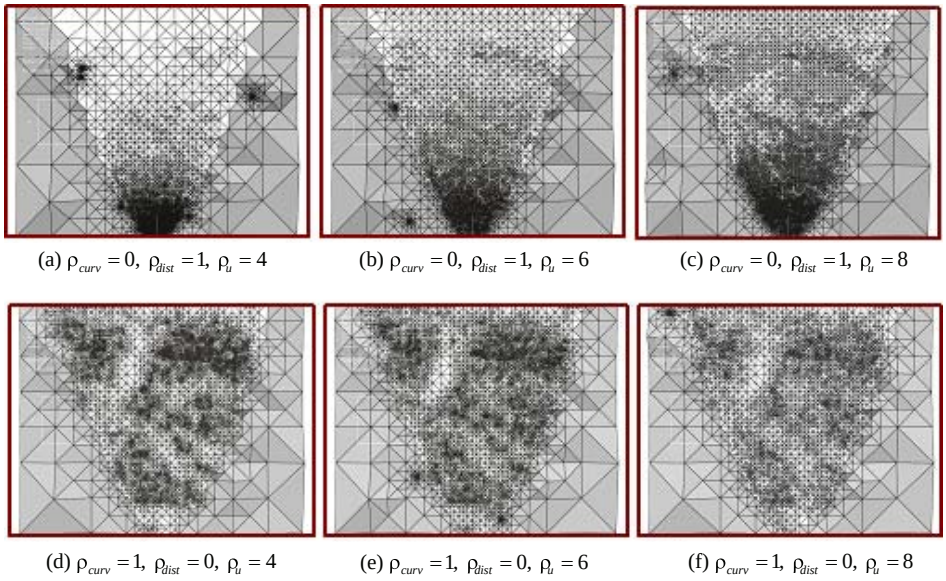


A mesh can be considered as higher dimensional generalization of the concept of graph used in a variety of graphics applications. For instance, a mesh $M = (K, V)$ defines a graph $G = (V, \wp)$ where V is the set of vertices in M and $\wp$ is the 1-simplices of K. Therefore G is the minimum unrestricted topological realization of M. Nevertheless, higher simplices of K (i.e. faces) could be reconstructed from G by means of a convex combinatorial relationship of the transitive closure of $\wp$. For example, a triangulation of the mesh could be obtained from the transitive closure of edges defining a mesh M.

Mesh optimization is the process of reducing a mesh M_0 to a mesh M_k, where M_k contains less number of vertices and geometric primitives (i.e. triangles) than M_0. The goal is to find M_k such that the no other mesh M'_k exists, which represent a better approximation of the mesh M_0. In practical applications, it is sufficient to converge to any of the optimal solutions. There are many variations of mesh optimization techniques. Intuitively, mesh optimization is a compression method for geometric models with large details. In computer graphics, various processes such as regular tessellations, polygonized spline surfaces, polygonized parametric surfaces, polygonized implicit surfaces, range scanned surfaces and subdivision surfaces generate polygonal meshes to render or store the object. In most cases, these meshes consist of a large number of geometric primitives. In order to render them or store them efficiently, one needs to reduce the number of primitives significantly. This process of simplification must be performed in a way such that the loss of details is minimal while conforming as much as possible to the specified criteria.

The novel approach to mesh optimization based on adaptive dynamic viewer-dependent level of detail method was developed in (Apu and Gavrilova 2005). The introduced data structure, called Adaptive Loop Subdivision (ALS), can intuitively be viewed as a special filter that increases the details and smoothness properties of a mesh. It is a subdivision method based on triangle meshes. In general, every triangle in the base mesh M^i is split into four inner triangles (see Figure 4b). Each vertex position is adjusted ac-

cording to a combinatory mask. The refined mesh M^{i+1} contains exactly four times the number of triangles than M^i. This four to one augmentation of LOD is a direct correspondent to the refinement of Haar wavelet.

Standard subdivision technique was first introduced by Loop in 1987 (Loop, 1987) in his Master's Thesis. It became widely acceptable and numerous improvements were suggested subsequently. However, the scheme does not allow local refinements. If one triangle is subdivided without the neighboring triangles, cracks will become visible. The new ALS scheme allows a way to repair those cracks without noticeable visual artifacts through the following conditions imposed on subdivision procedure:

1. If f_i are the faces adjacent to the face f in M^i and $\Im: F(M^i) \rightarrow \mathbb{Z}$ is a function corresponding to the LOD of a face ($F(M_i)$) is the set of faces of M^i) then:

   $$\forall i(\text{neighbor}(f, f_i) \rightarrow 0 \leq |\Im(f) - \Im(f_i)| \leq 1$$

2. A face f can be subdivided if and only if $\aleph(f) = 1$; $\aleph: F(M^i) \rightarrow \{0, 1\}$. Here,

   $$\aleph(f) = \begin{cases} 0; & \text{if f is a T-face} \\ 1; & \text{otherwise} \end{cases}$$

3. Let $\prod: F(M^i) \rightarrow F(M^{i-1})$ be the parent relation ship of a face. That is $f' = \prod(f)$ if and only if f in M^i has been generated by splitting f'. The following condition must hold:

   $$\forall f_i \ \forall f_j = ((\aleph(f_i) = 0) \wedge (\aleph(f_j) = 0) \wedge \text{neighbor}(f_i, f_j) \rightarrow (\Im(f_i) \neq \Im(f_j)) \vee (\prod(f_i) = \prod(f_j)))$$

These constrains are the prime directives of the developed ALS method. They enforce the regularity of the scheme and ensures that no thin triangle is introduced. Their application leads to fine results shown in Figure 4 as well as numerous other advantages. ALS scheme was subsequently successfully used not only for terrain visualization, but in geographical information systems, motion planning and computer simulation applications.

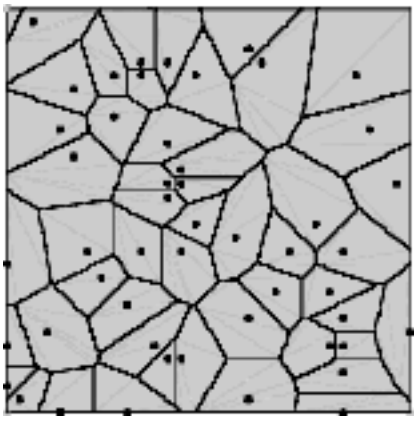
ADAPTIVE METHODOLOGY IN TRADITIONAL APPLICATIONS

Adaptive Geometric Methods

At the same time as adaptive methods were making their way in the area of terrain rendering, the renewed interest to topology-based data structures, Voronoi diagram and Delaunay triangulation in particular, has grown significantly (Okabe et.al. 1992). The key developments on both conceptual and implementation level are regularly presented at the International Symposium on Voronoi Diagrams in Science and Engineering Conference Series. Utilization of these developments in molecular modeling, bioinformatics and robotics promotes further stimulus to research on adaptive and dynamic problems. Thus, article (Gold and Dakowicz 2006) studies dynamic ship navigation visualization system using kinetic Voronoi diagram as an underlying concept. Utilization of the dynamic Voronoi diagram for 3D robot planning and navigation is studies in (Kolingerova 2005). Adaptive Voronoi diagram based approach to swarm simulation is presented in (Apu and Gavrilova 2006). These developments lead the way toward utilization of adaptive hierarchical models in computational geometry.

Recently, some preliminary results on utilization of computational geometry techniques in biometrics began to appear, such as research on image processing using Voronoi diagrams (Asano 2006, Liang and Asano_2004), work on utilizing Voronoi diagram for fingerprint synthesis (Bebis 1999), and studies on 3D modeling of human faces using triangular mesh (Li and Jain 2005). Some interesting results were recently obtained

Figure 5. Planar Voronoi diagram representation



in the BTLab, University of Calgary, through the development of topology-based feature extraction algorithms for fingerprint matching, 3D facial expression modeling and iris synthesis (Wang et. al. 2005, Wecker et. al. 2006, Bhattachariya and Gavrilova 2006).

Adaptive Image Processing and Visualization

Adaptive image processing is one of the most important techniques in visual information processing, especially in image restoration, filtering, enhancement, and segmentation. While existing literature presents some important aspects of the issue, there were no works that would treat the problem from a viewpoint that is directly linked to human perception – until the book "Adaptive Image Processing: A computational Intelligence Perspective Book" appeared (William et. al. 2001). This comprehensive collection of references treats adaptive image processing from a computational intelligence viewpoint, relating neural networks, fuzzy logic, and evolutionary computation to adaptive image processing. Based on the fundamentals of human perception, this book also gives a detailed account of computational intelligence methods and algorithms for adaptive image processing in regularization, edge detection, vision and any area where intelligent visual information processing is required.

Adaptive processing has been tightly linked not only to image processing, but to computer graphics and scientific visualization. In (Lopse et.al. 2002), authors provide an algorithm for computing a *robust adaptive polygonal approximation* of an implicit curve in the plane. The approximation is adapted to the geometry of the curve because the length of the edges varies with the curvature of the curve. Robustness is achieved by combining interval arithmetic and automatic differentiation.

Another example is adaptive visualization area of research, which is often explored in connection with geographical, urban or medical applications. A variety of engineering disciplines use large high-resolution geometric models whose computational requirements exceed current computer hardware capacities. The research presented in (Lu and Hammersley 2000) describes an *adaptive visualization* solution for interactively building such models. While adaptive visualization techniques have conventionally been applied to existing complete models, their method provides adaptive visualization of models while still under construction, through a clever utilization of multiresolution methods.

A common application of adaptive paradigm can be found in the area of medical imaging. A common active contour (*snake*) model is a popular choice for medical imaging applications, however the article by (Shen and Davatzikos 2000) goes further in exploring adaptive paradigm in this context. They propose a clever approach to geometric design and the structure of the model through *adaptive method for carrying out model deformations* in the most reliable way. Specifically, authors suggest to use an attribute vector to characterize the geometric structure around each point of the snake model, which allows to deform to nearby edges with considering geometric structure. They also provide an adaptive-focus statistical model which allows the deformation of the active contour in each stage to be influenced by the most reliable matches. Finally, they propose the deformation mechanism that is robust to local minima and is based on evaluating the snake energy function on segments of the snake at a time, instead of individual points. The approach is novel and unique, and is proven to perform very well experimentally.

Adaptive Information Systems

The current fast evolution in the areas of software, hardware and networks suggests that it will be possible to offer access to information systems through variety of interactive means, including computers, notebooks, PDA's, cellular phones, game consoles, GPS devices etc. Thus, this variety of technologies and information available required creation of a flexible environment to support adaptive interaction and services according to changing requirements, interfaces, devices, communication and user needs.

One of the research initiatives that started in 2002 was devoted specifically to this problem. The *Multichannel Adaptive Information Systems* project (MAIS) was funded by Basic Research Funds of the Italian Department of Education and involved six Universities and industry collaborations. The project research areas were information systems, database systems, human computer interaction, computer networks and telecommunication, hardware design, middleware, management engineering, with the focus on adaptive computing paradigm. Adaptive e-services, adaptive portable devices and adaptive networks were at the focus of the research. The prototype applications of the methods were developed in the areas of tourism, education, and risk management in archeology.

Another relevant project is described in (Doerr 1999). Authors state that one way to increase software system adaptability is to allocate resources dynamically at run-time rather than statically at design time. For example, fine-grained run-time allocation of processor utilization and network bandwidth creates an opportunity to execute multi-modal operations. Thus, this allocation strategy enhances adaptability by combining deterministic and non-deterministic functionality. Authors next showcase that adaptability is essential to improve versatility and decrease lifecycle maintenance costs for embedded real-time systems.

Adaptive Networks

As already seen from the above applications, the driving force behind the need for adaptive paradigm is variety of situations, variability in backgrounds and needs of different user groups or applications. The further expansion of Internet communications, not only for electronic exchange of ideas, but also as a means of collecting a wide range of information, has lead to a variety of other applications besides e-learning. Thus, electronic commerce, Internet transactions, collaborative newsgroups, facebooks, on-line teleconferencing are all rapidly developing. However, one of the problems is the difference in information available to network users. Network systems and services are becoming increasingly complex and diverse, and the processes involved in accessing required information are growing ever more advanced.

As a result, the information disparity that arises from the presence or absence of knowledge about networks and computers is becoming a problem that cannot be overlooked. Another problem is one that is derived from changes and increases in communications traffic.

The key to dealing with the above challenges is *user adaptability* and *adaptability to changes in communication demand*. User adaptability means that the user does not conform to the conditions of the network, but rather the network adapts instantaneously to the user environment and to service needs, which change with every passing moment. Adaptability to changes in communication demand means that the network configuration and equipment functions change dynamically to absorb the introduction of new services and macro-fluctuations in traffic. NTT Laboratories is one of the organizations that combines knowledge, expertise and application research in the area of *adaptive networks*, which constantly change their functions and configurations to respond immediately to changes in the environment, and to be the network platform of the Information Sharing Society of the future. Their key terms to describe the research in adaptive networks is Intellect, Evolution, and Simple & Seamless.

ADAPTIVE METHODS IN EMERGING AREAS

Biometrics and Adaptive Computing

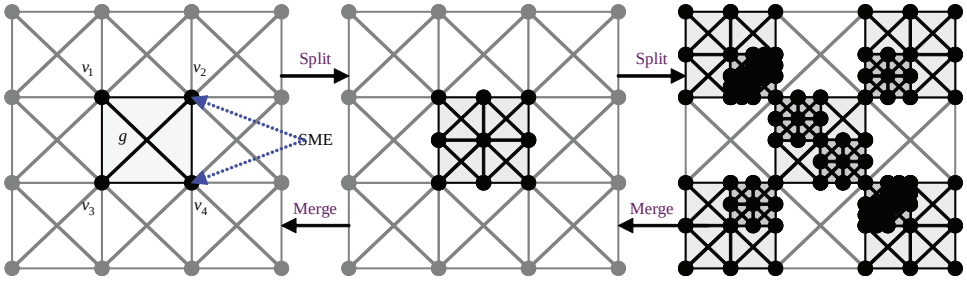
Adaptive techniques have made their way in emerging scientific areas such as *biometric computing*. In information technology, biometric refers to a study of physical and behavioral characteristics with the purpose of person identification. In recent years, the area of biometrics has witnessed a tremendous growth, partly as a result of a pressing need for increased security, and partly as a response to the new technological advances that are literally changing the way we live. Availability of much more affordable storage and the high resolution image capturing devices have contributed to accumulating very large datasets of biometric data. On the other hand, it also created significant challenges driven by the higher than ever volumes and the complexity of the data, that can no longer be resolved through acquisition of more memory, faster processors or optimization of existing algorithms. This justifies the need for the development of a new concept for biometric data storage and visualization based on adaptive paradigm.

It is obvious to anyone who works in the area of biometric computing that the problem is not trivial. It is not enough to simply fill the existing deficiency in data representation and visualization through application of advanced results from the areas of computational geometry and computer graphics. The backbone of the methodology is in the application of adaptive hierarchical data representation to achieve flexible and versatile data representation, fast data retrieval, reliable matching, easy updates and smooth and continuous data processing.

To achieve this objective, we suggest a novel way to represent complex biometric data (e.g. a bitmap, a graphics file, a set of vectors, a polygonal curve) through the organization of the data in a hierarchical tree-like structure. Such organization is similar to *Adaptive Memory Subdivision (AMS)* representation (see Figure 6).

AMS is a hybrid method based on the combination of traditional hierarchical tree structure with the concept of expanding or collapsing tree nodes, depending on the amount of information and level of detail (LOD) that needs to be represented. *Spatial quad-tree* is used to hold the information about the system, as well as the instructions on how to process this information. Expansion is realized through the spatial subdivision technique that refines the data and increases LOD, and collapsing is realized through the merge operation that simplifies the data representation and makes

Figure 6. Adaptive Memory Subdivision (AMS) model



(a) Base Patch LOD=0 Shaded Region is a primitive cluster

(b) After first split, LOD=1

(c) Subsequent refinements of ASM primitive clusters

it more compact. The greedy strategy is used to optimally adapt to the best representation based on the user requirements, amount of available data and resources, and required LOD. This powerful technique enables to achieve compact data representation with required LOD. For instance, it enables to efficiently store and retrieve minor details of the facial image (e.g. scars, wrinkles) or detailed patterns of the compared irises.

Adaptive methods have been studied for increasing hand geometry reliability while new processing algorithms, such as symmetric real Gabor filters, have been used to decrease the computational cost involved in iris pattern recognition (Sanchez-Reillo et. Al. 1999). This work explores adapting these methods to small *embedded systems*, and proposes the design of new biometric systems, where the users template is stored in a portable storage media for added security. Such media could be used to store sensitive information, for instance related to user's health records, and proposed adaptive access methods are devised to avoid the reading of this data unless the biometric verification has been performed.

While the above research is aimed at increase reliability and security of biometric data, another highly interesting direction is merging *adaptive paradigm with multimodal biometric fusion*. Multimodal biometric is intended to utilize biometric information obtained by multiple sensors and from multiple sources in order to increase authentication reliability. The paper by (Veeramachaneni 2003) introduces a new Adaptive Multimodal Biometric Fusion Algorithm(AMBF) algorithm, which is a combination of *Bayesian decision fusion* technique and a *particle swarm optimization* method. A Bayesian framework is typically used to fuse decisions received from multiple biometric sensors. The optimal rule is a function of the error cost and a priori probability of an intruder. This Bayesian framework formalizes the design of a system that can adaptively increase or reduce the security level. Particle swarm optimization searches the decision and sensor operating points (i.e. thresholds) space to achieve the desired security level. The optimization function aims to minimize the cost in a Bayesian decision fusion. The particle swarm optimization algorithm results in the fusion rule and the operating points of sensors at which the system can work. The swarm algorithm can easily handle the scalability issue as the number of sensors increases and efficiently search through the highly large fusion rule search space.

The presented method successfully merges two highly interesting and important paradigms: adaptive method based on evolutionary computing and multimodal biometric system with Beyesian decision rule. As a result, it can successfully address the varying security needs and user access

requirements in a biometric system. The authors report that the adaptive algorithm allows to achieve desired security level and to seemingly switch between different rules and sensor operating points for varying user needs.

The adaptive approach can be successfully sued not only for biometric modeling but also in synthesis of the biometric data. A combination of the method with *multi-resolution approach*, suitable for extracting details of the model at different scales of resolution, is a promising new direction of research which can be used to complement the missing information or to recreate the model. The method performs the high-level detail extraction and capturing of the model characteristics, and then applies this information for synthesis of new biometric data. This novel approach has shown a high potential in a recent study on iris synthesis (Wecker et.al. 2006). Moreover, *adaptive learning method can assist in* examining extracted features, retrieval patterns, and dynamic updates with the purpose of making the model more flexible.

Adaptive Methods in Robotics

Another highly important and rapidly developing area of research, that encompasses artificial intelligence, engineering, vision, geometric processing and decision-making, is robotics. *Adaptive robots* is an area of research that studies the design of robots that function in a changing environment by using high-level cognitive abilities and/or adaptive behaviors. The Dutch AIBO team, composed by research groups from the DECIS Lab and Universities of Amsterdam, Delft, Twente and Utrecht, is the leading force behind research on collaborative robot behavior and intelligent behavior of the team of robots, through robot soccer simulation and applied studies (Wong et. al. 2001). Exploring adaptive paradigm in a variety of areas essential to success of this project, including *adaptive robot vision, adaptive navigation and adaptive learning* are just some of the examples of the current state-of-the art research related to this project. Adaptive methods to improve *self-localization* in robot soccer were devised in (Dahm and Ziegler 2003). The authors utilized adaptive strategies to improve the reliability and performance of self-localization in robot soccer with legged robots. Adaptiveness is the common feature of the presented algorithms and has proved essential to enhance the quality of localization by a new classification technique as well as to increase the confidence level of information about the environment. Cooperative strategy based on *adaptive Q-learning* for robot soccer was developed in (Hwang et.al. 2004). The strategy developed enabled robots to cooperate with each other to achieve the objectives of offense and defense. Through the mechanism of learning, the robots learned from experiences in either successes or failures, and utilized these experiences to improve the performance. The cooperative strategy is based on a hierarchical architecture. An adaptive Q-learning method showed to allow more flexibility in learning that the traditional Q-learning approach, especially in the context of cooperative strategy.

Adaptive Knowledge Representation and Learning

Adaptive Knowledge Representation and Reasoning Conference (AKRR) is one of the unique events devoted completely to the emerging paradigm of *adaptive knowledge representation*. The forum is concerned with all adaptive aspects related to knowledge representation and reasoning. Specifically, such areas as adaptive systems in economic sciences and organizational theory, new generation of semantic web, adaptive systems in medical education, research and practice, and adaptive machine translation are within the conference scope.

The idea of utilizing *adaptive methods in e-learning* is not new. One of the first articles on the subject that appeared in 1998 describes web-based educational applications that are

expected to be used by very different groups of users (Brusilovsky 1998). Thus, authors argue that such a system needs to adapt to users with very different backgrounds, prior knowledge of the subject and learning goals, without human assistance. They next describe an approach for developing *adaptive electronic textbooks* and present InterBook—an authoring tool based on this approach which simplifies the development of adaptive electronic textbooks on the Web.

An extensive research in the area of adaptive learning was undertaken since that time. One example is the research on knowledge representation in the area of learning design and adaptive learning, presented in (Kravcik and Gasevic 2006). The authors deal with learning design and adaptation, and state that the procedural knowledge is highly important. They examine the degree of reusability and interoperability of procedural knowledge in the current adaptive educational hypermedia systems, and discuss several useful strategies and techniques, including informal scripts, system encoding, elicited knowledge, and standardized specifications.

Hierarchical Models in Cognitive Informatics

As it has been seen in the previous sections, adaptive computing heavily relies on hierarchical models of knowledge representing various natural and artificial phenomena. Such models can represent, for instance, complex three-dimensional terrain patterns, evolutionary behaviour of a swarm of living organisms, or an intricate structure of a web-linked virtual library. As it was recently discovered at the front line of the cognitive science and cognitive informatics research, hierarchical cognitive models can be also efficiently use to study internal information and knowledge presentation in human brains (Wang 2007).

It is commonly accepted that memory is the foundation of all forms of natural intelligence. Neural Informatics (NeI) is a branch of cognitive informatics, where memory is recognized as the foundation and platform of any natural or artificial intelligence (Wang 2003). While traditionally the Long-Term Memory (LTM) is perceived as static and fixed in adult brains, recent discoveries in neuroscience and cognitive informatics indicate that LTM is dynamically reconfiguring, particularly at the lower levels of the neural clusters (Wang 2007). The article explains the memory establishment, enhancement, and evolution, which are typical functions of the brain, are not limited to only childhood developmental stage; thus the more complex, dynamic model is necessary to represent such functions. In order to achieve this task, the pioneering theory is presented in the article that is based on the concept of the Hierarchical Neural Cluster (HNC) Model of Memory. Furthermore, the Object-Attribute-Relation (OAR) model is introduced to formally represent the structures of internal information and knowledge acquired and learned in the brain (Wang 2007). The OAR model explains the mechanisms of internal knowledge and information representation, as well as their physical and physiological meanings, and allows to better understand learning mechanisms and help to develop more powerful algorithms for a variety of complex problems faced by scientists everyday.

CONCLUSION

The article presented a comprehensive survey of the new paradigm of the algorithmic models of intelligence, based on the adaptive hierarchical model of computation. It started with the adaptive methods for terrain modeling, and presented methodically the adaptive paradigm in geometric computing, biometric, robotics, image processing and vision, knowledge representations, information systems, e-learning and networks. Illustrations were further provided to explain some concepts related to adaptive information processing and models. Aside from the areas

covered in the survey, there constantly appear a variety of new and emerging applications utilizing adaptive models of computations. It is our hope that this survey inspires readers to further in-depth study of the exciting topic of adaptive computations.

Chapter 8.6
Agile Software Methods: State-of-the-Art

Ernest Mnkandla
Monash University, South Africa

Barry Dwolatzky
University of Witwatersrand, South Africa

ABSTRACT

This chapter is aimed at comprehensively analyzing and defining agile methodologies of software development from a software quality assurance perspective. A unique way of analyzing agile methodologies to reveal the similarities that the authors of the methods never tell you is introduced. The chapter starts by defining agile methodologies from three perspectives: a theoretical definition, a functional definition, and a contextualized definition. Then an agile quality assurance perspective is presented starting from a brief review of some of the traditional understandings of quality assurance to the innovations that agility has added to the world of quality. The presented analysis approach opens a window into an understanding of the state-of-the-art in agile methodologies and quality, and what the future could have in store for software developers. An understanding of the analysis framework for objectively analyzing and comparing agile methodologies is illustrated by applying it to three specific agile methodologies.

INTRODUCTION

Agile software development methodologies have taken the concepts of software quality assurance further than simply meeting customer requirements, validation, and verification. Agility innovatively opens new horizons in the area of software quality assurance. A look at the agile manifesto (Agile Alliance, 2001) reveals that agile software development is not just about meeting customer requirements (because even process-driven methodologies do that), but it is about meeting the changing requirements right up to the level of product deployment. This chapter introduces a technique for analyzing agile methodologies in a way that reveals the fundamental similarities among the different agile processes.

As for now, there is a reasonable amount of literature that seeks to describe this relatively new set of methodologies that have certainly changed the way software development is done. Most of the existing work is from the authors of the methodologies and a few other practitioners. What lacks is

therefore a more balanced evaluation comparing what the original intents of the authors of agile methodologies were, to the actual things that have been done through agile methodologies over the last few years of their existence as a group, and the possible future applications.

While most of those who have applied agile methods in their software development projects have gained margins that are hard to ignore in the areas of product relevance (a result of embracing requirements instability) and quick delivery (a result of iterative incremental development), some have not joined this new fun way to develop software due to a lack of understanding the fundamental concepts underlying agile methodologies. Hence, this chapter intends to give the necessary understanding by comprehensively defining agile methodologies and revealing how agile methodologies have taken software quality assurance further than traditional approaches. The second concern resulted from more than three years of research into agile methodology practices where the author discovered that the individual agile methods such as extreme programming, scrum, and lean development etc. are not that different from each other. The apparent difference is because people from different computing backgrounds authored them and happen to view the real world differently. Hence, the differences are not as much as the authors would like us to believe. The evaluation technique introduced here will reveal the similarities in a novel way and address the adoption concerns of agile methodologies. This also reveals what quality in an agile context means.

CHAPTER OBJECTIVES

The objective of this chapter is to introduce you to the fundamentals of analyzing agile methodologies to reveal the bare bones of agile development. After reading this chapter, you will:

- Understand three approaches to the definition of agile methodologies (i.e., a theoretical definition, a functional definition, and a contextualized definition).
- Understand the state-of-the-art in agile methodologies.
- Understand the presented framework for objectively analyzing and comparing agile methodologies.
- Understand the meaning of software quality assurance in an agile context.

BACKGROUND

This section will start by defining agile methodologies based on what people say about agile methodologies, what people do with agile methodologies, and what agile methodologies have done to the broad area of software development.

DEFINING AGILE METHODOLOGIES

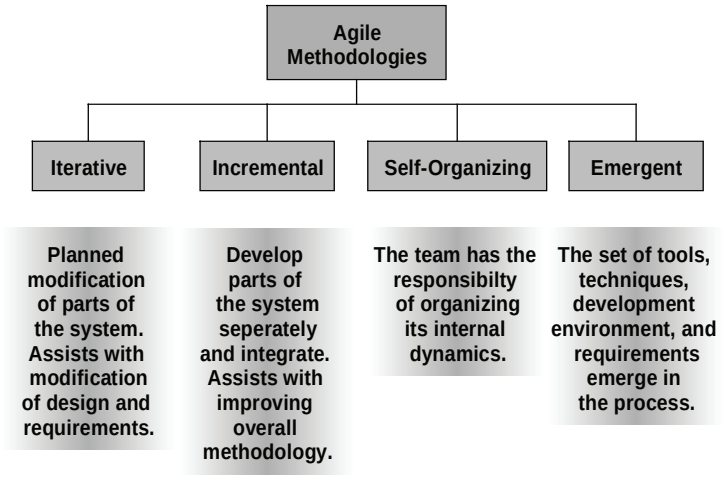
The agile software development methodologies group was given the name “agile” when a group of software development practitioners met and formed the Agile Alliance (an association of software development practitioners that was formed to formalize agile methodologies) in February 2001. The agile movement could mark the emergence of a new engineering discipline (Mnkandla & Dwolatzky, 2004a) that has shifted the values of the software development process from the mechanistic (i.e., driven by process and rules of science) to the organic (i.e., driven by softer issues of people and their interactions). This implies challenges of engineering complex software systems in work environments that are highly dynamic and unpredictable.

THEORETICAL DEFINITION

After the first eWorkshop on agile methodologies in June 2002, Lindvall et al. (2002) summarized the working definition of agile methodologies as a group of software development processes that are iterative, incremental, self-organizing, and emergent. The meaning of each term in the greater context of agility is shown next.

1. **Iterative:** The word iterative is derived from iteration which carries with it connotations of repetition. In the case of agile methodologies, it is not just repetition but also an attempt to solve a software problem by finding successive approximations to the solution starting from an initial minimal set of requirements. This means that the architect or analyst designs a full system at the very beginning and then changes the functionality of each subsystem with each new release as the requirements are updated for each attempt. This approach is in contrast to more traditional methods, which attempt to solve the problem in one shot. Iterative approaches are more relevant to today's software development problems that are characterized by high complexity and fast changing requirements. Linked with the concept of iterations is the notion of incremental development, which is defined in the next paragraph.
2. **Incremental:** Each subsystem is developed in such a way that it allows more requirements to be gathered and used to develop other subsystems based on previous ones. The approach is to partition the specified system into small subsystems by functionality and add a new functionality with each new release. Each release is a fully tested usable subsystem with limited functionality based on the implemented specifications. As the development progresses, the usable functionalities increase until a full system is realized.
3. **Self-organizing:** This term introduces a relatively foreign notion to the management of scientific processes. The usual approach is to organize teams according to skills and corresponding tasks and let them report to management in a hierarchical structure. In the agile development setup, the "self-organizing" concept gives the team autonomy to organize itself to best complete the work items. This means that the implementation of issues such as interactions within the team, team dynamics, working hours, progress meetings, progress reports etc. are left to the team to decide how best they can be done. Such an approach is rather eccentric to the way project managers are trained and it requires that the project managers change their management paradigm all together. This technique requires that the team members respect each other and behave professionally when it comes to what has been committed on paper. In other words management and the customer should not get excuses for failure to meet the commitment and there should be no unjustified requests for extensions. The role of the project manager in such a setup is to facilitate the smooth operation of the team by liaising with top management and removing obstacles where possible. The self-organizing approach therefore implies that there must be a good communication policy between project management and the development team.
4. **Emergent:** The word implies three things. Firstly, based on the incremental nature of the development approach the system is allowed to emerge from a series of increments. Secondly, based on the self-organizing nature a method of working emerges as the team works. Thirdly, as the system emerges and the method of working emerges a framework of development technologies will also emerge. The emergent nature of agile methodologies means that agile

Figure 1. Definition of agility © copyright Ernest Mnkandla PhD thesis University of the Witwatersrand



software development is in fact a learning experience for each project and will remain a learning experience because each project is treated differently by applying the iterative, incremental, self-organizing, and emergent techniques. Figure 1 sums up the theoretical definition of agile methodologies.

The value of agility is in allowing the concepts defined above to mutate within the parameters set by the agile values and principles (For details on agile values and principles see the agile manifesto at http://www.agilealliance.org.. There is always a temptation to fix a framework of software development if success is repeatedly achieved, but that would kill the innovation that comes with agile development.

FUNCTIONAL DEFINITION

Agile methodologies will now be defined according to the way some agile practitioners have understood them as they used them in real world practice.

The term "agile" carries with it connotations of flexibility, nimbleness, readiness for motion, activity, dexterity in motion, and adjustability (Abrahamsson, Salo, Ronkainen, & Warsta, 2002). Each of these words will be explained further in the context of agility in order to give a more precise understanding of the kinds of things that are done in agile development.

- **Flexibility:** This word implies that the rules and processes in agile development can be easily bended to suit given situations without necessarily breaking them. In other words, the agile way of developing software allows for adaptability and variability.
- **Nimbleness:** This means that in agile software development there must be quick delivery of the product. This is usually done through the release of usable subsystems within a period ranging from one week to four weeks. This gives good spin-offs as the customer will start using the system before it is completed.
- **Readiness for motion:** In agile development, the general intention is to reduce

all activities and material that may either slow the speed of development or increase bureaucracy.

- **Activity:** This involves doing the actual writing of code as opposed to all the planning that sometimes takes most of the time in software development.
- **Dexterity in motion:** This means that there must be an abundance of skills in the activity of developing code. The skills referred to are the mental skills that will arm the developers for programming challenges and team dynamics.
- **Adjustability:** This is two fold; firstly there must be room for change in the set of activities and technologies that constitute an agile development process, secondly the requirements, code, and the design/architecture must be allowed to change to the advantage of the customer.

According to Beck (1999), agile methodologies are a lightweight, efficient, low-risk, flexible, predictable, scientific, and fun way to develop software. These terms will be defined in this context to give a functional perspective of agile development.

- **Lightweight** implies minimizing everything that has to be done in the development process (e.g., documentation, requirements, etc.) in order to increase the speed and efficiency in development. The idea of minimizing documentation is still a controversial one as some assume agility to mean no documentation at all. Such views are however not unfounded because some agile extremists have expressed connotations of zero documentation claiming that the code is sufficient documentation. As agile methodologies approach higher levels of maturity minimizing documentation has evolved to generally imply providing as much documentation as the customer is willing pay for in terms of time and money.
- **Efficient** means doing only that work that will deliver the desired product with as little overhead as practically possible.
- **Low-risk** implies trading on the practical lines and leaving the unknown until it is known. In actual fact, all software development methodologies are designed to reduce the risks of project failure. At times, a lot of effort is wasted in speculative abstraction of the problem space in a bid to manage risk.
- **Predictable** implies that agile methodologies are based on what practitioners do all the time, in other words the world of ambiguity is reduced. This however does not mean that planning, designs, and architecture of software are predictable. It means that agility allows development of software in the most natural ways that trained developers can determine in advance based on special knowledge.
- **Scientific** means that the agile software development methodologies are based on sound and proven scientific principles. It nevertheless remains the responsibility of the academia to continue gathering empirical evidence on agile processes because most of the practitioners who authored agile methodologies seem to have little interest and time to carryout this kind of research.
- **Fun way** because at last developers are allowed to do what they like most (i.e., to spend most of their time writing good code that works). To the developers, agility provides a form of freedom to be creative and innovative without making the customer pay for it, instead the customer benefits from it.

Schuh (2004) defines agile development as a counter movement to 30 years of increasingly heavy-handed processes meant to refashion computer programming into software engineering, rendering it as manageable and predictable as any other engineering discipline.

On a practical perspective, agile methodologies emerged from a common discovery among practitioners that their practice had slowly drifted away from the traditional heavy document and process centered development approaches to more people-centered and less document-driven approaches (Boehm & Turner, 2004; Highsmith, 2002a; Fowler, 2002). There is a general misconception that there is no planning or there is little planning in agile processes. This is due to the fact that the agile manifesto lists as one of its four values the preference for responding to change over following a plan (Agile Alliance, 2001). In fact, planning in agile projects could be more precise than in traditional processes it is done rigorously for each increment and from a project planning perspective agile methodologies provide a risk mitigation approach where the most important principle of agile planning is feedback. Collins-Cope (2002) lists the potential risks as: risks of misunderstandings in functional requirements, risks of a deeply flawed architecture; risks of an unacceptable user interface; risks of wrong analysis and design models; risks of the team not understanding the chosen technology et cetera. Feedback is obtained by creating a working version of the system at regular intervals or per increment according to the earlier planning effort (Collins-Cope, 2002).

Besides dealing with the most pertinent risks of software development through incremental development, agile methodologies attack the premise that plans, designs, architectures, and requirements are predictable and can therefore be stabilized. Agile methodologies also attack the premise that processes are repeatable (Highsmith, 2001; Schwaber & Beedle, 2002). These two premises are part of fundamental principles on which traditional methodologies are built, and they also happen to be the main limitations of the traditional methodologies.

Boehm et al. (2004) view agile methodologies as a challenge to the mainstream software development community that presents a counter-culture movement, which addresses change from a radically different perspective. All agile methodologies follow the four values and 12 principles as outlined in the agile manifesto.

CONTEXTUAL DEFINITION

From these definitions of agile methodologies, a contextual definition can be derived which looks at what agility means in terms of certain specific software engineering concepts. Examples of that would be concepts are software quality assurance, software process improvement, software process modeling, and software project management. Agile methodologies will now be defined according to these concepts. Since this book is specifically focused on agile software quality assurance the definition of agile software quality assurance will be given in more detail.

AGILE SOFTWARE QUALITY ASSURANCE

This section starts by summarizing the traditional definitions of quality and then presents a summary of the work that has been done in the area of agility and quality. References to older literature on software quality are not intended to be exhaustive, but to be simply present a fare baseline for evaluating software quality perspectives in the modern processes. The authors are aware of a number of initiatives in research and academic institutions where evaluation of quality concepts is performed on some agile practices.

DEFINING QUALITY

Have you ever wondered what Joseph Juran generally considered to be a quality legend would have said about agile processes and the quality movement? Well, this is what he said about the

ISO 9000 when he was asked by Quality Digest if he thought ISO 9000 had actually hindered the quality movement; "Of course it has. Instead of going after improvement at a revolutionary rate, people were stampeded into going after ISO 9000, and they locked themselves into a mediocre standard. A lot of damage was, and is, being done" (QCI International, 2002).

According to Juran, quality is fitness for use, which means the following two things: "(1) quality consists of those product features that meet the needs of the customers and thereby provide product satisfaction. (2) Quality consists of freedom from deficiencies" (Juran & Gryna, 1988).

Philip Crosby, who developed and taught concepts of quality management, whose influence can be found in the ISO 9000:2000 standard, which differs from the 1994 standard in the context of each of the eight principles, defines quality as conformance to requirements and zero defects (Crosby, 1984).

ISO 9000 defines quality as the totality of characteristics of an entity that bear on its ability to satisfy stated or implied needs. Where "stated needs" means those needs that are specified as requirements by the customer in a contract, and 'implied needs' are those needs that are identified and defined by the company providing the product. These definitions of quality have a general bias towards the manufacturing industry although they should in general apply to all products, nevertheless, software products are rather complex hence they should be defined in a slightly different way.

Weinberg defines quality simply as "the value to some people" (Weinberg, 1991) and some have expanded on that to mean the association of quality with human assessment, and cost and benefit (Hendrickson, 2004).

Some software engineers have defined software quality as follows:

1. Meyer (2000) defines software quality according to an adapted number of quality parameters as defined by McCall (1977), which are correctness, robustness, extendibility, reusability, compatibility, efficiency, portability, integrity, verifiability, and ease of use.
2. Pressman, who derives his definition from Crosby, defines quality as a "conformance to explicitly stated functional requirements, explicitly documented development standards, and implicit characteristics that are expected of all professionally developed software" (Pressman, 2001).
3. Sommerville (2004) defines software quality as a management process concerned with ensuring that software has a low number of defects and that it reaches the required standards of maintainability, reliability, portability, and so on.
4. van Vliet (2003) follows the IEEE definition of quality as stated in the IEEE Glossary of Software Engineering Terminology, which defines quality assurance in two ways as: "(1) A planned and systematic pattern of all actions necessary to provide adequate confidence that the item or product conforms to established operational, functional, and technical requirements. (2) A set of activities designed to evaluate the process by which products are developed or manufactured" (IEEE, 1990). van Vliet's perspective then combines this definition with the analysis of the different taxonomies on quality.
5. Pfleeger (2001) aligns her perspective with Garvin's quality perspective, which views quality from five different perspectives namely; the transcendental meaning that quality can be recognized but not defined, user view meaning that quality is fitness for purpose, manufacturing meaning that quality is conformance to specification, product view meaning that quality is tied to inherent product characteristics, and

the value-based view meaning that quality depends on the amount the customer is willing to pay for the product.

6. Bass (2006) argues that the common practice of defining software quality by dividing it into the ISO 9126 (i.e., functionality, reliability usability, efficiency maintainability, and portability) does not work. His argument is that "in order to use a taxonomy, a specific requirement must be put into a category" (Bass, 2006). However, there are some requirements that may be difficulty to put under any category, for example, "denial of service attack, response time for user request, etc." What Bass (2006) then proposes is the use of quality attributing general scenarios.

From an agile perspective, quality has been defined by some practitioners as follows:

Table 1. Agile quality techniques as applied in extreme programming

Technique	**Description**
Refactoring	Make small changes to code, Code behaviour must not be affected, Resulting code is of higher quality (Ambler, 2005).
Test-driven development	Create a test, Run the test, Make changes until the test passes (Ambler, 2005).
Acceptance testing	Quality assurance test done on a finished system, Usually involves the users, sponsors, customer, etc. (Huo, Verner, Zhu, & Babar, 2004).
Continuous integration	Done on a daily basis after developing a number of user stories. Implemented requirements are integrated and tested to verify them. This is an important quality feature.
Pair programming	Two developers work together in turns on one PC, Bugs are identified as they occur, Hence the product is of a higher quality (Huo et al., 2004).
Face-to-face communication	Preferred way of exchanging information about a project as opposed to use of telephone, email, etc. Implemented in the form of daily stand-up meetings of not more than twenty minutes (Huo et al, 2004). This is similar to the daily Scrum in the Scrum method. It brings accountability to the work in progress, which vital for quality assurance.
On-site customer	A customer who is a member of the development team, Responsible for clarifying requirements (Huo et al., 2004).
Frequent customer feedback	Each time there is a release the customer gives feedback on the system, and result is to improve the system to be more relevant to needs of the customer (Huo et al., 2004). Quality is in fact meeting customer requirements.
System metaphor	Simple story of how the system works (Huo et al., 2004), Simplifies the discussion about the system between customer/ stakeholder/ user and the developer into a non-technical format. Simplicity is key to quality.

McBreen (2003) defines agile quality assurance as the development of software that can respond to change, as the customer requires it to change. This implies that the frequent delivery of tested, working, and customer-approved software at the end of each iteration is an important aspect of agile quality assurance.

Ambler (2005) considers agile quality to be a result of practices such as effective collaborative work, incremental development, and iterative development as implemented through techniques such as refactoring, test-driven development, modelling, and effective communication techniques.

To conclude this section, Table 1 gives a summary of the parameters that define agile quality as specifically applied in extreme programming--a popularly used agile methodology. These aspects of agile quality have eliminated the need for heavy documentation that is prescribed in traditional processes as a requirement for quality. Quality is a rather abstract concept that is difficult to define but where it exists, it can be recognized. In view of Garvin's quality perspective there may be some who have used agile methodologies in their software development practices and seen improvement in quality of the software product but could still find it difficult to define quality in the agile world.

EVALUATING QUALITY IN AGILE PROCESSES

So can we evaluate quality assurance in agile processes? This can be done through:

- The provision of detailed knowledge about specific quality issues of the agile processes.
- Identification of innovative ways to improve agile quality.
- Identification of specific agile quality techniques for particular agile methodologies.

Literature shows that Huo et al. (2004) developed a comparison technique whose aim was to provide a comparative analysis between quality in the waterfall development model (as a representative of the traditional camp) and quality in the agile group of methodologies. The results of the analysis showed that there is indeed quality assurance in agile development, but it is achieved in a different way from the traditional processes. The limitations of Huo et al.'s tool however, are that the analysis:

- Singles out two main aspects of quality management namely quality assurance and verification and validation.
- Overlooks other vital techniques used in agile processes to achieve higher quality management.
- Agile quality assurance takes quality issues a step beyond the traditional software quality assurance approaches.

Another challenge of Huo et al.'s technique is that while the main purpose of that analysis was to show that there is quality assurance in agile processes, it does not make it clear what the way forward is. Agile proponents do not seem to be worried about comparison between agile and traditional processes as some of the more zealous "agilists" believe that there is no way traditional methods can match agile methods in any situation (Tom Poppendieck, personal e-mail 2005).

The evaluation described in this section improves on (Huo et al., 2004) framework by further identifying some more agile quality techniques and then in an innovative way identifies the agile process practices that correspond to each technique. The contribution of this evaluation is the further identification of possible practices that can

Table 2. Mapping software quality parameters to agile techniques

Software Quality Parameters	**Agile Techniques**	**Possible Improvements**
Correctness	Write code from minimal requirements. Specification is obtained by direct communication with the customer. Customer is allowed to change specification. Test-driven development.	Consider the possibility of using formal specification in agile development, Possible use of general scenarios to define requirements (note that some development teams are already using this).
Robustness	Not directly addressed in agile development.	Include possible extreme conditions in requirements.
Extendibility	A general feature of all OO developed applications. Emphasis is on technical excellence and good design. Emphasis also on achieving best architecture.	Use of modeling techniques for software architecture.
Reusability	A general feature of all OO developed applications. There are some arguments against reusability of agile products (Turk, France, & Rumpe, 2002; Weisert, 2002).	Develop patterns for agile applications.
Compatibility	A general feature of all OO developed applications.	Can extra features be added for the sake of compatibility even if they may not be needed? This could contradict the principle of simplicity.
Efficiency	Apply good coding standards.	Encourage designs based on the most efficient algorithms
Portability	Practice of continuous integration in extreme programming.	Some agile methods do not directly address issues of product deployment. Solving this could be to the advantage of agility.
Timeliness	Strongest point of agility, Short cycles, quick delivery, etc.	
Integrity	Not directly addressed in agile development.	
Verifiability	Test-driven development is another strength of agility.	
Ease of use	Since the customer is part of the team, and customers give feedback frequently, they will most likely recommend a system that is easy to use.	Design for the least qualified user in the organization.

be done to improve on the already high quality achievements enjoyed by agile processes.

TECHNIQUES

The parameters that define software quality from a top-level view can be rather abstract. However, the proposed technique picks each of the parameters and identifies the corresponding agile techniques that implement the parameter in one way or another. Possible improvements to the current practice have been proposed by analysing the way agile practitioners work. Of great importance to this kind of analysis is a review of some of the intuitive practices that developers usually apply which may not be documented. You may wonder how much objectivity can be in such information. The point though is that developers tell their success stories at different professional forums and some of the hints from such deliberations have been captured in this technique without following any formal data gathering methodology. The authors believe that gathering of informal raw data balances the facts especially in cases where developers talk about their practice. Once the data is gathered formally, then a lot of prejudices and biases come in and there will be need to apply other research techniques to balance the facts. Tables 2 and 3 summarize the evaluation approach.

In formal software quality management, quality assurance activities are fulfilled by ensuring that each of the parameters listed in Table 2 are met to a certain extent in the software development life cycle of the process concerned. A brief definition of each of these parameters is given according to Meyer (2000):

- **Correctness:** The ability of a system to perform according to defined specification.
- **Robustness:** Appropriate performance of a system under extreme conditions. This is complementary to correctness.
- **Extendibility:** A system that is easy to adapt to new specification.
- **Reusability:** Software that is composed of elements that can be used to construct different applications.
- **Compatibility:** Software that is composed of elements that can easily combine with other elements.
- **Efficiency:** The ability of a system to place as few demands as possible to hardware resources, such as memory, bandwidth used in communication and processor time.
- **Portability:** The ease of installing the software product on different hardware and software platforms.
- **Timeliness:** Releasing the software before or exactly when it is needed by the users.
- **Integrity:** How well the software protects its programs and data against unauthorized access.
- **Verifiability:** How easy it is to test the system.
- **Ease of use:** The ease with which people of various backgrounds can learn and use the software.

SOFTWARE PROCESS IMPROVEMENT

A bigger-picture view of agile processes leads to a notion that agile methods are a group of processes that have reduced the development timeframe of software systems and introduced innovative techniques for embracing rapidly changing business requirements. With time, these relatively new techniques should develop into mature software engineering standards.

SOFTWARE PROCESS MODELING

The agile perspective to software process modeling is that whether formal or informal when

approaches to modeling are used the idea is to apply modeling techniques in such a way that documentation is minimized and simplicity of the desired system is a virtue. Modeling the agile way has led to breakthroughs in the application of agile methods to the development of large systems (Ambler, 2002)

SOFTWARE PROJECT MANAGEMENT

The agile approach to managing software projects is based on giving more value to the developers than to the process. This means that management should strive to make the development environment conducive. Instead of worrying about critical path calculation and Gantt chart schedules, the project manager must facilitate face-to-face communication, and simpler ways of getting feedback about the progress of the project. In agile development there is need to be optimistic about people and assume that they mean good hence give them space to work out the best way to accomplish their tasks. It is also an agile strategy to trust that people will make correct professional decisions about their work and to ensure that the customer is represented in the team throughout the project.

THE AGILE METHODOLOGY EVALUATION FRAMEWORK

All agile methodologies have striking similarities amongst their processes because they are based on the four agile values and 12 principles. It is interesting to note that even the authors of agile methodologies no longer emphasize their methodology boundaries and would use practices from other agile methodologies as long they suit a given situation (Beck & Andres, 2004). In fact, Kent Beck in his extreme programming (XP) master classes frequently mentions the errors of extremism in the first edition of his book on XP (Beck, 1999). A detailed review of agile methodologies reveals that agile processes address the same issues using different real life models.

The evaluation technique presented in this chapter reveals, for example, that lean development (LD) views software development using a manufacturing and product development metaphor. Scrum views software development processes using a control engineering metaphor. Extreme programming views software development activities as a social activity where developers sit together. Adaptive systems development (ASD) views software development projects from the perspective of the theory of complex self-adaptive systems (Mnkandla, 2006).

Tables 3 to 6 summarize the analysis of agile methodologies. Only a few of the existing agile methodologies have been selected to illustrate the evaluation technique. The first column from the left on Tables 3, 4, and 5 lists some methodology elements that have been chosen to represent the details of a methodology. There is a lot of subjectivity surrounding the choice of methodology elements. It is not within the scope of this chapter to present a complete taxonomy of methodologies. For more detailed taxonomies see Avison and Fitzgerald (2003), Boehm et al. (2004), Glass and Vessey (1995), and Mnkandla (2006). Therefore, the elements used here were chosen to reveal the similarities amongst different agile methodologies. The importance of revealing these similarities is to arm the developers caught up in the agile methodology jungle wondering which methodology to choose. While the methodology used in your software development project may not directly lead to the success of a project and may not result in the production of a high quality product use of a wrong methodology will lead to project failure. Hence, there is in wisdom selecting a correct and relevant process. Most organization may not afford the luxury of using different methodologies for each project though that would be ideal for greater achievements. It

also sounds impractical to have a workforce that is proficient in many methodologies. Sticking to one methodology and expect it to be sufficient for all projects would also be naïve (Cockburn, 2000). This evaluation technique therefore gives software development organizations an innovative wit to tailor their development process according to the common practices among different agile methodologies. The advantage is to use many methodologies without the associated expenses of acquiring them.

There is a need to understand in detail each agile methodology that will be analyzed so as to reveal the underlying principles of the methodology. This technique gives the background details as to why the methodology was developed in the first place. An answer to this question would reveal the fundamental areas of concern of the methodology and what fears the methodology addresses. The prospective user of the methodology would then decide whether such concern area is relevant to their project. Identifying what problems the methodology intends to solve is another concern of this evaluation. Some methodologies have a general bias toward solving technical problems within the development process (i.e., extreme programming deals with issues such as how and when to test the code). There are other agile methodologies that solve project management problems (i.e., Scrum deals with issues such as how to effectively communicate within a project). Yet other agile methodologies solve general agile philosophy problems (i.e., Crystal deals with issues such as the size of the methodology vs. the size of the team and the criticality of the project. There may be other agile methodologies that solve a mix of problems right across the different categories mentioned here for example Catalyst puts some project management aspects into XP (see www.ccpace.com for details on Catalyst).

Evaluation of each methodology should also reveal what sort of activities and practices are prevalent in the methodology. This should assist prospective users of the methodology to determine the practices that could be relevant to their given situation. This evaluation technique reveals that some of the practices from different methodologies actually fulfill the same agile principles and it would be up to the developers to decide which practices are feasible in their situation. Therefore, the implication is that at the level of implementation it becomes irrelevant which agile methodology is used, for more on this concept see Mnkandla (2006). Another aspect of agile methodologies revealed by this evaluation technique is what the methodology delivers at the end of the project. When a developer looks for a methodology, they usually have certain expectations about what they want as an output from the methodology. Hence, if the methodology's output is not clearly understood problems may result. For example if the developer expects use of the methodology to lead to the delivery of code and yet the aim of the methodology is in fact to produce a set of design artifacts such as those delivered by agile modeling this could lead to some problems. Finally, this evaluation technique also reveals the domain knowledge of the author of the methodology. In this phase of analysis, there is no need to mention any names of the authors but simply to state their domain expertise. The benefit of revealing the background of the methodology author is to clarify the practical bias of the methodology, which is usually based on the experience, and possible fears of the methodology's author.

Tables 3 to 5 give a summary of the analysis of specific agile methodologies to illustrate how this analysis technique can be used for any given agile methodologies.

ANALYZING SCRUM

Scrum has been in use for a relatively longer period than other agile methodologies. Scrum, along with XP, is one of the more widely used agile methodologies. Scrum's focus is on the fact that "defined and repeatable processes only

Table 3. Analyzing scrum methodology

Elements	Description
Real Life Metaphor	Control engineering.
Focus	Management of the development process.
Scope	Teams of less than 10, but is scalable to larger teams.
Process	Phase 1: planning, product backlog, & design. Phase 2: sprint backlog, sprint. Phase 3: system testing, integration, documentation, and release.
Outputs	Working system.
Techniques	Sprint, scrum backlogging (writing use cases).
Methodology Author (two)	1. Software developer, product manager, and industry consultant. 2. Developed mobile applications on an open technology platform. Component technology developer. Architect of advanced internet workflow systems.

work for tackling defined and repeatable problems with defined and repeatable people in defined and repeatable environments" (Fowler, 2000), which is obviously not possible. To solve the problem of defined and repeatable processes, Scrum divides a project into iterations (which are called Sprints) of 30 days. Before a Sprint begins, the functionality required is defined for that Sprint and the team is left to deliver it. The point is to stabilize the requirements during the Sprint. Scrum emphasizes project management concepts (Mnkandla & Dwolatzky, 2004b) though some may argue that Scrum is as technical as XP. The term Scrum is borrowed from Rugby: "A Scrum occurs when players from each team clump closely together…in an attempt to advance down the playing field" (Highsmith, 2002b). Table 3 shows application of the analysis technique to Scrum.

ANALYZING LEAN DEVELOPMENT

Lean software development like dynamic systems development method and Scrum is more a set of project management practices than a definite process. It was developed by Bob Charette and it draws on the success that lean manufacturing gained in the automotive industry in the 1980s. While other agile methodologies look to change the development process, Charette believes that to be truly agile, there is need to change how companies work from the top down (Mnkandla et al., 2004b). Lean development is targeted at changing the way CEOs consider change with regards to management of projects. LD is based on lean thinking whose origins are found in lean production started by Toyota Automotive manufacturing company (Poppendeick & Poppendeick, 2003). Table 4 shows application of the analysis technique to LD.

ANALYZING EXTREME PROGRAMMING

Extreme programming (XP) is a lightweight methodology for small-to-medium-sized teams developing software based on vague or rapidly changing requirements (Beck, 1999). In the second version of XP, Beck extended the definition of XP

Table 4. Analyzing lean development methodology

Elements	Description
Real Life Metaphor	Manufacturing and product development.
Focus	Change management. Project management.
Scope	No specific team size.
Process	Has no process.
Outputs	Provides knowledge for managing projects.
Techniques and Tools	Lean manufacturing techniques.
Methodology Author	Research engineer at the US Naval Underwater Systems Center, author of software engineering books and papers, advisory board in project management.

to include team size and software constraints as follows (Beck et al., 2004):

- **XP is lightweight:** You only do what you need to do to create value for the customer.
- **XP adapts to vague and rapidly changing requirements:** Experience has shown that XP can be successfully used even for project with stable requirements.
- **XP addresses software development constraints:** It does not directly deal with project portfolio management, project financial issues, operations, marketing, or sales.
- **XP can work with teams of any size:** There is empirical evidence that XP can scale to large teams.

Software development using XP starts from the creation of stories by the customer to describe the functionality of the software. These stories are small units of functionality taking about a week or two to code and test. Programmers provide estimates for the stories, the customer decides, based on value and cost, which stories to do first. Development is done iteratively and incrementally. Each two weeks, the programming team delivers working stories to the customer. Then the customer chooses another two weeks worth of work. The system grows in functionality, piece by piece, steered by the customer. Table 5 shows application of the analysis technique to XP.

A WALK THROUGH THE ANALYSIS TECHNIQUE

Each of the methodology elements as represented in Tables 3 to 5 will be defined in the context of this analysis approach.

METHODOLOGY'S REAL LIFE METAPHOR

This element refers to the fundamental model/metaphor and circumstances that sparked the initial idea of the methodology. For example watching the process followed by ants to build an anthill could spark an idea of applying the same process to software development.

METHODOLOGY FOCUS

The focus of the methodology refers to the specific aspects of the software development process targeted by the methodology. For example, agile

Table 5. Analyzing extreme programming

Elements	Description
Real Life Metaphor	Social activity where developers sit together.
Focus	Technical aspects of software development.
Scope	Less than ten developers in a room. Scalable to larger teams.
Process	**Phase 1:** Writing user stories. **Phase 2:** Effort estimation, story prioritization. **Phase 3:** Coding, testing, integration testing. **Phase 4:** Small release. **Phase 5:** Updated release. **Phase 6:** Final release (Abrahamsson et al, 2002).
Outputs	Working system.
Techniques and Tools	Pair programming, refactoring, test-driven development, continuous integration, system metaphor.
Methodology Authors (two)	1. Software developer (Smalltalk). Strong believer of communication, reflection, and innovation. Pattern for software. Test-first development. 2. Software developer (Smalltalk). Director of research and development. Developed the Wiki. Developed Framework for Integrated Test (Fit).

modeling targets the design aspects of the software development process and also considers issues of how to model large and complex projects the agile way.

METHODOLOGY SCOPE

This element outlines the details to which the methodology's development framework is spelled out. This is where the methodology specifies what it covers within a project. The importance of this parameter is to help the user to identify the list of tasks that the methodology will help manage. Remember a methodology does not do everything but simply gives guidelines that help in the management of a project. The scope of a software development project is relevant in determining the size of the team.

METHODOLOGY PROCESS

This parameter describes how the methodology models reality. The model may be reflected in the life cycle or development process of the methodology. The model provides a means of communications, captures the essence of a problem or a design, and gives insight into the problem area (Avison et al., 2003). The importance of this parameter is that it gives the user a real worldview of the series of activities that are carried out in the development process.

METHODOLOGY OUTPUTS

This parameter defines the form of deliverables to be expected from the methodology. For example if an organization purchased lean development

methodology today, would they get code from application of the methodology, or would they get some documents, etc (Avison et al., 2003). Each agile methodology will give different outputs hence the user can choose the methodology that gives them the output they require.

TECHNIQUES AND TOOLS

This parameter helps the user to identify the techniques and tools applicable to the methodology. Tools may be software applications that can be used to automate some tasks in the development process, or they can be as simple as whiteboards and flip charts. In fact, it is the use of tools that makes the implementation of a methodology enjoyable. Organizations therefore tend to spend a lot of money acquiring tools and training staff on tools. As technology evolves and new tools emerge, more acquisitions and training are usually done. However, most agile methodologies do not specify tools and most agile practitioners use open source tools, which reduces potential costs on software tools.

Each methodology has its own techniques that may be relevant or irrelevant to the problem at hand. Examples of techniques in extreme programming would be pair programming, and the scrum meeting in Scrum methodology. The user then analyzes these techniques in relation to the present project, to determine need for the techniques and include variations that will be part of tailoring the methodology.

METHODOLOGY AUTHOR

This parameter defines the domain knowledge of the methodology author. The benefit of doing this is to clarify the background from which the methodology was conceived. There is no need to mention the name of the author or a detailed biography of the methodology author.

Table 6 summarizes the phase of the analysis where all the practices are brought together and similar practices are identified across different methodologies.

Table 6 classifies the practices using the superscripts 1, 2, 3, 4, and 5. The practices with the same superscript implement the same agile principle.

- "1" represents practices that deal with planning issues such as requirements gathering. The three methods shown here use different

Table 6. Identifying similarities among the practices

	Practices
XP	The planning process[1], small releases[2], metaphor, test-driven development[2], story prioritization[3], collective ownership[3], pair programming[3], forty-hour work week[3], on-site customer[4], refactoring[5], simple design[5], and continuous integration[5].
LD	Eliminate waste[1], minimize inventory[1], maximize flow[2], pull from demand[2], meet customer requirements[2], ban local optimization[2], empower workers[3], do it right the first time[4], partner with suppliers[4], and create a culture of continuous improvement[5].
Scrum	Capture requirements as a product backlog[1], thirty-day Sprint with no changes during a Sprint[2], Scrum meeting[3], self-organizing teams[3], and Sprint planning meeting[4].

terms but the principle is to capture minimal requirements in the simplest available way and start coding.
- "2" represents practices that deal with improvement of quality in terms of meeting the volatile requirements.
- "3" represents practices that facilitate freely working together of developers, effective communication, empowered decision-making, and team dynamics issues.
- "4" represents practices that deal with quick delivery of the product.
- "5" represents practices that deal with agile quality assurance property of ensuring that the product is improved continuously until deployment.

When the similar practices are identified, the developers can then decide to select and tailor some practices to their environment according to relevance, and project and customer priorities. You will notice that the choice of the activities of the development process according to this analysis have shifted from focusing on the individual methodologies to a focus on practices.

ISSUES AND CONTROVERSIES SURROUNDING AGILE DEVELOPMENT

Software Development Common Ground

This section looks at issues that are done in a similar way among different software development methodologies. Most software development processes in use today involve some of the following activities: planning, estimation, and scheduling of the tasks, design, coding, and testing, and deployment and maintenance. What varies among the different processes is the sequence followed in implementing each of the phases, and the level of detail to which each phase is carried out. Some methodologies may implement all of the activities and some partial methodologies may specialize in just a few. The other difference is in the way the process values the people involved in the development activities and what value is attached to the customer in relation to what needs to be done. These differences mark the major boundaries among software development methodologies.

Agile Development Higher Ground

This section looks at issues that are done in a peculiar way by agile methodologies. The role of the domain expert in agile methodologies is rather unique. Software development experts with practical experience in this field have a lot of knowledge that can be classified as *tacit knowledge* due to the fact that it is gained through practice and is not written down in any form. Tacit knowledge is difficult to quantify hence this concept remains quite subjective in the implementation of agile methodologies. However, the strength of using tacit knowledge rests in the team spirit that puts trust on experts to do what they know best within their professional ethics. This in fact is what differentiates the "agile movement" from other development processes. Another hot issue about agile development is the concept of *self-organizing* teams. This concept means that agile development teams are allowed to organize themselves the best way they want in order to achieve the given goals. As a result of applying this concept, managing agile projects becomes different from the traditional approaches to project management. The role of a project manager becomes more of a facilitator than a controller. Detailed discussions on what has become known as "agile project management" can be found in Highsmith (2004) and Schwaber (2004) and at http://finance.groups.yahoo.com/group/agileprojectmanagement/.

Agile methodologies also emphasize on *light documentation*. This concept has been quite controversial since agile methodologies started. The main reason for the controversy is that the

traditional methodologies have always associated documentation with proper planning, software quality assurance, deployment, user training, maintenance, etc. Agile methodologists however, believe that documentation should be minimum because of the associated expenses. In agile methodologies, the general belief is that correctly written code is sufficient for maintenance. The *Test first* technique, which was originally an XP practice and is now widely applied in other agile methodologies is another peculiar agile practice (though its origins may be from earlier processes). The test first technique is a software development approach that implements software design through writing tests for each story before the code is written. The test code then amounts to design artifacts and replaces the need for design diagrams etc.

Challenges Faced by Agile Development

This section looks at issues that are still grey areas to agile methodologies. One of the interesting issues about agility is what is going to happen to the issues of innovative thinking embedded in agile development as the processes attain higher and higher levels of maturity and quality assurance. Are we going to see a situation where agility retires and fails to be agile? Another area of software development that is always heavily debated at agile gatherings is the area of how to cost projects that are developed the agile way. The main difficulty is estimating the cost of an entire project based on iterations. There has been some effort towards dealing with this challenge especial at big agile conferences, for example the extreme programming and agile processes in software engineering held in Europe once per year (see www.XP2006.org). Another example is the Agile Development Conference also held once per year in the USA (see www. agiledevelopmentconference.com).

As agile processes begin to enter grounds such as enterprise architecture, patterns, and software reuse, their software process jacket is getting heavier and heavier and if this is not watched by agile proponents we might have a situation sometime in the future where another software development revolution emerges to maintain the legacy of agility.

THE FUTURE TRENDS OF AGILE SOFTWARE DEVELOPMENT

Agile methodologies are certainly moving toward higher levels of maturity due to a number of things. The first contribution to agile maturity is the availability of comprehensive sources of simple descriptive and analytical information about agile methodologies. The second contribution to agile maturity is the growth in academic research interest in agility, which has resulted in a lot of empirical data being collected and scientifically analyzed to prove and disprove anecdotal data about agile processes. The third contribution to agile maturity is the massive exchange of practical experiences amongst the different practitioners involved in agile software development. The general direction of the agile movement seems to be towards more and more demand for the adoption of agile practices by the larger organizations that have been traditionally associated with traditional processes. There have been reports of higher demands for agile consultancy and training as more and more organizations adopt agile development practices, Poppendieck (personal communication, November 07, 2005) said there was more demand in North America, Europe, and even Japan where his book on lean software development sold more than ten thousand copies. Another interesting development by the agile alliance is their offer to sponsor agile research. This will certainly go a long way in boosting the process maturity of agile methodologies.

CONCLUSION

In this chapter, an overview of agile methodologies was presented without going into the details of describing each existing agile methodology. The focus of the chapter was to provide an informed review of agile methodologies that included a comprehensive definition of what agility and agile quality assurance is all about. The approach to the definition as presented in this chapter was to give a theoretical definition, which is the perspective of those who are philosophical about agile methodologies, a practical definition, which is the perspective of those who are on the development work floors, and a contextual definition, which is a perspective based on the different contexts of the activities of the software development process. In order to enhance understanding of the agile processes, an analysis model was presented. The philosophy of this technique is to cut deep into each given agile methodology and reveal the core values, principles, and practices of the methodology so as to compare the common activities among different agile processes. The aim of doing such an analysis is to provide a technique for striking the balance between these two extremes: "getting lost in the agile methodology jungle and holding onto one methodology." The benefit of using this analysis method is the attainment of a deeper understanding of all the agile methodologies analyzed. This should lay the ground for training and adoption of agile methodologies from a generic point of view rather than worrying about individual agile methodologies.

Chapter 8.7
Bridging the Gap between Agile and Free Software Approaches: The Impact of Sprinting

Paul J. Adams
Sirius Corporation Ltd., UK

Andrea Capiluppi
University of Lincoln, UK

ABSTRACT

Agile sprints are short events where a small team collocates in order to work on particular aspects of the overall project for a short period of time. Sprinting is a process that has been observed also in Free Software projects: these two paradigms, sharing common principles and values have shown several commonalities of practice. This article evaluates the impact of sprinting on a Free Software project through the analysis of code repository logs: sprints from two Free Software projects (Plone and KDE PIM) are assessed and two hypotheses are formulated: do sprints increase productivity? Are Free Software projects more productive after sprints compared with before? The primary contribution of this article is to show how sprinting creates a large increase in productivity both during the event, and immediately after the event itself: this argues for more in-depth studies focussing on the nature of sprinting.

INTRODUCTION

Agile and Free Software development have received rapid growth in popularity, both as development paradigms and as research topics. In theory they are very different concepts; the latter, strictly speaking, being just a licensing paradigm with implications for code reuse and redistribution.

The interface between Agile and Free Software is very interesting and a fertile area in which not much rigorous research has been carried out to date. Some comparative studies have been made in the past, but given the scarcity of data from

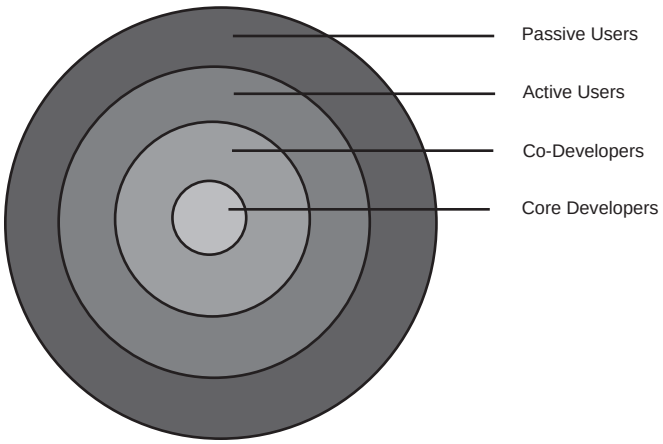
Agile processes, most of the studies have remained on the surface of theoretical discussions (Koch, 2004)(Warsta and Abrahamsson, 2003). Empirical attempts have been also made to measure, on an empirical basis, the degree of *agility* within other development paradigms (Adams, Capiluppi and deGroot, 2008).

This article examines and compares the Free Software and Agile approaches by observing typical Agile practices when deployed within Free Software teams: in particular, it reports on the Plone and KDE PIM projects, where sprinting (Beck, 1999) is commonly used by developers to focus the activity for a limited period of time. Sprinting allows developers to meet in person, get to know each other and create the basis for collaborating more effectively in a distributed environment (During, 2006). In previous works, the PyPy and the Zope projects have been reported to use sprinting regularly within their projects (Sigfridsson, Avram, Sheehan and Sullivan, 2007), and its use is advocated as an *"applied (...) idea of Agile development to the very difficult problem of distributed software development"* (Goth, 2007).

What past literature has not provided yet is a quantitative evaluation of the impact of sprinting on productivity of developers: what has instead been reported is that traditional productivity metrics could fail in capturing the effects of the interactions among developers within sprints (Goth, 2007). In order to tackle this issue, this article explores the use of automatic measures to determine the productivity of developers both before and after the sprinting efforts. A research hypothesis has been formulated as follows: when quantitatively evaluating sprinting, the productivity of developers will display higher values after a sprint than before it. If the null hypothesis can be rejected, this result could prove useful to others in the Free Software communities, encouraging them to adopt this practice and to focus their efforts within a constrained period of time to increase their productivity.

This article is structured as follows: Section 2 introduces the context of the work, explaining how the Agile and Free Software paradigms share some of their process characteristics. Section 3 reports on the methodology, the attributes and the definitions used throughout the article. Section 4 describes how sprinting is accomplished within the two reported case studies, while Section 5 summarises the main findings of measuring the effects of sprinting on developers productivity. Since this work reports on empirical analysis of public data, Section 6 will report on the threats to validity. Finally Section 7 will conclude the article, and illustrate avenues of further research.

Figure 1. The open development model



SPRINTS WITHIN THE AGILE DEVELOPMENT

As an activity, sprinting has its roots within the Agile development, specifically the SCRUM development model (Schwaber and Beedle, 2001). The SCRUM model is not a method per se, in that it does not prescribe specific practices to be followed in the release cycle. Within SCRUM, the principal period of development is focused during the sprints. Typically, a sprint would be a short period of development, typically 4 to 6 weeks (although they can be shorter). Within this period, developers would work to solve a specific and well-focused problem, such as the addition of a new set of functionality. Normally a sprinting team is collocated, with a dedicated manager who monitors progress on a daily basis in a short stand-up meeting.

As described, this model is in great contrast to the open development approach, as found within many Free Software projects. Again, the Free Software model does not prescribe specific practices, just how contributions should be handled. Originally Eric Raymond argued for what he called the "bazaar'' model of development (Raymond, 1999). In this model contributions to the code may be made by anyone whilst concurrently this openness leads to many people discovering and fixing bugs. In practice this is not what is found (Crowston, Annabi, Howison and Massango, 2004). Instead it is more common to have a model with a "cathedral'' component at its center, managed by core developers. This model is shown in Figure 1. It has been also shown that some Free Software projects show transitions between one stage to the other, and that this transition can be started by explicit actions of the core developers of a Free Software project (Capiluppi and Michlmayr, 2007).

At the centre of the model are the core developers, who are typically long-term contributors to a project and drive its development. They are the *de facto* management of Free Software developments. Other contributors to a project typically move in towards the centre of the model from the outside, where they began as users of the software.

Despite the commercial nature of the Agile approach, sprinting practices have been adopted by Free Software teams: given the differences as described above, and due to the unique nature of this model, Free Software developers have so far preferred to maintain the Free Software name instead of using the much more structured "Agile'' term to define their approach (Goth, 2007), even when blended with tools coming from other development approaches.

EMPIRICAL APPROACH

The following concepts and attributes have been used to extract data from the two Free Software projects, and used to compare the effectiveness of their sprinting practices:

- **Commit:** the atomic action of developers checking in one or more files (being source code or other) into a central repository. Both the Plone and the KDE PIM projects store the source code and other artifacts within similar Configuration Management Systems (subversion), therefore the same scripts were used to extract the relevant information out of each project.
- **Lines of code (LOCs):** in this study, the number of lines of code (LOCs) of each commit is also recorded. They will be used in conjunction with the commits to describe the output produced by Free Software developers.
- **Productivity:** in its most basic definition, it evaluates the amount of work produced during an observed period. Considering the information stored in configuration management systems, the productivity was in first instance evaluated by taking the amount of commits in a day. Secondly, the LOCs of the

commits were also extracted, to provide a clearer picture of the productivity of developers during sprints.

- **Sprint duration:** since their inception, sprints are considered one of the core practices within the SCRUM development model (Beck, 1999). Short periods of focused development work, preceded by a precise set of requirements both by stakeholders and final users, are at the core of the practice. Within this work, the sprints are characterised by evaluating the time (in days) when the sprints were held. The measurement of productivity was evaluated not only in each of the sprint periods, but also one week (*i.e.*, 7 days) before and one week after those events.

KDE PIM and Plone

The KDE website[1] hosts a large number of Free Software projects under a common name which together form both a desktop environment and associated application software, primarily for Unix-like operating systems. The complete project repository is roughly 50GB large and has grown steadily, along with contributors, since the project's launch over ten years ago. The KDE repository has somewhere in the order of 300 projects, ordered by application domain, one of which is Personal Information Management (PIM). KDE as a whole lists more than 1500 developers as committers in its Subversion CMS; considering the KDE PIM project alone, an overall of 380 committers are traceable in its evolution history.

Plone[2] is a Free Software content management system based upon the Zope web application server. Written in Python, it can run on all major platforms. As a project it is much smaller than KDE with 163 accounts in the project repository. Although Plone is focussed on one particular product, development is subdivided into teams working on specific issues within the system: css, programmed logic, work flow management, etc.

GQM: Goal Question Metric

The Goal-Question-Metric (GQM) method evaluates whether a goal has been reached, by associating that goal with questions that explain it from an operational point of view, and providing the basis for applying metrics to answer these questions (Basili, Caldiera and Rombach, 1994). The aim of the method is to determine the information and metrics needed to be able to draw conclusions on the achievement of the goal.

In the following, we applied the GQM method to first identify the overall goal of this research; we then formulate a number of hypotheses related to the two Free Software projects and their sprinting methods; and finally we collected adequate productivity metrics to determine whether the goal was achieved.

- **Goal:** The long-term objectives of this research are both to assess the presence, and to evaluate the efficacy of Agile processes within a Free Software development paradigm. If confirmed on these initial case studies, the results should be made public to other Free Software projects, in order to take advantage of Agile practices and tools.
- **Question:** The aim of this study is to establish the efficacy of an Agile practice (sprinting) within the Free Software paradigm. The productivity of the two Free Software systems will be studied: based on the "productivity'' and "sprint duration'' attributes defined above, two research hypotheses were formulated:

  HP1: *There is a difference between the average productivity of Free Software projects and the productivity as achieved during the sprints.*

  HP2: *In the presence of sprinting, there is a difference in the productivity of Free Software developers between the periods*

immediately before and immediately after the selected sprints.

- **Metrics:** based on the number of sprints actually performed during the lifecycle of the two projects, 6 sprints were selected from each project, and the productivity evaluated during the week before the sprint, during the sprint duration, and during the week after the sprint.

A summary of the research hypotheses is displayed in Table 1: the null and the alternative counterparts are formulated, as well as the metrics used to assess the hypothesis, and the type of test conducted to evaluate the hypothesis.

Sprinting in Free Software Projects

As one might expect, the implementation of sprinting varies between different Free Software projects. Even when the activities are similar, the frequency and motivation can be very different. A common value for all the observed sprints in the Free Software approach has been the location of these sprints: being it a distributed development, the face-to-face meetings have been typically run alongside main Free Software conferences, or developers meet-ups (During, 2006). In this section the sprinting practices of Plone and KDE PIM are described: one of the authors has been involved in the development of the KDE PIM, while directly collaborating with several developers from the other.

Sprinting in Plone

Since early 2003 there have been 32 Plone project sprints. Typically these involve less than 10 developers. However, as sprints have become more regular, so has the number of sprinters increased with meetings growing to be as large as 120 registrants[3]. These larger meetings are a-typical in that they are not, in themselves, one sprint alone. Instead, they are a gathering of many sprint meetings. Here, this larger type of meeting is described based upon observation of a sprint held in October 2007.

Each team, within the larger event, works on an individual subcomponent of the entire system: work flow, cascading style sheets, ZODB, etc. These teams set their own daily targets and share them with the entire sprint team in a short meeting at the beginning of the day. A similar meeting is held at the end of the day in order to convey progress made. In general, these Plone sprints are focused on the rapid introduction of new functionality to the system and optimisation of existing functionality. Some Plone sprints have also had a shared focus on system documentation. Six sprints (out of 32) were randomly selected between 2003 and 2007, with sprint durations varying from 3 to 8 days. A summary of the sprints' dates (in ISO format) and their durations is displayed in Table 2.

Table 1. Summary of the research hypotheses and the applied tests

Hypo	Null	Alternative	Metrics	Test
HP1	Productivity during sprints is larger than the baseline productivity	Productivity is larger during sprints	Commits-per-day (C)	$C_{sprints} > C_{baseline}$
HP2	Productivity after the sprints is larger than productivity after the sprints	Productivity after the sprints is equal to before	Commits-per-day (C)	$C_{after} > C_{before}$

Sprints in KDE-PIM

The sprints of this project have been held annually since 2003. As with the Plone sprints they are generally larger than an Agile sprint, typically with around 15 developers. However, unlike Plone sprints, there is no structure (explicit or otherwise) to each day and the primary focus of the event is not on coding, although this is one of the activities[4].

The annual KDE PIM plays a specific role within the product release cycle. KDE PIM development, like KDE as a whole, is based upon a 6 month release cycle for major releases. Minor releases for bug fixing and small amounts of new functionality happen monthly. The KDE PIM sprints occur at the beginning of one of these release cycles and is primarily focused with planning the next release.

In order to be consistent with the Plone case, six sprints were selected between 2003 and 2008, with reported shorter sprint durations, varying from 3 to 4 days. This corresponds to all of the sprints happened within the KDE PIM project: details of these sprint dates are in Table 2.

Sprint Impact: Setting Base Rates

The impact that a particular event may have on the development cycle is inevitably hard to assess without insider knowledge of what may be happening within that project at that time. There are, however, simple metrics that can be applied to public data sources in order to produce results which are indicative of the impact of an event (*i.e.*, sprinting) without needing to know specifically what has occurred. As reported above, the Configuration Management servers of the two studied projects have been analysed to extract the amount of commits recorded in the development activities. The number of commits per day was then used as a means of assessing productivity before and after development sprints, as well as within the sprint period.

As a start, a simple means of establishing any trends in commit rates is to plot the commit rates for the entire project history. Example for KDE PIM and Plone development are given in Figure 2 and Figure 3.

Figure 2 shows the distribution of commits-per-day in the Plone project. From this distribution,

Table 2. Summary of the dates of the sprints in Plone and KDE PIM

Project / Event		Start Date	End Date	Duration (days)
Plone	Sprint 1	2003-05-09	2003-05-11	3
	Sprint 2	2004-09-16	2004-09-19	4
	Sprint 3	2005-02-20	2005-02-27	8
	Sprint 4	2005-03-24	2005-03-27	4
	Sprint 5	2006-04-23	2006-04-29	7
	Sprint 6	2007-02-17	2007-02-20	4
KDE PIM	Sprint 1	2003-01-03	2003-01-05	3
	Sprint 2	2004-01-02	2004-01-05	4
	Sprint 3	2005-01-06	2005-01-09	4
	Sprint 4	2006-01-06	2006-01-08	3
	Sprint 5	2007-01-12	2007-01-15	4
	Sprint 6	2008-02-01	2008-02-03	3

it is also possible to evaluate an overall average commit rate of 10 commits per day, and a median value is 6. Since the distribution of Figure 2 is clearly not uniform, using the global average and median as base rates could produce spurious results. It was therefore decided to use different base rates of productivity for the various sprints: the base rates were in fact computed only during the year when the sprint happened, and are summarised in Table 3.

Similar to the Plone plot of commits, Figure 3 shows that largely due to an increase in activity between late 2003 and early 2006, KDE PIM has an average commit rate of 10 (31,214 commits assessed over 2,853 days), with a median value of 8. As there have only ever been 6 KDE PIM sprints, they were all assessed in the same manner as the Plone sprints. The dates are shown in Table 2. As seen above for the Plone system, different base rates were used to assess whether the effect of sprinting could be visible on the productivity of developers (Table 3).

Productivity During the Sprints

In order to tackle the first research hypothesis (HP1), an approach to measuring the impact of sprints upon project development is to compare the commit rate during the sprints to the base rate established in the previous section. In the

Figure 2. Growth of commits-per-day in plone

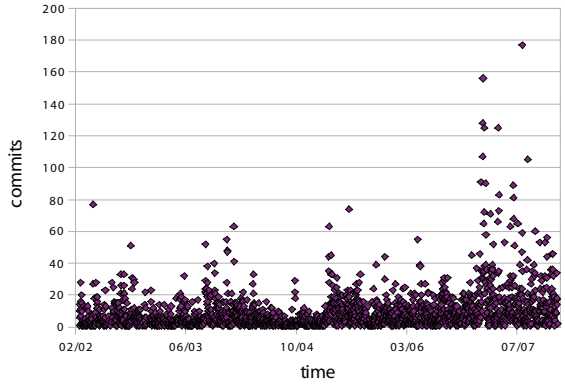


Figure 3. Growth of commits-per-day in KDE PIM

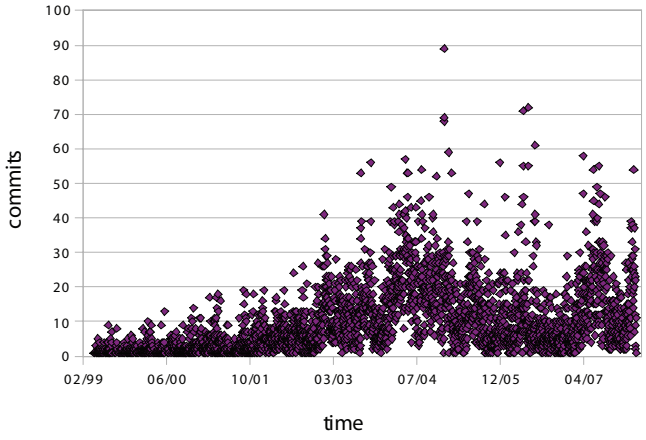

Table 3. Different base rates of commits-per-day for the two projects

	Plone			KDE PIM		
Base Rates	Year	Median	Average	Year	Median	Average
Sprint 1	2003	4	5,97	2003	12	12,9
Sprint 2	2004	4	4,75	2004	20	20,57
Sprint 3	2005	6	7,97	2005	11	13,26
Sprint 4	2005	6	7,97	2006	7	9,67
Sprint 5	2006	7	8,32	2007	12	16,42
Sprint 6	2007	12	19,1	2008	15	20,37

next subsections, the productivities of the two selected projects are evaluated during the six sprints, and compared to the base rates of the appropriate year. The test of the hypothesis HP1 is based on the principle of majority: if the majority of sprints achieve a larger productivity with respect to the yearly base rate, the null hypothesis will be rejected.

Effects of Sprinting – Plone

Figure 4 shows the commits per day for the 6 randomly selected sprints and the context weeks before and after: a vertical line divides the context week before the sprint from the sprint itself. Since the sprints have different durations, no common vertical line is displayed between the end of the sprint and the context week after it. As an example, the data for sprint 4 in Figure 4 displays 18 points: 7 points for the week before the sprint, 4 for the sprint duration, and 7 for the week after.

For each sprint, the average productivity and the median were recorded during each sprint duration, and compared with the base rates of the productivity within Plone. A summary of these results is shown in Table 4. As visible, in general the productivity during the six sprints in Plone has not increased, when compared with the base rates (depicted in bold within the Table), apart from two events where the values are greatly larger. One of the possible explanations is that Plone sprints have a large amount of participants turning up for the meetings, and coordination problems could arise which could make the productivity decrease.

The amount of lines of code in a day (i.e., LOCs-per-day) was also evaluated during the sprints of Plone, in order to test whether the commits-per-day and the LOCs-per-day trends followed the same pattern. Table 5 summarises the results: the Plone case shows that the average LOCs-per-day metrics follow the same pattern also seen in commits-per-day: in the presence of more commits, the Plone system experienced an increased productivity in LOCs, as compared to the week immediately after the sprint.

Effects of Sprinting: KDE PIM

Shows the commits per day for the 6 randomly selected sprints and the context weeks before and after. As done above, the productivity of KDE PIM developers was recorded during the sprints, and evaluated against the base rates (Table 4). As visible in the table, the majority of the sprints in KDE PIM achieve a larger productivity (either as medians, averages, or both) than the base counterparts. Differently from the Plone case, KDE PIM sprints tend to gather the same developers to work on the selected requirements, and this could be reflected on the improved productivity during these events. KDE PIM sprints are generally starting with a commit rate lower than that of the project base rate. However a crucial difference between the KDE PIM and Plone sprints is that KDE PIM

sprints are not only more consistent at improving productivity, but they are also successfully raising the commit rate above the base.

As done for the Plone case, the amount of LOCs-per-day in KDE PIM was evaluated during the sprints, as compared to the week immediately after the sprint, and the results reported in Table 5. The KDE PIM case shows that the LOCs-per-day metric follows the same pattern of commits-per-day: the three sprints where data of LOCs was available (sprint 4, 5 and 6) achieved a higher rate of LOCs-per-day than the weeks immediately after them. Sprints 1, 2 and 3, due to the recent conversion to Subversion, have no data available regarding the LOCs involved in the commits.

Productivity after the Sprints

The study of the first research hypothesis above showed a mixed picture: the development of Plone does not achieve (overall) an increased productivity during sprints with respect to its base rates of effort. Instead, the KDE PIM productivity during sprints largely differs from its average, showing a very focused development process during certain periods of the project's lifecycle.

The second research hypothesis was designed in order to assess how the process of development reacted after the sprinting event, and to ascertain whether the productivity before was impacted by the event itself, showing a clear increase after the event. For each sprint the average commits per day, and their medians, were noted for the week immediately before and immediately after the sprint. As a base line for this hypothesis, one would expect an increased productivity after the event, when compared with the period just before it. The results of this analysis are shown in Table 6.

Productivity after the Sprints: Plone

Comparing the base rate medians and averages with the sprints' achievements, Table 6 shows that the productivity has not steadily increased after the event, as compared with the period before the event: sprint 1, 2 and 3 clearly show that the overall activity, in terms of commits per day, not only dropped after the sprints, compared to just before; but it also decreased to lower levels than the overall base rates for the Plone project itself.

By analysing the remaining sprints, two additional findings were instead revealed: first, the high productivity accomplished during the sprints 4 and 6, was not paired to a similar productivity after the sprint effort (see Table 4). Second, in either the median or average, or both the measurements, an increase of productivity is detected after the event. An explanation for that was given by Plone insiders, revealing that sprints were more and more effective, as long as the use of this practice became clearer and more diffused. In summary, these results are indicative of sprints improving the productivity of the project as a whole, but the null hypothesis of HP2 could not be rejected for Plone: in the majority of cases, the productivity of developers is not larger after sprints as compared to before the sprints.

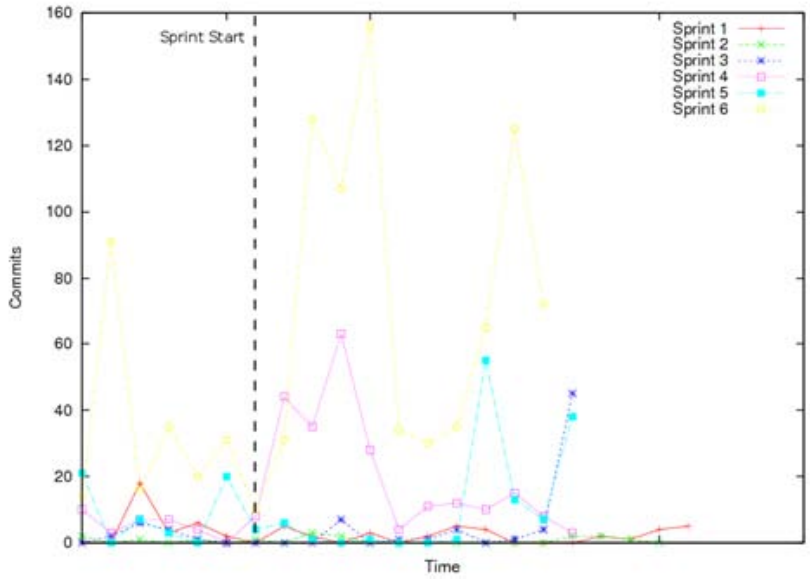
Productivity after the Sprints: KDE PIM

Table 6 confirms for KDE PIM what was already learned from the analysis of the sprint effort. All the studied sprints experienced an increase of either the median or the average productivity, or both. In the majority of the sprints, differently from the Plone case, the week after these sprints also accomplished a higher productivity than the observed base rates for the project itself.

An interpretation for that is the increased focus of the development work as a result of the sprint events. Therefore the null hypothesis could not be rejected: in the majority of cases, the productivity of KDE PIM developers after the sprints was higher than before.

As a more general message, Plone and KDE PIM share the same pattern: after the sprints

Figure 4. Commits during plone sprints



developers increase their efforts as compared to before the sprints. Also, the sprinting events serve as gatherings of exceptional productivity: even simple metrics like the one proposed in this article can be used to share knowledge, motivate and reinforce standard rates of effort.

Threats to Validity

The following aspects have been identified which could lead to threats to validity of the present empirical study:

- **Productivity:** This metric as discussed above (number of commits per day) is limited by its fragility; there are a large series of events which may affect this figure. The major consideration in the applicability of this metric is the requirement of other community knowledge in order to provide qualitative explanation for the measurements. Commit-per-day is a sensitive measurement and can be affected by many external forces, e.g.~lower commit rates are probable on public holidays. Commits-per-day can also be affected by many internal forces, e.g.~reaction to a security flaw in the codebase may increase the commit rate. As a result the observer must be careful to understand the full context of commit rates within the project and around the dates of the events being assessed.
- **Context Periods:** The commit examination period, *i.e.*~one week before and one week after the sprint, could be problematic. Some developers could skew the distribution with many exogenous causes: they could profuse very little effort just before the sprint as they prepare for travel, or on the other hand, some developers might do a lot beforehand to make their code look better.
- **KDE PIM Timings:** The evaluation of KDE PIM sprints is problematic due to their timing. Each KDE PIM sprint occurs within around the first week of a new year. It is possible that the productivity for the week before a KDE PIM sprint is reduced in this new year period.

Figure 5. Commits during KDE PIM Sprints

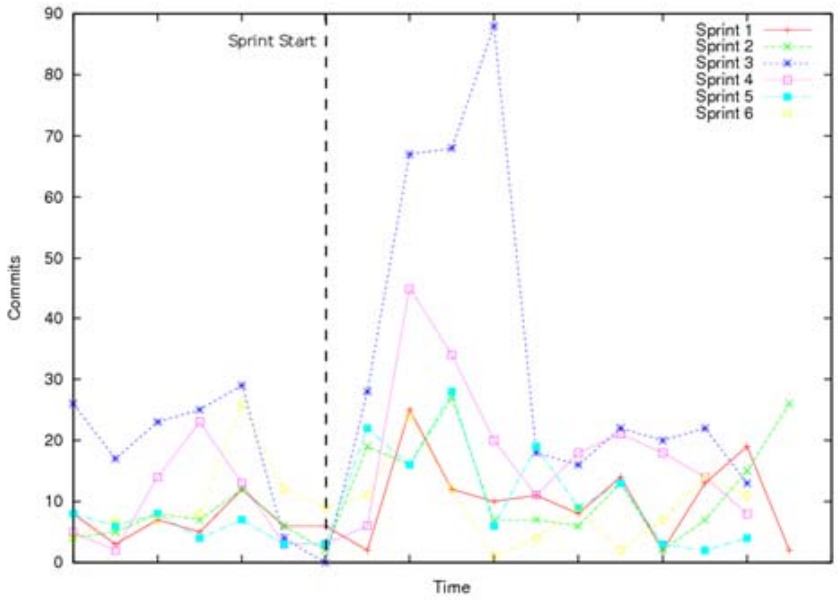


Table 4. Average commits-per-day during plone and KDE PIM Sprints

		Median		Average		Test of HP1 – Commits-per-day

FURTHER WORK AND CONCLUSION

This article provided a research study into the increasing phenomenon of mixed software development paradigms, when blending together some aspects, practices or shared tools. From the theoretical standpoint, both the Agile and Free Software methodologies have been studied in the past, and several shared concepts have been identified. The Agile paradigm has been deemed as the "commercial'' counterpart of the Free Software approach in many respects, and Free Software developers have been reported in

Table 5. LOCs-per-day in the sprints, as compared with the seven days immediately after the sprints. For the first three KDEPIM sprints, and the fifth Plone sprint, no LOCs data is available from the SVN servers.

Average				
		During the sprint	7 days after the sprint	Test of HP2 – LOCs per day
Plone	Sprint 1	0.63	8.29	x

the past to have adopted Agile techniques and practices. Still, no rigorous studies have been carried out to evaluate the results and the effects when a development approach (*i.e.*, Free Software) incorporate a practice (sprinting) belonging to another paradigm (*i.e.*, Agile).

Recent empirical research has looked beyond the usual data sources for indicators of quality within Free Software development projects. As such, measuring aspects of the developer community has become of interest (SQO-OSS, 2008). Within this article, commits-per-day was

presented as a simple metric for developers productivity and it was shown how it can be used to measure the impact of events within the release cycle, specifically developer sprints. Through this metric, it was also possible to characterise an Free Software project based on its "base rates'', *i.e.* the global average and median of the accomplished productivity.

Two Free Software projects were selected for study, Plone and KDE PIM: the rationale of this selection was based on a reported use of the sprinting practices in the two projects, and insider knowledge was available due to one author being part of one of the projects. The first project had a larger number of sprinting events, attended by an increasing amount of developers. The second had sprint events just once in a year, and overall only 6 events have been recorded. Two research hypothesess were formulated: first, the productivity during the sprinting events increases with respect to the base rates observed in a Free Software project. Second, the sprinting event has a follow-up effect on productivity, and the amount of commits per day increases after the events, compared to the period before.

Results and insider knowledge showed a composite picture: the Plone project had just 2 sprints during which the productivity increased over the base rates, whereas all the KDE PIM events produced a larger amount of commits per day than the average. It was reported also that Plone meetings hosted an increasing numbers of developers, which could hint a higher cost of coordination of efforts. On the other hand, results showed that within Plone, the sprint events have lately started to show an increasing productivity after the event (compared to before), whereas the earlier meetings did not achieve the same levels. The sprints in KDE PIM, instead, always increased the rate of commits per day: less frequent, and more focused meetings have been deemed responsible for this pattern.

Further work has been identified in further studying the quality of the alleged increased productivity: the code committed during the events should be analysed in order to assess its quality compared to the average baseline within the project. Its complexity should also be assessed: Free Software developers should consider whether to commit large amounts of new code, but with higher complexity, or to commit smaller portions, but with an overall lower complexity. assessed: Free Software developers should consider whether to commit large amounts of new code, but with higher complexity, or to commit smaller portions, but with an overall lower complexity.

ABSTRACT

This chapter presents Agile SPI, a framework in which the main goal is to motivate small and medium size enterprises (SMEs) towards improving and certifying their software development processes. This framework was born in the SIMEP-SW project where a software process improvement model for supporting process improvement in the

Colombian software industry context was built. We present Agile SPI, its origin, development, principles, architecture, main components, and the initial experiences.

INTRODUCTION

Nowadays, the software industry represents an important economical activity; it offers different possibilities for business and it aims to be a great opportunity for developing countries. In Latin American countries, the software industry is usually immature; companies face an undisciplined process and that means quality is unpredictable (Mayer&Bunge, 2004). Not only will it be impossible to plan and manage quality without a mature environment, but also when we achieve it, we will not know why and we could not repeat it (Hurtado, Pino, & Vidal, 2006). The Latin American software industry has grown smoothly, so the generation of strategies for achieving the software process improvement (SPI) environment that would allow organizations to take advantage of effective software processes. Software quality assurance through software process improvement is one of the strategies software companies could engage in with two goals: the first one is to improve the quality process so that they can get into a new market, and the second one is the need for their processes, like administrative units, to become more efficient and effective (Pino, Garcia, Ruiz, & Piattini, 2006).

One of the characteristics of the Latin American software industry is that it is mainly formed by small and medium size enterprises (SMEs). Most of these companies did not have a defined software process improvement project basically due to the great initial investment required and the disadvantage of their personnel competitiveness on the software process areas. The special characteristics of small companies cause that processes improvement programmes must be applied of a way particular and visibly different from the typical way the great organizations do it, this is not as simple as the fact to consider these programmes as versions to minor scale of great organizations (Richardson, 2001; Storey, 1982).

Agile SPI (Hurtado et al., 2006) is a framework SPI based on a strategy for institutionalization the software process in the small organizations context. For the process to be sustained, process behaviour needs to be integrated into the organization's culture. A process is institutionalized when it is followed consistently and performed naturally by everyone involved in performing the process activities. This will happen when the SME has in place a framework for software process improvement appropriate, for that reason Agile SPI is composed by three components:

- Two light models, a light reference model and an evaluation model, with a set of processes which are typically used by the Colombian small software organizations.
- Agile process for supporting a project SPI. A process SPI model for guiding a SPI program of way agile. A process definition model for supporting the implementations of improvements.

In the context of the SIMEP_SW[1] project, a pilot experience was carried out in order to validate the theoretical results of this research. Some programs SPI in a Colombian software development companies was implemented according to the guidelines suggested by Agile SPI. The results were analysed for validating our model and improving it.

In the second section is presented the background. The third section presents the Agile SPI origins including a description of the SIMEP-SW project and its developing. Agile SPI, its principles, architecture and main components are presented in the fourth section. The study cases are presented in the fifth section. Finally, the sixth section presents the main conclusions and describes perspectives.

BACKGROUND

The software industry is characterised for a fast product innovation but not by the process refinement. Software process improvements are required to increase the productivity of software companies. Generally, it is the aim to increase the quality of the produced software and to keep budget and time. Quality models for software process improvements were developed in context of large organisations and multinational companies. In the Latin American software industry, there are many problems in a SPI efforts because they are based on models created for others contexts (geographical, human, sizes of organizations, technologies used, process users and others factors). In some countries like Colombia, most of the organizations are small, with undisciplined behaviour, ad hoc process and absence of process focus. The same situation is presented in most of the countries of the world, even in development countries exists a great capacity in small enterprises. The models and technologies associated to the process must be adapted to the organization's needs. The quality models usually do not consider the factors of success for the companies, such as profitability, competitiveness, strategy of market and satisfaction of users (Conradi & Fuggetta, 2002).

The traditional frameworks focuses the efforts for the discipline and the risk reduction. Nowadays, the software products looks for the competitiveness: faster, better, and cheaper. Inside the focus of SPI models, Conradi and Fuggetta (2002) present three differences: process assessment, process refinement, and process innovation. Models like CMMI contribute to assessment and refinement focus, however the Quality Improvement Paradigm (QIP) contributes to innovation focus through the reuse concept. Printtzel and Conradi (2001) presented a taxonomy in order to compare the SPI frameworks based on some causal relations between process quality and process quality. They compare CMMI, ISO, ISO/IEC 15504, QIP, Experience Factory (EF), Gode Question Metric (GQM), and Software Process Improvement for better Quality (SPIQ). This strategy was important for defining the causal relations for Agile SPI.

Latin American countries have been concerned in recent years about software quality and development processes in their own industry, becoming as a main feature in increasing product quality (Bedini, Llamosa, Pavlovic, & Steembecker, 2005). For example, the "MoProSoft" model from Mexico and the "MR.MPS" from Brazil, amongst others that could be mentioned.

In Mexico, the MoProSoft model has been developed - "Modelo de Procesos para la Industria de Software" (Oktaba, 2005) (Processes Model for the Software Industry). This model is based on ISO 9001:2000, ISO/IEC 15504-2:1998 y CMM. MoProSoft aims to provide the software industry in Mexico with a model based on the best international practices. This model is at the same time easy to understand, simple to apply and economical to adopt. It seeks to assist organizations in standardizing their practices, in the assessment of their effectiveness and in the integration of ongoing improvement. MoProSoft defines three process categories: organizational, management, and operation. It specifies three parts for each process categories: a general definition, practices, and a guide for adjustments. A tenet of its improvement strategy is that the organization should establish its own strategy for the setting up of the processes defined by the model. The processes should evolve in alignment with the suggestions for improvement. The organization's strategic plan will be reached with increasingly ambitious goals being set all the time. In this way the organization can reach maturity progressively, by this ongoing and continual improvement in its processes.

In Brazil, the MPS.BR project (Weber, Araújo, Rocha, Machado, Scalet, & Salviano, 2005) has been developed. Its basis lies in ISO/IEC 12207:2002, CMMI e ISO/IEC 15504:2003. The MPS.BR project has two models: a Refer-

ence Model for the software improvement process– MR_MPS along with a Business Model for the software improvement process– MN_MPS. MN_MPS defines the elements and interactions involved in the certification of the organization by implementing MR_MPS in two ways: first one for an organization and second one for a group of organizations together (thus managing to make it more affordable for SMEs). MR_MPS is made up of maturity levels, along with an assessment model. The maturity level is organized in two dimensions: capability and process. The process maturity is classified into seven levels: optimized, managed quantitatively, defined, almost completely defined, partially defined, managed, and partially managed. Process areas are attributed to each maturity level based on the levels of CMMI. This is so as to ensure a gradual and fully appropriate implementation in Brazilian SMEs. The implementation level of the practices, associated with each process area, is evaluated by means of indicators.

In the previous models have been set out explicitly no improvement strategy for guiding an improvement process. Agile SPI improvement strategy is based on providing the organization with an agile process which supports the basis for addressing a SPI Program.

In Blowers and Richardson (2006); Garcia, Graettinger, and Kost (2006); Scott, Jeffery, Carvalho, D'Ambra, and Rutherford (2001); Wangenheim, Weber, Rossa Hauck, and Trentin (2006), among others, are observed others related efforts to software process improvement in small software organizations.

Agile SPI was developed inside to SIMEP-SW project (An Integrated System for the Improvement of Software Development Processes), between the 2004 to 2006 years, supported by the University of Cauca, Colciencias and some Small enterprise of South Colombian.

Agile SPI - Process is an agile process of software processes improvement, which can be used as guide for the implementing of a software process improvement program in SMEs. Agile SPI - Process takes as premise the precepts of the Agile Manifesto and the requirements for a light SPI, which have been adapted to the necessities of a software processes improvement program for small software enterprises. These are:

1. The highest priority is to satisfy the client's necessity through the early and continuous delivery of significant improvements to the development process because of Agile SPI - Process provides a light and agile process of software processes improvement.
2. There are not stable requirements of improvement. For this reason, the diagnosis is a key phase. Even so, requirements of improvement that arise will be prioritized and welcomed as it is feasible to carry out them.
3. To give frequently improvements of the software process.
4. An improvement program with Agile SPI - Process should be based on the effective collaboration among the consultants, the improvement group, the top management, the development group, the SQA group, marketing and other dependences related with the SPI project.
5. To build projects around motivated individuals toward the improvement of individual, group, and organizational processes. To give them the opportunity and the support that they need and to offer to them trust so that they carry out the tasks.
6. The most efficient and effective form of communicating round trip information inside an improvement team is through face-to-face conversation.
7. The maturity of process, as the average performance of the projects, should be the main measure of the progress improvement. The base measurements to measure the performance are the productivity and the quality.

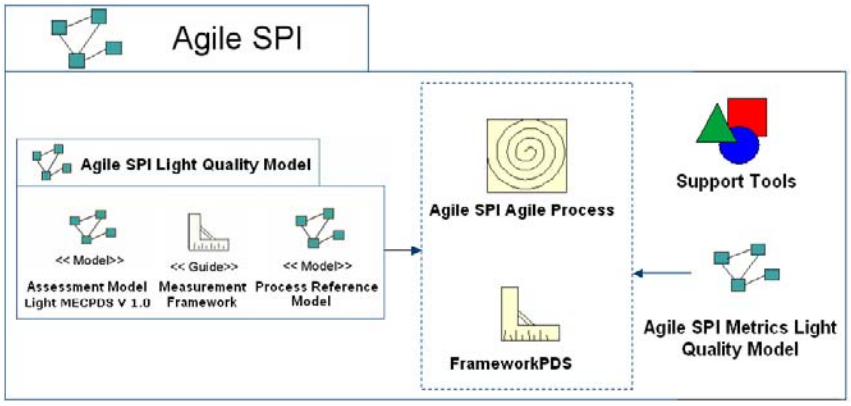
8. Agile SPI - Process promotes the sustained development. The work must be continuous and indefinite.
9. Agile SPI - Process promotes a technical and management infrastructure, appropriate to support the process improvement.
10. Agile SPI - Process promotes the conformation of a dynamic organizational infrastructure, based on objectives, not in control strategies.
11. Agile SPI - Process promotes the continuous learning as a key discipline. The objective of this discipline is to allow knowing the work, to meditate about this and to adjust the work through short and concise iterations.
12. Agile SPI - Process promotes the effective conformation of the teams proposed by its infrastructure, it worries about the quality of the human work to carry out.

Agile SPI aims to support process improvement for the Colombian software industry. Its main goal was to motivate small and medium size companies towards improving and certifying their development processes. The framework must include practical recommendations for process implementation, in order to facilitate their internalisation by a person when following the process and institutionalisation by organizations when everyone follows the common process and the process discipline is enforced, and also it should consider a tool for process definition. In the context of the SIMEP-SW project, a pilot experience was carried out in order to apply the theoretical results of this research. Inside these project researchers of University of Cauca and some small enterprise worked for to analyse, design, and proof the different models and strategies for improve the local industry in the Popayán and Cali cities. Some strategies was adopted in addition to the Agile Model, requirements for a company to achieve a maturity level CMMI using: agile practices, adoption of reuse strategies like software product line and adoption of agile methods for implementing some practices, and a collaborative focus for improve the humans process. The most important contribution of SIMEP-SW project was its participation in the project Competisoft Project[2]. This new project supported by CYTED aims "To increase the competitiveness level of the Latin American Software SMEs by means of the creation and diffusion a methodologic framework.

Framework Agile SPI for Software Process Improvement

Agile SPI is a framework based on models lightweight, international standards, agile improvement, and agile practices. Agile SPI promotes an improvement with lacking of agility, promotes the agility with quality and recognizes in the innovation the most promissory source for the improvement of all the aspects that involves a process: people, methods, techniques, and tools. The SMEs will be able to create its processes, if these do not exist, following its principles and needs, or will be able to follow the cycles and the models, if it is supporting a process previously defined and wants to improve it. The improvement focuses in the quality of the product and the productivity of the organization, from which to organize by disciplines it aims towards the securing of the quality of the product and that to maintain the process agile and to innovate in their components is the principles that move the productivity. The discipline give reliability in the process, a mature process offers to certain degree of reliability on the accomplishment of a project in the organization as far as the reach of its goals of quality and costs. The agility and the innovation are present to support the feature in which the traditionally mature processes never will consider, under this approach the process must be agile with the purpose of being able to be reconciled to a SME with its time and resource restrictions. And of course, the process must be

Figure 1. Agile SPI architecture



defined and institutionalised, and prudentially controlled.

Agile SPI Architecture

Agile SPI is an integral model for the Software Process Improvement that exhibits the following characteristic: the main focus is SME. In this kind of organisations there are a great interest in innovating as far as products or services, but not as far as the organization processes. The processes are ad-hoc, light or chaotic, there is not great motivation in improving this aspect. Agile SPI was created like a framework for supporting improvement in software SME. Usually, the quality assurance is more focused to the test than to have a complete program of quality control. In the best of the cases the quality assurance is focused to control processes instead of facilitating its improvement. The academy is looking for new forms of development, nevertheless is more focused in the technologies than in the processes or methodologies. The improvement of process is considered a remote work, reaching for a great companies. It isn't known that the improvement is possible from teams and its members up to enterprise level. The universities that distribute the work related to the improvement show the models of quality, their interpretation and all the required infrastructure to do it, this can motivate to work to improve the state-of-the-art, but it don't to change the state of the practice.

The Agile SPI architecture has been influenced by the structure of models defined by SEI and ISO, but considering others quality models of processes well-known internationally. Agile SPI structure has a main components of an improvement program: an improvement guide and models for supporting, Agile SPI - Light Quality Model and Agile SPI - Light Metrics Model. There are two dynamic elements of the static structure: the conceptual model Framework SPD (Software Process Definition) and the improvement process. The Figure 1 depicted the Agile SPI architecture.

Due to the context SME, Agile SPI is a complete framework (it is not a model that says what makes lack, but like complementing the process). It is functional, its application facilitate the complete operation of an improvement program. It search be understandable, to guarantee his learning and application: therefore it is simple and clear. It aims to be usable, that implies that the strategy must be clear, intuitive, flexible and adjustable to the needs. It aims to motivate, that implies that the improvements must be visible in short periods, it is necessary the sufficient motivation to guarantee

that the improvement project has continuity. It aims to implement a model for applying in the SME, that is to say, to apply the model must be viable (economically) and feasible (attainable). The flexibility of Agile SPI is based on its models independence. Agile SPI can be used in different contexts with several models.

The framework Agile SPI presents the following components:

- A guide for an improvement program called Agile SPI Process. It is a process that guides the efforts of a SME towards the adjustment of a software process adequate to its necessities. This process is the framework of reference for the management of the improvement projects, the framework includes a method, models, infrastructure, techniques, and the tools of support.
- A light quality model for Agile SPI. Agile SPI Light Quality Model integrated process and product, and that guides the organization of the people and the teams, the disciplines and the areas of work associated to the definition, application and improvement of the process towards a defined maturity level. Defining a set of processes which are typically used by the Colombian SME's. It allows to identify and diagnose problems of the industry as far as the process and that allows to planning the improves according to a process reference model.
- A light measurement model for Agile SPI. Agile SPI Light Measurement Model allows to measure: the performance of the process in the projects in which it is applied, to improve the estimations of the projects through the measurement of the effort, the maturity of the this and improvement of the process within the framework of a program SPI.
- A conceptual and technological frame for the definition, visualization and application of processes, Agile SPI - Conceptual Framework. This conceptual frame is based on metamodel SPEM - Software Process Engineering Metamodel, this frame is the conceptual base on which SPI and the tools of support are supported to all the models of Agile SPI. This conceptual framework allows to relate elements of process, with the elements of the quality model, with the model of evaluation, the measurement model. For example, the disciplines concept is a separating element of areas of the process and the structure of Agile SPI are defined based on this concept.

Agile SPI Focused on Disciplines and Process Components

Agile SPI allows to organize an improvement project, very integrated with the development projects, and each organizational and technical change is to handle through an experience with the purpose of visualizing in an isolated way, if the improvement really has been done. The improvement project follows a process of defined by Agile SPI - Agile Process, this is organized by small iterations, in which the different disciplines participates in a greater or smaller degree of intensity. Agile SPI is based on the concept of discipline like representative areas of process like approach of assurances. In the approach of refinement of the process Agile SPI defines the concept of capacity, which usually measures the quality degree of a discipline with respect to a quality model or process model. See Figure 2.

Agile SPI define three dimensions for improvement: capability, innovation, and agility with the following causal relationship:

- F1 (Discipline)→F2 (Capacity)→ Quality(Process)→ Quality (Product)
- F1' (Component Process)→F2'(Innovation in Component)→Quality (Process) → Quality (Product)
- F1'' (Discipline)→F2''(Agility on Discipline)→Performance(Process)→Productivity

(Project).

- F1’’’(Component Process)→F2’’’ (Learning in component)→Quality (Process) && Performance (Process)→Quality (Product) & Productivity (Project).

Therefore F1 + F1’+ F1’’+ F1’’’ ⇔ Quality(Product) & Productivity (Project)

The process components are created, evolved and replaced according to the results of the evaluation and the priorities of each organization. The improvement is visualized by disciplines and components of process. The improvements are organized by iterations that lean in the technology of processes to manage the configuration of process.

The Agile SPI: Process Life Cycle

Agile SPI – Process is an agile and light process of software processes improvement, which can be used as guide for the execution of a software processes improvement program in small and medium enterprises (SMEs). Light because enterprises like the SMEs which possess certain characteristics as: low resources, light processes, small human resource, limited economic availability, and so forth, need a model that supports an improvement program that consider the real characteristics of their industry, besides offering quick results in their improvement programs.

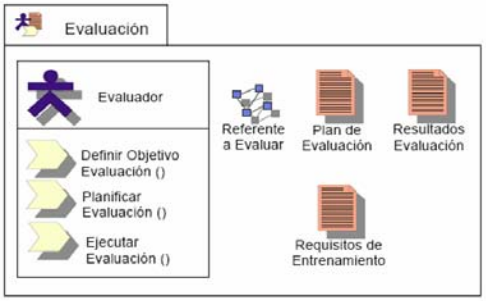
Agile SPI – Process is an iterative and incremental process is based on improvement cases, which has the feature of throwing quick results of improvement because it allows to create mini improvement programs that include improvement cases inside a global improvement program. The improvement cases are atomic units of improvement in the processes areas that have been selected to be improved either because the enterprise follows a certification or because for it its priority is to improve a specific process.

Obtaining quick improvement results will allow in consequence to the improvements to be visible from the early phases of the improvement project, more agile and quicker as the mini improvement programs finish depending on the prioritize criteria that the enterprise has defined previously. This seeks to maintain the personnel’s motivation toward the improvement program, through permanent improvement results, removing the risks of the project in the first phases, to focus the major effort in the areas that the enterprise considers more important for its business. The life cycle is highly influenced by the iterative and incremental life cycle models present in many development processes such as RUP, XP, Scrum, among others; since the improvement projects cover extensive requirements and they impact the whole organizational structure of any enterprise, some characteristics of these models have been adapted to create a complete, agile, and less bureaucratic improvement process and sensitive to the related activities with the management (meetings, documents, infrastructure, etc.).

Agile SPI – Process allows the parallelism between iterations or improvement programs, being very advantageous because improvements can be developed in processes areas where an evident independence exists. In the certification processes, the appraisal before the beginning of an improvement program is very important, since this allows estimating which processes areas the enterprise has and which is their maturity level. Currently many tools exist with which the process areas of an enterprise can be appraised according to a particular quality model, for example: CMMI (SEI, 2002) in its continuous or staged version, ISO/IEC 15504 (ISO_15504-2, 2004; ISO_15504-5, 2006), ISO 9001-2000 (ISO_9001, 2000), and others. In this aspect Agile SPI – Process can be used independently of the quality model and evaluation method, for example this it can be used if a continuous or staggered CMMI has been selected or if the choice is ISO 15504.

Figure 2. Example of discipline in Agile SPI framework.

Discipline **Evaluation** *from* **Agile SPI Process** *(e.g. apply to* **Discipline ABC.***)*
Apply to **Process Component:** *{Description - Artifacts - Roles - Workflow }* **Disciplina ABC**
Based on **Quality Model Component:***{Description, Goals, Practices, Measurement , verification }* **Disciplina ABC.**
With **Evaluation Component:** *{ Measurement, verification }* **Disciplina ABC.**
Measurement Component: {Productivity, defects} **Disciplina ABC.**
Composed by:
{Roles: Evaluator - Artifacts: Referent Quality Models and sub artifacts, evaluation plans, evaluation results, training requirements - Roles: evaluator - Workflow: Define evaluation objective, planning evaluation, execute evaluation}



Agile SPI – Process also includes, documents, and explains a set of disciplines to any improvement process that can be applied in smaller or bigger measure in each one of the phases in which several iterations can be developed, for this we were based on the Software Development Unified Process. When we identify in Agile SPI – Process the disciplines to be developed in each one of the improvement process phases, we are assuring that personnel involved in the improvement program will be able to visualize in major detail the behaviours and activities that should be developed inside an improvement program. We have considered as vital disciplines in any improvement program: Training, Improvement Management, Evaluation, Analysis, Design, Installation, Process Configuration Management and Learning.

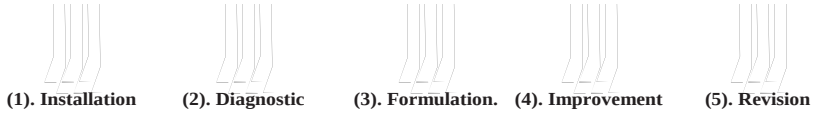
The Agile SPI - Process Phases

Agile SPI - Process describes a process of software processes improvement in five phases, next we will see each one of them:

The Figure 3 presents to Agile SPI – Process phases: installation, diagnostic, formulation, improvement, and revision of the program.

- **Phase 1 —Installation:** This is the beginning phase for Agile SPI - Process. Motivation should exist in the organization to undertake a plan of improvement of its processes. In this phase a proposal of improvement is created based on the business needs, which will help to guide to the organization through each one of the following phases, this proposal must be approved by the management to guarantee this way the assignment of the necessary resources for the improvement project. During this phase some objectives also are defined, which are established from the enterprise needs. Besides a feature very important in Agile SPI - Process is offering a guide in the improvement of software processes, also provides a management infrastructure, which describes the way in which committed people are organized inside the improvement effort; this infrastructure organizes the improvement

Figure 3. Agile SPI: Process phases modeled under SPEM



effort keeping in mind a management team (MT), a processes technology team (PTT), and improvement teams (ITs); these teams have been influenced by the infrastructure proposed by IDEAL, complementing it with the creation of effective groups proposed by the methodology TSP (Team Software Process), adapted by Agile SPI - Process like TSPI (Team Software Process Improvement) and some of the features in the administration of a project using the SCRUM methodology.

- **Phase 2—Diagnostic:** In this phase, a program has already begun toward the improvement of processes and the work that here is realized is fundamental for the realization of the following phases. An appraisal is realized to know the general state of the enterprise processes, besides an analysis of the results that will allow establishing the priority of the improvement cases, allowing this way to create one of the main products of this phase known as "improvement general guide or plan."
- **Phase 3—Formulation:** In this phase, the most high-priority cases of improvement (1 or 2) are taken to improve according to the results of the appraisal made in the previous phase and the planning of a first improvement iteration is realized, this with the purpose of finding a measure of the effort that serves as base for the estimate of the effort that the rest of the improvement project will take to carry out.
- **Phase 4 —Improvement:** In the improvement phase of Agile SPI - Process the whole effort of the improvement cases is managed based on the estimate made in the improvement execution plan created in the previous phase and consequently the plans corresponding to the different iterations of the process areas to improve or to create are developed. A document should exist where it is registered the execution of the test pilots, the evaluation of the new process areas or the new improvement that has been realized. If the pilot plans have been developed satisfactorily it is necessary to create acceptance and institutionalisation plans of the new processes in the enterprise.
- **Phase 5 —Revision:** In this phase, a feedback is made before starting the beginning phase again. In this phase all the learned lessons and the metrics developed to measure the accomplishment of the objectives serve like knowledge base or source of information for people involved in the following improvement cycle. With all the gathered information the realized work should be evaluated and all the elements related with the execution of the program SPI should be corrected or adjusted, how for example the established infrastructure, the used methods, the communication channels and if the solutions to the identified problems were the appropriate ones.

Iterations in Agile SPI - Process and Their Correspondence with the SCRUM Development Process

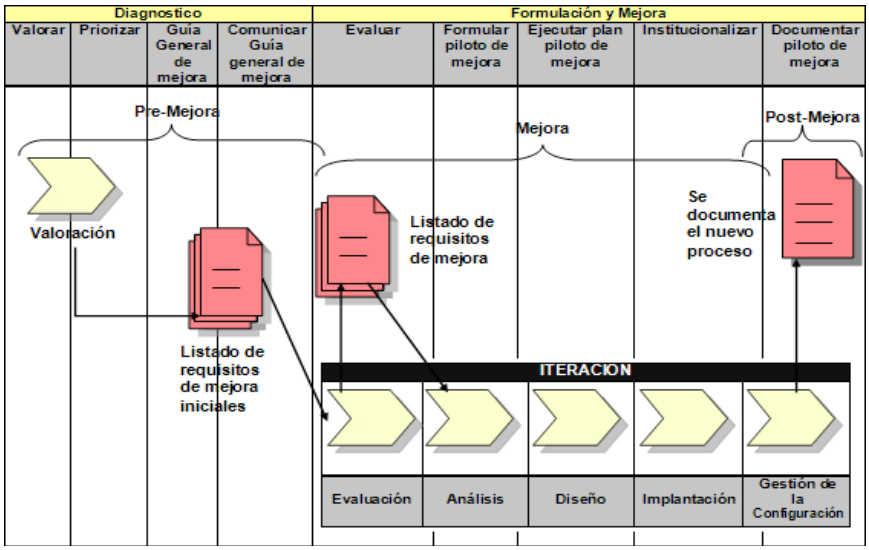
Iteration in Agile SPI - Process is a mini cycle improvement that allows advancing the development and management of a set of improvement cases in an independent way. The iteration is the integrative concept between phases and disciplines. The phases can be decomposed in time and space (teams) for iterations, and an iteration, being itself a guide of improvement, is defined starting from a set of disciplines according to the phase where it is and to the characteristics of the improvement project. Iterations in Agile SPI - Process is a very important part in the Software Processes Improvement because this way independent improvements can be developed, and so to deliver quicker improvements. The key resides in developing iterations in areas that are independent of others, this way the work in them can be achieved in parallel, and the work of improvement that in them is developed doesn't cause problems; nevertheless it is necessary to keep in mind that a dependence can exist among areas, in that case it is necessary to study which is the impact that could create a improvement case and based on this to order the way of how improvements will be developed in the other improvement cases.

The iterations for the improvement cases in the diagnostic, formulation, and improvement phases can be developed in a similar way to the Scrum development process with its sprints, in each one of them there are three phases: pregame, game, and postgame, which we have called them pre-improvement, improvement, and post-improvement.

Improvement cases can be seen as Sprint Backlog (Improvement Requirements List), which have been divided in smaller improvement tasks, and these in their entirety and respective correspondence would conform a specific area that would be seen as a prioritised list of features required by the improvement, which has been obtained thanks to the appraisal achieved to the enterprise; in relation to the SCRUM development process this list of features is created starting from the client's requirements and is called Product Backlog (Initial Improvement Requirements List).

In Figure 4 is showed how the iterations in Agile SPI - Process are developed. In the pre-improve-

Figure 4. Iterations in Agile SPI – Process



ment phase the appraisal discipline is developed for the creation of the product accumulation or delay registry (initial improvement requirements list). After prioritising the areas to improve, an improvement requirements list is created through the evaluation of each area, which allows defining an order for each one of the improvement iterations to execute. It is important the assistance of dependences net to order in a detailed way the improvements to achieve in the selected areas. The dependences net allow identifying the improvement cases or the number of iterations to develop for each area. The improvement cases are the activities that compose the area.

After identifying the improvement cases that compose the area and ordering them through dependences net, the next is the analysis and design of the new or improved process and its respective installation and documentation.

Agile SPI - Process also adapts and proposes techniques and practices for the teams conformation and management, it exemplifies the net of dependences that can exist between areas or practices that they compose depending of the quality model and the way of treating this characteristic. It also documents and identifies the milestones and workproducts resultants of these and it proposes some control and management templates for the improvement process, all this inside a guide that doesn't seek to be an extensive model but a friendly, easy to use, and agile process of software processes improvement independent of the quality model and evaluation methods, and the most important: adapted to the characteristics of the Colombian software industry and in general Latin America.

At the moment, Agile SPI - Process is in its verification stage, we are achieving improvement programs in some small enterprises of our region, which have demonstrated from the beginning a great interest to improve their processes after they knew the advantages that it can bring to the quality of their products, as well as the benefit of having an international certification. With this process for the software processes improvement we seek to help to the enterprises not only of our region but also of Latin America to reach a level that allows them to compete with companies like the American and European in software development.

STUDY CASE: APPLYING AGILE SPI IN A SMALL SOFTWARE ORGANIZATION

This section aims to present the applying the framework Agile SPI in the organization SIDEM Ltda (http://www.sidemltda.com) - Colombia.

SIDEM Ltda.

Sidem Ltda. is an organization in Cauca's Valley, from the Cali City, Colombia. This organization is dedicated to production, integration, maintenance, supporting and consulting of Information Systems, using multiplatform design to support the constant challenges of productive processes.

Nowadays, Sidem Ltda. account with more of 300 clients in Colombia, using his management and financial solution. These solutions allowed to this organization to be classified by the "Cámara de Comercio de Occidente" like enterprising industrialists of the Cauca's Valley and to position itself like one of the best organizations in the Colombian south.

Experience with SIDEM Ltda.

Previous View to the Software Improvement Process

At the beginning six years ago, Sidem Ltda. was a small organization with four people, which one developed several activities. There were not defined roles or positions in a specific way and the software process was not documented. Two

years ago, Sidem Ltda. is growing because account with 18 persons: one person is in charge to assign activities of client support, 11 development engineers, 2 persons in marketing and management area, 2 people in quality area, and 2 persons in management jobs.

In Sidem Ltda there are not areas defined in a clear way, we just found defined one organizational structure of the organization with some activities and persons assigned to them, overlapping among them and without documents. For that reason, there are chaos and immaturity process without relation. Almost all the time, the activities are not finished in time, budget and quality, because it is necessary to attend other problems and activities, which wastes too much time.

As a first step, Sidem Ltda created a Quality Team composed by 2 people. This team was created because:

- Defining software development activities
- Madding documents about development process
- Establishing control activities on the development process.

But, due to problems inside Sidem Ltda, the Quality Team finished madding another activities and that first effort was lost.

Any way, we founded another effort for improving process. Sidem Ltda there was implemented two projects with adoption UP Methodology and UML. The results obtained were a very good results for the team project. These results showed a better management and planning of the activities.

Initial Phase

First, we made an install meeting with Sidem Ltda. The Sidem manager presented the organization and necessities. Also, he was concerned about immature process, bad development methodologies, problems with estimating time and cost and chaos generated in management and development of projects.

The SIMEP-SW Team explained that an improvement project could be one of the most important solutions and decisions that Sidem Ltda should take and support. Consequently, the organization decided to initiate an improvement project based on the components of the Framework Agile SPI.

The SIMEP-SW Team proposed: 2 researchers to develop the appraisal on CMMI, 1 researcher in charged to obtain the development process implicit in the organization and 2 researchers in charge to manage all the Improvement Program based on Agile SPI Process, 1 researcher as a leader team.

At the same way, Sidem Ltda assigned an Improvement Team, working as a management bridge for supporting all the necessities during the Improvement Program. Fits, schedules, meetings, and necessary material in each meeting program. Each meeting should be programmed with two weeks before, with the objective of having a suitable management time.

When the two teams were ready for starting activities, we started a training about:

- Bases of Agile SPI Process.
- Reference Model CMMI.
- Presenting study cases.

After of training to the people, the SIMEP-SW Team prepared a plan or proposal of improvement with: objectives of improvement, the identified necessities of business, the necessary resources, roles and people, strategies in the development of the objectives, a schedule of work, and possible risks in the course of the project. Finally, we presented the improvement program to Sidem Ltda and we installed it.

Diagnose Phase

In order to know the current state of Sidem Ltda the SIMEP-SW Team made an appraisal in Level 2 CMMI, using SPQA Web Tool, which we would obtain an overview in the process capacity. With this process baseline, we could apply evaluations more detailed. In according to the results and recommendations generated by SPQA.WEB Tool:

- In a general way, acceptable requirement management. Then it is necessary an improvement of this area because this allows to collect and to control requirements, and to avoid deviations throughout the development of products.
- Project Planning, Project tracing and subcontract management are in a low degree of implementation. In consequence, the organization cannot control its development processes.
- Quality Assessment, configuration management and metrics are not implemented in the organization.

With the appraisal results, it was established a meeting with the objective to obtain the areas that should be improve. Finally, we obtained the next conclusion:

CMMI Engineering Area

- First Iteration: Management Requirements and Development Requirements.
- Second Iteration: Technical Solution and Product Integration.
- Third Iteration: Validation and Verification

Later, we began the training activities about:

- CMMI Engineering Area
- Management Requirements and Development Requirements

The work product about to improvement program was updated and new dates were specified. We planned evaluation activities in process areas selected. With the evaluation results, we designed a improvement plan based on the priorities selected by Sidem Ltda. Consequently, we generated a work product, which was communicated in all the organization, the objective was to establish a feeling of responsibility in the areas selected.

Formulation Phase

Nowadays, the Improvement Project in the organization Sidem Ltda is in this phase.

Once we made formulation of improvement cases, we will prepare the design of improved process. We will implement pilot proof. After studying of the impact, if the improvement is positive and advisable for the Sidem Ltda Process, we will deployment in formal way all of the new improved process.

This study case presents the results of one first stage or cycle for the first period of a improvement project. In this study case until now the deployment of Agile SPI Process has been made during eight weeks. Two weeks for Installing, two weeks in diagnose phase and four weeks for the formulation phase. We hoped that the Improvement Project will continue and that always represent one of the primary targets of the Sidem Ltda.

Learned Lessons

The following lessons have been learned as a result of application Agile SPI Process:

- The management leader must agree in applying Agile SPI - Process and promoting.
- Communicate to all organization about the applying Agile SPI - Process.
- Develop tasks in a smooth way.
- It is important to obtain results quickly to maintain motivation in the improvement program.

- The improvement process must be planned, be managed and the necessary resources for their development are due to assign.
- Good communication between organization team leader and improvement team leader.
- If the personnel available in the organization is limited, then to make sure that parity in the assigned work exists.
- There is a confusion between processes and structure.
- The organization not always knows clearly his processes.
- Many organizations have a implicit process, it is necessary to document.
- Training about modelling of the business process and the development process.
- It is not necessary planning objectives of improvement that will not be carried out.
- If an improvement first cycle has not all support and commitment, it is better to choose not to generate negative experiences in organization with unsuccessful improvement programs.
- The improvement process does not have to be left, to be suspended, or diminished because of other events, this it must be considered of greater or equal importance than the projects or diverse situations that can be presented in the organization.

CONCLUSIONS AND PERSPECTIVES

The software process in the organizations requires evolution and maturity to approach to its different stakeholders and continues improvement and Assessment. Therefore, they have arisen different kinds of Frameworks normally named like Quality Models and Improvements methods for supporting SPI strategies. In this paper we had presented Agile SPI, a framework based on models lightweight, international standards, agile improvement, and agile practices. Agile SPI is mainly influenced by the SMEs, the agile manifest, Conradi-Fuggetta thesis, and the existent and well-know models. Agile SPI includes a flexible infrastructure based on Discipline concept of SPEM and define five contexts for applying itself. The initial improvement is measured by the product quality and the project productivity, and then by the process capability and agility. Agile SPI is differenced of others Frameworks due and this is complete respect to the models, is flexible due a permits the inclusion of other models and was designed for SME industry. Agile SPI respect to other Latin-American initiatives is different because include a improvement model. This model permits apply the framework to an improvement program.

ACKNOWLEDGMENT

This work has been funded by the following projects: SIMEP_SW financed by Colciencias and University of the Cauca; COMPETISOFT (506AC287) financed by CYTED and MECENAS (PBI06-0024) granted by the “Junta de Comunidades de Castilla-La Mancha.”

Chapter 8.9
Machine Learning and Value-Based Software Engineering

Du Zhang
California State University, USA

ABSTRACT

Software engineering research and practice thus far are primarily conducted in a value-neutral setting where each artifact in software development such as requirement, use case, test case, and defect, is treated as equally important during a software system development process. There are a number of shortcomings of such value-neutral software engineering. Value-based software engineering is to integrate value considerations into the full range of existing and emerging software engineering principles and practices. Machine learning has been playing an increasingly important role in helping develop and maintain large and complex software systems. However, machine learning applications to software engineering have been largely confined to the value-neutral software engineering setting. In this paper, the general message to be conveyed is to apply machine learning methods and algorithms to value-based software engineering. The training data or the background knowledge or domain theory or heuristics or bias used by machine learning methods in generating target models or functions should be aligned with stakeholders' value propositions. An initial research agenda is proposed for machine learning in value-based software engineering.

INTRODUCTION

Software engineering research and practice thus far are mainly conducted in a value-neutral setting where each artifact in software development such as a requirement, a use case, a test case, a defect, and so forth, is treated as equally important during a software system development process (Boehm, 2006a). There are a number of shortcomings of such value-neutral software engineering (Biffl et al. 2006): (1) its exclusion of economics, management sciences, cognitive sciences, and humanities from the body of knowledge needed to develop successful software systems;

(2) its delimitation of software development by mere technical activities; and (3) its failure to explicitly recognize the fact that software systems continue to satisfy and conform to evolving human and organizational needs is to create value. Value-based software engineering (VBSE) is to integrate value considerations into the full range of existing and emerging software engineering principles and practices so as to increase the return on investment (ROI = (benefits–costs)/costs) for the stakeholders and optimize other relevant value objectives of software projects (Biffl et al. 2006; Boehm, 2006a, Wang, 2007).

Machine learning (ML) has been playing an increasingly important role in helping develop and maintain large and complex software systems. However, machine learning applications to software engineering have been largely confined to the value-neutral software engineering setting (Zhang, 2000; Zhang & Tsai, 2003; Zhang & Tsai, 2005; Zhang & Tsai, 2007, Wang, 2008). In this paper, the general message we attempt to convey is to apply ML methods beyond the value-neutral software engineering setting and to VBSE. The training data or the background knowledge or domain theory or heuristics or bias used by ML methods in generating target models or functions for software development and maintenance should be aligned with stakeholders' value propositions (SVPs) and business objectives. Even though the transition to VBSE from the traditional value-neutral setting is necessarily evolutionary because not all the theories, infrastructures, methodologies and tools for VBSE have been fully developed yet, there are a number of agenda items for VBSE (Boehm, 2006a).

The goal of the road map in VBSE is to make software development and maintenance decisions that are better for value creation (Boehm, 2006a). On the other hand, the hallmark of ML is that it results in an improved ability to make better decisions. VBSE offers a fertile ground where many software development and maintenance tasks can be formulated as ML problems and approached in terms of ML methods. The purpose of this paper is to describe an initial research agenda for ML applications to VBSE with regard to the identified areas in VBSE (value-based requirement engineering, architecting, design and development, verification and validation, planning and control, risk/quality/people managements, and a theory of VBSE (Boehm, 2006a)).

The rest of the paper is organized as follows. Section 2 offers an overview of the related work. Section 3 highlights some important concepts in VBSE. In Section 4, we describe an initial research agenda for ML applications in VBSE. Finally Section 5 concludes the paper with remark on future work.

RELATED WORK

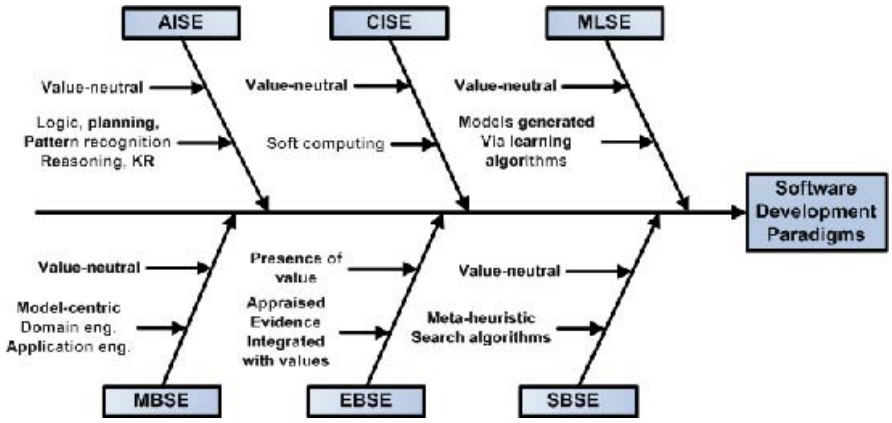
In this section, we provide a brief account for some of the major and emerging software development paradigms which are related to the main theme of this paper. The intent is to highlight the state-of-the-art in the software development landscape and to delineate differences between the existing approaches and the one advocated in this paper.

Besides machine learning in (value-neutral) software engineering (MLSE), there are a number of related and emerging software development paradigms: search-based software engineering (SBSE), evidence-based software engineering (EBSE), model-based software engineering (MBSE), artificial intelligence in software engineering (AISE), and computational intelligence in software engineering (CISE). Figure 1 highlights their similarities and differences.

MLSE

ML falls into the following broad categories: *supervised* learning, *unsupervised* learning, *semi-supervised* learning, *analytical* learning, *reinforcement* learning, and *multi-agent* learning.

Figure 1. Emerging software development paradigms



Each of the categories in turn includes various learning methods. Supervised learning deals with learning a target function from labeled examples. Unsupervised learning attempts to learn patterns and associations from a set of objects that do not have attached class labels. Semi-supervised learning is learning from a combination of labeled and unlabeled examples. Analytical learning relies on domain theory or background knowledge to learn a target function. Reinforcement learning is concerned with learning a control policy through reinforcement from an environment. Multi-agent learning is an extension to single-agent leaning. There are of course many emerging learning methods such as argument based machine learning, interactive learning, and so forth.

In software development, there are processes, products and resources (Fenton & Pfleeger, 1997). Processes are collections of software related activities, such as constructing specification, detailed design, or testing. Products refer to artifacts, deliverables, documents that result from a process activity, such as a specification document, a design document, or a segment of code. Resources are entities required by a process activity, such as personnel, software tools, or hardware. The aforementioned entities have internal and external attributes. Internal attributes describe an entity itself, whereas external attributes characterize the behavior of an entity (how the entity relates to its environment).

A partial list of ML applications in value-neutral software engineering includes (Zhang, 2000; Zhang & Tsai, 2003; Zhang & Tsai, 2005; Zhang & Tsai, 2007): (1) Predicting or estimating measurements for either internal or external attributes of software development processes, products, or resources (e.g., quality, size, cost, effort). (2) Discovering either internal or external properties of the processes, products, or resources (e.g., loop invariants, objects, normal operation boundary, equivalent mutants, process models, architecture information, aspects). (3) Transforming products to accomplish some desirable or improved external attributes (e.g., serial programs to parallel ones, improving software modularity). (4) Synthesizing or generating various products (e.g., evolutionary testing for

generating test data, project management rules and schedules, design repair knowledge, design schemas, programs/scripts/agents). (5) Reusing products or processes (e.g., similarity computing, locating/adopting software to specifications, generalizing program abstractions, clustering of components). (6) Enhancing processes (e.g., extracting specifications from software, acquiring specification consistent with scenarios). (7) Managing products (e.g., managing knowledge for software development process).

There were many different ML methods utilized in the aforementioned applications (instance-based learning and case-based reasoning, neural networks, decision trees, genetic algorithms, genetic programming, inductive logic programming, explanation-based learning, Bayesian learning, concept learning, analytic learning, support vector machines, multiple instance learning, active learning, clustering, association rules, and expectation maximization) (Zhang, 2000; Zhang & Tsai, 2003; Zhang & Tsai, 2005; Zhang & Tsai, 2007). A common property in the existing ML applications is that the software engineering issues were tackled solely from technical or logical perspectives (involving mappings and transformations, for instance) without the value dimension being taken into consideration (e.g., how to increase ROI for the stakeholders and optimize other relevant value objectives of software projects). The training data or the background knowledge or domain theory or heuristics or bias used by the ML methods in generating target functions did not contain any value propositions.

SBSE

SBSE treats software development tasks as a search problem with regard to a set of constraints and a search space of possible solutions (Clark et al, 2003; Harman & Jones, 2001). It relies on evolutionary algorithms, gradient ascent/descent, particle swarm intelligence, simulated annealing, tabu search or colony optimization techniques to tackle the software development or maintenance tasks. So far its applications have included the following areas in software engineering: requirement engineering, project planning, cost estimation, maintenance, reverse engineering, refactoring, program comprehension, service oriented tasks, quality assessment, and testing (structural, functional, non-functional, state-based properties, robustness, stress, security, mutation, regression, interaction, integration, and exception). Value considerations are not explicitly incorporated into the search process.

EBSE

EBSE is geared toward improving the decision making process related to software development and maintenance by integrating current best evidence from research with practical experience and human values (Dyba, Kitchenham & Jorgensen, 2005; Kitchenham, Dyba & Jorgensen, 2004). There are five main steps in EBSE as delineated in (Dyba, Kitchenham & Jorgensen, 2005; Kitchenham, Dyba & Jorgensen, 2004): (1) Translate a relevant problem or need of information into an answerable question. (2) Glean the literature for the best available evidence that can be used to answer the question. (3) Assess the evidence for its validity, impact, and applicability. (4) Combine the appraised evidence with practical experience, and stakeholders' values and circumstances to make decisions. (5) Evaluate performance and find ways to improve it. One important strength of EBSE is that it does take into consideration the SVPs.

MBSE

MBSE is centered on software models, modeling, and model transformation technologies. It is a disciplined approach to developing and extending a product family. The software models provide the necessary information to support, economically and effectively, future changes to a software

product family. By focusing on models that capture and consolidate developers' understanding of a family of software products, reusable assets can be developed that satisfy a wide variety of uses and can be utilized to analyze existing software to quickly compose or synthesize new solutions for subsequent products in a product family (Brown, Iyengar & Johnston, 2006; MBSE, 2008; Sendall & Kozacaynski, 2003). The goal is to achieve the benefits of reuse, shorter time to market, product maintainability and higher quality. However, value considerations are not prominently factored into the paradigm.

MBSE consists of two parallel engineering processes: domain engineering and application engineering, and sanctions the concepts of product families, a production system, and software assets (the reusable resources needed in application engineering such as domain models, software architectures, design standards, communication protocols, code components and application generators).

Domain engineering is a process of analysis, specification and implementation of software assets in a domain which are used in the development of multiple software products. Application engineering is a process that develops software products from software assets.

Many organizations have model-based development paradigm in place: Microsoft's Software Factory (Greenfield & Short, 2004), Lockheed Martin's Model Centric Software Development (Waddinggton & Lardieri 2006), and NASA JPL's Defect Detection and Prevention (Feather et al, 2008).

CISE

In CISE (or software engineering with computational intelligence), soft computing techniques such as fuzzy sets, neural networks, genetic algorithms, genetic programming and rough sets (or combinations of those individual technologies) are utilized to tackle software development issues recently [Khoshgoftaar, 2003a; Khoshgoftaar, 2003b; Lee, 2003a; Lee, 2003b; Pedrycz & Peters, 1998). The results have been largely confined to the value-neutral setting.

AISE

The application of some general artificial intelligence techniques to software engineering (AISE) has produced some encouraging results (Mendonca & Sunderhaft, 1999; Mostow, 1985; Partridge, 1998; Rich & Waters, 1986; Tsai & Weigert, 1993). Some of the successful AI techniques include: knowledge-based approach, automated reasoning, expert systems, heuristic search strategies, temporal logic, planning, and pattern recognition. Again the results thus far have been obtained in the value-neutral setting.

VBSE

The essence in VBSE is that the approach aims at aligning software development and maintenance with customer requirements and strategic business objectives. It offers a framework where SVPs are incorporated into the technical and managerial decisions made during software development and maintenance (Biffl et al. 2006; Grunbacher et al, 2006).

Value includes product, process and resource attributes. Value attributes include: profits (generated from products), strategic positioning in market share, utility, relative worth, reputation, customer loyalty, innovation technology, cost reduction, quality of life, improved productivity.

An emerging agenda of issues in VBSE has been proposed in (Boehm, 2006a), that includes the following areas:

- Value-based requirements engineering. The key objectives include recognition of success-critical stakeholders, elicitation of SVPs, and reconciliation of SVPs.

- Value-based architecturing. The goals are to iron out the discrepancy between a system's objectives and achievable architectural solutions.
- Value-based design and development. The goals are to ensure that a software system's objectives and its value considerations are embodied in the software's design and development practices.
- Value-based verification and validation. The objectives are to ascertain that a software solution meets its value objectives and that V&V tasks are sequenced and prioritized as investing activities.
- Value-based planning and control. The objectives in this area are to incorporate the value delivered to stakeholders into the product planning and control techniques.
- Value-based risk management. How to factor the value considerations into principles and practices for risk identification, analysis, prioritization, and mitigation is the main focus in this area.
- Value-based quality management. The goals are to prioritize desired software quality considerations with respect to SVPs.
- Value-based people management. The tasks involve building stakeholder team, manage expectations, and reconcile SVPs.

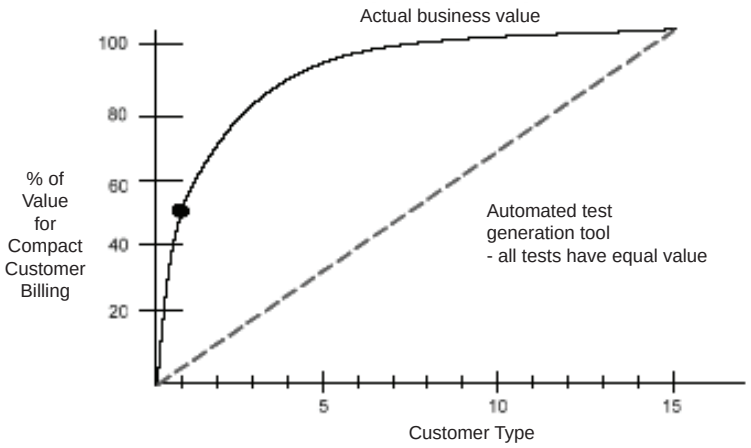
A number of concepts need to be in place to facilitate ML applications in VBSE. Of the important and useful concepts is the one about Pareto modules.

Figure 2 depicts a reported study in (Bullock, 2000) where the dotted line reflects the value-neutral practice in which an automated test data generation tool assumes that all tests have the same value. The Pareto curve for the empirical data, on the other hand, displays the actual business value where one of the fifteen customer services accounted for 50% of all billing revenues.

We refer to module(s) that realizes a service of such a high positive impact on the system's ROI as *Pareto modules.* They are the most important modules of a software system with regard to its product value. How modules contribute to a product's overall value hinges on reconciled SVPs.

For a given software system Ω, we can define a set $\mathbf{M}_{\Omega}$ of modules, a valuation function υ, and a value set $\boldsymbol{V}$ as follows:

Figure 2. Pareto distribution for varying test case value



$\mathbf{M}_\Omega = \{m_i \mid m_i \in \Omega\}$;
$\upsilon: \mathbf{M}_\Omega \rightarrow [0, 1]$;
$\boldsymbol{V} = \{\upsilon(m_i) \mid m_i \in \mathbf{M}_\Omega\}$

The valuation function υ can be defined by SVPs and has the following properties:

- $0 < \upsilon(m_i) \leq 1$, for all i;
- $\Sigma\, \upsilon(m_i) = 1$.

We define a partially ordered set $(\boldsymbol{V}, \leq)$ where $\leq$ is a binary order relation on $\boldsymbol{V}$ and satisfies reflexivity, anti-symmetry and transitivity for all elements in $\boldsymbol{V}$. We say that $\upsilon(m_p)$ is a *principal element* for $(\boldsymbol{V}, \leq)$ if we have the following:

$\forall \upsilon(m_j) \in \boldsymbol{V}\ [\upsilon(m_j) \leq \upsilon(m_p)]$[1]

We use ρ to denote the *principal module* as specified by $\upsilon(m_p)$. We define a *principal-element-ordered subset* $\boldsymbol{V}_{[mi, \rho]}$ of $\boldsymbol{V}$ and its cumulative value $\mu_{[mi, \rho]}$ as follows:

$\boldsymbol{V}_{[mi, \rho]} = \boldsymbol{V} - \{\upsilon(m_k) \mid \upsilon(m_k) \leq \upsilon(m_i)\}$
$\mu_{[mi, \rho]} = \Sigma\, \upsilon(m_j) \in \boldsymbol{V}_{[mi, \rho]}$

Now we are in a position to formally define the concept of Pareto modules.

Definition 1. *Given a threshold value* $\tau \in (0, 1]$, *we identify a principal-element-ordered subset* $\boldsymbol{V}_{[mi, \rho]}$ *such that* $\tau = \mu_{[mi, \rho]}$. *Modules in* $\boldsymbol{V}_{[mi, \rho]}$ *are referred to as Pareto modules with regard to* τ.

If $\tau < \mu_{[mi, \rho]}$ but removing any m_j from $\mu_{[mi, \rho]}$ would result in $\tau > \mu_{[mi, \rho]}$, then the condition of $\tau = \mu_{[mi, \rho]}$ is relaxed to that of $\tau \leq \mu_{[mi, \rho]}$.

In practice, to identify the Pareto modules, we can apply the Pareto principle as follows: (1) arrange modules according to the descending order of their value contributions to the total product value; (2) calculate cumulative percentages of contribution with regard to all the modules; (3) draw a line graph based on the cumulative percentages and modules involved; and (4) identify the most valuable modules with regard to an established threshold value.

The next set of useful concepts pertains to modules with varying defect densities. Item four on the software defect reduction top ten list in (Boehm & Basili, 2001) indicates that "*About 80% of the defects come from 20% of the modules, and about half the modules are defect free*." Thus, there are three types of modules here in terms of defect density measure: *defect-intensive modules* that refer to those 20% of the modules causing the bulk (80%) of defects, *defect-prone modules* that are the next 30% of modules containing the remaining 20% of defects, and *defect-free* modules that include the rest 50% of modules. In practice, there are different ways to specify the criteria for defect-intensive and defect-prone modules. Here we describe a possible way to define modules with varying defect densities that is based on the software Constructive Quality Model COQUALMO (Huang & Boehm, 2006; Steece, Chulani & Boehm, 2002).

In COQUALMO, there are two components: a defect introduction sub-model that estimates the rates at which software requirements, design and code defects are introduced, and a defect removal sub-model. Let KSLOC stand for thousand source line of code. The calibrated baseline (nominal) defect introduction rates DIR_{nom} in COQUALMO are given in Table 1 (Boehm et al, 2000; Huang & Boehm, 2006; Steece, Chulani & Boehm, 2002):

Thus the total of the nominal defect introduction rate for a software system is 60 defects/KSLOC. Multiplying the baseline rates with the size of a software system provides the total number of defects introduced in each of the three categories (requirements, design, and coding) and summing them up returns the total number of nominal defects introduced into a software system. We use $\mathbf{NDI}_\Omega$ to denote it[2]. Scaling $\mathbf{NDI}_\Omega$ down to the module level (e.g., if a module m has a size of 100 SLOC, then its nominal coding defects are

Table 1. Nominal defect introduction rates

Type of Defects	**DIR_{nom}**
Requirements defects	DIR_{nom}(req) = 10/KSLOC
Design defects	DIR_{nom}(des) = 20/KSLOC
Coding defects	DIR_{nom}(cod) = 30/KSLOC

scaled down to 3 accordingly), let $\mathbf{NDI}_m$ denote the nominal defects introduced into a module *m* and $\mathbf{TDI}_m$ the actual total number of defects in *m*. we can define defect-intensive and defect-prone modules using $\mathbf{NDI}_m$ as follows.

Definition 2. *A module m is defect-intensive if its defect introduction rates (in some or all three categories) are higher than the nominal rates DIR_{nom}. Therefore, we have* $\mathbf{TDI}_m > \mathbf{NDI}_m$.

Definition 3. *A module m is defect-prone if its defect introduction rates (in some or all three categories) are lower than the nominal rates DIR_{nom}. Therefore, we have* $\mathbf{TDI}_m \leq \mathbf{NDI}_m$.

There is another dimension about the nature of defects. Item five on the software defect reduction top ten list in (Boehm & Basili, 2001) states that "*About 90% of the downtime comes from, at most, 10% of the defects.*" We refer to those 10% of the defects as *impact defects*.

Definition 4. *Impact defects (or high risk defects) are those defects that result in loss of human life or high financial loss. This translates into the Required Reliability (RELY) ratings of Extra High, Very High and High according to the Constructive Cost Model (COCOMO) II (Boehm et al, 2000), and rough Mean Time Between Failures (MTBF) of one million hours, 300K hours and 10K hours, respectively (Boehm et al, 2004; Huang & Boehm, 2006).*

Definition 5. *Non-impact defects are those defects that result in moderate recoverable loss, easily recoverable loss or slight inconvenience. They have the RELY ratings of Nominal, Low and Very Low, and the MTBF of 300 hours, 10 hours and 1 hour, respectively (Huang & Boehm, 2006).*

The definitions of the aforementioned concepts will pave the way for ML to be utilized in various VBSE agenda issues. Further effort will be needed to fully develop concepts that accommodate comprehensive ML applications in VBSE.

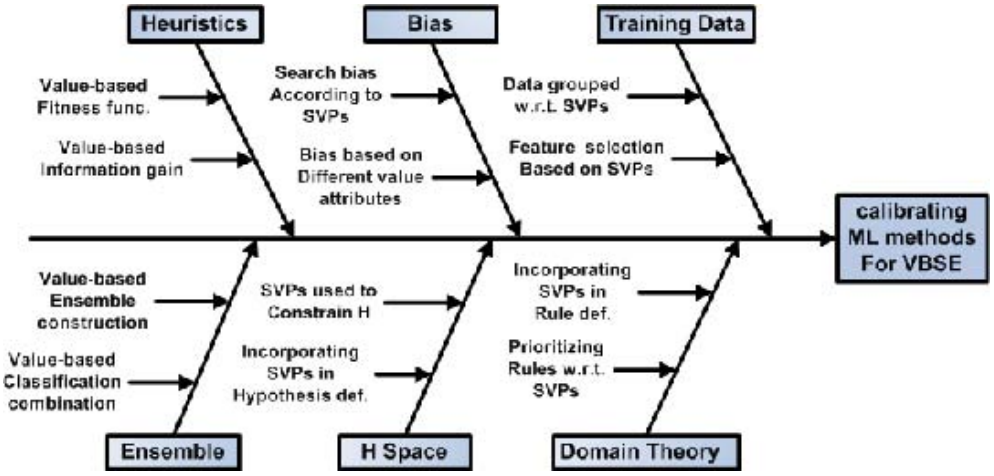
RESEARCH AGENDA FOR ML IN VBSE

In this section, we first discuss some general issues on how to calibrate ML methods for VBSE tasks. Using Boehm' VBSE agenda in (Boehm, 2006a) as a roadmap, we then describe some preliminary agenda items on how ML can help with the goals, objectives and tasks in VBSE.

How to Calibrate ML Methods

ML methods formulate various general hypotheses, models and target functions through either

Figure 3. Calibrating ML methods for VBSE



observed training data, or some background knowledge or domain theory, or a combination of both. The generalization process during leaning also hinges on certain adopted bias or heuristics.

To calibrate ML methods for VBSE tasks, the fundamental issue is how to incorporate SVPs from the business value level into the technical level details of ML model generation process. Specifically, this translates into the following issues: how to use SVPs to select data features and to group training data, how to incorporate SVPs into domain knowledge representation, how to prioritize rules, based on SVPs, in domain knowledge during model generation, how to include SVPs in defining search bias, how to use different value attributes in defining domain-specific biases for the search process, how to utilize SVPs in defining hypotheses and constraining hypothesis space, how to factor SVPs into ensemble construction and classification combination process when ensemble learning is used to generate models, and how the value concept plays a role in defining ML method-specific heuristics (e.g., fitness function, information gain measure).

Value-Based Requirements Engineering

For the objectives in value-based requirements engineering, techniques such as business case analysis, requirements prioritization and release prioritization have proven to be effective (Boehm, 2006a).

ML methods can be utilized to assist business case analysis, and requirements and release prioritization. Specifically, ML methods can be used to predict or estimate software cost, software size, software development efforts, and release prioritization and timing. These prediction, estimation or cost models would help stakeholders gain insight on what capabilities are not feasible with regard to budget, schedule and technology constraints, which features of a system are most important and attainable, and which aggregate of capabilities will meet stakeholders' critical needs

given the resource constraints. This in turn will assist stakeholders in prioritizing and reconciling potential conflicting value propositions. Possible ML methods for generating the models include: decision trees, Bayesian learning, neural networks, genetic algorithms, genetic programming, case-based reasoning, and inductive logic programming.

Value-Based Verification and Validation

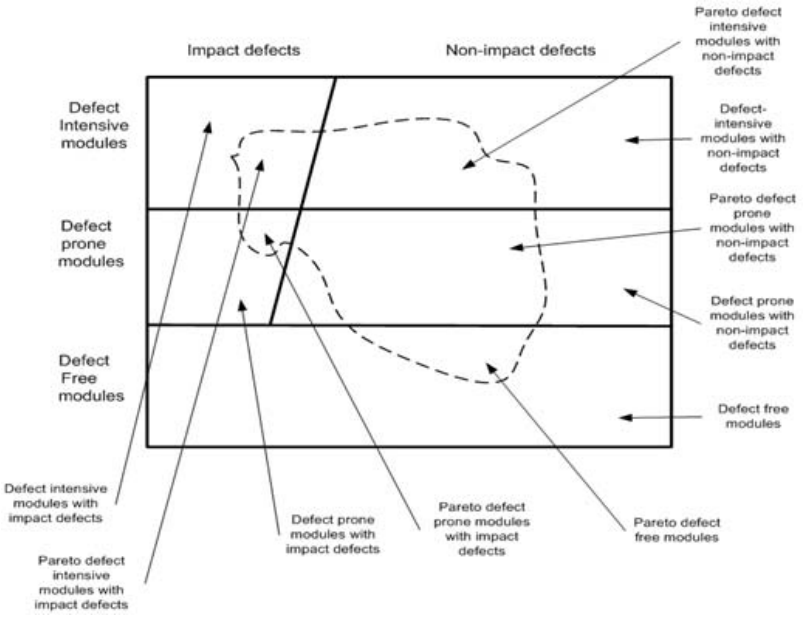
The key techniques in value-based V&V are value-based and risk-based testing techniques (Boehm, 2006a). Central to those techniques is how to align SVPs with the technical level details in test construction and execution and how to sequence and prioritize testing activities as investing activities (Ramler, Biffl & Grunbacher, 2006).

Since we have the following concepts in place: Pareto modules, defect-intensive and defect-prone modules, impact and non-impact defects (see Section 3), we can use an SVPs-based approach to identify modules of the aforementioned types and decompose the overall test data generation process for a given software system into a sequence of test data generation cycles with each focusing on some specific testing objective(s). Based on the types of modules and the types of defects, we have a landscape of possible testing scenarios as shown in Figure 4.

The dotted area indicates Pareto modules that can also be defect-intensive, defect-prone, or defect-free modules, and that can intersect with impact or non-impact defects.

From a value-based standpoint, to improve the return on investment, we want to make sure to first maximize the success rate of Pareto modules and

Figure 4. Possible testing scenarios



to minimize the chance of having impact defects that devastate the value contribution. Afterwards, attention can be focused on non-impact defects and non-Pareto modules. Thus, a prioritization of cycles can be generated that is driven by the value consideration and allows the most critical modules with regard to SVPs to be thoroughly tested first. For instance, we may have the following priority groups: (1) the top priority is to thoroughly test Pareto modules with impact defects; (2) the next priority is to devote attention to modules with impact defects; (3) the third priority group is to deal with Pareto modules with non-impact defects or defect-free Pareto modules; and (4) the last priority group consists of modules with non-impact defects or defect-free modules[3].

For each cycle, a number of ML methods can be utilized to generate test cases for different classes of modules. Some possible ML methods include: genetic algorithms (McMinn, 2004), genetic programming, inductive logic programming and rule-based active learning.

There are a number of issues here: how many cycles are needed, what goes to each cycle, and how cycles are prioritized.

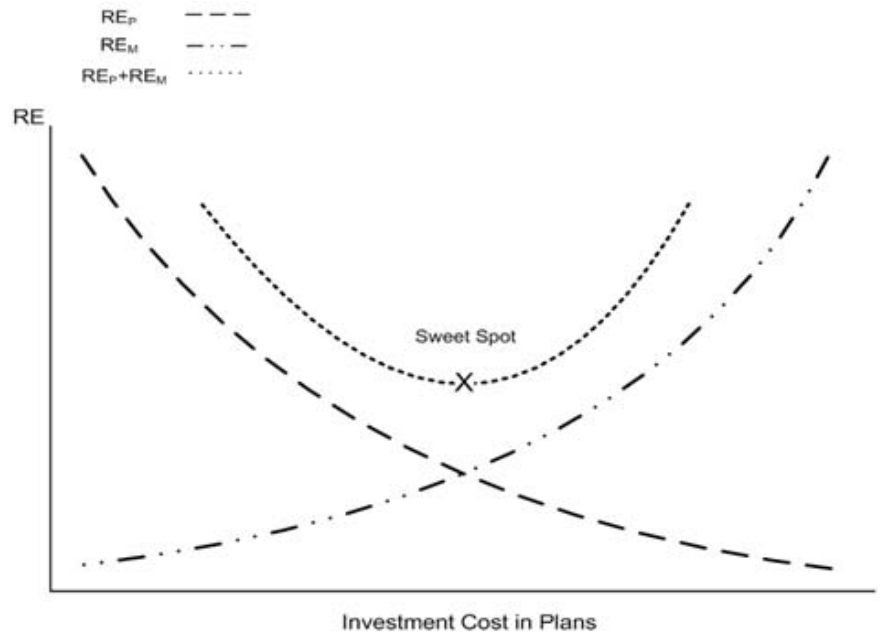
Value-Based Risk Management

There are a number of techniques for value-based risk management: the risk-based "how-much-is-enough" techniques, the risk-based analysis for project predictability, the risk-based simulation, and the risk-based testing techniques (Boehm, 2006a).

A pivotal concept in risk management is the *risk exposure* (***RE***) involved in a prescribed course of actions. ***RE*** is defined as follows:

$$\boldsymbol{RE} = \boldsymbol{P}(\mathcal{L}) \times \boldsymbol{S}(\mathcal{L})$$

Figure 5. Sweet spots for different risk exposure profiles



where $\boldsymbol{P}(\mathcal{L})$ is the probability of loss $\mathcal{L}$, and $\boldsymbol{S}(\mathcal{L})$ is the size of loss. $\mathcal{L}$ can be defined based on any value attribute as discussed in Section 3. In the risk exposure profile analysis (Boehm, 2006b), there is a dichotomy between planning and market share as the value attribute: inadequate planning results in little delay to capture market share but high ***RE*** due to oversights and rework (RE_P in Figure 5); excessive planning reduces the chance of major problems but at the expense of high ***RE*** because of time-to-market delays (RE_M in Figure 5).

ML methods can be used to help find the "sweet spot" for different risk profiles and different risk exposure profiles (see Figure 5). Depending on the circumstances, either inductive learning, or analytical learning, or a combination of inductive and analytical learning can be deployed.

Value-Based Design and Development

To ensure that a system's objectives and its value considerations are embodied in the software's design and development practices, the software traceability techniques play an important role (Boehm, 2006a). During the software development process, many artifacts are produced and maintained: documents, requirements, design models, test scenarios, and so forth. Trace dependencies are to identify relationships among those artifacts and the quality of the trace dependencies should reflect the value of the artifacts they attempt to bridge. This is vital for a number of reasons, from documentation, program understanding, impact analysis, consistency checking, reuse, quality assurance, user acceptance, error reduction, cost estimation, to customer satisfaction.

ML methods can be used to establish value-based trace dependencies among different artifacts. Methods such as instance-based learning (case-based reasoning), inductive logic programming, rule-based learning would lend themselves to the task.

Value-Based Quality Management

ML methods can be used to generate predictive models for identifying high risk or fault prone components as an integral part of the quality management. Because of the need to align desired quality properties with SVPs, value considerations should be, directly or indirectly, involved in defining or contributing to those quality properties. SVPs should also help prioritize the desired quality factors.

ML methods that are appropriate for the task include: decision trees, genetic programming, neural networks, case-based reasoning, inductive logic programming, and concept learning.

CONCLUSION

VBSE offers a new software development paradigm that recognizes the importance of business and customer value considerations. It tackles the decision making process in software development and maintenance from a value-based perspective. In this paper, we discuss the issue of ML applications to VBSE. Because ML applications to software engineering thus far have been largely confined to the value-neutral setting, we reviewed the landscape in the field and took a closer look at the emerging agenda for VBSE to find out how ML can be positioned to play a larger role in VBSE. We propose some guideline on how to calibrate ML methods to accommodate the value considerations that are so critical in accomplishing VBSE agenda items. Using Boehm' VBSE roadmap as a guide, we describe some preliminary agenda items on how ML can help with the goals, objectives and tasks in VBSE.

The take-home message of this work is two-fold: VBSE offers a ROI-conscious approach to software development and maintenance, and ML has an active and important role to play in various agenda items in VBSE.

The viability of ML applications in VBSE hinges on the outcomes of empirical studies, which will be pursued as our future work. How to solidify SVPs into various ML methods is an open issue worth studying.

Chapter 8.10
An Operational Semantics of Real-Time Process Algebra (RTPA)

Yingxu Wang
University of Calgary, Canada

Cyprian F. Ngolah
University of Calgary, Canada, & University of Buea, Republic of Cameroon

ABSTRACT

The need for new forms of mathematics to express software engineering concepts and entities has been widely recognized. Real-time process algebra (RTPA) is a denotational mathematical structure and a system modeling methodology for describing the architectures and behaviors of real-time and nonreal-time software systems. This article presents an operational semantics of RTPA, which explains how syntactic constructs in RTPA can be reduced to values on an abstract reduction machine. The operational semantics of RTPA provides a comprehensive paradigm of formal semantics that establishes an entire set of operational semantic rules of software. RTPA has been successfully applied in real-world system modeling and code generation for software systems, human cognitive processes, and intelligent systems.

INTRODUCTION

Real-time process algebra (RTPA) is a denotational mathematical structure and a system modeling methodology for describing the architectures and behaviors of real-time and nonreal-time software systems (Wang, 2002, 2003, 2006a, 2006b, 2007a, 2008a-c). RTPA provides a coherent notation system and a rigorous mathematical structure for modeling software and intelligent systems. RTPA can be used to describe both *logical* and *physical* models of systems, where logic views of the architecture of a software system and its operational platform can be described using the

same set of notations. When the system architecture is formally modelled, the static and dynamic behaviors that perform on the system architectural model, can be specified by a three-level refinement scheme at the system, class, and object levels in a top-down approach. Although CSP (Hoare, 1978, 1985), the timed CSP (Boucher & Gerth, 1987; Fecher, 2001; Nicollin & Sifakis, 1991), and other process algebra (Baeten & Bergstra, 1991; Milner, 1980, 1989) treated a computational operation as a process, RTPA distinguishes the concepts of meta processes from complex and derived processes by algebraic process operations.

Definition 1: *Operational semantics of a programming language or a formal notation system is the semantics perceived on a given virtual machine, known as the abstract reduction machine, that denotes the semantics of programs or formal system models by its equivalent behaviors implemented on the reduction machine.*

One way to define an operational semantics for a language or formal notation system is to provide a state transition system for the language, which allows a formal analysis of the language and permits the study of relations between programs (Jones, 2003; Plotkin, 1981; Schneider, 1995). An alternative way is to describe the operations of the language on an abstract deductive machine whose operations are precisely defined (Sloneger & Barry, 1995; Winskel, 1993). In operational semantics, the reduction machine is a virtual machine that is adopted for reducing a given program to values of identifiers modeled in the machine by a finite set of permissible operations (Louden, 1993; McDermid, 1995).

This article presents a comprehensive operational semantics for RTPA on the basis of an abstract reduction machine, which defines inference rules for repetitively reducing a system model in RTPA into the computational values of identifiers and data objects. The abstract syntaxes of RTPA are introduced, and the reduction machine of RTPA is elaborated. Based on these, the operational semantics of 17 RTPA meta processes and 17 RTPA process relations are systematically developed. A comparative analysis of a set of comprehensive formal semantics for RTPA may be referred to (Wang, 2007a). The *deductive semantics* of RTPA is presented in Wang (2006a, 2008b). The *denotational semantics* of RTPA is reported in Tan and Wang (2008).

THE ABSTRACT SYNTAX OF RTPA

On the basis of the process metaphor of software systems, abstract processes can be rigorously treated as a mathematical entity beyond sets, relations, functions, and abstract concepts. RTPA is a denotational mathematical structure for denoting and manipulating system behavioral processes (Wang, 2002, 2003, 2006a, 2006b, 2008a-c). RTPA is designed as a coherent algebraic system for software and intelligent system modeling, specification, refinement, and implementation. RTPA encompasses 17 meta processes and 17 relational process operations.

Definition 2: *RTPA is a denotational mathematical structure for algebraically denoting and manipulating system behavioural processes and their attributes by a triple, that is:*

$$RTPA \triangleq (\mathfrak{T}, \mathfrak{P}, \mathfrak{R}) \quad (1)$$

where

- $\mathfrak{T}$ is a set of 17 primitive types for modeling system architectures and data objects;
- $\mathfrak{P}$ a set of 17 meta processes for modeling fundamental system behaviors;
- $\mathfrak{R}$ a set of 17 relational process operations for constructing complex system behaviors.

Detailed descriptions of $\mathfrak{T}$, $\mathfrak{P}$, and $\mathfrak{R}$ in RTPA will be extended in the following subsections (Wang, 2007a).

The Meta Processes of Software Behaviors in RTPA

RTPA adopts the foundationalism in order to elicit the most primitive computational processes known as the *meta processes*. In this approach, complex processes are treated as derived processes from these meta processes based on a set of algebraic process composition rules known as the *process relations*.

Definition 3: *A meta process in RTPA is a primitive computational operation that cannot be broken down to further individual actions or behaviors.*

A meta process is an elementary process that serves as a basic building block for modeling software behaviors. *Complex processes* can be composed from meta processes using *process relations*. In RTPA, a set of 17 meta processes has been elicited from essential and primary computational operations commonly identified in existing formal methods and modern programming languages (Aho, Sethi, & Ullman, 1985; Higman, 1977; Hoare et al., 1986; Louden, 1993;

Table 1. The meta processes of RTPA

No.	Meta Process	Notation	Syntax
1	Assignment	:=	$y\mathbb{T} := exp\mathbb{T}$
2	Evaluation	$\hat{}$	$\hat{}_{\mathbb{T}} exp\mathbb{T} \rightarrow \mathbb{T}$
3	Addressing	$\Rightarrow$	$id\mathbb{T} \Rightarrow \text{MEM}[ptr\mathbb{P}]\ \mathbb{T}$
4	Memory allocation	$\Leftarrow$	$id\mathbb{T} \Leftarrow \text{MEM}[ptr\mathbb{P}]\ \mathbb{T}$
5	Memory release	$\not\Leftarrow$	$id\mathbb{T} \not\Leftarrow \text{MEM}[\perp]\mathbb{T}$
6	Read	$\gtrdot$	$\text{MEM}[ptr\mathbb{P}]\mathbb{T} \gtrdot x\mathbb{T}$
7	Write	$\lessdot$	$x\mathbb{T} \lessdot \text{MEM}[ptr\mathbb{P}]\mathbb{T}$
8	Input	$\|\gtrdot$	$\text{PORT}[ptr\mathbb{P}]\mathbb{T} \|\gtrdot x\mathbb{T}$
9	Output	$\|\lessdot$	$x\mathbb{T} \|\lessdot \text{PORT}[ptr\mathbb{P}]\mathbb{T}$
10	Timing	$\overset{@}{=}$	$@t\mathbb{TM} \overset{@}{=} \S t\mathbb{TM}$ $\mathbb{TM} =$ yy:MM:dd | hh:mm:ss:ms | yy:MM:dd:hh:mm:ss:ms
11	Duration	$\triangleq$	$@t_n\mathbb{TM} \triangleq \S t_n\mathbb{TM} + \Delta n\mathbb{TM}$
12	Increase	$\uparrow$	$\uparrow(n\mathbb{T})$
13	Decrease	$\downarrow$	$\downarrow(n\mathbb{T})$
14	Exception detection	!	! (@*e*S)
15	Skip	$\otimes$	$\otimes$
16	Stop	$\boxtimes$	$\boxtimes$
17	System	§	§(*SysID*ST)

Wilson & Clark, 1988; Woodcock & Davies, 1996). Mathematical notations and syntaxes of the meta processes are formally described in Table 1.

Lemma 1: *The essential computing behaviours state that the RTPA meta process system $\mathfrak{P}$ encompasses 17 fundamental computational operations elicited from the most basic computing, that is:*

$$\mathfrak{P} = \{:=, \blacklozenge, \Rightarrow, \Leftarrow, \not\Leftarrow, \gg, \ll, |\gg, |\ll, @, \triangleq, \uparrow, \downarrow, !, \otimes, \boxtimes, \S\} \quad (2)$$

As shown in Lemma 1 and Table 1, each meta process is a basic operation on one or more operands such as variables, memory elements, or I/O ports. Structures of the operands and their allowable operations are constrained by their types as described in previous sections. It is noteworthy that not all generally important and fundamental computational operations, as shown in Table 1, had been explicitly identified in conventional formal methods. For instances, the evaluation, addressing, memory allocation/release, timing/duration, and the system processes. However, all these are found necessary and essential in modeling system architectures and behaviors.

Process Operations of RTPA

Definition 4: *A process relation in RTPA is an algebraic operation and a compositional rule between two or more meta processes in order to construct a complex process.*

A set of 17 fundamental process relations has been elicited from fundamental algebraic and relational operations in computing in order to build and compose complex processes in the context of real-time software systems. Syntaxes and usages of the 17 RTPA process relations are formally described in Table 2. Deductive semantics of these process relations may be referred to (Wang, 2006a, 2007a, 2008a).

Lemma 2: *The software composing rules state that the RTPA process relation system $\mathfrak{R}$ encompasses 17 fundamental algebraic and relational operations elicited from basic computing needs, that is:*

$$\mathfrak{R} = \{\rightarrow, \curvearrowright, |, |\ldots|\ldots, R^*, R^+, R^i, \circlearrowleft, \rightarrowtail, \|, \square, |||, », \nleftrightarrow, \hookrightarrow_t, \hookrightarrow_e, \hookrightarrow_i\} \quad (3)$$

The Type System of RTPA

A type is a set in which all member data objects share a common logical property or attribute. The maximum range of values that a variable can assume is a type, which is associated with a set of predefined or allowable operations. A type can be classified as *primitive* and *derived* (complex) types. The former is the most elemental types that cannot further divided into simpler ones; the latter is a compound form of multiple primitive types based on given type rules. Most primitive types are provided by programming languages; while most user defined types are derived ones.

Definition 5: *A type system specifies data object modeling and manipulation rules in computing.*

The 17 RTPA primitive types in computing and human cognitive process modeling have been elicited from works in (Cardelli & Wegner, 1985; Martin-Lof, 1975; Mitchell, 1990; Stubbs & Webre, 1985; Wang, 2002, 2003, 2007a), which is summarized in the following lemma.

Lemma 3: *The primary types of computational objects state that the RTPA type system $\mathfrak{T}$ encompasses 17 primitive types elicited from fundamental computing needs, that is:*

$$\mathfrak{T} \triangleq \{\mathsf{N}, \mathsf{Z}, \mathsf{R}, \mathsf{S}, \mathsf{BL}, \mathsf{B}, \mathsf{H}, \mathsf{P}, \mathsf{TI}, \mathsf{D}, \mathsf{DT}, \mathsf{RT}, \mathsf{ST}, @e\mathsf{S}, @t\mathsf{TM}, @int\odot, \circledS s\mathsf{BL}\} \quad (4)$$

where the primitive types stand for natural number, integer, real, string, Boolean, byte, hexadecimal,

Table 2. The process relations and algebraic operations of RTPA

	Process Relation	Notation	Syntax
1	Sequence	$\rightarrow$	$P \rightarrow Q$
2	Jump	$\curvearrowright$	$P \curvearrowright Q$
3	Branch	|	$\Box exp\mathsf{BL} = \mathsf{T} \rightarrow P$ $\mid \Box\sim \rightarrow Q$
4	Switch	| … |	$\Box \exp\mathbb{T} =$ $\mathrm{i} \rightarrow P_i$ $\mid \sim \rightarrow \oslash$ where $\mathbb{T} \in \{\mathsf{N}, \mathsf{Z}, \mathsf{B}, \mathsf{S}\}$
5	While-loop	R^*	$\overset{\mathsf{F}}{\underset{\exp\mathsf{BL}=\mathsf{T}}{R}} P$
6	Repeat-loop	R^+	$P \rightarrow \overset{\mathsf{F}}{\underset{\exp\mathsf{BL}=\mathsf{T}}{R}} P$
7	For-loop	R^i	$\overset{n_N}{\underset{i_N=1}{R}} P(i\mathsf{M})$
8	Recursion	$\circlearrowleft$	$\overset{0}{\underset{i_N=n_N}{R}} P^{i\mathsf{M}} \circlearrowleft P^{i\mathsf{M}-1}$
9	Function call	$\rightarrowtail$	$P \rightarrowtail F$
10	Parallel	||	$P \mid\mid Q$
11	Concurrence	$\Box$	$\mathrm{P} \Box Q$
12	Interleave	|||	$P \mid\mid\mid Q$
13	Pipeline	»	$P \gg Q$
14	Interrupt	$\lightning$	$P \lightning Q$
15	Time-driven dispatch	$\hookrightarrow_t$	$@t_i\mathsf{TM} \hookrightarrow_t P_i$
16	Event-driven dispatch	$\hookrightarrow_e$	$@e_i\mathsf{S} \hookrightarrow_e P_i$
17	Interrupt-driven dispatch	$\hookrightarrow_i$	$@int_j\circledcirc \hookrightarrow_i P_j$

pointer, time, date, date/Time, run-time determinable type, system architectural type, random event, time event, interrupt event, and status.

In Lemma 3, the first 11 primitive types are for mathematical and logical manipulation of data objects in computing, and the remaining six are for system architectural modeling. More rigorous description of RTPA type rules may be referred to (Wang, 2007a).

THE REDUCTION MACHINE OF RTPA

A reduction machine is an abstract machine that defines inference rules for repetitively reducing language constructs until a solid value or behavior is obtained. Reduction machines model the operational semantics of a given language or formal notation system in three components: *specification*, *control*, and *store*. In other words, an operational

semantics describes how the *control* of the machine reduces a given *specification* to values of variables and how the *memory (store)* is changed during the execution of the specification.

In the operational semantics approach, the underlying target machine that operates and implements the semantic rules is modeled by an abstract reduction machine. A program and its behavior space or the semantic environment are realized by the target computer. An abstract model of a generic reduction machine as the system platform for embodying software semantics can be modeled below.

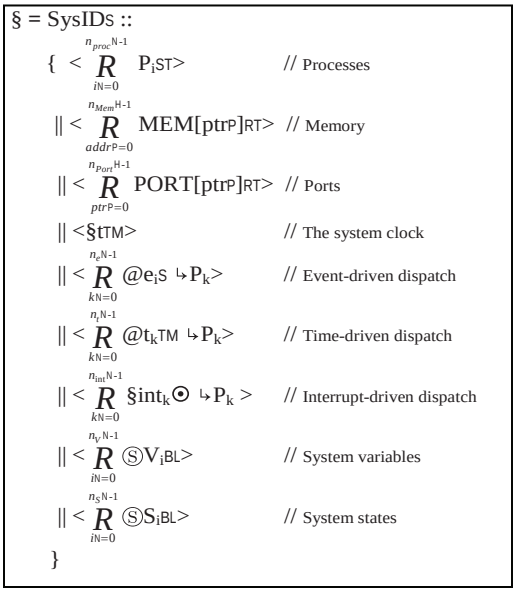
Definition 6: *The reduction machine, §, is an abstract logical model of the executing platform of a target machine denoted by a set of parallel or concurrent computing resources as shown in Figure 1.*

As shown in Figure 1, the reduction machine § for operational semantics is the executing platform that controls all the computing resources of an abstract target machine. The system is logically abstracted as a set of processes and underlying resources, such as the memory, ports, variables, statuses, and the system clock. A process is dispatched and controlled by the system §, which is triggered by various external, system timing, or interrupt events. The reduction machine of RTPA is not only the platform of the computing resources such as processes, memory, ports, and system clocks, but also the implementation of the computing mechanisms such as system dispatches, timing, interrupt handling, and system event captures.

Definition 7. *The semantic environment of the deduction machine, Θ, is the entire set of identifiers and their combinations declared and constrained in the abstract reduction machine, that is:*

$$\Theta \triangleq (I, T, V, A) = I \times T \times V \times A \quad (5)$$

Figure 1. The abstract model of the RTPA deduction machine



where I is a nonempty set of identifies, T is a set of types corresponding to each identifier in I, V is a set of values corresponding to each identifier in I, and A is a set of addresses corresponding to each identifier in I.

The semantic environment Θ can be divided into three subcategories known as the *operational environment* Θ_{op}, *system environment* Θ_{sys}, and *interrupt environment* Θ_{int}, that is:

$$\Theta \triangleq \Theta_{op} \cup \Theta_{sys} \cup \Theta_{int} \tag{6}$$

where only the operational environment Θ_{op} is controllable by users and applications.

Definition 8. *An inference rule in operational semantics, R_{os}, is a formal structure in which a propositional conclusion C is derived based on a set of given true premises P, that is:*

$$R_{OS} \triangleq \frac{\text{Premise(s)}}{\text{Conclusion}} = P \vdash C \tag{7}$$

where P and C are usually Boolean propositions. However, C can be a sequence of behavioral processes.

The semantic environment Θ forms the context of inference rules in operational semantics. Therefore, the following convention is adopted in all notations of inference rules:

$$< P \parallel \Theta > \Rightarrow < \varnothing \parallel \Theta' > \tag{8}$$

where ‖ denotes a parallel relationship between a *process* or an *expression P* and its underlying semantic environment Θ, ⇒ denotes a transition between a pair of semantic items, ∅ denotes an empty operation and/or the completion of a preceding process, and Θ' denotes an updated semantic environment as a result of the operation or effect of a process.

Definition 9. *The evaluations of an identifier id on its type t, value v, and address addr in Θ can be denoted as follows:*

$$\begin{aligned} t_{id} &\triangleq T(id \parallel \Theta) \\ v_{id} &\triangleq V(id \parallel \Theta) \\ addr_{id} &\triangleq A(id \parallel \Theta) \end{aligned} \tag{9.a-c}$$

where $id \in I \sqsubseteq \Theta$, or simply denoted $id \in \Theta$ when there is no confusion.

OPERATIONAL SEMANTICS OF RTPA META-PROCESSES

Using the reduction machine as defined in preceding section, the operational semantics for the 17 meta processes of RTPA can be described as follows.

Definition 10. *The reduction rule for the assignment process of RTPA, y*RT *:= exp*RT*, in operational semantics is shown in Box 1. The assignment rule indicates that an assignment transfers the value*

Box 1.

$$\frac{exp\text{RT}, y\text{RT} \in \Theta, \text{T}(exp\text{RT} \parallel \Theta) = \text{T}(y\text{RT} \parallel \Theta)}{<(y\text{RT} := exp\text{RT}) \parallel \Theta> \Rightarrow (< \text{V}(y\text{RT}) = \text{V}(exp\text{RT})) \parallel \Theta' >} \quad \text{(Rule 1)}$$

*of exp*RT *into y*RT *whenever both variables' types are identical or equivalent.*

Definition 11. *The reduction rule for the Boolean evaluation process of RTPA,* $\diamondsuit exp\mathbf{BL} \rightarrow \mathbf{BL}$*, in operational semantics is shown in Box 2, where | denotes a pair of alternative rules.*

The above rule for Boolean evaluation can be extended to more general cases where numeri-

Box 2.

$$\frac{exp\mathbb{BL}, \mathtt{T}, \mathtt{F} \in \Theta, <\diamondsuit exp\mathbb{BL} \parallel \Theta> \Rightarrow \mathrm{V}(exp\mathbb{BL}) = \mathtt{T} \parallel \Theta'_{sys}>}{<(\diamondsuit exp\mathbb{BL} \rightarrow \mathbb{BL}) \parallel \Theta> | \Rightarrow <exp\mathbb{BL} = \mathtt{T} \mid \Theta'>}$$
$$| \quad \frac{exp\mathbb{BL}, \mathtt{T}, \mathtt{F} \in \Theta, <\diamondsuit exp\mathbb{BL} \parallel \Theta> \Rightarrow \mathrm{V}(exp\mathbb{BL}) = \mathtt{F} \parallel \Theta'_{sys}>}{<(\diamondsuit exp\mathbb{BL} \rightarrow \mathbb{BL}) \parallel \Theta> | \Rightarrow <exp\mathbb{BL} = \mathtt{F} \mid \Theta'>}$$

(Rule 2.a)

Box 3.

$$\frac{exp\mathbb{T}, n\mathbb{T} \in \Theta, \mathbb{T} = \{\mathtt{N}, \mathtt{Z}, \mathtt{R}, \mathtt{B}\} \subset \Theta, <(\diamondsuit exp\mathbb{T} \rightarrow \mathbb{T}) \parallel \Theta> \Rightarrow <\mathrm{V}(exp\mathbb{T}) = n\mathbb{T} \parallel \Theta'_{sys}>}{<(\diamondsuit exp\mathbb{T} \rightarrow \mathbb{T}) \parallel \Theta'> \Rightarrow <exp\mathbb{T} = n\mathbb{T} \parallel \Theta'>}$$

(Rule 2.b)

Box 4.

$$\frac{id\mathbb{S}, ptr\mathbb{P} \in \Theta, <(id\mathbb{S} \Rightarrow ptr\mathbb{P}) \parallel \Theta> \Rightarrow <\varnothing \parallel \Theta'>}{<(id\mathbb{S} \Rightarrow ptr\mathbb{P}) \parallel \Theta> \mathrm{A} \Rightarrow <(id\mathbb{S}) = ptr\mathbb{P} \parallel \Theta'>}$$

(Rule 3)

Box 5.

$$\frac{id\mathbb{S}, ptr\mathbb{P}, n\mathbb{N} \in \Theta, <id\mathbb{S} \Leftarrow \mathrm{MEM}[ptr\mathbb{P}]\mathbb{RT}> \Rightarrow <\varnothing \parallel \Theta'>}{<(id\mathbb{S} \Leftarrow \mathrm{MEM}[ptr\mathbb{P}]\mathbb{RT}) \parallel \Theta> \Rightarrow <\mathrm{A}(id\mathbb{S}) = [ptr\mathbb{P}\mathbb{P}ptr + \mathrm{size}(\mathbb{RT})\text{-}1] \parallel \Theta'>}$$

(Rule 4)

cal evaluations are needed. The reduction rule for the *numerical evaluation process,* $\Diamond exp\mathbb{T} \rightarrow \mathbb{T}$, in operational semantics is shown in Box 3,where $\mathbb{T}$ is a numerical type, i.e., $\mathbb{T} = \{N, Z, R, B\} \subset T \sqsubseteq \Theta$.

It is noteworthy that, although the evaluation process does not affect Θ_{op}, but it changes Θ_{sys}.

Definition 12. *The reduction rule for the addressing process of RTPA, id*$S \Rightarrow ptrP$*, in operational semantics is shown in Box 4.*

Definition 13. *The reduction rule for the memory allocations process of RTPA,* $idS \Leftarrow MEM[ptrP]RT$*, in operational semantics is shown in Box 5, where size(RT) is the length of a certain type of variable, RT, in bytes, which is implementation specific.*

Definition 14. *The reduction rule for the memory release process of RTPA,* $idS \Leftarrow MEM[\perp]RT$*, in operational semantics is shown in Box 6, where* $\perp$ *denotes an empty or unassigned value.*

Definition 15. *The reduction rule for the read process of RTPA,* $MEM[ptrP]RT \geqslant xRT$*, in operational semantics isshown in Box 7.*

releases all existing identifiers and their values in the environment.

Definition 26. *The reduction rule for the system process of RTPA, §(SysID$), in operational semantics is shown in Box 16.*

The rule for the system process in RTPA is an axiom, which does nothing functionally from users' point of view, but it creates the system identifier and allocates necessary resources to the newly created system.

OPERATIONAL SEMANTICS OF PROCESS RELATIONS

RTPA process relations are rules of algebraic operations of processes, which describe how the meta processes can be combined to form complex processes. The operational semantics of the 17 process relations of RTPA is elaborated in this section on the platform of the reduction machine.

Definition 27. *The reduction rule for the sequential process of RTPA, $P \rightarrow Q$, in operational semantics is shown in Box 17.*

Definition 28. *The reduction rule for the jump process of RTPA, $P \curvearrowright Q$, in operational semantics is shown in Box 18.*

Definition 29. *The reduction rule for the branch process of RTPA, $\diamond exp\$ \rightarrow P \mid \diamond\sim\rightarrow Q$, in operational semantics is shown in Box 19, where | denotes a pair of alternative sub-rules dependent on given conditions.*

Definition 30. *The reduction rule for the switch process of RTPA, $\diamond exp_i\$ \rightarrow P_i \mid \diamond\sim\rightarrow\otimes$, in operational semantics is shown in Box 20, where*

$$\mathop{\mathrm{R}}_{i=1}^{n}$$

denotes a set of recurrent structures.

The operational semantics of iterations are presented in the following definitions. It is noteworthy that iterations were diversely interpreted in literature (Louden, 1993; McDermid, 1991). Although the decision point may be denoted by branch constructs, most existing operational semantic rules failed to express the key semantics of "while" and the rewinding action of loops. Further, the semantics for more complicated types of iterations, such as the repeat-loop and for-loop, are rarely found in the literature.

Box 17.

$$\frac{<\mathrm{P} \parallel \Theta> \Rightarrow <\varnothing \parallel \Theta'>, <\mathrm{Q} \parallel \Theta> \Rightarrow <\varnothing \parallel \Theta'>}{<(P \rightarrow Q) \parallel \Theta> \Rightarrow \{<\mathrm{P} \parallel \Theta'> \rightarrow <\mathrm{Q} \parallel \Theta">\}} \quad \text{(Rule 18)}$$

Box 18.

$$\frac{<\mathrm{P} \parallel \Theta> \Rightarrow <\varnothing \parallel \Theta'>, <\mathrm{Q} \parallel \Theta> \Rightarrow <\varnothing \parallel \Theta'>}{<(P \curvearrowright Q) \parallel \Theta> \Rightarrow \{<\mathrm{P} \parallel \Theta'> \rightarrow <\varnothing \parallel \Theta' \cup \Theta'_{sys}> \rightarrow <\mathrm{Q} \parallel \Theta" \cup \Theta'_{sys}>\}} \quad \text{(Rule 19)}$$

Box 19.

$$\begin{array}{l} \dfrac{exp_{\mathrm{BL}} \in \Theta, <exp_{\mathrm{BL}} \parallel \Theta> \Rightarrow exp_{\mathrm{BL}} = \mathrm{T}, <P \parallel \Theta> \Rightarrow <\varnothing \parallel \Theta'>}{<\diamond exp_{\mathrm{RT}} \rightarrow P \mid \diamond\sim \rightarrow Q> \Rightarrow <P \parallel \Theta'>} \\ \mid \dfrac{exp_{\mathrm{BL}} \in \Theta, <exp_{\mathrm{BL}} \parallel \Theta> \Rightarrow exp_{\mathrm{BL}} = \mathrm{F}, <Q \parallel \Theta> \Rightarrow <\varnothing \parallel \Theta'>}{<\diamond exp_{\mathrm{RT}} \rightarrow P \mid \diamond\sim \rightarrow Q> \Rightarrow <Q \parallel \Theta'>} \end{array} \quad \text{(Rule 20)}$$

Box 20.

$$\begin{array}{l} i\mathrm{N}, n\mathrm{N} \in \Theta, <exp_{\mathrm{RT}} \parallel \Theta> \Rightarrow exp_{\mathrm{RT}} = i\mathrm{N}, 1 \le i\mathrm{N} \le n\mathrm{N}, \\ <\mathop{\mathrm{R}}_{i\mathrm{N}=1}^{n\mathrm{N}} P \parallel \Theta> \Rightarrow <P_i \parallel \Theta'> \\ <\diamond exp_{\mathrm{i}\,\mathrm{RT}} \rightarrow \mathrm{P_i} \mid \diamond\sim\rightarrow \otimes> \Rightarrow <P_i \parallel \Theta'> \\ i\mathrm{N}, n\mathrm{N} \in \Theta, <exp_{\mathrm{RT}} \parallel \Theta> \Rightarrow exp_{\mathrm{RT}} = i\mathrm{N}, i\mathrm{N} \notin [1, n\mathrm{N}], \\ \mid \dfrac{<\mathop{\mathrm{R}}_{i\mathrm{N}=1}^{n\mathrm{N}} P \parallel \Theta> \Rightarrow <\otimes \parallel \Theta>}{<\diamond exp_{\mathrm{i}\,\mathrm{RT}} \rightarrow \mathrm{P_i} \mid \diamond\sim\rightarrow \otimes> \Rightarrow <\otimes \parallel \Theta'_{sys}>} \end{array} \quad \text{(Rule 21)}$$

Definition 31. *The reduction rule for the while-loop process of RTPA,*

$$\underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P,$$

in operational semantics is shown in Box 21, where the while-loop is defined recursively on Θ.

The above rule indicates that, when a Boolean expression *exp*$\mathbb{BL}$ in the environment Θ is true, the execution of the loop body *P* as a process for an iteration under Θ can be reduced to the same loop under an updated environment Θ', which is resulted by the last execution of *P*; When *exp*$\mathbb{BL} = \mathbb{F}$ in Θ, the loop is reduced to a termination or exit $\otimes$.

Definition 32. *The reduction rule for the repeat-loop process of RTPA,*

$$P \rightarrow \underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P,$$

in operational semantics is shown in Box 22.

The above rule indicates that the semantics of a repeat-loop process is semantically equivalent to the sequential composition of *P* and a while-loop.

Box 21.

$$\frac{exp\mathbb{BL} \in \Theta, \langle exp\mathbb{BL} \parallel \Theta \rangle \Rightarrow exp\mathbb{BL} = \mathbb{T}, \langle \mathbb{P} \parallel \Theta \rangle \Rightarrow \langle \varnothing \parallel \Theta' \rangle}{\langle \underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P \parallel \Theta \rangle \Rightarrow \{\langle \mathbb{P} \parallel \Theta' \rangle \rightarrow \langle \underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P \parallel \Theta' \rangle\}}$$

$$\mid \frac{exp\mathbb{BL} \in \Theta, \langle exp\mathbb{BL} \parallel \Theta \rangle \Rightarrow exp\mathbb{BL} = \mathbb{F}, \langle \otimes \parallel \Theta'_{sys} \rangle}{\langle \underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P \parallel \Theta \rangle \Rightarrow \langle \otimes \parallel \Theta'_{sys} \rangle}$$

(Rule 22)

Box 22.

$$\frac{exp\mathbb{BL} \in \Theta, \langle \mathbb{P} \parallel \Theta \rangle \Rightarrow \langle \varnothing \parallel \Theta \rangle}{\langle P \rightarrow \underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P \parallel \Theta \rangle \Rightarrow \{\langle \mathbb{P} \parallel \Theta' \rangle \rightarrow$$

$$(\frac{\langle exp\mathbb{BL} \parallel \Theta' \rangle \Rightarrow exp\mathbb{BL} = \mathbb{T}, \langle \mathbb{P} \parallel \Theta' \rangle \Rightarrow \langle \varnothing \parallel \Theta'' \rangle}{\langle \underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P \parallel \Theta' \rangle \Rightarrow \{\langle \mathbb{P} \parallel \Theta'' \rangle \rightarrow \langle \underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P \parallel \Theta'' \rangle\}}$$

$$\mid \frac{\langle exp\mathbb{BL} \parallel \Theta' \rangle \Rightarrow exp\mathbb{BL} = \mathbb{F}, \langle \otimes \parallel \Theta'_{sys} \rangle}{\langle \underset{exp\mathbb{BL}=\mathbb{T}}{\overset{\mathbb{F}}{\mathbb{R}}} P \parallel \Theta' \rangle \Rightarrow \langle \otimes \parallel \Theta'_{sys} \rangle}$$

$$) \}$$

(Rule 23)

Definition 33. *The reduction rule for the for-loop process of RTPA,*

$$\mathop{\mathrm{R}}_{i\mathbb{N}=1}^{n} P(i\mathbb{N}),$$

in operational semantics is shown in Box 23.

The above rule indicates that the semantics of a for-loop process is semantically equivalent to a sequence of *n* serial processes. The semantic rule of for-loop processes may also be defined recursively as that of the while-loop rule as shown in Box 24.

Definition 34. *The reduction rule for the function call process of RTPA, $P \rightarrowtail F$, in operational semantics is shown in Box 25.*

Definition 35. *The reduction rule for the recursion process of RTPA, $P \circlearrowleft P$, in operational semantics is shown in Box 26.*

The semantic rule of recursion processes may also be defined iteratively as that of the for-loop rule as shown in Box 27, where the base process P^0 should be able to be reduced to a constant.

Box 23.

$$\frac{i\mathbb{N},\ n\mathbb{N} \in \Theta, 1 \le i\mathbb{N} \le n\mathbb{N},\ <\mathrm{P}_i \parallel \Theta> \Rightarrow <\varnothing \parallel \Theta'>}{<\mathop{\mathrm{R}}_{i\mathbb{N}=1}^{n} P(i\mathbb{N}) \parallel \Theta> \Rightarrow \{<P(i\mathbb{N}=1) \parallel \Theta'> \rightarrow <P(i\mathbb{N}=2) \parallel \Theta''> \rightarrow \ldots \rightarrow <P(i\mathbb{N}=n\mathbb{N}) \parallel \Theta^{n'}>\}}$$

(Rule 24)

Box 34.

$$\frac{\begin{array}{c}k\mathsf{N},\ n\mathsf{N}, e_k \mathsf{S} \in \Theta, 1 \le k\mathsf{N} \le n\mathsf{N}, \\ <\mathrm{P} \parallel \Theta> \Rightarrow \mathop{\mathrm{R}}_{k\mathrm{N}=1}^{n\mathrm{N}} <P_k \parallel \Theta'>, <\S \parallel \Theta> \Rightarrow <\S \parallel \Theta'>\end{array}}{<(@e_k \mathsf{S} \hookrightarrow \mathrm{P}_k) \parallel \Theta> \Rightarrow \{<\S \parallel \Theta> \rightarrow <P_k \parallel \Theta> \rightarrow <\S \parallel \Theta''>\}} \quad \text{(Rule 35)}$$

Box 35.

$$k \in \mathbb{N},\ n \in \mathbb{N},\ int_k \odot \in \Theta, 1 \le k \le n \in \mathbb{N},$$

$$\frac{<P \parallel \Theta_{int}> \Rightarrow \mathop{\mathrm{R}}_{k=1}^{n} <P_k \parallel \Theta'_{int}>, <\S \parallel \Theta> \Rightarrow <\S \parallel \Theta'>}{<(@int_k \odot \hookrightarrow P_k) \parallel \Theta> \Rightarrow \{<\S \parallel \Theta> \rightarrow <P_k \parallel \Theta'_{int}> \rightarrow <\S \parallel \Theta \cup \Theta'_{int}>\}}$$

(Rule 36)

upon its completion, it returns the control of system resources and the environment to the system.

Definition 42. *The reduction rule for the event-driven process of RTPA, $@e_k \mathbb{M} \hookrightarrow P_k$, in operational semantics is shown in Box 34.*

The rule of event-driven processes models the second type of top level system dispatching behaviors, where the system transfers control to a process P_k after capturing a corresponding event $@e_k \mathbb{S}$; upon its completion, it returns the control of system resources and the environment to the system.

Definition 43. *The reduction rule for the interrupt-driven process of RTPA, $@int_k \odot \hookrightarrow P_k$, in operational semantics is shown in Box 35.*

The rule of interrupt-driven processes models the third type of top level system dispatching behaviors, where the system transfers the control to an interrupt subroutine P_k after capturing a corresponding interrupt event $@int_k \odot$; upon its completion, it returns the control of system resources and the environment to the system.

CONCLUSION

The operational semantics of Real-Time Process Algebra (RTPA) has been developed in this article, which explains how syntactic constructs in RTPA can be reduced to values on an abstract reduction machine. The operational semantics of RTPA has provided a comprehensive paradigm of formal semantics, which extends the conventional express power of operational semantics to an entire set of semantic rules for complicated RTPA process structures and their algebraic operations. Especially, the operational semantics of the parallel, concurrent, and system dispatches have been formally and systematically elaborated.

RTPA has been presented as both a denotational mathematical structure and a system modeling methodology for describing the architectures and behaviors of real-time and nonreal-time software systems. The formal semantics of RTPA has helped to the comprehension and understanding of the RTPA syntactical and semantic rules as well as its expressive power in software engineering, cognitive informatics, and computational intelligence. RTPA has been used not only in software system specifications, but also in human and intelligent system modeling.

ABSTRACT

Validation and verification techniques have been identified as suitable mechanisms to determine if the software meets the needs of the user and to verify if the software works correctly. However, the existing verification techniques do not support friendly visualization. Also, validation techniques with friendly visualization mechanisms do not allow the verification of the system's correctness. In this chapter, we present a method for the validation and verification of software systems through the integration of formal methods and virtual reality. Furthermore, a software tool associated with such a method is also described along with an embedded system case study.

INTRODUCTION

The complexity of software systems is increasing and, consequently, making it more difficult and necessary to determine if they work correctly. In the context of the currently applied development techniques and processes, tests are commonly used for validating software, but they cannot ensure that the software is in accordance with important behavioral properties, such as robustness or safety requirements.

Verification techniques aim to detect and aid the designer to correct mistakes during the software development, being useful when defining whether the software satisfies its requirements and specifications. Through formal modeling and verification methods, it is possible to determine if the system works correctly while considering all possible behaviors.

On the other hand, validation techniques determine if the software meets the needs of the user (Fuhrman, Djlive, & Palza, 2003). Thus, a graphical and friendly visualization of the system model is very useful in validating software in different domains. However, even though most of the formal modeling techniques have their own graphical representations, such as automata and Petri nets, they do not allow a friendly visualization and, subsequently, validation of the system's behavior. Without such friendly visualization, the final user needs to understand formal modeling concepts, which are not easily understood by nonengineers.

Coloured Petri nets (CPN) (Jensen, 1992) are used to model and verify the correctness of software systems, and virtual reality modeling language (VRML) (International Organization for Standardization, 1998) is applied to validate the software behavior considering the user acceptance.

We will present a software platform for managing the integration of CPN and VRML, easing the application of the proposed method. In order to illustrate the use of the method and the platform, an embedded software case study is presented. Finally, related approaches and concluding remarks are discussed.

Using the proposed method, it is possible to separate the formal verification and the validation activities of the system, allowing the verification of its correctness while still giving a friendly visualization for the final user. Moreover, the proposed tool aids the developers in integrating the CPN formal and the friendly VRML models, hiding the integration complexity.

BACKGROUND

As we have said in the preceding section, the verification and validation phases of the approach we present here are based on coloured Petri nets and the VRML language. Therefore, in order to provide a better understanding of the next sections, it is desirable to present some background information.

Coloured Petri Nets

Petri nets are a formal method with a graphical representation used to model concurrent systems. With Petri nets, it is possible to specify and verify properties like precedence relation and deadlocks, among others. The graphical representation of a Petri net is a bipartite graph composed of places and transitions. Arcs connect places to transitions and transitions to places but never places to places or transitions to transitions. Each place can have zero or several tokens at a given moment. This is called the marking of the place. Therefore, the marking of a Petri net model is the set of markings of all places at a given moment. The transitions represent the actions that can take place.

Different extensions to the Petri nets formalism exist, such as timed Petri nets (Wang, 1998) and coloured Petri nets. In the context of this chap-

ter, the hierarchical coloured Petri nets (HCPN), an extension of the coloured Petri nets, is the formalism we have used in our approach. The HCPN formalism has been used in the verification of many kinds of systems. Analysis of mobile distributed protocols (Zaslavsky, Yeo, Lai, & Mitelman, 1995), verification of multiagent plans (Almeida, Silva, Perkusich, & Costa, 2005) and embedded systems (Silva & Perkusich, 2005), and simulation of network management systems (Christensen & Jepsen, 1991) are some of the practical uses of HCPN.

Hierarchical coloured Petri nets incorporate data types and hierarchy concepts to ease the modeling task. In HCPN, a system is represented by a set of nonhierarchical CPN models, and each of these models is called a CPN page. Hierarchical characteristics are achieved due to the inclusion of two mechanisms: substitution transition and fusion places. The former is a transition that is replaced by a CPN page. The page to which the substitution transition belongs is called a superpage. The page represented by such a transition is called a subpage. Subpages and superpages are associated by means of sockets and ports. Fusion places are places that are graphically distinct but logically the same. Two or more fusion places form a fusion set and all the places in a fusion set always have the same marking.

Indeed, these two additional mechanisms, substitution transition and fusion places, are only graphical, helping in the organization and visualization of a CPN model. They favor the modeling of larger and more complex systems by giving the designer the ability to model by abstraction, specialization, or both. Moreover, the modeling activities in CPNs are supported by a set of computational tools named Design/CPN[1] (Christensen & Mortensen, 1996). These tools provide a graphical environment for the editing and syntax checking, as well as analysis methods like simulation and verification of CPN models.

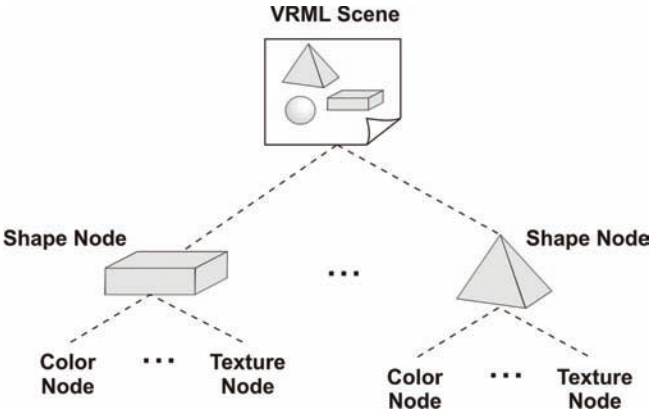
Virtual Reality Modeling Technologies

Different virtual modeling technologies exist. In this section, we outline some of these technologies by exposing their main characteristics.

VRML[2] is a platform-independent language for modeling three-dimensional (3D) worlds. The intent of its creators was to allow 3D scenes to be visualized through the World Wide Web even over low-bandwidth connections. It became the *de facto* approach for providing 3D content on the web. Furthermore, as 3D modeling tools were able to export files to the VRML language, non-VRML experts, like architects and mechanical engineers, were able to build their 3D models and export them to the Web. This characteristic has allowed the usage of VRML in several branches of academy and industry, such as chemical-molecules validation (Casher, Leach, Page, & Rzepa, 1998), virtual buildings modeling (Ferreira, et al., 2004), mathematical functions visualization (Wang & Saunders, 2005), robot simulation (Rohrmeier, 2000), terrains representation (Reddy, Iverson, & Leclerc, 1999), and manufacturing systems (Krishnamurthy, Shewchuk, & McLean, 1998; Silva & Perkusich, 2003).

In a general way, VRML worlds are tree-like structures, as illustrated in Figure 1. Almost everything in VRML is viewed as a node. Cylinders, spheres, lights and even colors, are some examples of VRML nodes. However, these nodes have no behavior associated with them. It means that, 3D scenes composed only of VRML nodes are static. Therefore, in order to embed some dynamics in such scenes, three further mechanisms have been provided: *sensors*, *routes*, and *scripts*. A *sensor*, as its name indicates, senses the changes of a specific feature, such as time and mouse clicking. The information gathered by a *sensor* can be redirected to the other nodes in the 3D world through *routes*. These *routes*, therefore,

Figure 1. The structure of a VRML world



act like event-dispatching mechanisms. Finally, *scripts*, also considered nodes, are the ways by which the developer manipulates the objects of a VRML scene.

Although VRML *scripts* are, most of the time, written in the JavaScript language (Goodman & Morrison, 2004), this is not the only option. It is also possible to implement such *scripts* by using the Java language. This can be performed through a mechanism called *external authoring interface* (EAI). EAI provides a set of Java classes that communicate with a VRML browser in order to manipulate a 3D world. The difference between these approaches is that in the second one the code of the script is separated from the VRML file. As we will show later in this chapter, this feature will be essential for the validation approach we are proposing.

The Java 3D[3] (Selman, 2002) API is part of Sun's JavaMedia suite and is devoted to the construction of Java applications and applets filled with 3D graphics. Like in VRML, Java 3D scenes are structured in a tree-like way. Therefore, each object in a scene is viewed as node of the tree. Through Java 3D, it is possible to control the shape, color, and transparency of objects. Furthermore, it allows the developer to define how such objects move, rotate, shrink, stretch, and morph as time goes by. Environmental manipulations are also possible, by defining background images, lighting modes, and even fog effects.

Internally, Java 3D uses the system native libraries, such as Direct3D and Open GL, to speed up performance. It provides applications with three different rendering modes: immediate, retained, and compiled-retained. The basic difference between these modes is concerned with performance, where the immediate mode is the slowest one and the compiled-retained is the fastest. Each of these modes has its own advantages, and therefore, the choice of which mode to use will depend on the application.

Extensible 3D graphics (X3D)[4] is both a language, based on extensible markup language (XML), and a format for creating and interchanging 3D content. As the X3D is compatible with the VRML specification, X3D files can be modeled using either X3D or VRML syntax.

Different from the previously presented technologies, X3D is embedded with the notion of *profiles*, each one providing a specific set of characteristics. The profiles are based on a componentized architecture, allowing the insertion of new components to support features not provided by the profile. This allows the definition of profiles targeted to specific fields, for example, medical and automobile visualizations.

The structure of a virtual world in X3D is similar to that of Java 3D and VRML, that is, a tree-like model. From the functional perspective, X3D provides many of the functionalities of VRML and Java 3D, such as scripts, lighting, materials, and animations. However, an interesting feature of X3D is the possibility of building virtual worlds by composing objects entirely from other scenes or locations on the Web.

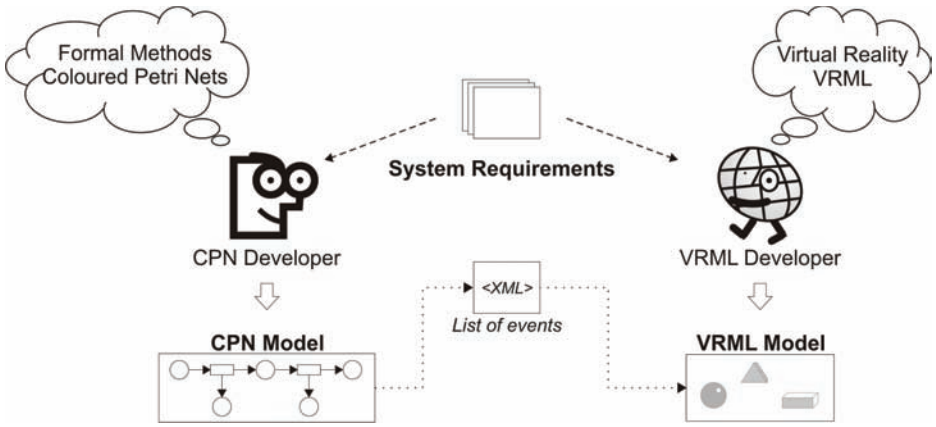
VALIDATION AND VERIFICATION METHOD

In the context of our method for software verification and validation, we have defined three roles: *CPN Developer*, *VRML Developer*, and *Final User*. Based on these roles, some steps for verifying and validating the software have been defined. Figure 2 illustrates such separation of roles in a macro view of our method.

The *CPN Developer* knows how to model and verify the system according to its requirements using coloured Petri nets. The *CPN Developer* aims at proving that the specification is correct. In case of modeling, he or she must identify the global system behavior and model it using arcs, places, and transitions. In general, each transition represents an occurrence of a system execution (e.g., an event, a process, etc.). Therefore, firing a transition or a set of transitions simulates a system behavior. For example, the firing of a transition named "input" may simulate the fact that the user inputs data on the system. When verifying the system, the specification modeling is proved correct for all possible behaviors.

The *VRML Developer* knows how to model and validate the system. However, unlike the *CPN Developer*, the *VRML Developer* aims at final user validation. For that, he or she must model the system as simply as possible, yet still

Figure 2. Separation of roles



in accordance with the specification. The VRML modeling must be performed based on the events defined as transitions by the *CPN Developer*. Thus, the *VRML Developer* is responsible for correlating CPN and VRML events.

The *Final User* knows how the system works. He or she is responsible for specifying the system and validating if the system modeled is the one specified previously. For that, the *Final User* must describe the system requirements and visualize the VRML model in determining if it covers the requirements.

In what follows, we describe a set of steps for validating and verifying systems using CPNs and VRML. Each step is related to a specific role. In Figure 3, the phases of the method are depicted. A simple manufacturing system is used for illustrating the application of each phase (Silva & Perkusich, 2003).

System Specification (Final User)

The specification of the system is the first and main phase. Functional and nonfunctional requirements are described and, based on them, the modeling can be performed. A manufacturing system is a system organized into cells. Each cell has one or more related machines and a transport system. Two

Figure 3. Verification and validation method

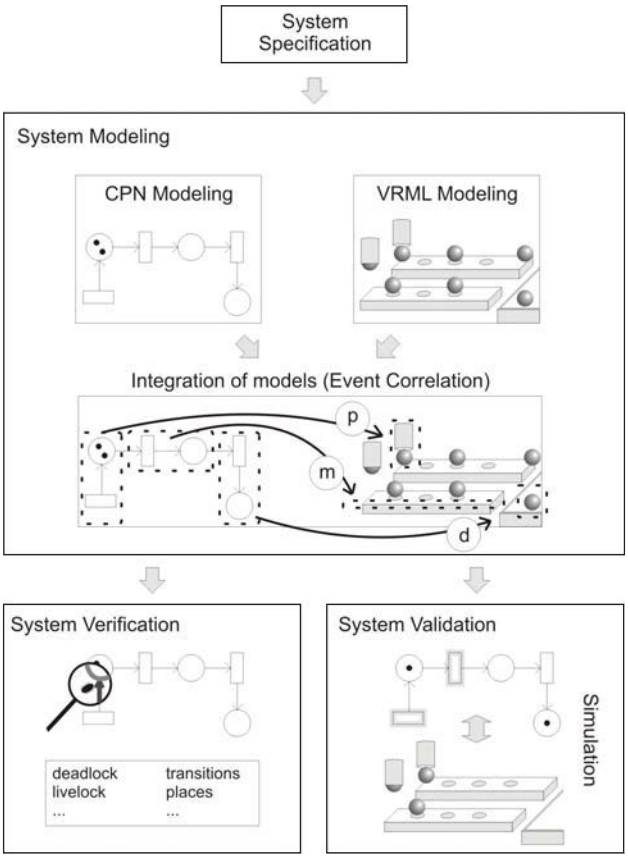


Figure 4. Simple manufacturing system

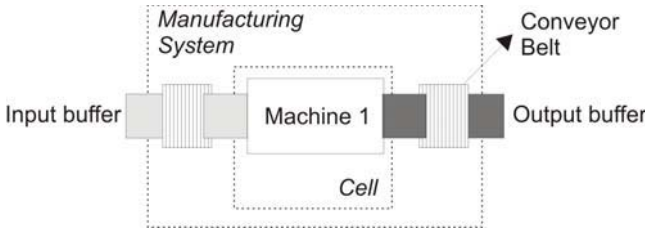

kinds of transport systems are considered: those inside cells and those outside cells. For simplicity, in this example the focus is on production and transport issues. In Figure 4, the architecture of the manufacturing system is illustrated.

CPN Modeling (CPN Developer)

The system is modeled using hierarchical coloured Petri nets. The Design/CPN tools set should be used in this phase. The result of this activity is a set of CPN models that can be simulated and later verified. Figure 5 illustrates the CPN modeling for the manufacturing system, presenting the places and transitions that are used to model the system specification.

VRML Modeling (VRML Developer)

In the third phase, the system is modeled using VRML. Any VRML modeling tool can be used to perform this activity. This modeling is usually sim-

Figure 5. CPN modeling for the manufacturing system

OCB	Output Conveyor Belt
CO	Cell Output
OV	Output Vehicle
SO	System Output

pler and friendlier than the CPN modeling, since the objective is to validate the system according to the user needs. Figure 6 illustrates the VRML modeling for the manufacturing system.

Integration of Models (VRML Developer)

The fourth step involves the correlation between the CPN and VRML events. The result of this activity is a map structure that represents the integration of the CPN and VRML models. For example, the event of firing a transition in the CPN model could represent a VRML event, such as a sphere moving. Figure 7 illustrates the correlation of events for the manufacturing systems. The correlated events are named CO, IV, OCB, and OV.

After the *system-modeling* phases, the system can be verified and validated. The generated

Figure 6. VRML modeling for the manufacturing system

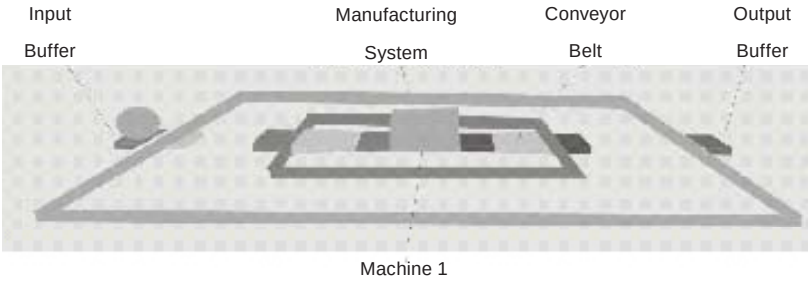

Figure 7. Correlating events for the manufacturing system models

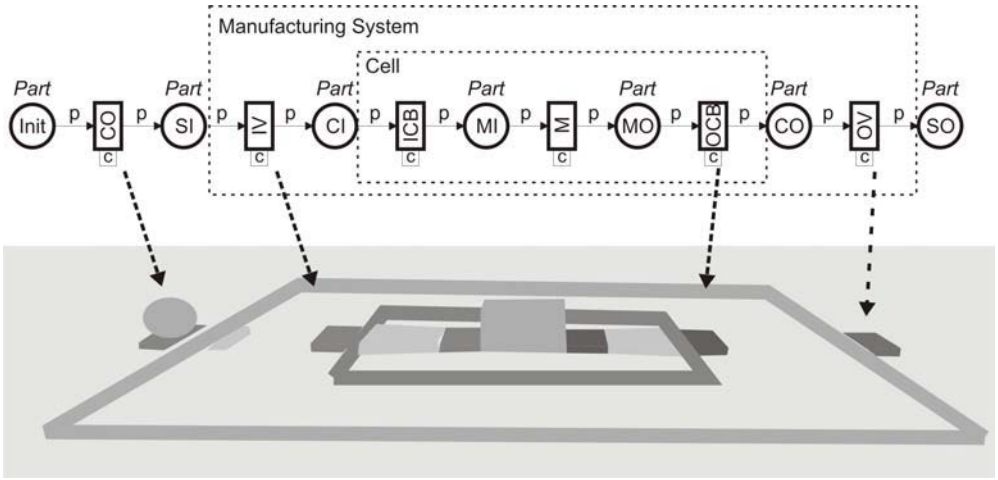


models are used in the *system-verification* and the *system-validation* activities. Such activities are described below.

System Verification (CPN Developer)

In the fifth phase, the system is verified through the CPN models created during the *CPN-modeling* phase. Such models are passed to Design/CPN tools, in order to verify the correctness of the system according to behavioral properties using verification techniques such as model checking. Modeling and verification guidelines for CPNs using the Design/CPN tools and model checking can be found in Almeida et al. (2005).

System Validation (Final User)

In the last step, the system is validated through both the CPN and VRML models. A simulation of the system through the VRML models is performed based on the events generated by the simulation of the CPN models. Each event generated by the CPN model and defined as a "mapped event" in the *integration-of-models* activity can change the state of the VRML world. Thus, it is possible to visualize the behavior of the CPN-model simulation through the friendly VRML graphical animations.

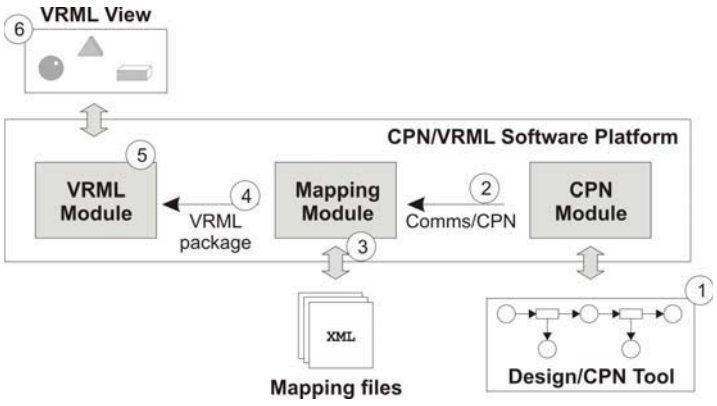
A SOFTWARE PLATFORM FOR INTEGRATING VRML AND CPN

In order to make the application of the steps for the validation and verification of software systems easier, a software platform is described here.

The *CPN/VRML Software Platform* manages the integration of VRML and CPN models. For that, the Design/CPN tool is used for CPN modeling and simulation, and a Java-compliant VRML browser is used for the model visualization. The architecture of the software platform is presented in Figure 8, and the integration steps are described below, considering the event correlation performed in the *integration-of-models* phase.

1. The *CPN Module* is responsible for receiving event notifications from the Design/CPN simulation tools. During the simulation, each event is announced for the *CPN Module*. The communication is performed via sockets.

Figure 8. Software-platform architecture



2. The *CPN Module* extracts the CPN model information using the Comms/CPN library (Gallasch & Kristensen, 2001) and forwards the event notifications to the mapping module.
3. The *Mapping Module* retrieves from the XML mapping files the VRML events that are related to the CPN event.
4. The *Mapping Module* forwards the identification of the VRML events that should be announced through a VRML-Java package.
5. Finally, the *VRML Module* updates the virtual world according to the CPN simulation events, allowing a friendly visualization of the CPN model. The *External Authoring Interface* mechanism, described in the "Background" section, is used to manipulate the VRML view.

CASE STUDY: A COMPONENT-BASED EMBEDDED AUTOMATION AND CONTROL SYSTEM

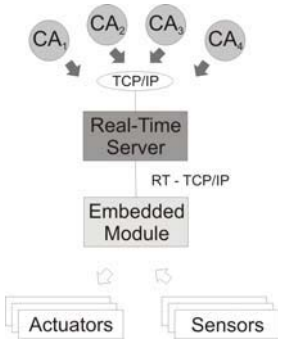
In this section the application of the proposed method and software platform for validating and verifying a component-based embedded automation and control system is described.

System Specification

In Figure 9, the architecture of the embedded system, which is based on the framework structure introduced in Perkusich, Almeida, and Araújo (2003) is illustrated.

The entities shown in this figure are: sensors and actuators, client applications (CAs), the embedded module, and the real-time server. Sensors and actuators are not described since their roles in the architecture are clear. Client applications, in turn, represent application front-ends that access the services of the real-time server, like a Web application. Since Web-based software architectures are well-defined, a more detailed discussion about client applications is omitted from this chapter.

Figure 9. Architecture of the real-time embedded automation and control application



Embedded Module

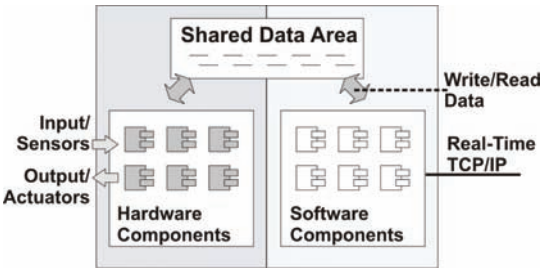
The embedded module is a real-time system that interacts with the physical environment by means of the sensors and actuators, as well as distributed devices connected by a real-time TCP/IP network. The hardware components of the module receive events or alarms from sensors and write information in a shared-data area. Then, software components can read such alarm and event information, convert them to an adequate format, and send them to the real-time server.

On the other hand, the real-time server can request for an actuator through the software components that write the request in the shared-data area. Thus, hardware components can read the requests from a shared area and send them to the specific actuators. The internal architecture for the embedded module is shown in Figure 10.

Since the focus of this chapter is on the validation and verification of software systems, the software components that belong to such infrastructure are depicted in Figure 11 and are detailed in what follows.

- **I/O interpreter:** The I/O interpreter mediates the communication between software components and information in a shared area. It also interprets the information recovered from the shared area and instantiates objects that represent such information. On the other hand, the I/O interpreter receives information from the components as objects, translates them to the shared-data language, and then writes them in the shared area. The type of information present in the shared area may vary according to the sensor and actuators that are being used.
- **Data converter:** The data converter implements data conversion specific algorithms defined by the application. The data are converted from the I/O interpreter language to the specific application language. For example, when the I/O interpreter returns an object with a binary content, the data converter may transform it into an object with a decimal content, if this is the application format. The data conversion also depends on the type of information.
- **Synchronizer:** The synchronizer implements the synchronous communication among the software components of the embedded module and the software components of the real-time server. As said before, a real-time TCP/IP network is used. This component acts as a bridge between the two sides of the distributed application, and all the requests, or the response for the requests, issued between the real-time server and the embedded module occur through this component.
- **Device controller:** The device controller implements the initialization, tests, and liberation of devices connected to the interfaces of the embedded module. Such services are executed based on the requests submitted by the *Device Controller* to the shared area through the interpreter.

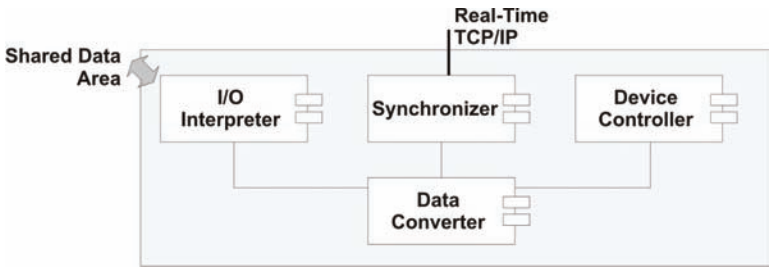
Figure 10. Internal architecture of the embedded module



Real-Time Server

The real-time server can be a personal or industrial computer that manages the network. It runs the

Figure 11. Software components infrastructure for the embedded module



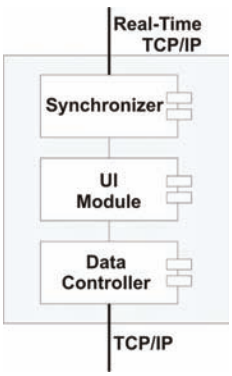
Linux/RT real-time operating system (Abbott, 2003). The internal architecture of the real-time server is shown in Figure 12. The software components that belong to the real-time-server infrastructure are briefly described as follows.

- **Synchronizer:** The synchronizer implements the communication on the real-time-server side. The implementation is similar to the embedded-module synchronizer.
- **Data controller:** The data controller provides data-flow control for the system (i.e., read, write, and parameter forwarding) based on the implementation of the services that are made available by the *UI Module*.
- **UI module:** The user-interface module provides an interface for the services implemented by the software components, so that they can be used by the application connected to the Internet.

CPN Modeling

In Figure 13, the CPN model for the embedded module is shown. The places, arcs, and transitions that model the *I/O-interpreter*, *Data-converter*, *Synchronizer*, and *Device-controller* modules are depicted in this figure. The complete description of the CPN modeling for this case study is presented in Silva and Perkusich (2005).

Figure 12. Software components infrastructure for the real-time server



VRML Modeling

Figure 14 illustrates the VRML modeling of the real-time embedded automation and control application. The software components detailed earlier and the communication among them have been modeled using VRML nodes. Box nodes, with their names modeled with *Text* nodes, represent the software components; whereas *Cylinder* nodes represent the communication among the components.

The "System Validation" section will detail how the dynamic features (i.e., data exchange among the components and data processing) of the system are simulated in VRML.

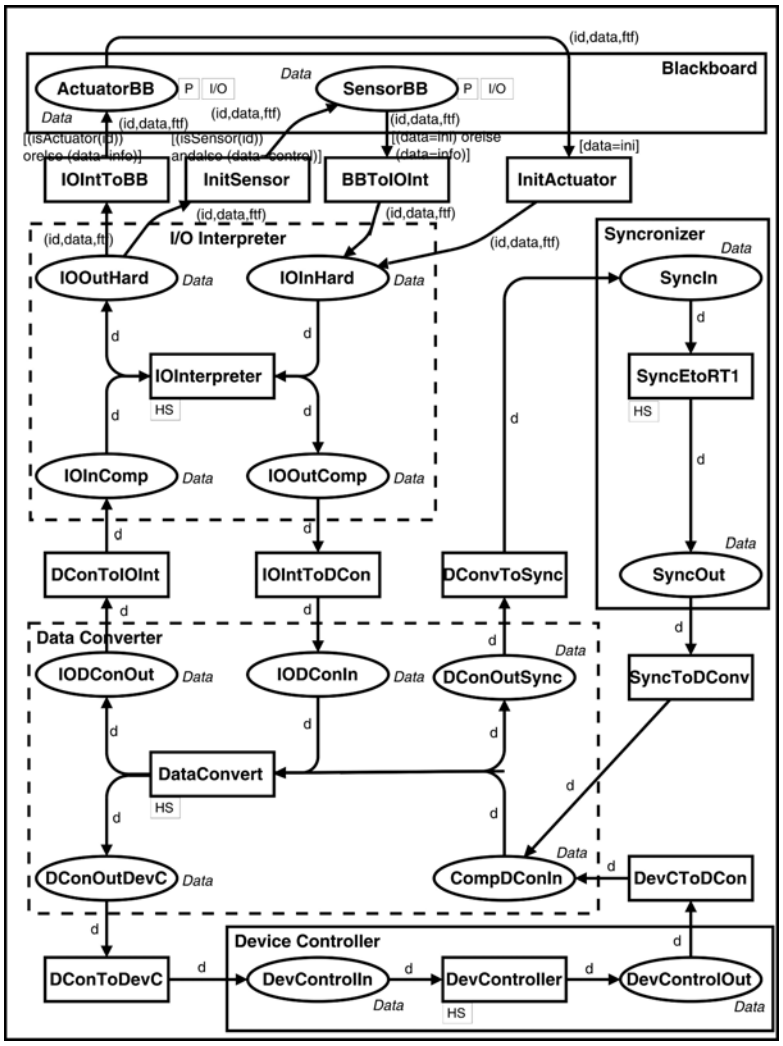
Integration of Models

Some VRML events have been created in order to allow the integration between the CPN and VRML models. Such events are implemented in JavaScript and they are grouped into a *Script* node through VRML input events. In Listing 1, the JavaScript function that implements the VRML-event behavior correlated to the CPN transition *UIModule* is presented. Such an event simulates the data exchange between the *Data Controller* and the *UI Module* of the *Real-time Server.*

The *rtsDataControllerToUIModule* function forwards the received event *value* to the input event *communicateForward* of the *Cylinder* situated between the *Data Controller* and the *UI Module*. Besides, this function also forwards the value *true* to the input event *showDataExchange* of the *UI Module*.

The other VRML events are similarly implemented. The complete mapping between the CPN transitions and the correlated VRML events is presented in Table 1.

Figure 13. CPN modeling for the embedded module

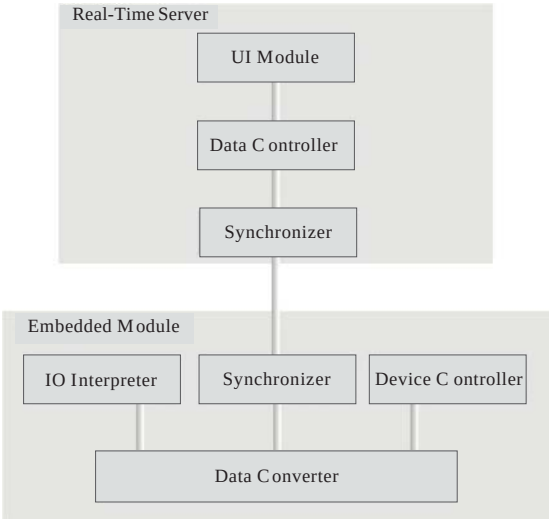


System Verification

Suppose that the sensors send an initial signal when the system is turned on or a new device is plugged in. Also, suppose that the system performs some task when it receives this kind of message and sends an acknowledgment, a calibration, or even an initialization message to the sensor. Such a scenario is illustrated in Figure 15.

When a sensor sends an initialization signal, the *Data Converter* sends it to the *Device Controller* to perform the associated control tasks. Since the simulation captures a single execution sequence or information flow in the model, the expected sequence or flow may have been violated. Thus, we must verify the scenario for all possible situations based on model checking (Clarke, Emerson, & Sistla, 1986) to guarantee that the expected flow has always been satisfied. For that, the desired system properties should be described in a propositional temporal logic such as computation tree logic (CTL) (Clarke et al.).

Figure 14. VRML modeling for the real-time embedded automation and control application



Listing 1. Function that implements the VRML event for the transition UIModule

```
function rtsDataControllerToUIModule(value, timestamp) {
        RTSDataControllerTOUIModuleCylinder.communicateForward = value;
        UIModuleComponent.showDataExchange = true;
}
```

Its semantic is defined with respect to paths in a Kripke structure. A path on such a structure is an infinite sequence of states (s_0; s_1; …) such that s_{i+1} is reached from s_i for all $i \geq 0$. The CTL formula *AG*φ means that for all paths starting from s_0, φ holds at every state along those paths. In other words, φ holds globally. The CTL formula *AF*φ means that for all paths starting from s_0, φ holds at some state along the path. In other words, φ is inevitable.

Considering the scenario shown in Figure 15, we must prove that when some device sends an initialization message, the flow will be through the device controller. To prove this scenario, two atomic propositions *PA* and *PB* are used. The proposition *PA* is true if there is a token in place *IODConIn*, illustrated in Figure 13. The proposition *PB* is true if there is a token in place *DConOutDevC*, also illustrated in Figure 13. The CTL formula to prove this scenario is shown below:

$$AG\ (\ PA \rightarrow AF\ (\ PB\ )\ )$$

Therefore, the formula is true if *PA* is true and *PB* is true in the future. It means that if there is a token in the data converter input, this token is sent to device controller input, which

Table 1. Mapping between the CPN transitions and the correlated VRML events

CPN transition	VRML event

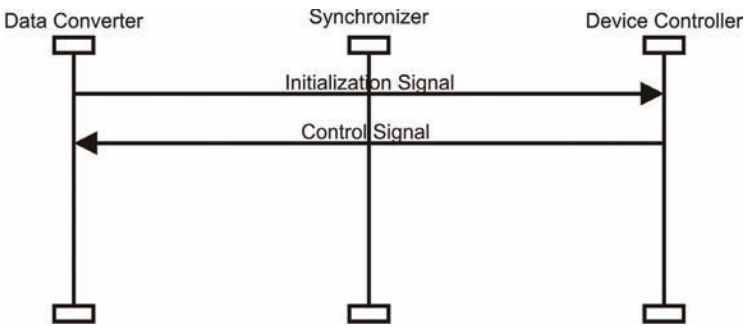
IOInterpreter	emIOInterpreterProcessing

is the component that implements control tasks such as initialization, calibration, and changing devices working parameters. The evaluation of this formula to true means that this part of the model behaves as expected for all possibilities of model execution. We can proceed with the same reasoning to prove that the flow of information back to the device also behaves as expected for all possibilities.

System Validation

The validation of the real-time embedded automation and control application is performed through the CPN and VRML models. The final user visualizes the interaction among the software components through the events generated by the CPN model and through a friendly user interface provided by the VRML model. The

Figure 15. Data converter flow to control signal



system validation becomes easier for the final user, since the VRML model entities are more abstract than the CPN model entities. In what follows, it is described how the dynamic features of the system are modeled in VRML.

The data exchange among the components is simulated through oriented *Cone* nodes (situated inside the *Cylinder* nodes), depending on the direction of the data flow. For example, in Figure 16, the data exchange between the *Data Controller* and the *UI Module* is presented: the *Cone* nodes are directed to the *UI Module* component, representing a data flow from the *Data Controller* to the *UI Module*. Besides, the *Sphere* node at the *UI Module* component represents the data that are sent from the *Data Controller* to the *UI Module*.

Another feature modeled for the system is data processing, which occurs within the software components. For that, a *Text* node with the word "Processing" is displayed at the bottom right of the current processing component and the letter "P" is displayed at the *Sphere* node, which represents the data being processed. In Figure 17, the data

Figure 16. VRML modeling for data exchange among components

processing within the *Synchronizer* component of the *Real-time Server* is illustrated.

RELATED APPROACHES

Some related approaches are discussed in this section. A short description showing their features is presented along with some comparisons with our work.

Kindler and Páles (2004) present a prototype tool that allows the 3D visualization of Petri-net models, called PVNis. Such a tool is based on the Petri net kernel (PNK) (Weber & Kindler, 2003) and uses Java 3D for implementing the 3D-visualization. The approach used by this tool is based on the equipment of the Petri net with information on the physical objects used for 3D-visualization. The physical objects are included in the Petri net model. A 3D model representing the shape of the object and an *animation function* representing the behavior of the object must be created for each place of the Petri net that corresponds to a physical object.

There is no method for validation and verification associated with this tool. Its purpose is only to provide the visualization of Petri net models in a 3D way. Therefore, there is also no effort to integrate the validation process through the 3D-visualization, with the verification process, or through the Petri net model. Such activities are realized separately.

Bardohl, Ermel, and Ribeiro (2000) introduce ideas towards visual specification and animation of Petri net-based models. In this work, the animation of algebraic high-level (AHL) nets (Padberg, Ehrig, & Ribeiro, 1995), which are a combination of place-transition nets and algebraic specifications (Ehrig & Mahr, 1985), is described. For that the animation, transformation rules are applied to the behavior rules (semantically equivalent to the transitions of the net) of an AHL net model, generating an animation view from the model. Such a view allows the visualization of the behavior of the system in a domain-specific layout.

In a Petri net Editor,the user defines the transformation rules from the Petri-net view to the animation view. In this way, there is no separation of the roles concerned with the use of this approach. Either the user that knows Petri nets must know the visual-modeling language or the visual modeler must know Petri nets. Finally, it seems the visual-modeling language is not as full-featured as VRML.

CONCLUSION AND FUTURE TRENDS

This chapter describes a method for the verification and validation of software systems using coloured Petri nets (CPN) and VRML. The method is defined over three separated roles: the *CPN Developer*, responsible for CPN issues; the *VRML Developer*, responsible for VRML issues; and the *Final User*, responsible for specifying and validating the system.

According to the proposed method, the system is modeled using CPN and VRML based on its requirements. Next, the CPN and VRML events are correlated in order to allow the CPN model simulation to control the VRML model simulation. For that, we propose a software tool that is used to correlate CPN and VRML events.

We describe the method as a set of phases for modeling and verification. The application of each phase is illustrated using a flexible manufacturing-system example. This makes it easier to understand the implementation of our method. As a real case study, we described the validation and verification of an embedded software system using the proposed method and platform.

The main future trend in the context of software verification and validation related to our work is to provide mechanisms for reducing the gap between validation and verification techniques. In this chapter, we propose a method and a tool that reduce such a gap, promoting the integration between VRML and CPN developers, still obtain-

ing software verification and friendly software validation.

However, for some domains, the integration can be improved. For example, a VRML-component library for a specific domain may be created. Thus, when verifying and validating software for such domain, the integration tool could generate the VRML model based on the name of the component events. This automatic approach would reduce the effort on mapping CPN events to VRML ones.

On the other hand, verification tools could be improved in order to provide friendly mechanisms for visualizing what is being verified. It will be very important to the large-scale use of verification techniques in the context of industrial software engineering.

In this future, we plan to apply our method for validating and verifying software in other domains, focusing on complex interaction-centric ones (e.g., multiagent systems, as in Weiss, 2000, and workflow management systems, as in van der Aalst & van Hee, 2002). The validation of these systems through VRML may be primordial.

Chapter 8.12
Software Component Survivability in Information Warfare

Joon S. Park
Syracuse University, USA

Joseph Giordano
Air Force Research Laboratory, USA

ABSTRACT

The need for software component survivability is pressing for mission-critical systems in information warfare. In this chapter, we describe how mission-critical distributed systems can survive component failures or compromises with malicious codes in information warfare. We define our definition of survivability, discuss the survivability challenges in a large mission-critical system in information warfare, and identify static, dynamic, and hybrid survivability models. Furthermore, we discuss the trade offs of each model. Technical details and implementation of the models are not described in this chapter because of space limitations.

INTRODUCTION

As information systems became ever more complex and the interdependence of these systems increased, the survivability picture became more and more complicated. The need for survivability is most pressing for mission-critical systems in information warfare. When components are exported from a remote system to a local system under different administration and deployed in different environments, we cannot guarantee the proper execution of those remote components in the current run-time environment. Therefore, in the run time, we should consider component failures (in particular, remote components) that may occur due to poor implementation, during integration with other components in the system,

or because of cyber attacks. Although advanced technologies and system architectures improve the capability of today's systems, we cannot completely avoid threats to them. This becomes more serious when the systems are integrated with commercial off-the-shelf (COTS) products and services, which typically have both known and unknown vulnerabilities that may cause unexpected problems and that can be exploited by attackers trying to disrupt mission-critical services (Kapfhammer, Michael, Haddox, & Colyer, 2000). Organizations, including the Department of Defense (DoD), use COTS systems and services to provide office productivity, Internet services, and database services, and they tailor these systems and services to satisfy their specific requirements. Using COTS systems and services as much as possible is a cost-effective strategy, but such systems—even when tailored to the specific needs of the implementing organization—also inherit flaws and weaknesses from specific COTS products and services that are used. Therefore, we need reliable approaches to ensure survivability in mission-critical systems that must rely on commercial services and products in a distributed computing environment.

Definitions of survivability were introduced by previous researchers (Knight & Sullivan, 2000; Lipson & Fisher, 1999). We define survivability as the capability of an entity to continue its mission even in the presence of damage to the entity (Park, Chandramohan, Devarajan, & Giordano, 2005). An entity ranges from a single software component (object), with its mission in a distributed computing environment, to an information system that consists of many components to support the overall mission. An entity may support multiple missions.

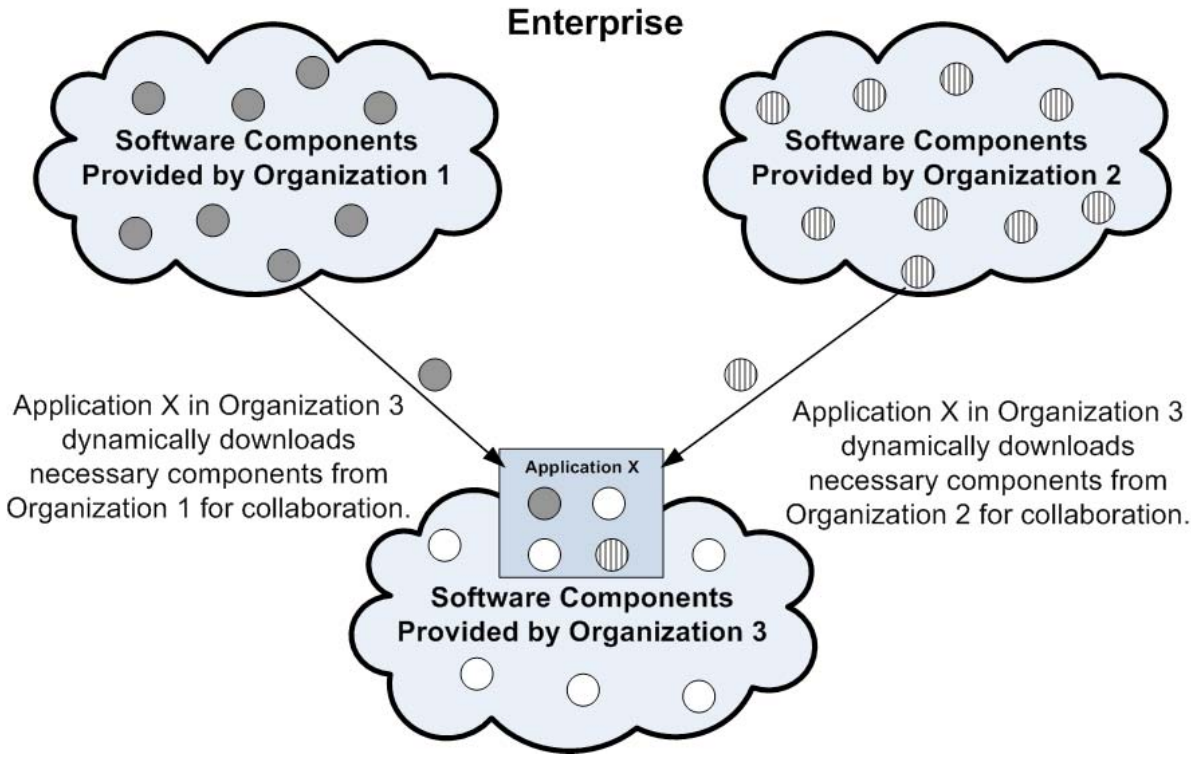
The damage caused by cyber attacks, system failures, or accidents, and whether a system can recover from this damage (Jajodia, McCollum, & Ammann, 1999; Knight, Elder, & Du, 1998; Liu, Ammann, & Jajodia, 2000), will determine the survivability characteristics of a system. A survivability strategy can be set up in three steps: protection, detection and response, and recovery (Park & Froscher, 2002). To make a system survivable, it is the mission of the system rather than the components of the system. This implies that the designer or assessor should define a set of critical services the system must provide in order to fulfill the mission. In other words, they must understand what services should be survivable by the mission and what functions of which components in the system should continue to support the system's mission.

In this article, we focus on the survivability of mission-critical software components downloaded on the Internet. We assume that all software components are susceptible to malicious cyber attacks or internal failures. Cyber attacks may involve tampering with existing source code to include undesired functionality (e.g., Trojan horses), or replacing a genuine component with a malicious one. When using such components, particularly in mission-critical applications in information warfare, we must check to see if the component was developed by a trusted source, and whether the code has been modified in an unauthorized manner since it was created. Furthermore, we should check to see if the component is functioning in an expected way. If all these conditions are satisfied, we call it "trusted component sharing."

CHALLENGES TO SOFTWARE SURVIVABILITY IN A MISSION-CRITICAL SYSTEM

Typically, an application running at an enterprise level may span more than one organization. Figure 1 shows an example of a distributed application that spans multiple organizations. The figure depicts three organizations interconnected to form a large enterprise-computing environment. In the real world, there may be more than two or three organizations connected to form a large

Figure 1. A distributed application spanning multiple organizations



enterprise, and some of the organizations in the enterprise may provide specialized services that other organizations do not provide (e.g., Department of Homeland Security). In the figure, for example, components in Organizations 1 and 3 are involved in application X. In this example the application running in Organization 3 downloads necessary components for some special features that it lacks. These components are dynamically downloaded from remotely administered hosts (in Organization 1 in the example) and run locally. This situation becomes complex when one must administer components downloaded from disparate administrations. For instance, Figure 1 shows that a user under Organization 3's administration can dynamically download software components under Organization 1's administration. From this point forward, the software running in Organization 3 should cooperate with the downloaded components that originated from different administrations. To employ autonomous administration, the local administrator must perform the extra job of dealing with interoperability problems and failures of or attacks via external components.

Based on the typical scenario described above, we identify the following generic challenges for software survivability in large distributed mission-critical systems.

Challenge 1. An autonomous mechanism to support component survivability between dif-

ferent organizations or systems is needed due to the fact that no single administrator can control every aspect (e.g., software component testing and implementation) of the various systems used in an enterprise. This is an inherent challenge because many systems, including those from different organizations, are integrated within current distributed computing environments. This implies that a remote component may have failures or malicious code that could affect a local computing environment. Unfortunately, a remote component cannot be tested in a local environment until runtime.

Challenge 2. Testing software components before deployment cannot detect or anticipate all of the possible failures or attacks that may manifest themselves during run time, especially when external components are integrated. Some failures are detected only when the components are deployed and integrated with other components in the operational environments. Existing faults in one component can be triggered by other components during runtime. Furthermore, since we cannot simply assume that all the participating organizations followed proper testing procedures for their software components, we need a new component-test mechanism that can test the component in the actual run-time environment—especially for components downloaded from different environments. The test criteria can vary, based on current applications or run-time environments, even for the same component. The remote component may cause an interoperability problem in a different run-time environment, although it passed its original test.

Challenge 3. In a distributed mission-critical system, we must check whether a remote component has been altered in an unauthorized manner, especially if it contains malicious codes, such as Trojan Horses, viruses, or spyware, before malicious codes are activated in the run-time environment. For instance, in Figure 1, when different organizations collaborate for a common enterprise but are competitors in the market, each organization should check the components from other organizations before they are used in the local environment. Furthermore, if a component includes any malicious codes, but the functionality of the original code is still needed for the system, we cannot simply reject the entire component. Instead, we should safely retrieve only the original code, enervating the malicious code.

Challenge 4, Currently available redundancy-based static approaches cannot solve the problem completely. If one component has failed because of reason R1, then the rest of the redundant components will fail for the same reason. It is only a matter of time before every redundant component is compromised for the same reason, especially when those components are identical. Furthermore, the strength of the redundancy-based approaches depends on the prepared redundancy, which brings up the question of "how many" redundant components we need to provide. Technically, one could maintain as many redundant components as necessary for a critical service. However, if the initially selected component is running in its normal state—meaning there is no need to use other redundant components as the component is not defective or compromised—the cost for running the redundant components has been wasted. In this situation, the resource efficiency is low, and the maintenance cost is high. Therefore, for mission-critical systems in information warfare, a dynamic technique is needed to detect and analyze the possible faults and attacks in the components and fix/immunize these components on-the-fly.

Challenge 5. Even if we know the reasons for and the locations of the software failures or attacks, in most currently available recovery approaches in distributed computing environments, changing the component's capability (e.g., for immunization) in run time is difficult, especially when the source code is not available (which is not an uncommon situation). When dealing with component failures, we are concerned with the problem of how to fix these failed components. One possibility is to modify the source code ac-

cording to the identified failures; however, this approach is possible only if the source code for that component is available. In the case of COTS components and other components downloaded from externally administered systems, the source code is often unavailable. Although some source codes are available to the public, if they are poorly documented, it will hardly be possible to modify the source code effectively. Furthermore, many mission-critical systems do not tolerate the suspension of operation for code debugging and recompilation. One must, therefore, employ other techniques to achieve the goal of fixing failed components on-the-fly—without access to the source code—in order for the mission of the component to continue.

SUPPORT MECHANISMS FOR SOFTWARE SURVIVABILITY

Component Recovery

Barga, Lomet, Shegalov, and Weikum (2004) introduced a framework for an application-independent infrastructure that provides recovery of data, messages, and states in Web-based applications. The framework requires an interaction contract between two components that specifies the joint behavior of those two interacting components. An application component can be replayed from an earlier installed state and arrive at the same state as in its prefailure incarnation. It masks from users the failures of clients, application servers, or data servers only if the replay could recover the component. Unfortunately, however, there are many component failures that cannot be fixed simply by replays. With this approach, a component may go back to the state before the failure; however, it cannot proceed further from that failure point again, unless the reason for the failure is fixed. Therefore, the component is not able to continue its mission. Furthermore, this approach does not consider malicious codes that are already included in the components. Similarly, the state-based recovery approaches for client-server systems were introduced by Freytag Cristian, and KŁhler (1987) and Barga, Lomet, Baby, and Agrawal (2000), and for databases by Liu et al. 2000) and Jajodia et al. (1999).

Ring, Esler, and Cole (2004) introduced self-healing mechanisms for kernel system compromises in run time, which analyze the system call table and enable the compromised addresses to return to their original values, terminate hidden processes, remove hidden files, and block hidden connections. As with state-based recovery, these can recover a compromised system to its state before the failure or attack and prevent the situation from getting worse. However, like the state-based approach, this approach does not fix the fundamental reason for the problem or let the system go to further states. Also, the scope of the work is within a kernel module in Linux.

Dowling and Cahill (2004) introduced the idea of K-components for self-adaptive decentralized systems. By using a component interface definition language called K-IDL, the definitions of component states and adaptation actions are used by decision-making programs to reason about and adapt component operation. Programmers can specify adaptation contracts for their local environments. However, this limits the overall robustness of the adaptive systems because, typically, programmers do not know all the possible adaptive options in various computing environments in which their components will be running. When the components are used in a large distributed application, which is the scope of our work, this approach is especially not scalable.

Helsinger, Kleinmann, and Brinn (2004) introduced a multitiered control framework between high-level observable metrics and low-level control actions for distributed multiagent systems that are composed of distributed autonomous agents interacting on a peer-to-peer basis. The framework imposes intermediate measurers of performance (MOPs) that measure the contri-

butions of different components and actions to higher-level functions. They observe the behaviors at one level and seek to manage those behaviors by taking control actions at a lower level, such as by restarting dead agents or load balancing by moving agents between hosts. Assuming that each agent will be developed correctly and trusted, this framework can improve the availability of agents and may optimize load balancing. However, the framework may not comply properly when the components have internal failures or are compromised by malicious codes, which is not unusual in a real mission-critical distributed system in information warfare.

Component Test

Existing technologies for identifying faulty components are more or less static in nature. One of these approaches employs black-box testing of the components. In this technique, behavioral specifications are provided for the component to be tested in the target system. This technique treats the target component as a black box and can be used to determine how the component behaves anomalously. Traditionally, black-box testing is done without knowledge of the internal workings of the component tested. Normally, black-box testing involves only input and output details of the component, while information on how the output is arrived at is not needed. The main disadvantage of this technique is that the specifications should cover all the details of the visible behavior of the components, which is impractical in many situations. Another approach employs a source-code analysis, which depends on the availability of the source code of the components. Software testability analysis employs a white-box testing technique that determines the locations in the component where a failure is likely to occur. Unlike black-box testing, white-box testing allows the tester to see the inner details of the component, which later helps him to create appropriate test data. Yet another approach is software component dependability assessment, a modification or testability analysis that thoroughly tests each component. These techniques are possible only when the source code of the components is available.

In the past, Kapfhammer et al. (2000) have employed a simple behavioral specification utilizing execution-based evaluation. This approach combines software fault injection (Avresky, Arlat, Laprie, & Crouzet, 1996; Hsueh, Tsai, and Iyer, 1997; Madeira, Costa, and Vieira, 2000) at component interfaces and machine learning techniques to: (1) identify problematic COTS components and (2) to understand these components anomalous behavior. They isolated problematic COTS components, created wrappers, and introduced them into the system under different analysis stages to uniquely identify the failed components and to gather information on the circumstances that surrounded the anomalous component behavior. Finally, they preprocessed the collected data and applied selective machine learning algorithms to generate a finite state machine to better understand and to increase the robustness of faulty components. In other research (Chen, Kiciman, Fratkin, Fox, & Brewer, 2002; Voas & McGraw, 1998), the authors developed a dynamic problem determination framework for a large J2EE platform, employing a fault-detection approach based on data-clustering mechanisms to identify faulty components.

COMPONENT SURVIVABILITY MODELS

In this section, we identify static, dynamic, and hybrid models for software survivability and discuss their trade offs. Technical details and implementation of these models are available in our previous publications (Park & Chandramohan, 2004; Park et al., 2005). We describe our approaches using client and server components in a typical distributed environment.

Static Survivability Model

The survivability of this model is based on redundant components, prepared before the operation, to support critical services continuously in a distributed client-server environment. Redundant servers can be located in the same machine, in different machines in the same domain or even in different domains. Existing approaches, such as dynamic reconfiguration, can be associated with this static model. Although the term "dynamic" is used in the terminology, it belongs to the static model, according to our definition, as long as the available components are generated before the operation starts. The same service can be provided by identical components (e.g., copies of the original servers) or by different components that are implemented in various ways. Isolated redundancy (in different machines or domains) usually provides higher survivability because the replaced component can be running in an uninfected area. For instance, if the redundant components are distributed in different network places, then the services provided by those components can be recovered in the event of network failures, in different environments. However, if there is a failure within a component, replacing that component with an identical copy is not effective, because identical components are vulnerable to the same failure.

Dynamic Survivability Model

In this model, unlike the static model, there is no redundant component. Components with failures or malicious codes are replaced by dynamically generated components on-the-fly and deployed in run time when required. Furthermore, this model allows replacement of the infected components with immunized components, if possible, which enables it to provide more robust services than the static model.

Basically, when failures or malicious codes are detected in a component, the corresponding factory generates an immunized component and deploys it into a safe environment, while the monitor issues a command to shut down the old component. The concept of "factory" was originally introduced as one of the commonly used design patterns in the object-oriented design. If we do not know the exact reason for the failures or types of malicious codes, or if it is hard to immunize components against known failures or malicious codes, we can simply replace the infected component with a new one in a safe environment. We call this a generic immunization strategy, which is effective against cyber attacks. If a component (a machine or a whole domain) is under attack, the generic immunization strategy suggests generating a new copy of the component and deploying it in a new environment that is safe from attack. Although this approach supports service availability continuously, the new component might still be susceptible to the same failures or attacks. Therefore, an immunized component, if possible, would provide a more robust survivability.

The Hybrid Model

The hybrid survivability model combines the features of the above two models. The dynamic model has an inherent disadvantage in terms of service downtime. The recovery process can range from seconds to a few minutes. This downtime drawback will cause major problems in mission-critical systems in information warfare because there will be no service available for clients during the recovery period. On the other hand, the static model has inherent disadvantages in terms of resource efficiency, adaptation, and robustness.

To compensate for the weaknesses in the two models, we incorporated the idea of a hybrid model. At the beginning of the operation, an array of n redundant components is initiated as described in the static model approach. These redundant servers will be used as a buffer while a more robust server is generated and deployed by the dynamic model approach. When a server fails

because of an attack or internal failure, the buffer servers will take over the service for a brief period until the new immunized server is initialized. Since all of the buffer servers are susceptible to the same failures or attacks, it is a matter of time before the redundant servers are also infected for the same reason, especially when those servers are identical. Therefore, if the transition period is long, multiple buffer servers may be used before the immunized server is ready. The hybrid model ensures the availability of service to the client and provides more robust services in the end. However, this model needs more complex implementations than the two models previously discussed.

Trade Offs

In the static survivability model there are *n* numbers of redundant servers running in parallel that are deployed even before the operation starts. If one server fails, the broker delegates incoming requests to another server in the remaining server pool. Since the redundant components are ready to be used (unlike those in the dynamic model) during the failure or attack, the service downtime is relatively shorter than in the dynamic model. The implementation of the static survivability model is comparatively simpler than the dynamic or the hybrid model. In the static survivability model, it is unnecessary to maintain a server component factory, whose main job is to replace faulty server components with immunized ones. On the other hand, the static model has inherent disadvantages in terms of resource efficiency, adaptation, and robustness.

The hybrid model combines the logic of both the static and dynamic models. Here, if the monitor finds a fault in one of the server components, it informs the factory (as in the dynamic model) to replace the faulty component with an immunized one, and, in the meantime, it also sends a message to the broker to temporarily deploy a redundant component (as in the static model) until the new immunized component is built and deployed. Since the dynamic and hybrid models are able to build immunized components, they are more robust than the static model. The static model uses more memory resources than the dynamic model to maintain the redundant server components, making it less resource-efficient than the dynamic model. But this resource efficiency is accompanied by higher downtime in the dynamic model. The hybrid model is a balance between the static and dynamic models in terms of its resource efficiency.

CONCLUSION

In this chapter, we have described how mission-critical distributed systems can survive component failures or compromises with malicious codes in information warfare. We defined our definition of survivability, discussed the survivability challenges in a large mission-critical system in information warfare, and identified static, dynamic, and hybrid survivability models. Furthermore, we discussed the trade offs of each model. Technical details and implementation of the models are not described here because of space limitations.

Components can be immunized based on the generic or specific strategies provided by the monitors. If the monitor figures out the reasons for the failures or types of attacks on the components, it can provide specific strategies to the corresponding component factories. The level of immunization depends on the monitor's capability. The more powerful monitoring mechanisms and their communication channels between other components can provide more resistance to failures and attacks. Analyzing specific reasons for unexpected failures in run time is another challenge. Monitors can cooperate with other monitors, and different monitors are in charge of different interests. To detect and analyze types of attacks, the monitors can be associated with existing intrusion detection systems, which is also part of our future work.

KEY TERMS

Commercial Off-the-Shelf (COTS): These software systems are developed to interoperate with existing systems without the need for customization and available for sale to public.

Software Component: This reusable software element provides predefined services and can communicate with other components with relatively little effort.

Spyware: This software program monitors a user's computer activity surreptitiously or collects sensitive information about users or organizations without their knowledge.

Survivability: This refers to the capability of an entity to continue its mission even in the presence of damage to the entity.

Trojan Horse: A rogue software program installed on the victim's machine that can run secretly with the user's privileges.

Trusted Component: This software component has not been modified by an unauthorized manner, since it was created by a trusted source and functions in an expected way.

Virus: This software program attaches itself to other programs, propagating itself in this way, and does something, usually malicious and unexpected.

Chapter 8.13
A Novel Application of the P2P Technology for Intrusion Detection

Zoltán Czirkos
Budapest University of Technology and Economics, Hungary

Gábor Hosszú
Budapest University of Technology and Economics, Hungary

INTRODUCTION

The importance of the network security problems come into prominence by the growth of the Internet. This article presents a new kind of software that uses the network itself to protect the hosts and increase their security. The hosts running this software create an application level network (ALN) over the Internet (Hosszú, 2005). Nodes connected to this ALN check their operating systems' log files to detect intrusion attempts. Information collected this way is then shared over the ALN to increase the security of all peers, which can then make the necessary protection steps, for example, blocking network traffic by their own *firewall*.

Different kinds of security software utilizing the network were also written previously (Snort, 2006). The novelty of Komondor is that its client software entities running in each host create a *peer-to-peer* (P2P) *overlay network* (Czirkos, 2006). Organization is automatic; it requires no user interaction. This network model ensures stability, which is important for quick and reliable communication between nodes. By this build-up, the system remains useful over the unstable network.

THE IMPORTANCE OF THE P2P COMMUNICATIONS

The Internet-based communication technology enabled people to share information with anybody in seconds. This has brought benefits to people spanning many spheres from social services to education (Frasz, 2005). Probably the best example of such extended network of content sharing is

the P2P that allows users to download media files off other computers free of charge. Once content enters the Internet, it can be downloaded by an unlimited number of people.

One of the latest steps in the steady advances in P2P technologies is the release of new P2P technologies in 2005 that enable a user community to filter out mislabeled or corrupt files (Goth, 2005). One approach to build a more trustworthy P2P overlay is the application credence (Sirer & Walsh, 2005). It rates a certain network object instead of a given peer node for trustworthiness. The reason is that nodes can be inhabited by various people over time, but the data in the object itself does not change. This system uses a secure and anonymous voting mechanism. Over time, users with similar votes or the legitimacy of a file will dynamically form a kind of community enabling enough correlation of trust. Similarly, a user that systematically answers contrarily will get an equally significant negative weighting; however, an inconsistent voter will have less statistical weight. In such a way, the more users who join credence overlay, the more accurate an overall rating each file will receive.

The trend of the P2P systems is building more resilient services. Centralized solutions are fragile, since a single link breakage in the network can cut access to the whole service. P2P enables higher ability to construct overlays that self-organizes and recovers from failures.

Another interesting and important feature of the development process of the P2P technology is that the most successful projects are open sources such as LimeWire, which is a Gnutella client with rapidly growing popularity (Bildson, 2005). Its business model has two sides. One version is free, however, advertising-supported, and the other is ad-free, but the users must pay for it. LimeWire guarantees no bundled software with downloads. The open source property of the LimeWire encourages its users to monitor its development. The largest competitor of LimeWire is BitTorrent, which is very efficient in sharing large files (BitTorrent, 2006). Its users upload portions of required documents to a requester instead of forcing one client to upload the whole file many times.

THE PROBLEM OF THE INTRUSION

Computers connected to networks are to be protected by different means (Kemmerer & Vigna, 2002). Information stored on a computer can be personal or business character, private or confidential. An unauthorized can person can therefore steal it; its possible cases are shown in Table 1.

We have to protect not only our data, but also our resources. Resources are not necessarily hardware only. Typical types of attack are to gain access to a computer to initiate other attacks from it. This is to make the identification of the attacker more difficult because this way the next intruded host in this chain sees the IP address of the previous one as its attacker.

Stored data can not only be stolen, but changed. Information modified on a host is extremely useful to cause economic damage to a company. The attacker can alter or obstruct its functioning properly and cause damage.

Intrusion attempts, based on their purpose, can be of different methods. But these methods share things in common, scanning networks ports or subnetworks for services, and making several

Table 1. The types of the information stealth

• An unauthorized person gains access to a host.
• Monitoring or intercepting network traffic by someone.
• An authorized but abusive user.

attempts in a short time. This can be used to detect these attempts and to prepare for protection.

Simple, low strength passwords are also a means of security holes. These are used by the so-called dictionary method, trying to log into the system with common names or proper names as somebody's password. They are of a relatively small number and easily guessable.

The attacker can also be trying to find resources through security holes. With this type of action, whole ranges of network addresses are scanned for a particular service having a bug or just being badly configured. The port number is fixed here. An example for this is scanning for an open e-mail (SMTP) relay to send junk mail anonymously.

A common feature of the attack methods described above is that the attacker makes *several attempts* against a host. The Komondor software developed by us uses this as a base. As one host running the Komondor detects an intrusion attempt and shares the address of the attacker on the overlay network, the other ones can prepare and await the *same attacker* in safety, who will usually arrive sooner or later.

Traditionally, organizations have relied on their firewall to enforce their corporate policies. To stop the use of P2P file sharing, organizations may add a rule that denies outbound ports not required for business (Sorensen & Richards, 2004). Unfortunately, many of the P2P applications today use a "port-hopping" method of communication to circumvent firewall rule sets that limit outbound connections to specifically allowed ports. If the firewall restricts the ports permitted to establish outbound connections to only the essential ports, such as port 80 (HTTP) and port 25 (SMTP), the P2P application modifies the port that it uses to communicate with other P2P nodes to use these ports allowed through the firewall.

To effectively detect this type of P2P application traffic in an environment requires the use of a device that can examine the contents of the packets allowed through the firewall. *Intrusion detection systems* (IDS) were designed to satisfy this need. These systems are designed to monitor network traffic to look for known signature attack patterns and/or deviations from protocol specifications that represent malicious intent. When potentially malicious traffic is observed, they generate an alert. More importantly, these "detection" technologies lack the capabilities to effectively prevent this traffic, leaving the burden with the administrator to manually investigate and respond.

WAYS OF PROTECTION

The P2P based file sharing software can cause various security problems. There are file sharing programs, which install further software known as spyware. Spyware monitors the browsing habits of the user and then sends the collected information to third parties. Typically, the user gets advertisements based on the data collected by the spyware. This kind of software can be hard to sense and to clean from the system. Before installing any file sharing program, the user should buy antivirus software that can detect the already downloaded spyware on the user's hard drive and prevent the operating system from downloading further spyware programs.

The active network vulnerability scanners such as the NMAP (2006), Nessus (2005), and ISS Scanner (ISS Scanner, 2005) send packets or communicate in some manner with the systems they are auditing. Naturally, they are bound by the physical limitations of the networks and systems they are auditing to send and receive these packets. In other words, scanning can take a long time, especially for large networks (Deraison, Gula, & Hayton, 2005).

In some rare cases, the act of probing may cause instability in the audited system. Network devices such as routers and switches may also be affected by large numbers of port scans, host enumeration, and vulnerability testing. Also,

networks change all too often. After the scan has been finished, it slowly becomes out of date as the network changes.

Active network vulnerability scanners may also have a political stigma within large organizations. For a variety of reasons, a system administrator may feel that there is no need to have a third party scan their systems. To compensate for this, a *passive vulnerability scanner* can be deployed in a manner to watch these "off limits" networks and report on their vulnerabilities.

Passive vulnerability scanning is the process of monitoring network traffic at the packet layer to determine topology, services, and vulnerabilities (Deraison et al., 2005). The passive scanners, such as NeVO, monitor for client and server vulnerabilities of a specific network through direct analysis of the packet stream. As NeVO observes network packets, it builds a model of the active hosts on a network and their services. For example, observing a TCP port 25 SYN-ACK packet from one of the monitored hosts will cause NeVO to reevaluate the network model.

NeVO uses different methods to determine if a host is alive and what the host is. It reconstructs both sides of a network conversation and then analyzes the data for evidence of specific client or server vulnerabilities. Unique client and servers for protocols such as HTTP, SMTP, and FTP have unique strings which identify the version of the service. NeVO also makes use of passive operating system identification by monitoring SYN packets which may be emitted by the system during network usage. Each operating system, such as Windows or Linux, builds its SYN packets in its own unique way, and this can be used to distinguish between some specific types.

Passive vulnerability scanning is not a replacement for active vulnerability scanning, but it is a very efficient technology. When it is deployed on its own, the passive vulnerability scanner will produce very interesting information about the security profile of a monitored network. However, this is by no means a full view of network security. When deployed together, both methods will efficiently detect vulnerabilities and changes to the monitored networks (Deraison et al., 2005).

The ability to correctly identify the attacks on the Internet is very important. The exchange of alert information between organizations can greatly supplement the knowledge obtained from local monitors (Locasto, Parekh, Keromytis, & Stolfo, 2005). The IDS usually operates within one administrative domain. Therefore, information about the global state of network attack patterns is usually unexamined. However, global information exchange can help organizations in ranking and addressing threats, which they would not have otherwise identified.

In order to construct an efficient IDS, a lot of problems must be solved before intrusion alert data can be safely distributed among cooperating organizations. For example, distributing all alert information in a P2P overlay quadratically increases bandwidth requirements. Also, information exchange between cooperating organizations must be carefully managed, since confidential network information can be distributed with the alert information by chance.

There are developments to construct a P2P system that can detect and identify attacks in a distributed manner. Krugel, Toth, and Kerer (2001) proved that only a small number of information exchanges need to be exchanged to determine an attack in progress. Their results confirm that a P2P solution is feasible and usable for creating decentralized IDS. They supposed that the attack signatures are known by the systems before the intrusion takes place. The DOMINO overlay system (Yegneswaren, Barford, & Jha, 2004) applies the Chord document routing protocol (Stoica, Morris, Karger, Kaashoek, & Balakrishnan, 2001) to disseminate alert data based on a hash of the source IP address. The DShield project uses a centralized repository to receive intrusion alerts from a lot of distributed sources (Ullrich, 2005). The DShield supports the exchange of information among administrative domains, too.

ALGORITHMS USED IN THE DEVELOPED SYSTEM

This section introduces a novel method, which utilizes the results of the existing IDS methods and efficiently combines the individual security solutions of the operating systems with the P2P technology to construct an overlay of the developed client programs running on individual hosts. The most important algorithms making up the proposed system will also be presented.

Table 2. The design goals of the proposed system

• Creating a stable overlay network to share information. • Reports of intrusions should spread as fast as possible over the network. • Decentralized system, redundant peers. • Masking the security holes of each peer based on the reports.

Figure 1. Architecture of the Komondor system

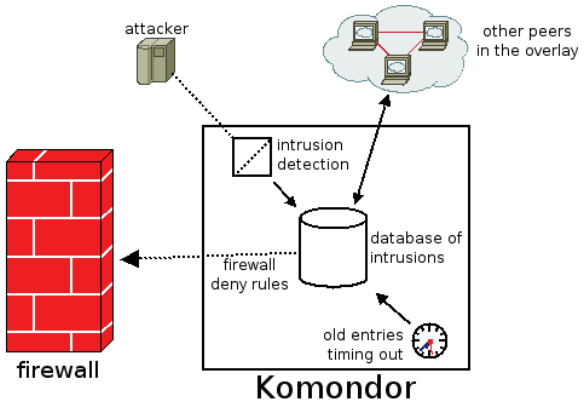

Figure 2. Attack against a Komondor node

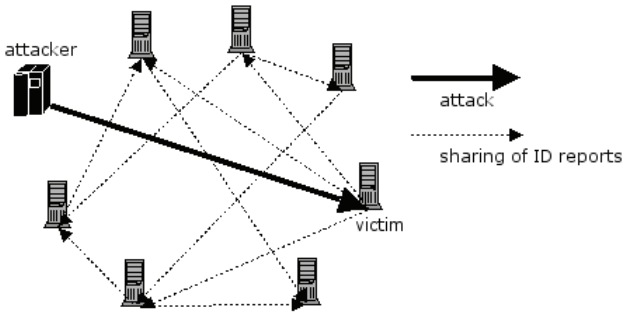

The use of the peer-to-peer network model for this purpose is new in principle. Test results proved its usefulness, with its aid were not only simulated, but also real intrusion attempts blocked. The design goal of the system is listed in Table 2.

The proposed method is implemented in software called *Komondor*, which got its name from the famous Hungarian guard dog. The Komondor software is intended to mask the security holes of services provided by the host, not to repair them. For this, it does not need to know about the security hole in detail. It can provide some protection in advance, but only if somewhere on the network an intrusion was already detected. It does not fix the security hole, but keeps the particular attacker from further activity. If the given security hole is already known, it is worth rather fixing that itself.

The inner architecture of Komondor is presented in Figure 1. Different hosts run the uniform copies of this program, monitoring the occurring network intrusion attempts. If one of the peers detects an attempt on a system supervised, it takes two actions:

1. Strengthens the protection locally, by configuring the firewall to block the offending network address.
2. Informs the other peers about the attempt.

Komondor nodes protect each other this way. If an intrusion attempt was recorded by a node, the other ones can prepare for the attack in advance. This is shown in Figure 2.

Information about intrusion attempts is collected by two means: intrusion detected by the node in question or intrusion detected by another one. The first working version of Komondor monitors system log files to collect information. These log files can contain various error messages, which may refer to an intrusion attempt. Possible examples are log-in attempt with an inexistent user name or several attempts to download an inexistent file through a HTTP server (Czirkos, 2005). The actual topology and related data of the Komondor overlay is continuously displayed on the Komondor project page (Czirkos, 2006).

CONCLUSION

The article reviewed some security-related problems of the P2P virtual networks and presented many useful and applicable approaches, which address the problem of the intrusion detection. A novel application of P2P theory was also introduced that helps the users of this system to increase security of their hosts.

The developed system is easy to use; the nodes organize the P2P overlay automatically and do not need any user interaction. It proves the reasonability of a security application utilizing local protection and P2P theory together. The dependability of a P2P overlay ensures that intrusion alerts will reach all hosts which need protection. The self-organizing property of such an overlay also ensures that it will remain functional in an environment with a high number of network link failures.

KEY TERMS

Active Network Vulnerability Scanner: Such systems send packets and communicate in some manner with the systems they are auditing.

Application Level Network (ALN): The applications, which are running in the hosts,

can create a virtual network from their logical connections. This is also called ***overlay network***. The operations of such software entities are not able to understand without knowing their logical relations. ALN software entities usually use the ***P2P model***, not the ***client/server*** model, for the communication.

Client/Server Model: A communicating way, where one host has more functionality than the other. It differs from the ***P2P model***.

Firewall: This is a host or router which provides a strict gateway to the Internet for a subnetwork, checking traffic and maybe dropping some network packets.

Intrusion Detection System (IDS): Examines the contents of the packets allowed through the firewall. It monitors network traffic to look for known signature attack patterns. When the malicious traffic is observed, the IDS generates an alert.

Overlay Network: The applications, which create an ***ALN***, work together and usually follow the ***P2P communication model***.

Passive Network Vulnerability Scanner: Monitors network traffic at the packet layer to determine topology services. They also try to identify the vulnerabilities of the client and the server in a specific network through direct analysis of the packet stream.

Peer-to-Peer (P2P) Model: A communication way where each node has the same authority and communication capability. They create a virtual network, overlaid on the Internet. Its members organize themselves into a topology for data transmission.

Chapter 8.14
Reducing the Complexity of Modeling Large Software Systems

Jules White

Egon Wuchner
Siemens AG, Germany

ABSTRACT

Model-driven development is one approach to combating the complexity of designing software intensive systems. A model-driven approach allows designers to use domain notations to specify solutions and domain constraints to ensure that the proposed solutions meet the required objectives. Many domains, however, require models that are either so large or intricately constrained that it is extremely difficult to manually specify a correct solution. This chapter presents an approach to provide that leverages a constraint solver to provide modeling guidance to a domain expert. The chapter presents both a practical framework for transforming models into constraint satisfaction problems and shows how the Command Pattern can be used to integrate a constraint solver into a modeling tool.

INTRODUCTION

Model-driven development (MDD) (Ledeczi, 2001a; Kent, 2002; Kleppe, Bast, & Warmer, 2003; Selic, 2003) is a promising paradigm for

software development that combines high-level visual abstractions—specific to a domain—with constraint checking and code-generation to simplify the development of a large class of systems (Sztipanovits & Karsai, 1997). MDD tools and techniques help improve software quality by automating constraint checking (Sztipanovits & Karsai, 1997). For example, in developing a software system for an automobile, automated constraint checking can be performed by the MDD tool to ensure that components connected by the developer, such as the antilock braking system and wheel RPM sensors, send messages to each other using the correct periodicity. An advantage of model-based constraint checking is that it expands the range of development errors that can be caught at design time rather than during testing.

Compilers for third-generation languages (e.g., Java, C++, or C#) can be viewed as a form of model-driven development (Atkinson & Kuhne, 2003). A compiler takes the third-generation programming language instructions (model), checks the code for errors (e.g., syntactic or semantic mistakes), and then produces implementation artifacts (e.g., assembly, byte, or other executable codes). A compiler helps catch mistakes during the development phrase and automates the translation of the code into an executable form.

Domain-specific Modeling Languages (DSML) (Ledeczi, 2001a) are one approach to MDD that use a language custom designed for the domain to model solutions. A metamodel is developed that describes the semantic type system of the DSML. Model interpreters traverse instances of models that conform to the metamodel and perform simulation, analysis, or code generation. Modelers can use a DSML to more precisely describe a domain solution, because the modeling language is custom designed for the domain.

MDD tools for DSMLs accrue the same advantages as compilers for third-generation languages. Rather than specifying the solution in terms of third-generation programming languages or other implementation-focused terminology, however, MDD allows developers to use notations specific to the domain. With a third-generation programming language approach (such as specifying the solution in C++), high-level information (such as messaging periodicity or memory consumption) is lost. Because a C++ compiler does not understand messaging periodicity (i.e., it is not part of the "domain" of C++ programs) it cannot check that two objects communicate at the correct rate.

With an MDD-based approach, in contrast, DSML developers determine the granularity of the information captured in the model. High-level information like messaging periodicity can be maintained in the solution model and used for error checking. By raising the level of abstraction for expressing design intent, more complex requirements can be checked automatically by the MDD tool and assured at design time rather than testing time (Sztipanovits & Karsai, 1997), as seen in Figure 1. In general, errors caught during the design cycle are much less time consuming to identify and correct than those found during testing (Fagan, 1999).

As model-based tools and methodologies have developed, however, it has become clear that there are domains where the models are so large and the domain constraints so intricate that it is extremely hard for modelers to handcraft correct or high quality models. In these domains, MDD tools that provide only solution-correctness checking via constraints provide few real benefits over the third-generation programming language approach. Even though higher-level requirements can be captured and enforced, developers must still find ways of manually constructing a model that adheres to these requirements.

Distributed real-time and embedded (DRE) systems are software intensive systems that require guaranteed execution properties (e.g., deadlines), communication across a network, or must operate with extremely limited resources. Examples of DRE systems include automobile

safety and aircraft autopilot systems. Inherent complexities in DRE systems is their large model sizes and the combinatorial nature of their constraints—not code construction per se. Specifying the deployment of software components to Electronic Control Units (ECUs, which are the automotive equivalent of a CPU) in a car, while observing configuration and resource constraints, can easily generate solution spaces with millions or more possible deployments. For these large modeling problems, it is impractical (if not impossible) to create a complete and valid model manually.

To illustrate the complexities of scale, consider a group of 10 components that must be deployed to one of 10 ECUs within a car. There are $9^{\wedge 9}$ = *387,420,489 unique deployments* that could be tried. Part of the complexity of a DRE system model is how quickly the solution space grows as the number of model elements increases. Figure 2 depicts the speed at which the solution space grows for our automotive example.

Clearly, any approach to finding a deployment that observes the constraints must be efficient and employ a form of pruning to reduce the time taken to search the solution space. A manual approach may work for a model with five or so elements. As shown in Figure 2, however, the solution space can increase rapidly as the number of elements grows, which render manual solutions infeasible for nontrivial systems.

Each component in an automobile typically has multiple constraints governing its placement. For example, an Antilock Braking System (ABS) must be hosted by a controller at least a certain distance from the perimeter of the car to enhance survivability in a crash. Moreover, the ABS will have requirements governing the CPU, memory, and bus bandwidth available on its host. When these constraints are considered for all the components, it becomes hard for modelers to handcraft correct solutions. The example in Figure 2 only has nine components and nine control units. Real automotive models typically contain 80 or more

Figure 1. Complexity of identifiable errors increases with level of abstraction

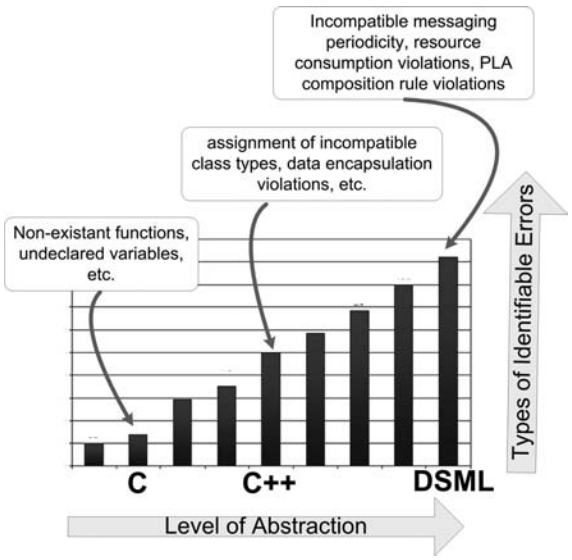

Figure 2. Number of unique deployments vs. model size

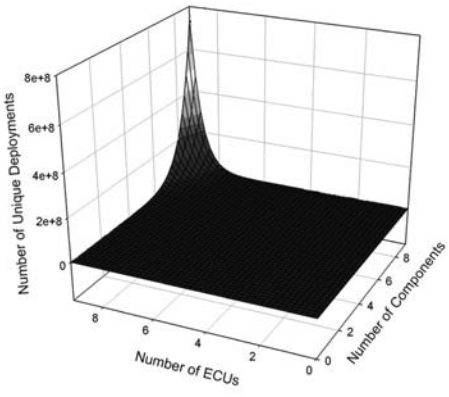


control units and hundreds of components. In models of this scale, manual approaches simply cannot handle the large numbers of possibilities and the complexity of the constraints.

The remainder of this chapter is organized as follows. The *Background* section illustrates the specific challenges of using MDD tools for these types of complex domains; The *Modeling Guidance* section presents techniques based on integrating constraint solvers into modeling environments that can be used to address these challenges; The *Future Research Directions* section describes future trends in modeling software intensive systems; and the final section presents concluding remarks.

BACKGROUND

Current Modeling Languages and Tool Infrastructure

There are a plethora of technologies and standards available for building MDD tools. This section explores some of the main frameworks, tools, and specifications that are available to develop model-driven processes for software systems.

Domain-Independent Modeling Languages

On one end of the MDD tool spectrum are Unified Modeling Language (UML) (Fowler & Scott, 2000) based tools, such as IBM's Rational Rose (Quatrani, 2003), that focus on building UML and UML-profile (Fowler & Scott, 2000) based models. When using UML, all models and languages must be specializations of the UML language. UML provides a single generic language to describe all domains. The advantage of the domain-independent approach of UML-based tools is the increased interoperability between modeling platforms that can be obtained by describing models using a single modeling language and the wide acceptance of the language. New languages can be constructed on top of UML by defining profiles, which are language extensions. UML is based on the MOF metamodel specified by the OMG.

UML is well established in software development. More recently, numerous extensions to the language based on profiles have been developed. *SecureUML* (Lodderstedt, Basin, & Doser, 2002) provides security-related modeling capabilities to UML. *Embedded UML* (Martin, Lavagno, & Louis-Guerin, 2001) is another profile available for UML that provides DRE-specific extensions, such as timing properties of components. The UML extension approach allows developers to customize the language to meet the application domain, while still maintaining (some degree of) compatibility between tools.

Domain-Specific Modeling Languages

On the other end of the MDD tool spectrum are domain-specific modeling language (DSML) (Ledeczi, 2001a) tools. In contrast to UML, DSML tools do not necessarily share a common metamodel or language format. This freedom allows DSMLs to have greater expressivity and handle domains (such as warehouse management, automotive design, and product line configuration), that contain concepts (such as spatial attributes) that are not easily expressed and visualized using UML-based tools. The drawback of DSMLs, however, is that choosing a language generally ties a development process not only to a specific way of representing the model but also generally to a specific tool. Although the loss of interoperability can be problematic, transformations can be written to convert between model formats and still achieve tool interoperability. In many cases, the greater expressivity gained by using a DSML can greatly improve the usability of the MDD tool.

Tools for Building DSMLs

To build a DSML, a metamodeling language must be used to define the syntax of the language. A metamodel describes the rules that determine the correctness of a model instance and specifies the types that can be created in the language. The OMG's current standard is the Meta-Object Facility (MOF) (Object Management Group, 2007) language. MOF provides a metamodel language, similar to UML, that can be used to describe other new languages. MOF itself is recursively defined using MOF. MOF is a specification and therefore is not wedded to a particular tool infrastructure or language technology. Many DSMLs can be described using MOF.

Another popular metamodeling language is the Eclipse Modeling Framework's (EMF) (Moore, 2004) Ecore language. Ecore has nearly identical language constructs to MOF but is a concrete implementation rather than a standard specification. Developers can describe DSMLs using Ecore (Moore, 2004) and then leverage EMF to automatically generate Java data structures to implement the DSML. EMF also possesses the capability to generate basic tree-based graphical editing facilities for Eclipse that operate on the Java data structures produced by EMF.

Complex diagram-like visualizations of EMF-based modeling languages can be developed using the Graphical Editor Framework (GEF) for Eclipse (Moore, 2004). GEF provides the fundamental patterns and abstractions for visualizing and interacting with a model. Editors can be developed using GEF that allow modelers to draw connections to create associations, nest elements to develop containment relationships, and edit element attributes. GEF editors are based on the Model, View, Controller (MVC) pattern (Gamma, Helm, Johnson, & Vlissides, 1995). GEF, however, requires complex graphical coding.

The Graphical Modeling Framework (GMF) (Graphical Modeling Framework, 2007), is higher level framework, built on top of GEF, that simplifies the development of graphical editors. GMF automates the construction of the controller portion of GEF editors and provides a set of reusable view classes. MVC controllers are developed using GMF by creating complex XML files that map elements and their attributes to views in the model. GMF takes the XML mappings of elements to views and generates controllers that developers can use to synchronize the model and view of the MDD tool automatically.

Even with the powerful development frameworks presented thus far, developing a visual MDD tool requires significant effort. *Metaprogrammable* modeling environments (Ledeczi, 2001a) help alleviate this effort by allowing developers to specify the metamodel for a DSML visually. After the visual specification for the language is complete, the metaprogrammable modeling environment can automatically generate the appropriate code and configure itself to provide graphical editing capabilities for the modeling language.

Metaprogrammable modeling environments also provide complex remoting, model traversal, library, and other capabilities that are hard to develop from scratch. Two examples of these environments are the Generic Modeling Environment (GME) (Ledeczi, 2001b), which a windows-based metaprogrammable MDD tool, and the Generic Eclipse Modeling System (GEMS) (Generic Eclipse Modeling System, 2007), a part of the Eclipse Generative Modeling Technologies (GMT) project. The main tradeoff in using metaprogrammable modeling environments is that they tend to provide less flexibility in the visualization of the model.

Constraint Checking with OCL

Many modeling techniques rely on a constraint specification language to provide correctness checking rules that are hard to concisely describe using a graphical language. Certain types of constraints that specify conditions over multiple

types of modeling elements, not necessarily related through an interface or inheritance, are more naturally expressed using a textual constraint specification language. The constraint language rules are run against instances of the UML, EMF, or other models to ensure that domain constraints are met. Constraint failures are returned to the modeler through the use of popup windows or other visual mechanisms.

The OMG Object Constraint Language (OCL) (Warmer & Kleppe, 1998) is a standard constraint specification for modeling technologies. OCL allows developers to specify invariants, preconditions, and postconditions on types in the modeling language. For example, the OCL constraint:

```
context ECU
inv: self.hostedComponents->collect(x
        | x.requiredRAM)->sum() < self.RAM
```

can be used to check that the sum of the RAM demands of the components hosted by an ECU do not exceed the available RAM on the ECU. The first line of the OCL rule defines the context or the type to which the OCL rule should be applied. The second part of the rule, beginning with "inv," defines the invariant condition for the rule. When there is a change to a property of a modeling element of the context type, the invariant conditions for the rules applicable to the element must be checked. Invariants that do not hold after the modification are flagged as errors in the MDD tool.

OCL works well for localized constraints that check the correctness of the properties of a single modeling element. As described earlier, however, the rule can only be used to check the correctness of the state of a modeling element and not to *derive valid states for a modeling element*, which is a process called ***backward chaining*** (Ginsberg, 1989). In a modeling context, backward chaining is a process whereby the MDD tool deduces correct modeling actions based on the domain constraints. For example, if it were possible to use the above OCL rule to backward chain, a MDD tool could not only determine whether or not an ECU was in a correct state but also, given the current state of an ECU, produce a list of components that could be hosted by the ECU without violating the rule.

For software systems with global constraints and large models, the inability of traditional modeling and constraint checking approaches, such as OCL, to not only flag errors but deduce solutions limits the utility of model-based development approaches. Backward chaining (providing modeling guidance) becomes more important as domains become more complex, and where it is thus harder to handcraft solutions.

Emerging Modeling Challenges

Deriving Solutions that Meet a Global Constraint

The increasing proliferation of DRE systems is leading to the discovery of further hard modeling problems. These domains all tend to exhibit problems, such as scheduling with resource constraints (Yuan & Nahrstedt, 2003), that are exponential in complexity because they are different types of NP problems. A key challenge in developing effective and scalable DSMLs and models for these domains is deriving the overall organization and architecture of MDD tools and software platforms that can simultaneously meet stringent resource, timing, or cost constraints.

Mobile devices are a domain that have become widely popular and typically exhibit tight resource constraints that must be considered when designing software (Forman & Zahorjan, 1994). Software design decisions, such as the CPU demand of the application, often have physical impacts on the device as well. For example, the scheduling of and workload placed on the CPU can affect the power consumed by the device. Poor scheduling or resource allocation decisions can therefore limit battery life (Yuan & Nahrstedt, 2003).

Determining the appropriate scheduling policies and application design decisions to handle the resource constraints of mobile devices is critical. Without the proper decisions, devices can have limited battery life and usability. Scheduling with resource constraints, however, is an NP problem (Cormen, Rivest, Leiserson, & Stein, 1990) and thus cannot be solved manually for nontrivial problems.

Adhering to Nonfunctional Requirements

Another challenge of DRE systems is that they often exhibit numerous types of nonfunctional QoS requirements that are hard to handle manually. For example, in automotive development, an application may have communication timing constraints on the real-time components (e.g., antilock braking control), resource constraints on components (e.g., infotainment systems), and feature requirements (e.g., parking assistance) (Weber & Weisbrod, 2002). In environments with this range of QoS requirements, a correct design must solve numerous complex problems and solve them in a layered manner so the solutions are compatible.

For example, the placement of two components on particular ECUs may satisfy a timing constraint but cause a resource constraint failure for another component, such as the infotainment system. Not only must modelers be able to solve numerous types of individually challenging problems, therefore, but they must be able to find solutions that meet all of the requirements.

Another area where complex constraints are common is in configuration management, which is key in emerging software development paradigms, such as product-lines (Jaaksi, 2002) and feature modeling (Antkiewicz & Czarnecki, 2006). In these domains, applications are built from reusable software components that interact through a common set of interfaces or framework. Applications are assembled using existing software assets for specific requirement sets. For example, in mission critical avionics product lines, such as Boeing Bold Stroke (Schmidt, 2002), the correct software component to update the HUD display is selected based on the timing, memory, and other requirements of the particular airframe to which the software is being deployed. Configuration-driven domains exhibit the same characteristics of computationally complex constraints that drive overall system organization as other complex domains.

The remainder of this chapter presents an approach to using a constraint solver integrated into a modeling environment to address these challenges. First, the chapter introduces the types of modeling assistance that can be provided to help alleviate these challenges. Second, the chapter illustrates how a constraint solver can be used to provide these types of modeling assistance. Finally, an architecture for integrating Prolog into a modeling environment as a constraint solver is described.

MODELING GUIDANCE

This section illuminates the challenges of modeling software intensive systems and then presents an approach to providing modelers with modeling guidance from a constraint solver. Specific emphasis is placed on how modeling guidance can be used to reduce the complexity of modeling software intensive systems. Finally, the chapter illustrates how a constraint solver can be integrated into a graphical modeling tool.

Measuring Domain Complexity

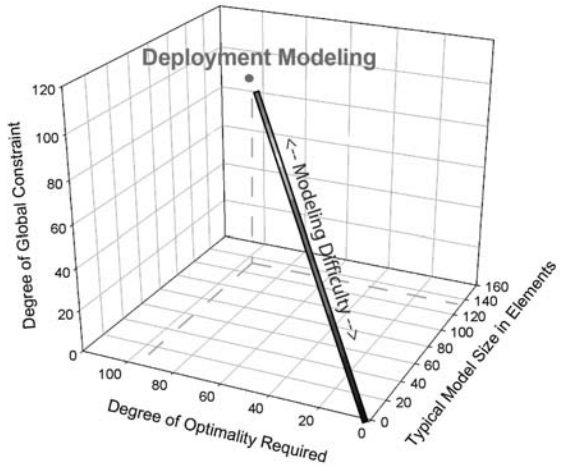
The complexity of modeling an arbitrary domain can be measured along the following three axes:

- **Typical model size in elements:** Large models are harder to work with using a manual approach. Clearly, modelers are more apt to

make mistakes managing—and much more likely to have trouble visualizing—a domain with hundreds of model elements than one with dozens of model elements.

- **Degree of global constraint:** Global constraints, such as resource constraints, that are dependent on multiple modeling steps or the order of modeling steps make a domain much harder to work with. For example, a constraint requiring the deployment of an ABS component to a single ECU at a certain distance from the perimeter of the car is relatively easy to solve. It is much harder to solve constraints of an ABS component requiring its deployment to two ECUs, both a minimum distance from the outside of the car and a minimum distance from each other (for fault tolerance guarantees).
- **Degree of Optimality Required:** Optimality is hard to achieve with a manual modeling approach. In many domains, such as manufacturing, a small increase in the cost of a solution can lead to a dramatic increase in the overall cost of manufacturing when the millions of units affected by the change are considered. Many solutions must therefore be tried to find the best one. Domains that require optimal or good answers are much more challenging to model.

Figure 3. Axes of measuring modeling complexity



The three axes described above can be used to categorize and evaluate different modeling domains. The difficulty of modeling a domain can be viewed as the distance of the domain from the origin when plotted according to its degree of global constraint, degree of required model optimality, and typical model size, as shown in Figure 3.

Key Challenges of Complex Domains

The key reasons that manual modeling approaches do not scale as a modeling domain moves further and further along the axes, shown in Figure 3, away from the origin is:

1. When there are thousands, millions, billions, or more possible ways that a model can be constructed and few correct ones, finding a valid solution is hard.
2. A valid solution may not be a good solution in these domains. Often, a modeler may find a solution that is valid but is far from the optimal solution. Automation and numerical methods, such as the Simplex method (Nelder & Mead, 1965), are needed to efficiently search the solution space and find good candidates. A human modeler cannot effectively search a solution space manually once it grows past a certain magnitude.
3. For large models, manual construction methods, such as pointing and clicking to intricately connect hundreds or more components, are tedious and error prone.
4. Often, global constraints rely on so much information that not all of the relevant bits of

information can be seen at once. When not all of the information can be seen, modelers cannot make an informed decision.

Another difficulty of highly combinatorial domains is that although modelers may create a model that satisfies the domain constraints, the model may be considered poor in quality. For example, a modeler creating a deployment of components to ECUs could easily select a scheme that utilized far more ECUs than the true minimum number required to host the set of components. For domains, such as automotive manufacturing, each modeling decision can have significant cost consequences for the final solution. For example, if a model can be constructed that uses three fewer control units to host the car's components and consequently saves $100 in manufacturing costs, millions of dollars in overall cost reduction for all cars of this make that are manufactured can be achieved. In these cases, it is crucial to not only find a correct solution but to find a cost effective one.

The difficulty of finding a good solution is that with large models and complex global constraints, modelers are lucky to find *any* valid solution. Because finding a single solution is incredibly challenging, it becomes infeasible or cost prohibitive to produce scores of valid solutions and search for an optimal one. Even if the set of valid solutions is large, there are numerous numerical methods to search for a solution with a given percentage of optimality. These methods, however, all rely on the ability to generate large numbers of valid solutions and are not possible without automation.

In domains with large models and intricate constraints, modelers must be able to see hundreds of modeling moves into the future to satisfy a global constraint or optimize a cost. The more localized a modelers decisions are and the less distant they peer into the future, the less chance there is that a correct or good solution will be found. Good local decisions, also known as "greedy decisions," do not necessarily produce a globally good decision.

For example, consider a simple model that determines the minimum number of ECUs needed to host a set of components. Assume that there are two types of ECUs, one that costs $10 and can host 2 components and another that costs $100 and can host 42 components. If modelers are deploying using a myopic view and not peering into the future, they will select many $10 ECUs and create a solution that costs $210, rather than looking ahead and choosing two $100 controllers for a final cost of $200. Making a series of locally good decisions may not produce the overall best decision (Cormen et al., 1990).

Solution: Integrating Constraint Solvers and MDD Tools

An MDD tool provides a visual language for a developer to build a solution specification. An instance of a visual model contains modeling entities or elements, similar to OO classes, and different visual queues (e.g., connections, containment) specifying relationships between the elements. For example, a connection between a component and an ECU specifies deployment in the automotive modeling example from the Introduction section.

The key objective of a modeler is to add the right model entities and relationships between the entities so that they create a solution that meets the application requirements. Modelers express relationships between entities by drawing connections between them, placing entities within each other for containment, or other visual means. For each relationship that a modeler creates between entities, such as deployment, the modeler must find the right source and target for the relationship so that the relationship satisfies any constraints placed on it. In the example of deploying components to ECUs, the modeler must only draw

a connection from a component to an ECU that has the OS and resource capabilities to support the component.

As has been shown in the *Introduction*, *Background*, and *Measuring Domain Complexity* sections, the large size of DRE models and their complex constraints can make manually finding the right endpoints for these relationships, such as deployment, infeasible. To address the scalability challenges of manual modeling approaches presented in the aforementioned sections, this section outlines how a constraint solver can be integrated with an MDD tool to help automate the selection of endpoints for relationships between model entities.

In the context of modeling, a constraint solver is a tool that takes as input one or more model elements, a goal that the user is attempting to achieve, and a set of constraints that must be adhered to while modifying the elements to reach the goal. As output, the constraint solver produces a new set of states for the model elements that achieves the desired goal while adhering to the specified constraints. For example, a set of components can be provided to a constraint solver along with the deployment requirements (constraints) of the components. The goal can then be set to "all components connected to an ECU." The constraint solver will in turn produce a mapping of components to ECUs that satisfies the deployment constraints.

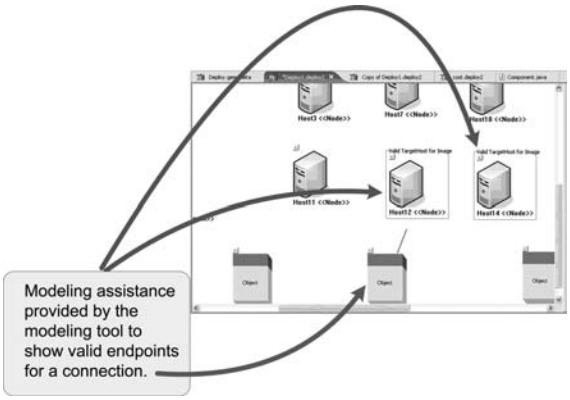
The remainder of this section first outlines the different type of modeling assistance that an MDD tool and integrated constraint solver can provide to a user. Next, the section discusses how a user's actions in an MDD tool can be translated into constraint satisfaction problems (CSPs) so that a constraint solver can be used to automatically derive the correct endpoints for the relationships the user wishes to create. Finally, the section illustrates an architecture for integrating Prolog as a constraint solver into an MDD tool.

Modeling Assistance

There are two types of constraint solver guidance that can be used to help modelers produce solutions in challenging domains: *local guidance* and *batch processes.* Local guidance is a mechanism whereby the constraint solver is given a relationship and one endpoint of the relationship and provides a list of valid model entities that could serve as the other endpoint for the relationship. One example is that a constraint solver could be provided a deployment relationship and a component and return the valid ECUs that could be attached to the other end of the connection. This type of local guidance for deploying components is shown in Figure 4.

The second type of modeling guidance is for deriving endpoints for a group of relationships so that the group as a whole satisfies a global constraint. An example of a batch process would be to connect each component to an ECU in a manner such that the no ECU hosts more components than its resources can support. A batch process takes an overall goal that the modeler is trying to achieve, such as all components connected to an ECU, and creates a series of relationships on

Figure 4. Local modeling guidance



behalf of the user to accomplish that goal. By offering both local guidance and batch processes, a MDD tool can help users to accomplish both small incremental refinements to a model and large goals covering multiple modeling steps.

Local Guidance

Local guidance helps modelers correctly complete a single modeling step. A single modeling step is defined as the creation of one relationship between two modeling elements. Local guidance can be implemented as a visual queue that shows the modeler the valid endpoints for a relationship that he or she is creating. For example, when a modeler creates a connection from a component to an ECU to specify where a component is deployed, the modeler must first click on the component modeling element to initiate the connection. When the connection is initiated, the constraint solver can be used to solve for the valid deployment locations for the component and the model elements corresponding to these deployment locations can be highlighted in the model.

Challenges 3 & 4 from the section *Key Challenges of Complex Domains* can be addressed with local guidance. By identifying the model elements that are valid target endpoints of the modeling action a user is performing, a modeling tool can use visual queues (e.g., highlighting, filtering, etc.) to show the user only the information relevant to the action. Furthermore, the modeling tool can use the list of valid targets to both help the modeler identify valid solutions (helping address challenge 1 of *Key Challenges of Complex Domains*) and to prevent the user from applying an action to an invalid target endpoint (addressing challenge 3 of *Key Challenges of Complex Domains*). With a traditional MDD approach, the correctness of a user's action is checked after completion and thus the user may have to do and undo an action multiple times before the correct target endpoint is found. By finding valid solutions before a modeler completes a modeling action, the tool can preemptively constrain (e.g., veto modeling actions) what modeling elements the action can be applied to and prevent tedious and error-prone manual solution searching.

Local guidance can not only provide suggestions of correct endpoints of a relationship but can provide rankings of the local optimality of each of the endpoints. For example, deployment locations could be ranked by the resource slack available on them so that modelers are led to choose deployment targets with sufficient free resources. This manner of local guidance provides a greedy strategy to modeling guidance. At each step, modelers are led towards a solution that provides the greatest immediate benefit to the model's correctness.

Correct solutions to modeling transactions of a single modeling step can be found using local guidance. In some cases, only considering single step transactions will not produce a solution that satisfies global constraints. For example, if modelers can add ECUs as needed to deploy components to, local guidance can produce a solution that is correct with respect to the constraints, although not necessarily optimal. If, however, ECUs cannot be added to the model and the local strategy guides the modeler to a solution where no ECU has free resources and several components are undeployed, the global constraints cannot be met.

Although a greedy strategy may not produce optimal results for certain types of CSPs, such as bin-packing, in many cases these localized strategies can provide a lower bound on the optimality of the final solution. With bin-packing, a First Fit Decreasing (FFD) (Coffman, Galambos, Martello & Vigo, 1998) packing strategy that sorts items to be placed into bins by their size and nondeterministically selects the first bin that can hold the item will guarantee that the solution never uses more than ~1.87 times as many bins as the optimal solution. Providing a lower bound on the quality of the solution that a modeler can produce can

be extremely important in some domains, such as automotive manufacturing, where you want to minimize risk or cost. Although not guaranteed, a localized strategy may in fact arrive at an optimal or nearly optimal solution. Moreover, local guidance is substantially less computationally complex than providing a global maximum and can be implemented easily with a number of the approaches discussed later in this section.

Batch Processes

Global constraints require the correct completion of numerous modeling steps and are typically not amenable to user intervention. For global strategies, therefore, ***batch processes*** guided by constraint solvers can be used to create multiple relationships to bring the model into a correct state. The key differentiator between local guidance and a batch process is that local guidance deals with modeling transactions involving a single relationship while batch processes operate on modeling transactions containing two or more relationships. The larger the number of relationships in the transaction, generally the more complicated it is to complete.

One possible batch process for the component-to-ECU deployment tool could take each component in the model and create a connection to an ECU in the model to specify a deployment location. Local guidance would produce a single deployment connection for a single component. By increasing the size of the modeling transaction to consider the deployment locations of multiple components, the batch process can use the constraint solver to guarantee that if a possible solution is found, it utilizes only the ECUs currently in the model. By expanding the transaction size that the solver operates on, the batch process allows it to make model modifications that are not locally optimal, but lead to a globally optimal or globally correct solution.

Batch processes help address challenges 1, 2, & 3 of the section *Key Challenges of Complex Domains*. First, a batch process can correctly complete large numbers of modeling actions on behalf of the user, eliminating tedious and error-prone manual modeling (addressing challenge 3). Second, a constraint solver can create both a correct and an optimal solution that can be enacted by a batch process on behalf of the modeler (addressing challenge 1). By tuning the parameters used by the constraint solver, as is discussed in the section *Transforming Non-functional Requirements into Constraint Satisfaction Problems*, the modeler can guarantee both optimality and correctness (addressing challenge 2).

Transforming Nonfunctional Requirements into Constraint Satisfaction Problems

To integrate local and batch process guidance from a constraint solver, a model and the actions that modelers can perform on the model must be transformed into a series of constraint satisfaction problems (CSPs). This transformation allows the MDD tool to translate the actions of users into queries for a constraint solver. Valid satisfactions of the CSPs correspond to correct ways of completing a modeling action, such as creating a connection.

A CSP is a set of variables and constraints over the values assigned to the variables. For example, $X < Y < 6$ is a CSP with integer variables *X* and *Y.* Solving a CSP is finding a set of values (a labeling) for the variables such that the constraints hold true. The labeling X = 3, Y=4, is a correct labeling of X < Y < 6. A constraint solver takes a CSP as input and produces a labeling (if one exists) of the variables. Solvers may also produce labelings that attempt to maximize or minimize variables. For example, X = 4, Y =5, is a labeling that maximizes the value of X.

For the deployment example, a deployment of a set of components to a set of ECUs can be viewed as a binary matrix where the cell at row *i* and column *j* is 1 if and only if the *i*th component

is deployed to the *j*th ECU (and 0 otherwise). Each cell can be represented as an independent variable in a CSP. Thus, each variable *Dij* determines if the ith component is deployed to the jth ECU. Finding a correct labeling of the values for the *D* variables creates a deployment matrix that can be used to determine where components should be placed.

Assume that the *ABS* (antilock braking system) component and the *WheelRPMs* components must be deployed to the same ECU. Also assume that the ABS component must be placed on an ECU at least 3 feet from the perimeter of the car. This series of deployment constraints can be translated in a CSP model. Let the ABS component be the 0^{th} component and the WheelRPMs component be the 1^{st} component. First, the constraint that the ABS component be deployed to the same ECU as the WheelRPMs component is encoded as $(D_{0j} = 1) \rightarrow (D_{1j} = 1)$. Next, for each ECU, a constant $Dist_j$ can be created to store the distance of the jth ECU from the perimeter of the car. Using these constants, the constraint on the placement of the ABS component relative to the perimeter of the car can be encoded as $(D_{0j} = 1) \rightarrow (Dist_j \geq 3)$. If this CSP is input into a constraint solver, the solver will label the variables and produce a deployment matrix that is guaranteed to be correct with respect to the deployment constraints.

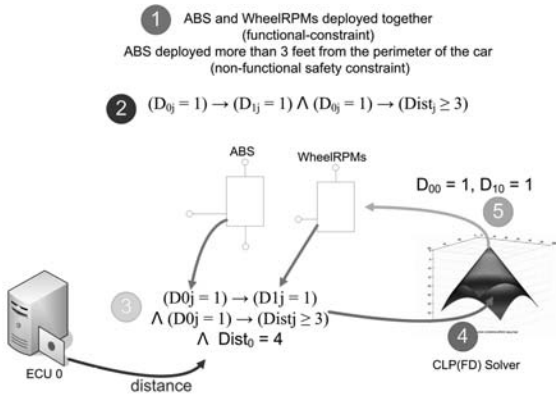
A constraint solver can also be used to derive a solution with a certain degree of optimality. Assume that *N* components need to be deployed to one or more of *M* ECUs using as few ECUs as possible. A new variable *UsedECUs* can be introduced to store the total number of ECUs used by a solution. The constraint $UsedECUs = \sum D_{ij}$ for all i from 0..N and all j from 0..M. The solver can then be asked to produce a labeling of the variables D_{ij} that minimizes the variable UsedECUs. The solver will in turn produce a valid deployment of the components to ECUs that also minimizes the total number of ECUs used.

Constraint solvers typically offer a number of solution optimization options. The options range from maximizing or minimizing a function to using a fast approximation algorithm that guarantees a specific worst-case percentage of optimality. Depending on the constraint solver settings used, a modeler can guarantee the optimality of a model or trade a certain percentage of model optimality for significantly reduced solving time. In contrast, a manual modeling approach provides no way to guarantee correctness, optimality, a percentage of optimality, or a tradeoff between optimality and solution time. For software intensive systems where optimality is important, allowing modelers to tune these parameters is a key advantage of using a constraint solver-integrated modeling approach.

One goal of using a constraint solver is to produce better solutions than a human modeler can create manually and to produce good solutions more reliably. When a solver uses either optimal or approximation algorithms, the solver's solution has a known and guaranteed worst case solution quality. In contrast, there is no guarantee on the solution quality with a manual approach.

As shown in Figure 5, the nonfunctional requirements for the software system must first be

Figure 5. Transforming a model into a constraint satisfaction problem



collected and documented (step 1). Each nonfunctional requirement must then be translated into a CSP, such as a system of linear equations (step 2). At this point, the data from the model, such as ECU distances to the car perimeter, are collected and bound to variables in the CSP produced in the previous step (step 3). Next, the CSP with some bound variables (such as resource demands) and some unbound variables (such as the D_{ij} variables in Figure 5) are input into the constraint solver (step 4). The constraint solver then produces bindings for the unbound variables and maps them back to changes in the model (step 5).

A crucial element for creating the right translation from nonfunctional requirements to a set of CSPs is the abstraction used to decompose the model into the variables and facts (i.e., bound variables) that the CSPs operate on. For example, should ECU and component be present in the formulation of the CSP to represent the bin-packing of the model's resources? The metamodel of a language, as described in *Background* section, provides the terminology and syntactic rules for a modeling language. Because the metamodel contains a precise definition of the relevant types in a modeling language it is ideal for identifying the key concepts that the CSPs should use. The metamodel of a modeling language can be viewed as a set of model entities and the role-based relationships between them. By using this abstraction based on entities and role-based relationships, a model can be conveniently decomposed for processing by a constraint solver. The idea of relationships between elements is the same as the widely used Resource Description Framework's predicate/argument format.

The role-based relationships of an entity represent both its properties (such as available CPU) and its associations (such as hosted components). Each entity can be decomposed into a unique ID and a set of role-based relationships associated with the ID. A requirement, such as "a component is only deployed to an ECU with the correct OS" can be translated into a CSP involving the *Deployment*, and *OS* relationships of a component and ECU. The variables of the CSP for this requirement would be the component and ECU that are being associated through the *Deployment* relationship. The constraint would be that the *OS* relationship of the component and the ECU had the same value (i.e., the same OS).

Associating Modeling Actions with the Constraint Solver

An important integration question is how/when to invoke the constraint solver and what CSPs and variable bindings should be passed to it. The goal is to use the constraint solver to provide local guidance and batch processes to bind the endpoints of relationships in the model. A constraint solver requires a CSP, a set of unbound variables (e.g., unbound endpoints), and a set of bound variables to produce a list of endpoints for relationships. Thus, users' actions and model state must be interpreted to find the correct CSPs, model entities, and unbound endpoints to pass to the solver. By defining the right formal model of the process by which users' actions are interpreted and translated into input data for the constraint solver, the integration process can be more cleanly defined. This section presents a formal abstraction for a user's interaction with a modeling tool and shows the point in the formal specification at which the constraint solver can be integrated and used to automate relationship endpoint binding decisions.

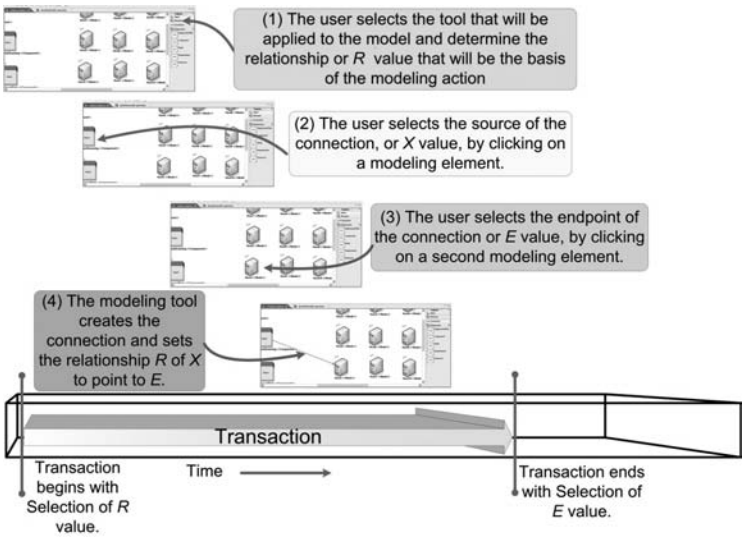
Modeling actions are transactions that take one or more elements of the model and modify the endpoints of the selected elements' role-based relationships. Creating a deployment connection takes a component (the source of the connection) and sets the endpoint of its *TargetECU* relationship. In the *Local Guidance* and *Batch Processes* sections, a modeling action was defined as a transaction by the user that takes a relationship and sets its source and target entities. More formally, a modeling action is a function, *action(X,*

R, E), that takes a model element *X*, a relationship of the element, *R*, and produces an endpoint for that relationship *E,* as shown in Figure 6.

The goal of a traditional MDD tool is to take the input produced by the user, such as mouse clicks, and translate them into the values for *X*, *R*, and *E* to update the model. With a traditional MDD tool, the values for *E* are explicitly bound by modelers. A MDD tool integrated with a constraint solver not only provides this traditional explicit binding capability but also provides a constraint solver binding process, in which the constraint solver deduces the proper endpoints for relationships on behalf of the modeler.

The GEF and EMF frameworks can be used to illustrate how X, R, and E are actually implemented in a modeling framework. GEF provides an MVC framework for displaying and editing EMF models. In GEF, each possible user action, such as connecting two elements with a line in the graphical model, is represented with a *Command* object. The command object is a part of the *Command Pattern* (Gamma et al., 1995), which encapsulates actions that can affect a model in an object. When the user clicks on an element and then presses the delete key, GEF constructs a *DeleteCommand*, sets the command's argument to be the element that was click on, and then calls the command's *execute()* method, which deletes the element from the EMF model. When the user wishes to create a connection, the user selects the connection tool from a tool palette. Selecting the connection tool causes GEF to construct a *ConnectionCommand*. When the user clicks on the first element for the connection, GEF passes the element to the ConnectionCommand as the source argument. When the user clicks on the endpoint for the connection, GEF passes the command the endpoint as the target argument and calls the command's execute() method, which creates the connection between the two elements. Tool implementers create Command objects to specify how each possible user action is translated into changes of the underlying EMF model.

Figure 6. Diagram of a modeling transaction



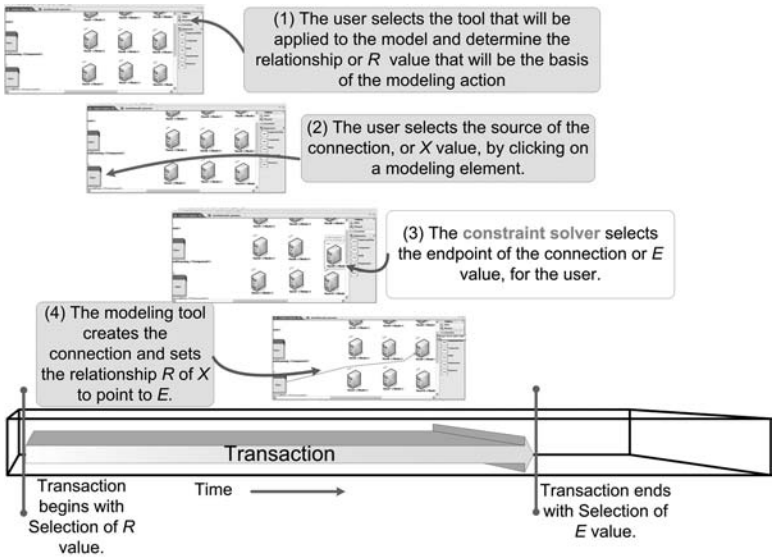
With GEF's command pattern, R is determined by the type of Command object that GEF instantiates. In the deployment example, when the user selects the *DeploymentConnection* tool, GEF creates a corresponding *DeploymentConnectionCommand* object. The Command knows (because it is coded into the command object's execute method) that it is modifying the *TargetECU* relationship of its source argument. The command also knows that its source argument is the X variable in the action(X,R,E) function. Finally, the command knows that its target endpoint represents the E variable. Each Command object is used to translate a graphical user action (e.g., adding a connection) into values for X, R, and E. The Command is also responsible for modifying the R relationship between X and E in its execute method. The execute() method of a DeploymentConnectionCommand is shown in the Java code below:

```
public class DeploymentConnectionCommand
extends Command{
 ....
 //apply action(X,R,E)
 public void execute() {
  Component source = (Component)this.get-
Source(); //the X
 ECU target = (ECU)this.getTarget(); //the E

 //the R relationship (targetECU) between X and
E is set here
 source.setTargetECU(target);
 }
}
```

In the modified binding process for *E*, each relationship *R* is associated with a CSP specifying what is considered a correct value for *E*. For example, a component could specify that a correct value for its *TargetECU's E* value requires that the chosen *E* value and the component both have the same OS type. When a user input is translated

Figure 7. A diagram of a modeling transaction with a constraint solver



into values for *X* and *R*, a constraint solver integrated MDD tool uses the CSP associated with *R* to automatically derive values for *E* on behalf of the user. In Figure 5, the CSP was found in step 2, the values for *X* and *R* were produced in step 4 and the bindings for *E* were delivered by the constraint solver in step 5. The modified modeling transaction process can be seen in Figure 7.

In the first step, the user selects a tool or action that will be applied to the model. The tool determines the *R* value or relationship that will be modified by the user's actions. In the second step, the user clicks on a modeling element to initiate a connection and hence modify a relationship in the underlying model. The element that the user clicks on becomes the *X* value that will be passed to the constraint solver. In the third step, the modeling environment looks up the correct CSP that must be satisfied by the endpoints of the relationship specified by the *R* value. The modeling environment then passes this CSP, the *X*, and *R* values to the solver. The solver finds the endpoints that satisfy the CSP and returns these endpoints as possible *E* values. Finally, the *E* values are presented graphically to the user.

The GEF *DeploymentConnectionCommand* can be modified to incorporate this new process by which the constraint solver chooses the value for *E*. The Command creation and initial argument setting remains unchanged. However, after the source of the connection has been set, the constraint solver can be invoked to solve for a value for E. If a value is returned, the execute() method can be called immediately. The new *DeploymentConnectionCommand* is:

```
public class DeploymentConnectionCommand
extends Command{
 ....
 public void setSource(Object obj) {
  this.source = obj;

  //the X
  Component source = (Component)obj;

  //call the solver to find valid values for E
 List endpoints = this.solver.findEndpoints(source.
getId(),
                    "targetECU");

  //if there is only one possible value, go ahead
and execute
  if(endpoints.size() == 1){
    setTarget(endpoints.get(0));
    execute();
  }
  else if(endpoints.size() > 0) {
    //otherwise, show the user valid E values by
    //modifying their background color
    for(Object obj : endpoints)
        ((ECU)obj).setBackgroundColor(Color.yel-
low);
  }
else {
 //notify the user that there are no
  //possible deployment locations for the Com-
ponent
 source.setBackgroundColor(Color.red);
}
 }

 //apply action(X,R,E)
 public void execute() {
  Component source = (Component)this.get-
Source(); //the X
 ECU target = (ECU)this.getTarget(); //the E

 //the R relationship (targetECU) between X and
E is set here
 source.setTargetECU(target);
 }
}
```

In the modified DeploymentConnectionCommand, immediately after GEF sets the source of the connection, the command invokes the constraint solver to find valid endpoints. If exactly one endpoint is found, the setTarget method is called with that endpoint and the Command is executed. If more than one valid endpoint is found, each valid target has its background color changed to yellow (a visual queue). If there is no possible deployment location for the Component, its background color is changed to red.

In a traditional process, the user would be required to click first on the source element, decide on a valid deployment location for the source, and then click on the deployment location. With the modified Command object, the object itself attempts to determine the valid targets (E) using the constraint solver. The Command can then automatically complete the action on the user's behalf, if there is exactly one possible endpoint. If there is more than one possible endpoint, the Command can highlight those endpoints for the user. If no endpoints are found, the Command can notify the user by changing the Component's background color to red.

In many situations, the user will wish to find a valid endpoint for a specified R relationship for every member of a set of modeling elements. For example, the user may wish to select some or all of the Components and have the solver find a valid target ECU for every Component such that no global deployment constraint, such as resource consumption, is violated. Using the GEF framework, a new *BatchDeploymentCommand* can be created.

Just as with other GEF commands, the BatchDeploymentCommand can have a tool palette entry associated with it that the user can select. When the user selects the corresponding tool entry, the BatchDeploymentCommand is created. The batch command takes a group of modeling elements, which the user specifies through a group selection, and creates a connection for each member of the group to a valid ECU. The Java code for the BatchDeploymentCommand is:

```
public class BatchDeploymentCommand extends
Command{
 ....

 public void execute() {
 //the set of Xs
  Component[] sources = (Component[])this.
getSources();
 //the solver deduces an E for each X
  Object[] targets = this.solver.findValidTargets(
sources,
                    "targetECU");

 if(targets != null){
  for(int i = 0; i < targets.length; i++) {
   sources[i].setTargetECU((ECU)targets[i]);
  }
 }
 }
}
```

Constraint Solver and MDD Tool Integration Frameworks

There are a large number of optimization, constraint solver, and inference engines available for use with local guidance and batch processes. As noted in Van Hentenryck and Saraswat (1996), however, automating the formulation of real problems in a suitable form for efficient algorithmic processing is hard. Transforming an arbitrary graphical model, a modeling action, and a set of modeling constraints into a CSP for a constraint solver is tedious and error-prone. Integrating the results of the solver back into a MDD tool and providing interactive capabilities is also hard. Each of the five steps from the section *Transforming Non-functional Requirements into Constraint Satisfaction Problems* may require substantial effort. By choosing the right approach and architecture, however, the difficulty of leveraging a constraint solver in a modeling environment can be reduced substantially.

The following are five important properties of an architecture for integrating a constraint solver with a MDD tool:

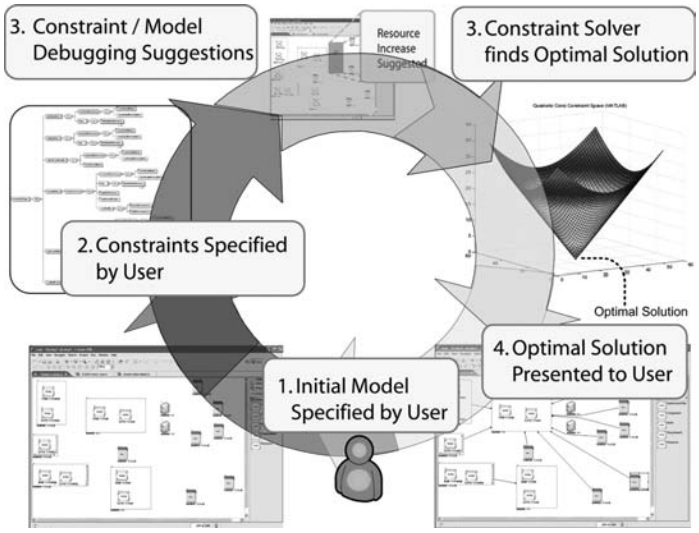
1. **Solver frameworks must respect domain-specific concepts from the MDD tool** and provide a flexible mechanism for translating nonfunctional requirements into CSPs using domain notations. MDD tool users should

be able to specify constraints in a language or notation that mirrors the domain rather than a system of linear equations and makes mapping requirements to a CSP easier.

2. **The local guidance and batch processes should lead modelers toward solutions that are considered optimal** or good based on quality metrics from the domain. Whenever possible, solvers should be used to iterate through multiple valid solutions and suggest only those considered most optimal. Modelers should be able to plug-in custom formulas for measuring optimality in the target domain and the tool should be able to present multiple suggestions based on various types of optimization.
3. **The constraint solver integration should automate tedious and complex modeling tasks**, such as solving for and assigning values for global constraints, performing repetitive localized decisions, or providing feedback to modelers to suggest valid modeling decisions.
4. **The solver framework must accommodate long-running analyses** for problem instances that cannot be solved online. For large optimization problems, such as finding the lowest cost assignment of components to ECUs, the constraint solver may need several hours or days to find a solution. In cost-critical situations, such as manufacturing, allowing the solver the extra time to find the best solution can be critical.

With a constraint-solver integrated modeling environment, a user goes through an iterative process of specifying portions of a model, adding or refining nonfunctional requirements as constraints, and using the constraint solver to automate model construction and optimization. Figure 8 illustrates the modeling processing with an integrated constraints solver.

Figure 8. A modeling cycle with constraint solver integration



In the first step, a user specifies the initial model entities in the solution. In the second step, the user adds constraints for the requirements of the solution into the MDD tool. During the third phase, the user invokes the constraint solver, using local-guidance or a batch process, to find valid endpoints for various relationships in the model. Finally, in the fourth step, the valid endpoints found by the constraint solver are shown to the modeler using visual queues, such as highlighting valid entities.

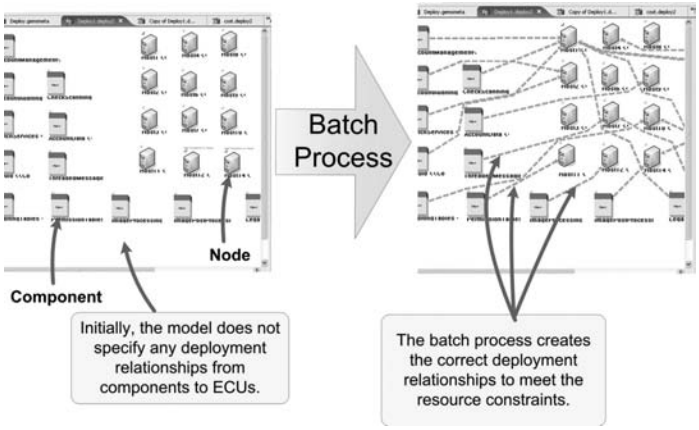

Figure 10. Transforming model elements into prolog facts

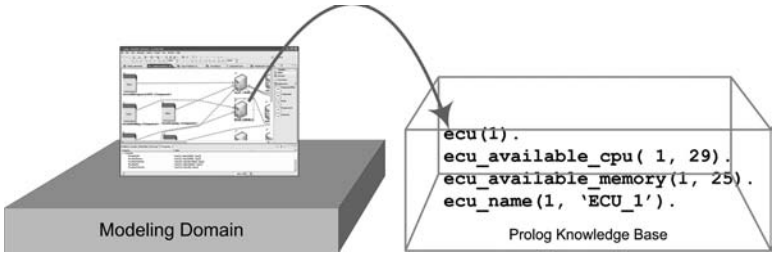


A Prolog-Based Approach to Constraint Solver Integration

Choosing a constraint solver is one of the driving forces in the process of transforming a set of nonfunctional requirements into a CSP. Each solver will generally have a unique representation of the problem in its native format. The choice of solver therefore affects how the transformation from nonfunctional requirements to a concrete representation of a CSP is performed. Many types of solvers are available and implemented in a number of languages. The remainder of this section presents an approach we have developed, called Role-based Object Constraints (White, Nechypuren, Wuchner, & Schmidt, 2006), to providing local guidance and batch processes based on Prolog (Bratko, 1986).

Using ROCs, we have implemented constraint-solver integrated modeling tools for automated product line variant selection (White, 2007a), component to ECU deployment in automobiles (White et al., 2006), and aspect weaving (Nechypurenko, Wuchner, White & Schmidt, 2007). Our implementation of ROCs is integrated with the Generic Eclipse Modeling System (GEMS) (White, 2005), a part of the Eclipse Generative Modeling Tools (GMT) project. A screenshot of a batch process executing in our GEMS- based deployment modeling tool is shown in Figure 10.

Prolog is a declarative programming language that allows programmers to define a Knowledge Base (KB) (also known as a fact set) and a group of rules that implement a set of CSPs (see Sidebar 1). Prolog can then evaluate these rules and determine if they can be satisfied by the known facts. Prolog uses a predicate syntax, where rules can be defined as predicates that resolve to the satisfaction of a conjunction of other predicates. Rules are akin to methods that check if a constraint over a set of variables holds true.

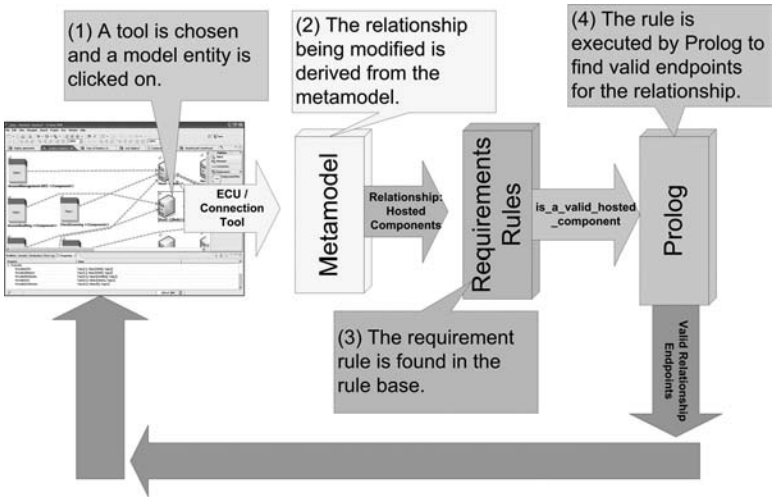
Predicate rules can be used to check constraints, by invoking the rule with all variables bound, in which case Prolog replies with whether or not the rule or CSP evaluates to true. If variables are left unbound when the rule is invoked, however, Prolog uses backward chaining to produce bindings from the KB of the unbound variables that will satisfy the CSP. Prolog therefore provides a key degree of flexibility because it can be used both to check constraints (similar to OCL described in the section *Constraint Checking with OCL*) or to derive solutions to the CSPs.

The remainder of this section presents an approach to integrating Prolog into a modeling tool. Prolog was chosen because it has a readable textual syntax as opposed to the linear-equation-based syntax of other possible solvers. Using Prolog, however, does trade some speed for readability and ease of use. Prolog also is a widely used and supported programming language for constraint solving and numerous existing solvers and libraries are available in Prolog.

Sidebar 1. Prolog

Prolog is a logic programming language that allows developers to specify a set of facts or Knowledge Base and then create rules specifying logical assertions or constraints on the facts. Prolog rules take one or more input variables, denoted by variable names with capital letters, and specify a series of logical assertions on these variables, other facts, or rules in the KB. When a Prolog rule is invoked with only bound variables, meaning all variables have values assigned to them, Prolog returns whether or not the logical assertions contained within the rule hold true. An important capability of Prolog is that if a rule is invoked with some unbound variables, Prolog will attempt to find bindings of those variables from the facts in the KB that satisfy the logical assertions in the rule. When constraints are implemented as Prolog rules, Prolog can deduce valid bindings for the variables that the constraints restrict.

Figure 11. Invoking requirement rules to find relationship endpoints



Transforming Models into Prolog Knowledge Bases

Integrating Prolog as a constraint solving engine involves capturing the state of the model and translating it into a Prolog KB, as seen in Figure 11. For the deployment of components to ECUs example from the *Introduction* section, the components, ECUs, and their resources must be translated into predicate facts in Prolog. Generally, predicates are created that relate a unique key or ID of each model element to various properties that the model element possesses. This concept is similar to the use of pointers and allows the flattening of an object-oriented model into a predicate KB.

Developers must select the format of the predicates used to translate the model into a Prolog KB. One approach is to use a consistent set of Prolog predicates across modeling languages and customize them by adding domain-specific information into the variables the predicates operate on. For example:

```
self_type(1, ecu).
self_attribute(1, available_cpu, 29).
self_attribute(1, available_memory, 25).
self_attribute(1, name, 'ECU_1').
```

describes a set of Prolog facts that provide a general predicate format applicable to a range of model types. This set of facts asserts that the element with ID "1" is of type "ecu." The facts also assert that the element has three attributes: *available_cpu*, *available_memory*, and *name*, with values: "29," "25," and "ECU_1," respectively. Different modeling languages can be accommodated by changing the second argument of the predicates, the attribute name, which is being defined. The tradeoff of using a general format, however, is it violates the first design criterion described in the section *Constraint Solver and MDD Tool Integration Frameworks*, that is, offering a domain-specific interface. The predicates do not vary across domains, which makes it harder for a domain expert to understand how they relate the concepts from his or her domain.

Rather than using terminology specific to the deployment of components to ECUs (e.g., ecu, available_memory, etc.), the predicates are based on describing the attributes and types.

A more domain-specific approach is to create custom predicates for each modeling language to mirror the notation from the domain. For example, the same set of facts can be rewritten as:

```
ecu(1).
ecu_available_cpu( 1, 29).
ecu_available_memory(1, 25).
ecu_name(1, 'ECU_1').
```

which provides a more domain-specific interface. The main drawback of this format, however, is that introspection is not possible, that is, rules cannot query for all of the properties of an arbitrary element. When translating nonfunctional requirements into Prolog rules, domain-specific predicates are generally more advantageous because they allow the production of more compact and readable rules. Introspection is also typically not needed for writing CSPs in Prolog.

To identify the domain-specific predicates to use for the KB, the metamodel for a modeling language can be viewed as a set of model entities and the role-based relationships between them. For each entity, a unique id and a predicate statement specifying the type associated with the entity. For example, each ECU in the model is transformed into the predicate statement ecu(id), where id is the unique id for the ECU. For each instance of a role-based relationship in the model, a predicate statement is generated that takes the id of the first participating entity and the id of the entity to which the first entity is being related.

For example, if a component, with id 23, has a *TargetECU* relationship with an ECU, with id 25, the predicate statement targetECU(23,25) is generated. This predicate statement specifies that the entity with id 25 is a *TargetECU* of the entity with id 23. Each KB provides a domain-specific set of predicate statements. As a model is manipulated in its graphical editor, the Prolog KB is updated using assert/1 and retract/1 statements, which add and remove facts from the Prolog KB, respectively.

Mapping Nonfunctional Requirements to Prolog Rules

Using a domain-specific knowledge base, modelers can specify nonfunctional requirements in the form of Prolog rules for each type of metamodel relationship. These constraints semantically enrich the model to indicate the nonfunctional requirements of a correct model. They are used by constraint solvers to deduce solutions to local guidance and batch process problems. For example, consider the following constraint to check whether an ECU is a valid ECU of a component:

```
is_a_valid_component_targetECU(Component,
ECU) :-
  component_requiredOS(Component, OS),
  ecu_providedOS(ECU, OS).
```

This constraint, which checks to ensure that the OS required by the component matches the OS provided by the ECU, can be used to check a component-ECU combination, that is:

```
is_a_valid_component_targetECU(component_
23, ecu_25).
```

by assigning the *Component* variable the value "component_23" and the *ECU* variable the value "ecu_25." The rule can also be used to find valid ECUs that can play the *TargetECU* role for a particular component using Prolog's ability to deduce the correct solution

```
is_a_valid_component_targetECU(component_
23, ECU)
```

by leaving the *ECU* variable unbound (unbound variables are begin with capital letters). In this example, the *ECU* variable will be bound to the

ID's of the ECUs in the KB that have the same OS as the component. This example shows how the nonfunctional requirement rules can be used both to check and to deduce solutions.

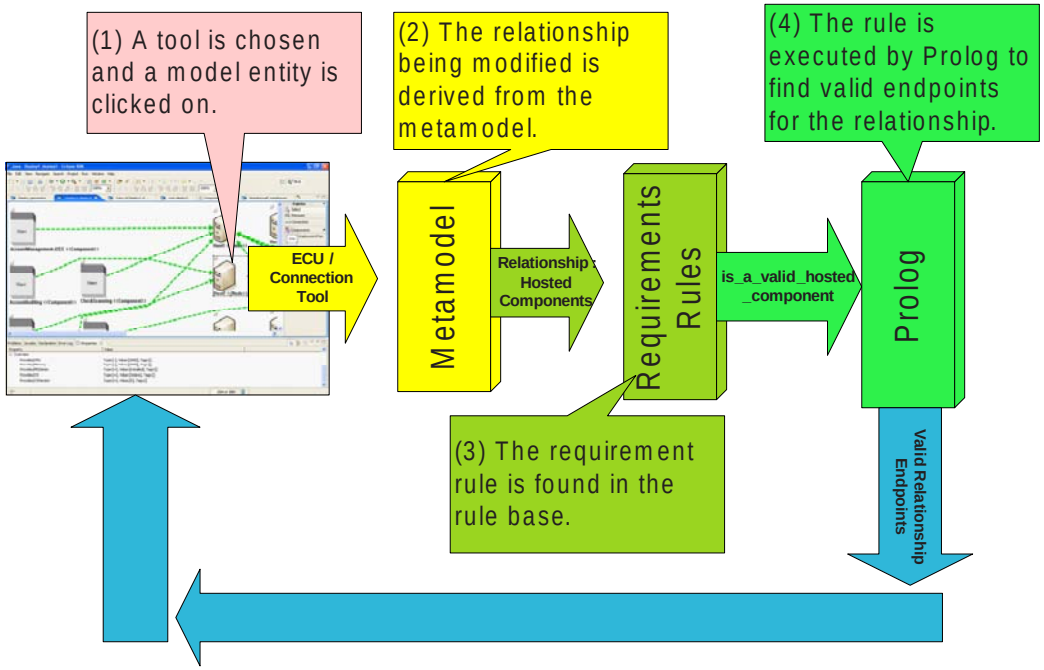
The role-based relationships present in the metamodel not only produce domain-specific predicates but also serve as the glue between graphical modeling actions, such as creating connections, and the constraint solver. The nonfunctional requirement rules that developers create can be associated with role-based relationships in the metamodel as seen in Figure 12.

When a model element is clicked on to initiate a change (step 1), the metamodel is consulted to determine the role-based relationship (step 2) affected by the change. The corresponding nonfunctional requirement rules can then be obtained (step 3) and executed by Prolog (step 4) to check the validity of the change.

To provide local guidance, the nonfunctional requirement rules associated with metamodel relationships can be executed with unbound variables to deduce endpoints for the relationship. For example, if a user begins creating a deployment connection originating from a component, the MDD tool can deduce that the deployment connection will set the *TargetECU* relationship of the component and execute the is_a_valid_component_targetECU rule with only the originating component bound as an argument. Prolog will then return bindings for the ECUs variable of the rule that are valid deployment targets for the component.

In a graphical modeling environment that does not include a constraint solver, graphical actions, such as mouse clicking and movement, are translated into changes in the underlying ob-

Figure 12. Invoking requirement rules to find relationship endpoints



ject graph of the model. By adding a constraint solver, graphical actions are translated into proposed model modification transactions and then the proposed transactions are turned into CSPs and solved. Users can therefore modify the model directly as in a traditional approach and use graphical actions to initiate constraint solvers that modify the model on their behalf.

In the connection creation example from the *Local Guidance* section, a modeler's mouse-click on the source component is translated into the initiation of a connection from the component. This connection initiation proposal is then used to query the metamodel to determine the relationship that is being modified on the component. Next, the CSPs or nonfunctional requirement rules that are bound to the relationship are obtained and finally they are executed in the constraint solver to find valid bindings for the unbound variables. The bindings produced represent the valid completions of the modeling transaction. These valid bindings can be returned to the user as graphical proposals, such as highlighting model elements, or committed as changes to the underlying model.

CONCLUSION

For large-scale DRE systems, traditional modeling approaches allow developers to raise the level of abstraction used for solution specification and illuminate design flaws earlier in the development cycle. Many DRE systems, however, have exponential design constraints, extremely large model sizes, or other complexities that make it hard to handcraft a model of a solution. For these types of challenging domains, automated design guidance based on the design constraints is needed.

A constraint solver can be integrated into a modeling environment to provide design guidance for complex domains. As shown in section *Modeling Guidance*, using the concepts of *local guidance* and *batch processes* a constraint solver can help modelers perform both single and multistep modeling activities.

The lessons learned from our ROCs approach, described in the section *Modeling Guidance*, to integrating a Prolog constraint solver with the GEMs modeling environment are:

- **Constraints can be used for reasoning by a constraint solver**. A constraint solver improves solution quality not by checking manually produced solutions, but by actively guiding a user toward a correct solution. The solver helps ensure that users do not produce an incorrect solution, rather than just notifying them if their solutions are invalid.
- **User actions can be abstractly modeled as functions**. User interactions with MDD tools can be viewed as a function that takes a set of modeling elements and maps the endpoints of a specific relationship of the elements to an endpoint explicitly provided by users. A constraint solver can be integrated into a modeling environment by dynamically choosing the endpoints for the relationships with the constraint solver rather than requiring endpoints to be explicitly enumerated by the modeler. Local guidance and batch processes can be used to produce the endpoints for relationships, as described in the section *Local Guidance*.
- **Constraint solvers should be reused**. Writing a constraint solver is hard. Developers of model-driven processes should therefore focus on integrating existing constraint solvers or constraint solving languages. Prolog is a good choice for a general purpose constraint solving language that can be integrated, as shown in the section *A Prolog-based Approach to Constraint Solver Integration*.
- **Debugging constraint conflicts or over constrained systems is hard.** When no valid solution to a CSP can be found, deriving why a solution can't be found can be complex. With global constraints, the cause of the failure can be the overall organization of the

solution, and thus it is difficult to provide a meaningful explanation to the modeler.

- **Constraint solvers typically perform well in practice.** Although many optimization and constraint satisfaction problems are combinatorialy complex, constraint solvers typically can solve them in a reasonable time frame. Constraint solvers can use approximation algorithms to quickly produce solutions that are good but not optimal.
- **The complexity of a constraint satisfaction problem is dependent on each problem instance.** Certain instances of a type of constraint satisfaction problem will be easier to solve than others. Predicting which instances are challenging is hard. Although it is hard to predict which instances are challenging, constraint solvers often work well on all instances in domains that humans manually produce solutions for.

As MDD tools continue to develop and capture more useful design decisions for larger and more complex applications, constraint solving and other design automation techniques will become more important. Design automation should not only improve design quality but should also help to allow model-driven processes to scale to handle next-generation models with significantly more complexity.

The tools and code presented in this chapter are a part of the Generic Eclipse Modeling System (GEMS). GEMS is an opensource project available from http://www.sf.net/projects/gems.

FUTURE RESEARCH DIRECTIONS

This section describes the emerging trends in the development of software intensive systems, how these trends will affect software development methodologies, and what future research will be needed to address future development problems. The future trends are presented in the context of MDD. Particular emphasis is placed on how these trends will impact the use of constraint solvers in software development.

Capturing Design Rules

Model-driven technologies are raising the level of abstraction for software development by enabling developers to express higher-level, more domain-specific intentions in the solution specifications they produce. These intentions have traditionally been captured through documentation, such as text files or MS Word documents. With MDD technologies, developers can formally specify the design goals and rules that traditionally could only be expressed in documentation, in the solution specification.

In the past, conventional tools could not document the rules that led a developer to make design decisions in a rigorous manner that could be used for automated design assistance. For example, implementation-based software development methodologies, such as coding a solution in C++, could not capture communication rate information, memory consumption, minimum distance from the car's perimeter, or other constraint information in a form that could drive application organization. With an MDD approach, however, a designer can specify that a connection needs to provide a guaranteed messaging rate rather than the type of connection that should be used, that is, designers can specify *why* one connection type should be preferred over another connection type.

Various MDD tools are developing that can utilize this design information. The Component Utilization and Test Suite (CUTS) (Hill & Gokhale, 2007) is an MDD tool that allows developers to empirically evaluate system designs before they are implemented. Other tools, such as J2EEML (White, 2007b), provide the ability to perform analysis on adaptive applications and anticipate conflicting design goals. Finally, feature

modeling tools (Antkiewicz et al., 2007) provide the capability to capture software component commonality and variability requirements and enforce them during system design.

Utilizing Design Information to Provide Automated Design Assistance

Automation can be applied to help guide designers to better solutions by formally capturing the goals of the application or *why* designers chose particular design decisions. MDD tools, and specifically domain-specific modeling languages, have allowed developers to tailor the solution specification to include information pertinent to their domain. As MDD technologies increase the breadth of information that can be distilled from designers into a solution specification, a wealth of new design guidelines or constraints will become available for constraint solving.

An emerging area of research therefore involves the integration of automated reasoning systems with MDD tools. In particular, the reuse of existing constraint solver, decision assistance, and other guidance mechanisms across will be an important software development goal. These solver and decision assistance mechanisms are costly to produce and thus will benefit from greater portability between MDD tool infrastructures, such as the Eclipse Modeling Framework, Microsoft DSL tools (Microsoft, 2007), and the Generic Modeling Environment.

One challenge of leveraging constraint solvers in a modeling environment is mapping the domain requirements to CSPs that can be used for automated solving. These mappings are often complex and tightly coupled to individual solver and metamodel formats, despite the fact that requirement types, such as resource requirements, occur across multiple domains. Current solutions for transforming requirements into CSPs tightly couple the translation to a specific solver or metamodel and require costly reinvention and rediscovery of existing mappings. Additional work is needed ensure that the complex mappings from requirements to CSPs can be templatized and reused across applications.

Model transformation techniques are developing rapidly and may provide a mechanism for future decoupling of CSPs from solvers and provide portability through translation. The Atlas Transformation Language (ATL) (Jouault & Kurtev, 2005) provides powerful transformation capabilities as well as compilation to bytecode. Other emerging approaches include Open Architecture Ware (oAW) (Open Architecture Ware, 2007). Finally, templatization approaches are also viable, such as those proposed by Willans, Sammut, Maskeri, and Evans (2002).

Constraint Solver Guided Software Reuse

Significant advances in the area of software reuse will drive the need for integrating constraint solvers and MDD tools. These advances are evident in the increased use of commercial-off-the-shelf (COTS) components (Schmidt, 2002) rather than customized proprietary solutions. In particular, using COTS components in the DRE systems domain requires constraint solvers because applications in this domain often have exponential constraints that must be met by selecting and assembling COTS components together with proprietary components into a final composite application.

The selection of components is an example of a CSP. Developers must take the requirements of an application in a DRE system, the capabilities of the COTS and proprietary components, and find a set of compatible components, possibly from numerous vendors, that will satisfy both the functional and complex nonfunctional constraints. Moreover, components may have complex

configuration needs, such as setting messaging policies, to enable them to function properly. Solving these challenging CSPs will require the use of constraint solvers to select components based on high-level design criteria captured in models.

COTS components will require further development and standardization in how metadata, such as messaging periodicity, is captured and disseminated to tools. Standardization will allow for greater interoperability between tools. A standard metadata format will also provide component developers with a consistent methodology for documenting component requirements, dependencies, and capabilities.

Services have seen the most standardization in metadata descriptions. The Resource Description Framework (RDF) (Lassila & Swick, 1999) and the Web Services Description Language (WSDL) are emerging as promising standards for describing services. Other approaches, such as those presented by O'Sullivan, Edmond, and Ter Hofstede (2002), focus on capturing the non-functional aspects of services. Formal methods for describing components are also emerging, such as those proposed by Poizat, Royer, and Salaun (2004).

Chapter 8.15
Heuristics and Metrics for OO Refactoring:
A Consolidation and Appraisal of Current Issues

University of London, UK

ABSTRACT

Refactoring, as a software engineering discipline, has emerged over recent years to become an important aspect of maintaining software. Refactoring refers to the restructuring of software according to specific mechanics and principles. While in theory there is no doubt of the benefits of refactoring in terms of reduced complexity and increased comprehensibility of software, there are numerous empirical aspects of refactoring which have yet to be addressed and many research questions which remain unanswered. In this chapter, we look at some of the issues which determine when to refactor (i.e., the heuristics of refactoring) and, from a metrics perspective, open issues with measuring the refactoring process. We thus point to emerging trends in the refactoring arena, some of the problems, controversies, and future challenges the refactoring community faces. We hence investigate future ideas and research potential in this area.

INTRODUCTION

One of the key software engineering disciplines to emerge over recent years is that of refactoring

(Foote & Opdyke, 1995; Fowler, 1999; Hitz & Montazeri, 1996; Opdyke, 1992). Broadly speaking, refactoring can be defined as a change made to software in order to improve its structure. The potential benefits of undertaking refactoring include reduced complexity and increased comprehensibility of the code. Improved comprehensibility makes maintenance of that software relatively easy and thus provides both short-term and long-term benefits. In the seminal text on the area, Fowler (1999) suggests that the process of refactoring is the reversal of software decay and, in this sense, any refactoring effort is worthwhile. Ironically, Fowler also suggests that one reason why developers do not tend to undertake refactoring is because the perceived benefits are too "long term." Despite the attention that refactoring has recently received, a number of open refactoring issues have yet to be tackled and, as such, are open research concerns. In this chapter, we look at refactoring from two perspectives.

This first perspective relates to the heuristics by which refactoring decisions can be made. Given that a software system is in need of restructuring effort (i.e., it is showing signs of deteriorating reliability), IS project staff are faced with a number of competing choices. To illustrate the dilemma, consider the question of whether completion of a large number of small refactorings is more beneficial than completion of a small number of large refactorings. A good example of the former type of refactoring would be a simple "rename method," where the name of a method is changed to makes its purpose more obvious. This type of refactoring is easily done. An example of the latter, more involved refactoring, would be an "extract class" refactoring where a single class is divided to become two. This type of refactoring may be more problematic because of the dependencies of the original class features.

As well as the decision as to "what" to refactor, we also look at the equally important decision as to "when" we should refactor. Throughout all of our analysis, we need to bear in mind that refactoring offers only a very small subset of the possible changes a system may undergo at any point in its lifetime. We return to this theme later on.

Combined with the need to choose refactorings and the timing of those refactorings, the need to be able to measure the refactoring process is also important. Software metrics (Fenton, 1996) provide a mechanism by which this can be achieved. A metric can defined as any quantifiable or qualitative value assigned to an attribute of a software artefact. The second perspective thus relates to the type of metric applicable for determining firstly, whether a refactoring is feasible, which of competing refactorings are most beneficial and how the effects of carrying out refactoring have impacted on the software *after* it has been completed. In terms of "when" to refactor, a metrics program implemented by an organization may provide information on the most appropriate timing of certain refactorings according to metric indicators as, for example, a rapid and unexplained rise in change requests.

For both perspectives investigated, there are a large number of issues which could possibly influence their role in the refactoring process. For example, most refactorings can at best only be achieved through a semi-automated process. For example, the decision on how to split one class into two can only be made by a developer (and aided by tool support once that decision has been made). Some metrics are subject to certain threats to their validity and are thus are largely inappropriate for judging the effect of a refactoring; the lines of code (LOC) metric is a good example of such a metric because of the unclear definition of exactly what a line of code is (Rosenberg, 1997). In our analysis, we need to consider these issues.

The objectives of the chapter are three-fold. Firstly, to highlight the current open issues in the refactoring field. In particular, some of the associated problems that may hamper or influence

any refactoring decision. Secondly, to highlight the role that software metrics of different types can play in the refactoring process and the interplay between refactoring mechanics and the measurement of refactoring. Throughout this chapter we appeal to a number of previous empirical studies to inform and support our ideas and opinions. A final objective of the chapter is to identify potential future research possibilities and concerns considering some of the problems and issues outlined.

The strategy we adopt for our analysis is as follows. We believe strongly that past and ongoing empirical evidence from a range of different systems provides the best mechanism for analyzing and achieving the goals of the chapter. Those goals are firstly, to distill from current empirical thinking (studies and metrics) the elements which impact on the theoretical and practical aspects of refactoring; secondly, to present that evidence in a relevant, interesting and meaningful way. Finally, to propose a set of heuristics from that evidence which we feel will be of value to refactoring practitioners, project managers, and researchers alike. We also feel that the results will be of interest to the wider software engineering community in terms of informing our understanding of change patterns and trends.

The chapter is arranged as follows. In the next section, we describe background and related work in the field of refactoring and discuss our viewpoint in a broad sense. Next, we focus on the "what" aspects of refactoring, drawing on previous empirical studies in the area to decide what refactorings to apply. We then look at the "when" of refactoring; when should we apply refactorings? Next, we summarize the heuristics presented in the chapter (in particular, those in previous sections) and then we describe some future research directions in the refactoring field. Finally, we draw some conclusions.

BACKGROUND

We view three interrelated areas as particularly relevant to our analysis; theory and the mechanics of refactoring, practical application and motivation of empirical studies of refactoring and finally, work in the metrics field. By "mechanics" of refactoring we mean the prescribed steps that need to be applied to complete a refactoring (Fowler, 1999).

Refactoring Theory and Mechanics

There are a number of works relevant specifically to refactoring that have contributed to the field and which could be said to be seminal. In terms of early work in the area, the main text and from which we will draw significantly in this chapter is that of Fowler (1999). In this text, Fowler describes the mechanics of 72 different refactorings and assorted "bad smells" in code. Bad smells in code have a special significance to the work in this chapter. According to Fowler, the key indicator of when refactoring is overdue is when code starts to "smell." An example of a bad smell is an inordinately long method and is thus an obvious candidate for splitting in two.

In the same text, Fowler categorizes the 72 refactorings according to four areas. These are whether a refactoring: makes method calls simpler, organizes data, moves features amongst objects, or deals with generalization. The Ph.D. work of Opdyke (1992), work by Johnson and Foote (1988) and Foote and Opdyke (1995) has also been instrumental in promoting refactoring as a discipline and demonstrating the viability of the refactoring approach. As well as investigating the "what" and "when" of refactoring, we also illustrate potential areas for novel empirical research to build on these foundations.

Most of the early refactoring literature focused on Java and Smalltalk as the target languages. The unique features of object-oriented (OO) languages (e.g., encapsulation and inheritance) make refac-

toring a particularly interesting challenge for the developer. For example, encapsulation issues and the need to conform to sound OO principles means that there is frequently a need to apply relatively *simple* refactorings. For example, the "encapsulate field" refactoring modifies the declaration of a field from public to private. The motivation according to Fowler (1998) is that:

One of the principal tenets of object-orientation is encapsulation, or data hiding. This says that you should never make your data public. (p. 206)

In the next section, we provide evidence that shows developers (for the C++ language) do not seem to attach importance to getting encapsulation "right"; the key (and worrying) point is that refactoring may require the breaking down of "bad developer habits."

In terms of the OO inheritance feature, there are a number of challenges for the developer. For example, ensuring that methods and fields are declared and used in the most appropriate place of an inheritance hierarchy. The "pull up field" refactoring for example requires that a field in a subclass is moved up to its superclass. According to Fowler, the motivation for this refactoring is that "two subclasses have the same field". In this case, the field in question should be moved to the superclass to avoid duplication of that field. This is a relatively simple refactoring related to inheritance. A less simple refactoring is the "pull up method" refactoring, where two identical methods are moved from subclasses to their superclass (again to avoid duplication of behaviour). Both the mechanics and testing effort required is significantly greater for the latter type of refactoring.

Empirical Studies

The benefits of refactoring are therefore clear in terms of qualitative (subjective) values. In terms of empirical studies, recent work by Najjar, Counsell, Loizou, and Mannock (2003) has shown that refactoring can deliver both quantitative and qualitative benefits; the refactoring "replacing constructors with factory methods" of Kerievsky (2002) was analyzed. The mechanics of the refactoring require a class to have its multiple constructors converted to normal methods, thus eliminating the code "bloat" which tends to occur around constructors. The moved methods thus have new, more meaningful names. Results showed quantitative benefits in terms of reduced lines of code due to the removal of duplicated assignments in the constructors as well as potential qualitative benefits in terms of improved class comprehension.

In Najjar, Counsell, and Loizou (2005), the problems associated with a simple refactoring such as the encapsulate field (EF) was studied. To investigate the EF refactoring, samples of classes were chosen from five different Java systems and the potential for applying the mechanics of the refactoring investigated. Results showed certain potential for applying the refactoring *per se*. In other words, no shortage of opportunity was found for applying the refactoring; public attributes were found in a number of classes in each system. However, three features exhibited by the five systems suggest that applying the EF refactoring is not as straightforward or applicable as it first seems. Firstly, the number of dependent classes requiring changes as a result of applying the refactoring may prohibit the refactoring; secondly, the large number of classes with zero attributes would seem to render the refactoring almost redundant. Finally, the features of the inheritance hierarchy in each system pose a dilemma with the use of the *protected* declaration (as opposed to private). A final finding was the practical trade-off and applicability of the EF refactoring when considering different application domains. Some of the systems studied were more amenable to the EF refactoring than others.

Recent work by Advani, Hassoun, and Counsell (2005b) describes the results of an empirical

study of the trends across multiple versions of open source Java software. A specially developed software tool extracted data related to each of fifteen refactorings from multiple versions of seven Java systems according to specific criteria. Results showed that, firstly, the large majority of refactorings identified in each system were the simpler, less involved refactorings. Very few refactorings related to structural change involving an inheritance relationship were found. Secondly, and surprisingly, no pattern in terms of refactorings across different versions of the software was found. Results thus suggested that developers tend to carry out simple "core" refactorings at the method and field level, but not as part of larger structural changes to the code (i.e., at the class level). The research in the same paper highlights an important refactoring issue. It is unlikely that we will be able to identify whether those "core" refactorings were done in a conscious effort by the developer to refactor, or as simply run-of-the-mill changes as part of the usual maintenance process. In other words, the question, "do developers refactor without realising it?" needs to be addressed. This then raises the question as to whether refactoring is subsumed by usual changes typically made by developers. Despite these issues, we feel that identification of the major refactoring categories is a starting point for understanding the types of change typically made by developers and the inter-relationships between changes typically made by developers. The same paper identified refactorings according to specific rules and heuristics. Developing heuristics for undertaking refactorings based on system change data has also been investigated by Demeyer, Ducasse, and Nierstrasz (2000).

Strategy Used for Empirical Studies

The empirical studies described as part of this chapter and from which we draw data were all undertaken over the past seven years. For each study, there was at least one underlying objective and/or hypothesis; as we describe each study, we point out what these were. This chapter represents an interleaving and distillation of these studies in a purely refactoring context. For one or two studies, the hypotheses were not stated from the outset. For example, it is difficult to reason about when most refactorings are likely to occur. On the other hand, hypotheses about cohesion and how human subjects would rate class cohesion are far easier to compose.

Many of the metrics used in the studies were collected manually and, wherever possible, collected automatically using tailored software. For example, the study described in the fourth section used human subjects as a basis and data from that study could only be collected from hand-written scripts. Data such as number of class attributes and methods, on the other hand, can easily be collected automatically. Where data was collected automatically, it was always verified afterwards through human inspection.

The threats to the validity of each study were also considered. For example, we tried to choose systems for each study that gave as wide a cross-section of application types as possible. We also tried to choose systems which were industrial-sized and which were developed by professional software engineers. Of course, we can never study too many systems and so many of results need to be supported by other studies in other research using other systems to build up a knowledge base in the area concerned. We have also provided evidence from both Java and C++ systems as a way of reflecting trends in different OO languages. Finally, we have included a variety of statistical techniques in this chapter; we chose different techniques for different studies as a way of highlighting the salient features we were trying to demonstrate.

Automation and Metrics

In terms of related work on automating the search for refactoring trends, research by Tokuda and Ba-

tory (2001) has shown that three types of design evolution, including that of hot-spot identification, are possible. A key result of their work was the automatic (as opposed to hand-coded) refactoring of fourteen thousand lines of code. Finally, the principles of refactoring are not limited to object-oriented languages. Other languages have also been the subject of refactoring effort including that of visual basic (Arsenovski, 2004).

A central feature of our analysis is the use of metrics to quantitatively capture the features of the system under study. Many metrics have been proposed and used for analyzing object-oriented and procedurally-based software both theoretically and empirically (Bieman & Ott., 1994; Briand, Devanbu, & Melo, 1997; Chidamber & Kemerer, 1994; Hitz & Montazeri, 1996). In most previous studies, we have used simple counts of the number of the class feature "number of attributes." Metrics play a central role in allowing us to measure features of systems at different levels of abstraction whether at the class or method level). In all the studies previously mentioned and studies we draw on in this chapter, metrics play a part.

Finally, as well as the need to understand "what" and "when" to refactor, it is also important to point to one other key motivation for our analysis of refactoring in this chapter. An earlier investigation by some of the authors to identify suitable candidates for refactoring failed for one simple reason. It highlighted obvious candidates for refactoring according to obvious criteria such as large numbers of class methods and attributes. Inspection of the same classes revealed very few opportunities for refactoring, because classes with large numbers of features often have those features for a good reason. For example, we found one class with several hundred attributes, a class called PageAttribute.MediaType. This class contained an attribute for each type of paper and other form of media (e.g., A4, A3, etc.). Refactoring this class would have been counterproductive in terms of benefits obtained, even it though it was identified according to specific refactorings and bad smells therein (e.g., large method, large class, and primitive obsession (Fowler, 1999). In the next section, we investigate the issue of "what" should be refactored and in the section following that the question of "when" refactoring should be done. We use results from previous empirical studies to support our arguments.

THE "WHAT" OF REFACTORING

One of the most fruitful research areas in recent years has been that of an empirical study. Carrying out empirical studies helps us to understand more in a quantitative and qualitative sense about how systems and the people using those behave (Bieman, Straw, Wang, Munger, & Alexander, 2003; Briand, Bunse & Daly, 2001; Counsell, Swift & Mendes, 2002; Harrison, Counsell & Nithi, 2000; Ostrand, Weyuker, & Bell, 2004). A multitude of empirical studies have thus been carried out covering all aspects of software engineering and related computer science fields. A particularly interesting area of empirical studies have been those which shed light on or which show how well stated theory stands up in practice. In this section we describe empirical experiences from which we can learn about rules and heuristics of what to refactor. In particular, we highlight some of the problems associated with refactoring observed through some of these empirical studies. More specifically, we highlight separately the empirical reality or refactoring and the applicability of refactorings thereof.

To facilitate an understanding of code features which the empirical studies try to evaluate, the following is a definition of a class APoint that models the operations of two coordinates x and y and two further attributes a and z. The class has a single attribute of each type of declaration (public, private and protected) and inherits from a class called BasePoint. It has a single constructor called APoint and a single method CalcDistance.

It is coupled to BasePoint through inheritance and to MathType via the return type in the method CalcDistance. We could also say that this class is reasonably cohesive because the methods are meaningful, operate on the same data and are named meaningfully. Although a simple class, the features demonstrate some of the major elements which empirical studies in later sections tackle in an empirical sense.

```
public class APoint extends BasePoint {
    public int x, y;
    private int a;
    protected int z;

 // constructor
 public APoint (int a, int x, int y, int z) {
    this.a = a;
    this.x = x;
    this.y = y;
    this.z = z;
 }

 public MathType CalcDistance() {
    return((x* y * a) + z);
 }

}
```

In the next section we investigate how the empirical reality is often different to the perceived reality with evidence to support the claims. We look at each study from a refactoring perspective.

The Empirical Reality

The applicability of certain refactorings relies, to a large extent, on the features of the application in question being present in that application. In the study where we replaced multiple constructors with a catchall constructor (Najjar, Counsell, Loizou, & Mannock, 2003), the study would have been impossible had every class had just a single constructor. The "what" to refactor is therefore dependent on the features of the refactoring being present in the systems under consideration. In subsequent sections, we use the terms "attribute" and "field" interchangeably.

Zero Attribute Classes

Figure 1 shows one of the results from the analysis of the "encapsulate field" refactoring (Fowler, 1999). The purpose of the study from which the data is taken was to empirically investigate the potential for simple refactorings. We wanted to show that even perceived trivial refactorings posed certain problems. Figure 1 shows the percentage of classes with zero attributes in samples taken from five Java systems.

One of the key impediments to this refactoring was thus the high percentage of zero-attribute classes found from the samples taken from each system. The applications ranged from a graph drawing package with the lowest proportion of zero-attribute classes (System 1) to the Swing class library (System 5) with the largest.

Table 1 shows summary data for the largest of the five systems investigated in the same research. It also shows the number of public features from the same sample. It shows that 52 of the classes from the sample size of 63 had zero attributes. Only 11 classes had more than one public attribute. Opportunities for the encapsulate field refactoring are thus limited to those 11 classes. The study thus cast doubt on the viability of even simple refactorings such as EF.

Another feature of the systems investigated in Najjar, Counsell, and Loizou (2005) is the existence of certain *key* classes (Counsell, Swift & Tucker, 2005). One obstacle to a decision as to what to refactor is the existence of certain class features which on the face of it, are excellent candidates for refactoring. One key indicator of a class which suggests it needs refactoring is a class with a large number of attributes. However, inspection of the class revealed it to require each

Figure 1. Five systems and the percentage of zero-attribute classes

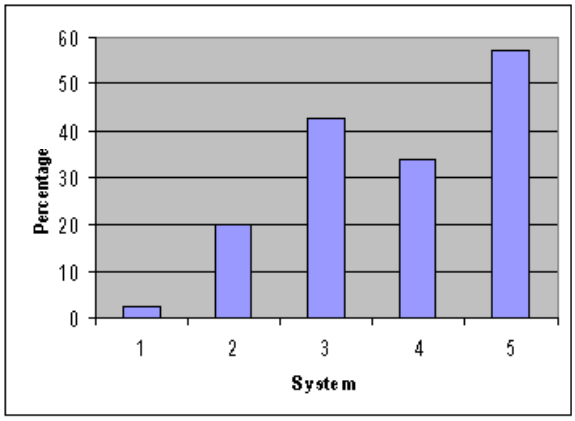

Table 1. Summary data for the Swing library

Sample Size	63
Classes with >= 1 public attr.	11
Classes with zero attributes	14
Classes with zero public attrs.	52
Max number of public attrs.	80

Table 2. Summary of dependencies for the Swing library

Sample Size	63
Median no. of dependencies	1
Max. no. of dependencies	14
Mean no. of dependencies	2.73

of those attributes as part of its essential functionality. The other problem with key classes is that they tend to have a large number of dependent classes. The purpose and underlying hypothesis of the investigation in Najjar et al. (2005) was to establish the problems associated with dependent classes; we believe that the larger the number of dependent classes, the harder it is, generally speaking, to refactor.

Inspection of the samples of classes chosen from System 3 (another library system) showed it to comprise a class called StrictMath, with

Table 3. Categorization of changes made to 52 Java classes

Change Type	Total	Distribution	Max.	Mean
New method added	32	7	14	0.62
Method call added	45	9	32	0.85
Parameter in method call added or modified	32	19	9	0.62
Method signature modified	51	26	14	0.98
"If" added or modified	67	14	11	1.26

112 attributes and 38 methods. Equally, System 1 (GraphDraw) has a class called GraphCanvas with 66 attributes and 63 methods.

Table 3 shows the summary data for the Swing system and shows that one class has 14 dependent classes. The important point about key classes is that while they may be eminently suitable for refactoring, the problem of dependent classes renders the process as problematic.

The conclusions we can draw from the data in Tables 1 and 2 relevant to the refactoring theme are that firstly, in many cases, the decision about refactoring is made for us by nature of the system itself. Deciding what to refactor is a decision aided partly by features of the systems themselves. If there are no attributes, then the number of potential refactorings is reduced significantly. In fact, the following are some of the refactorings which become impossible as a result:

- **Encapsulate field:** The declaration of a field is changed from public to private.
- **Move field:** "A field is, or will be, used by another class more than the class on which it is defined."
- **Rename field:** A field is renamed to make its purpose more obvious.
- **Push Down field:** "A field is used only by some subclasses." The field is moved to those subclasses.
- **Pull Up field:** "Two subclasses have the same field." In this case, the field in question should be moved to the superclass.

Secondly, the problem is more acute that the five refactorings above would suggest. The first three refactorings of the five listed are often part of larger refactorings (we will return to this principle in detail later). For example, the move field is part of the mechanics of the move method refactoring; if there are no attributes, then this is likely to make the move method process simpler. Absence of class features eliminates one refactoring and thus makes others simpler. Finally, in the existence of certain *key* classes may present a false impression of refactoring potential.

Ease of Automation

In a previous study described in Advani, Hassoun, and Counsell (2005b), we automatically extracted data about refactorings from seven Java systems of different types using a software tool (Advani, Hassoun, & Counsell, 2005a). The purpose of

the study was to investigate the potential for identifying refactorings automatically using a tool and some of what we perceived was common, popular refactorings. To do this, we developed rules for extracting refactoring data from the source code. For example, to detect whether the "Move Field" refactoring had taken place in the transition from one release to the next, the tool checked whether:

1. A field (name, type) that appeared in a class type (belonging to older version) appeared to be missing, that is, dropped from the corresponding type of a later version.
2. The field (name, type) did not appear in any superclass or subclass of the original type.
3. A similar field (name, type) appeared to have been added to another type (belonging to later version).

The mechanics of this refactoring are quite straightforward, and, therefore, we could easily automate it. According to Fowler, moving state and behaviour between classes is the essence of refactoring. However, certain refactorings can only be achieved through manual means and at best a tool can only assist. Consider the case of the "substitute algorithm" (SA) refactoring. The SA refactoring substitutes an algorithm for one which is clearer. The example given by Fowler is a series of "if" statements which can simply be replaced with a loop and an array. In the same way that the EF refactoring was relatively straightforward, the SA requires only that the code is changed and then run against a set of tests to ensure that the change has worked. However, changing code to meet the same requirements cannot be achieved by an automated process alone. There needs to be a manual component to the process.

In previous work (Counsell, Hassoun, Johnson, Mannock, & Mendes, 2003), it has been shown that the majority of the changes made to a Java Library system were to "if" conditions (yet interestingly not to "while" or "for" loops). The changes made to a set of fifty-two Java library classes over a three year period were investigated. The research attempted to support the hypothesis that certain types of changes made to Java code fall into distinct trends and, furthermore, are likely to be made at a high level of abstraction (i.e., at the method signature and parameter level).

Table 3 shows the distribution of changes categorized as part of the study in Counsell et al. (2003). The 67 additions or modifications to "if" statements were attributable to just fourteen classes. The maximum value in this table denotes the greatest number of changes of that type found for any single class. It shows that 32 new methods were added over the period to the classes studied. Interestingly, these 32 new methods were accounted for by only seven classes of the 52.

The problem from a refactoring point of view comes from two sources. Firstly, it is impossible for a tool to decide whether one section of code is functionally the same as another section of code unless it knows about the semantics of what each section of code does. Syntactically, we can make a wide range of observations about two sections of code. However, it would be virtually impossible to trace an instance of an SA refactoring (whether manually or automatically). This is particularly true if the change to the algorithm was complex in nature. In other words, and very much a topical refactoring issue, is that the most popular refactorings in the study described seem to be those which we cannot automate very easily. Secondly, the SA algorithm is likely to incorporate other refactorings; for example, the add parameter refactoring which may mask the SA refactoring even further. The lesson in terms of heuristics and relevant to the chapter is therefore that for convenience and speed (since developer time and resources are valuable and limited), refactorings which can be supported by a tool are likely to be a better investment of a developer's time. Some refactorings have no mechanics and this in turn make those refactorings difficult to apply.

The Role of Inheritance

Inheritance is claimed to be a fundamental principle of the OO paradigm. It is supposed to bring benefits in terms of reuse and inheritance hierarchy models information in a way which is easily understood and maintained. Despite the potential benefits of using inheritance, a number of studies have shown that the claims about ease of maintenance can be questioned (Briand et al., 2001; Counsell, Loizou, et al., 2002a).

In another recent study by the authors, it has been observed that the number of refactorings related to the category "dealing with generalization" were a very small part of the total overall number of refactorings. A tool was used to extract refactoring information from multiple versions of seven Java systems. The purpose of the study was to identify trends in core refactorings across a wide range of systems. Table 4 illustrates the number of refactorings extracted across the seven systems and *n* versions categorised according to the "dealing with generalization" type identified by Fowler.

It also shows the totals for that refactoring/version in the final row. Between versions 3-4, only 41 of the 236 refactorings were attributed to this category. Only 6 occurrences of the extract subclass were found in all versions of the systems (looking across the row). Clearly, the lack of inheritance-based refactorings is evident from Table 4. The large number of zero values suggests that

Table 4. Inheritance-based refactorings across multiple versions of seven Java systems

Refactoring Type	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9	9-10
Push Down Method	0	0	1	0	1	0	0	0	4
Extract Subclass	0	2	3	0	1	0	0	0	0
Pull Up Field	0	1	7	0	2	4	0	0	0
Extract Superclass	0	2	10	0	8	1	0	0	2
Push Down Field	0	16	3	0	7	0	0	0	0
Pull Up Method	0	9	17	0	24	5	0	0	10
Total	89	151	236	8	67	61	17	7	51

Table 5. Location of Java classes in the inheritance hierarchy

System	Leaf Classes	% of Total
Drawing Tool	5	2.45
Framework	34	20.06
Java Library	44	38.72
Compiler	73	32.59
Swing	577	54.59

across versions, inheritance-based refactorings are not common. The worrying trend is that the result suggests that developers avoid complex refactorings in favour of simpler refactorings (which accounted for the majority of the values in the final row of Table 4).

Evidence of the limited role that inheritance can play in the determination of refactorings can be found in Table 5. It shows that for the same five systems analyzed in Najjar et al. (2005), a high proportion of classes (except those for the drawing tool) are leaf classes, that is, have no subclasses. This feature should make the classes at leaves easier to refactor since, in theory they have less dependencies than classes with their own subclasses.

This would certainly apply to the encapsulate field refactoring where there are no subclasses dependent on the field in question. The same however could not be said of any refactoring which requires parts of the class to be moved — the methods of the class may use inherited features and this may cause problems.

The key lesson in terms of the chapter is that in certain circumstances, some refactorings may be trivial and easily completed. The same situation may however make other refactorings prohibitively expensive in terms of developer time and effort. Generally speaking, it seems that inheritance refactorings are so involved that they are avoided by developers. In the next section, we discuss the related issues of coupling and cohesion.

Cohesion and Coupling

We have seen already that one of the key impediments to refactoring for even a simple refactoring is the role that dependencies between classes plays. An accepted software engineering principle is that developers should try to make classes as cohesive as possible and that those classes should contain minimal coupling (Pressman, 2005). In the metrics community, cohesion is often associated with ease of comprehension. If a class is cohesive, then in theory it should be easy to understand. If a class is uncohesive then the purpose of the class is not obvious and it is difficult to understand what the purpose of that class is.

The best known of the cohesion metrics is that proposed by Chidamber and Kemerer (C&K) — the lack of cohesion of the methods of a class LCOM (Chidamber et al., 1994). The LCOM metric views a class as cohesive if the instance variables are distributed in such a way that all methods use all instance variables. Equally, a class is viewed as uncohesive if the use of instance variables amongst the methods of a class are disjoint. Various other metrics have been proposed to measure cohesion, but, as of yet, there is no general consensus on cohesion metric. In other words, we have no accepted way of measuring the benefit of a refactoring such as "extract class" whose purpose is to remove code from one class to make the source class more cohesive.

In terms of other related work, a number of attempts have been made to capture cohesion through software metrics. As well as the C&K LCOM metric, the cohesion amongst the methods of a class metric (CAMC) by Bansiya, Etzkorn, Davis, and Li (1999) based on the overlap of parameters used by a class was found to correlate with LCOM and the views of three developers on what constituted cohesion. Hitz and Montazeri (1996) also propose metrics for measuring cohesion (as well as coupling). Bieman and Ott (1994) demonstrated the measurement of functional cohesion in C software. Finally, Briand et al. (1998) propose a framework for measurement of OO cohesion and conclude that many of the cohesion metrics proposed are in most cases not validated theoretically and even fewer validated empirically.

In terms of refactoring, high cohesion would seem to be a synonym for high comprehensibility. If a class is cohesive, then the class will be easier to understand and modify. We note that any measure of cohesion based on the attributes

of a class cannot be assessed if the class has no attributes. In this chapter, we adopt the stance that coupling is a far better indicator of comprehensibility than any measure of cohesion. High coupling will make refactorings more difficult to apply. Lower coupling will make them easier to apply. This brings into question the whole issue of the coupling and cohesion interplay.

As part of an earlier study into OO (C++) cohesion, the correlation between coupling given by the number of associations metric (NAS) metric and a component of a metric called normalised hamming distance (NHD) metric was analyzed. The NAS represents the number of couplings of a class and can be counted as the number of lines emerging from a class on a UML class diagram. The NHD is based around the inter-relationship between the parameters of the methods of a class in a similar vein to the CAMC metric. The purpose of the study was to investigate the hypothesis that, in an OO sense, cohesion and coupling were so interrelated that one could be substituted for another.

Table 6 shows the strong relationship between the key component of our cohesion metric P (number of unique object "P"arameters in the class as a whole) and NAS metric; the results are a summary of the results from the study in Counsell, Swift, et al. (2002). Correlation at the 1% level is asterisked by the value in each case. We thus adopt the stance that firstly, coupling has a strong relationship with cohesion (where method parameters are assumed to be a key component of class cohesion). Secondly, that unlike coupling, cohesion is a subjective issue and cannot be measured objectively.

Reduced coupling has also been a claim of certain refactorings. For example, the motivation behind the "move field" refactoring is that "a field is, or will be, used by another class more than the class on which it is defined. It therefore makes sense to move that field to the class which needs to most and eliminate the coupling. Various metrics have been defined to measure coupling (Briand et al., 1997; Chidamber et al., 1994). The difficulty arises when the decision as to what represents too much coupling has to be made. For certain applications, a high level of coupling may be necessary. There is also the problem that certain types of coupling are more of a feature in some applications than others. A GUI-based system (with a high dependence on inheritance) lends itself well to a structure incorporating frames, panels and dialog boxes, all of which share certain generic properties. Although some amount of work has been done on finding an optimal level of coupling (El Emam, Benlarbi, Goel, Melo, Lounis & Rai, 2002), further empirical studies need to be carried out before a consensus can be reached.

When making refactoring decisions, we therefore suggest that coupling should be the prime determinant of which refactorings to carry out. We should choose refactorings which can be measured in reduced levels of coupling rather than aiming

Table 6. Pearson, Kendall and Spearman's correlation coefficients (NAS vs. P)

System	Pearson's	Kendall's	Spearman's
Framework	0.59*	0.61*	0.69*
Compiler	0.41	0.28	0.30
Graph Editor	0.83*	0.62*	0.79*

for high cohesion. Furthermore, in assessing the post-impact of any refactoring, coupling not cohesion should be used where possible. We accept that many refactorings involve no coupling issues and for these refactorings, the decision amongst competing refactorings may require subjective judgements.

Another point in terms of the overall chapter is that we should always look for refactorings which provide quantifiable benefits. In the next section, we address the issue of when to refactor; that is, we have looked at "what" to refactor, but the "when" is equally important.

THE "WHEN" OF REFACTORING

The decision as to when to refactor is as important a decision as to what to refactor. Fowler suggests that rather than being one large concerted effort, refactoring should be done in little bursts. He also suggests that a developer does not decide to refactor; the developer refactors because he/she wants to achieve something else and doing that "something else" requires that they refactor first. Similarly, Beck (2000) urges developers to refactor when the system tells them to, not through speculation alone. Very little research has empirically tackled the issue of when we should refactor.

To support the arguments about when to refactor, we return to the study of the seven open source Java systems analyzed in Advani et al. (2005b). The first question which arises is whether there any patterns within the systems studied as to "when" refactoring is carried out. Figure 2 shows that for the Antlr system, the majority of refactorings happen at versions 2-3 and 3-4. It is noticeable that some refactorings (particularly inheritance-based refactorings) are few and far between. Figure 3 for the same system shows the same trend for the HSQLDB system and similarly for the JasperReports system in Figure 4. In each

Figure 2. Refactorings for the Antlr system across five versions

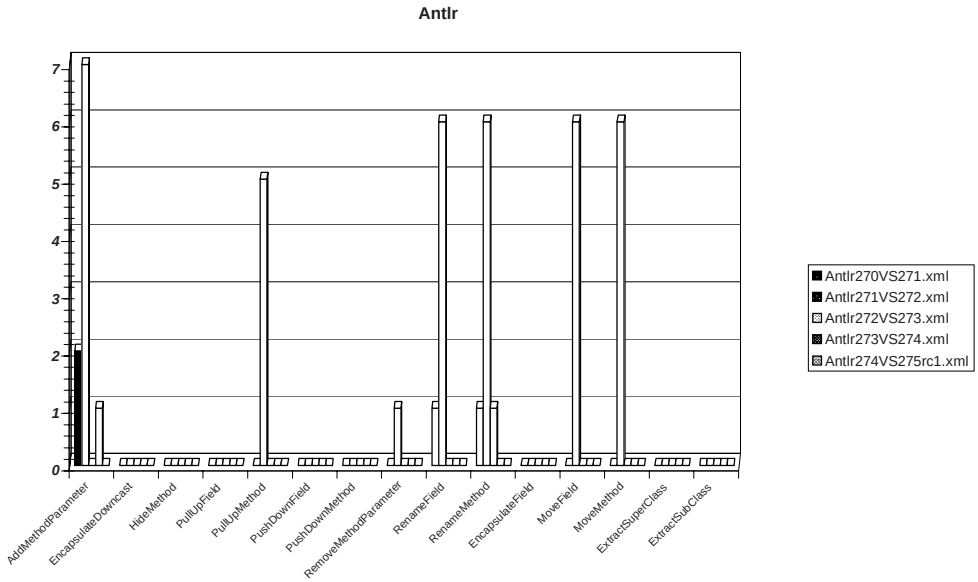

Figure 3. Refactorings for the HSQLDB system across four versions

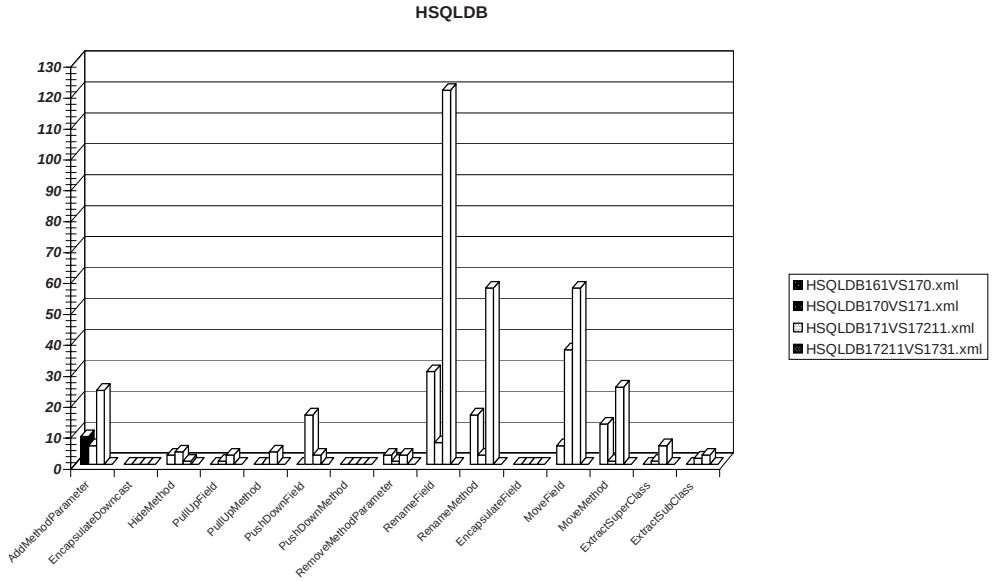

Figure 4. Refactorings for the JasperReports system across four versions

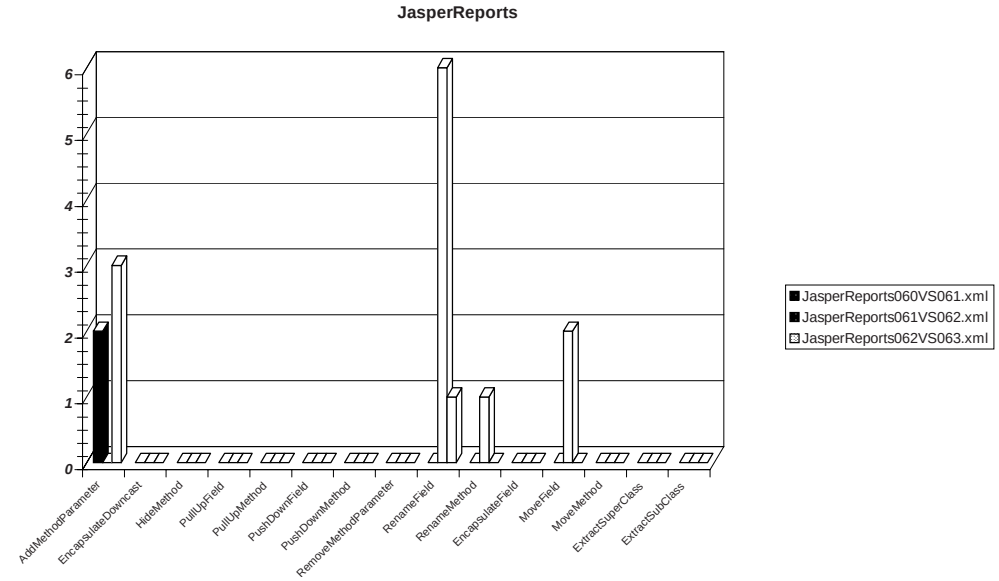

Figure 5. Refactorings across versions of the seven systems

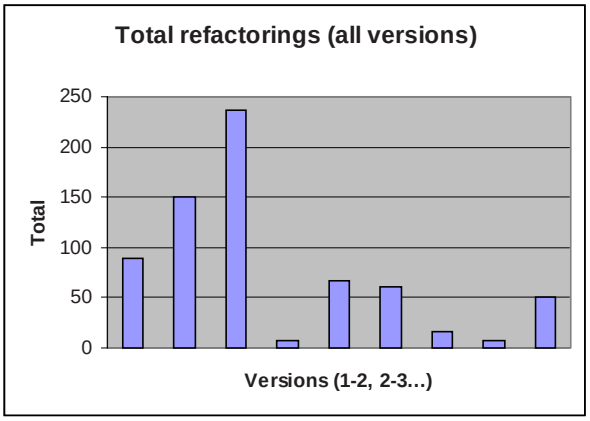

of the figures, there seems to be a trend of refactoring being undertaken at earlier stages of the system's life rather than at later versions.

Figure 5 shows the cumulative values of refactorings across time for all seven systems studied. It supports the results for the individual systems and shows that the bulk of refactorings tend to occur not at the earliest stages of a system, but around versions 2-3 and 3-4.

The evidence from Figures 2, 3, and 4 therefore supports the view that in terms of the need for refactoring, a system starts to degrade or decay after 3 or 4 versions.

The conclusion we can draw from the evidence in Figures 2, 3, 4, and 5 is that contrary to what Fowler states would be the best time to refactor (at constant intervals), there seems to be a peak around versions 3-4 for the systems studied in terms of when refactoring takes place. From Figure 5, it is also noticeable that after version 3-4, there is a dramatic drop in the number of refactorings. Although the study described relates to only seven systems, we feel that the results give useful evidence of the type of refactoring trends in systems.

Of course, we have no means of predicting the trend in refactoring beyond the versions studied, and it would be as unreasonable to suggest that there would not be any more peaks. Although the empirical evidence suggests that we need to devote refactoring efforts at early stages of the system's lifetime, we would urge consistent refactoring throughout the period of a system's life. Of course, more empirical studies need to be undertaken before we can draw any concrete conclusions.

Monitoring Growth

One of the key benefits of carrying out refactoring is reduced class complexity. For example, the motivation behind the "extract class" refactoring is that a class should be split into two classes because it is becoming too large to understand easily. In other words, the class is becoming too complex. One current issue is therefore that as a result of carrying out refactoring, we may well attain improved comprehension, but the difficulty arises when we try to measure that benefit. One conclusion is thus that if a class has zero attributes,

then it affects the number of refactorings which can be carried out and also the means by which we can measure the outcome of any refactoring. One of the other key potential benefits of refactoring is a reduction post-refactoring in the number of lines of code. However, the lines of code added to a class together with the number of changes that have been applied to a class may give a good indication of the potential for refactoring.

A previous study by Bieman et al. (2003) investigated the hypothesis that large, object-oriented classes were more susceptible to change than smaller classes. The measure of change used in the study was the frequency with which the features of a class had been changed over a specific period of time. From a refactoring perspective, the frequency of class change in terms of its versions is of real value. However, since for any relatively simple refactoring, multiple classes may be changed without any net increase in class (and hence overall system) size, we contest that including number of added lines of code in the assessment gives a better impression of which classes are most volatile and hence more suitable candidates for refactoring.

We thus support the view that refactoring should be applied to classes with a high growth rate as well as a high change frequency. To support our investigation, data relating to changes from 161 Java classes were used as an empirical basis. Our results supported the conclusion of Bieman et al. (2003) relating to the change-proneness of large classes. Finally, we believe refactoring effort is most economically applied to classes which have both a high number of versions and a large increase in added lines of code over their lifetime. The "when" to refactor should be informed by sudden changes to the system.

A high frequency of changes made to an object-oriented class may suggest that the class was poorly written and hence required a large amount of maintenance effort applied to it. In a refactoring sense, frequency of change takes on a different meaning. It is thus likely that refactoring will not significantly increase the number of physical lines of code in the system since most refactorings require either modifications to current code or corresponding deletions for each insertion required by the refactoring. The extract class refactoring is one example where code is removed from one class to become a class in its own right without any significant net increase in system size. In the recent study by Bieman et al., number of class changes was used as the measure of change-proneness for five C++ systems. While we believe that there is merit in using number of changes as a measure of class volatility, we believe that classes which have had a large number of changes made to them (i.e., have many versions) and which have had significant numbers of lines of code added to them are better potential candidates for refactoring. A previous study by some of the authors collected the change data and growth in class size from one hundred and sixty one Java classes. It was found that much more information about the growth f the system could be gleaned by using both number of changes and changes in the lines of code in those classes. Basing the choice of classes for refactoring on alarming increases in class size supports the dictum of Beck which urges developers to refactor when the system tells them to, not through speculation alone.

Experimental Evidence

The obvious experimental means of establishing whether comprehension has improved is to carry out a formal experiment using developers, but any experiment is subject to certain threats to validity. For example, the level of experience of the subjects used may influence the results. The measurement of experience is also itself subject to a range of criticisms.

Often, a refactoring is accompanied by a reduction in the number of lines of code. This was a feature of the refactoring undertaken as part of Najjar et al. (2003). The "replace constructors with factory methods refactoring" removed

duplicate lines in constructors which had arisen due to code "bloat" (Fowler, 1999). However, the lines of code (LOC) metric has been subject to a range of criticisms (Rosenberg, 1997) and so any refactoring which reduces the number of LOC is subject to the same criticism.

Table 7 illustrates the role that size and, in this case, comment lines can have on the perception of cohesion by subjects taking part in a controlled experiment (Counsell et al., 2005). Twenty-four subjects with varying levels of experience were asked to rate on a scale 1-10 how cohesive they thought a set of ten C++ classes (10 represents the most cohesive class, and 1 the least cohesive). The 24 subjects were each given a set of the ten C++ class header files being analyzed. The ten classes were chosen at random from two industrial-sized C++ systems. The only restriction placed on the choice of these classes was that there had to be a relatively broad range of class size and make-up, but at the same time not too wide a range as to bias the outcome of the study.

Table 7 shows the "Position" of the classes in terms of the rating of cohesion by experienced subjects. Class ApplnDialog was thus rated the least cohesive and class ArcList the most cohesive. The Number of Comment Lines (NCL) in the class is followed by the position rated by subjects without experience. For example, class ApplnDialog was ranked the seventh most cohesive class. Class BagItem was rated most cohesive by subjects without experience. The number of methods in the class (NMC) also included in the table is a measure of the size of the class.

Table 7 also shows that classes with relatively larger numbers of comment lines were generally considered by the experienced subjects to be cohesive. The same is true of the inexperienced group. Clearly, the top two classes in terms of comment lines were ranked relatively highly in terms of their cohesion values (by the inexperienced group). This would seem to indicate that comment lines are an aid to the assessment of cohesion. However, in saying this, an allied factor (or even the critical factor) may be the low NAS values found for those classes.

In other words, on the one hand, size and growth are important in our determination of when to refactor, but there may be features which do not contribute to size necessarily, but yet are

Table 7. Summary data for an empirical cohesion study

Position	Class Name	NCL	Position (Inexp,)	NMC
1.	ApplnDialog	0	7	5
2.	Alert	0	5	7
3.	Dialog	2	8	4
4.	CycleItem	0	2	14
5.	Arc	29	10	5
6.	Bitmap	0	3	22
7.	BagItem	3	1	11
8.	Assoc	3	4	11
9.	ArcList	47	9	9
10.	DDGNodePtrList	54	5	9

crucial to the mechanics of most refactorings (i.e., coupling). In the next section we describe a previous analysis carried out to see if, in an empirical sense, one refactoring triggers other refactorings.

A Dependency Analysis

As part of our refactoring research, we developed a dependency diagram which showed the inter-relationships between the 72 refactorings originally stated by Fowler. The diagram was developed by hand using Fowler's text as a basis. As a result of producing this graph, it becomes possible to see the likely implications of undertaking a specific refactoring in terms of how many other potential refactorings either *must* be carried out or *may* be carried out at the same time. In terms of the question about "when" and "what" to refactor, we must accept the possibility that one refactoring may embrace *n* other refactorings, and this would be an important consideration in the choice of both what and when to refactor.

For example, for the "Encapsulate Field" refactoring, Fowler (1998) himself suggests that one possible implication of the refactoring is that once he had completed encapsulate field he would look for methods that use the new methods (i.e., accessors needed for the encapsulated field) "to see whether they fancy packing their bags and moving to the new object with a quick Move Method" (p. 206).

The encapsulate field refactoring thus has only one possible "dependency." From a developer's point of view, the encapsulate field is an attractive and relatively easy refactoring to complete. The "add parameter" refactoring falls into the same category as the encapsulate field refactoring. It does not need to use any other refactorings. The only other refactoring that it may consider using is the "introduce parameter object" refactoring where groups of parameters which naturally go together are replaced by an object.

The extract subclass refactoring, on the other hand, requires the use of six (possible) other refactorings, two of which are mandatory. It has to use "push down method" and "push down field" as part of its mechanics. It *may* (under certain conditions) also need to use the "rename method," "self encapsulate field," "replace constructor with factory method," and "replace conditional with polymorphism" refactorings. The extract superclass refactoring requires a similar number of refactorings to be considered. In fact, for most of the refactorings involving a restructuring of the inheritance hierarchy, the mechanics are lengthy (requiring many steps and testing along the way).

Connections Between Refactorings

One explanation for the result found in Advani et al. (2005b) (i.e., the high values for simple refactorings and the low values for more "complex" refactorings) could be attributed to the relative effort required in terms of activities required to complete the refactoring. The testing effort of more complex refactorings has also to be considered; the more changes made as part of the refactoring then other things remaining equal, the more testing would be required.

In terms of whether refactorings are somehow linked, we can see from Table 8 that when the extract superclass refactoring is evident, the pull up method is also a feature for those versions. The mechanics of the extract superclass refactoring insist that pull up method is part of that refactoring. Equally, there seems to be evidence of pull up field for the same refactoring, also a part of the extract superclass refactoring. Rename field and method also seem to feature when extract superclass is carried out; rename method (but not rename field) play an important role in the extract superclass refactoring. The rename field refactoring is not specified in Fowler's text. This is interesting since it suggests that may be some

Table 8. Breakdown of related refactorings from study in Advani et al. (2005b)

Refactoring Type	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9	9-10
Pull Up Field	0	1	7	0	2	4	0	0	0
Extract Superclass	0	2	10	0	8	1	0	0	2
Extract Subclass	0	2	3	0	1	0	0	0	0
Pull Up Method	0	9	17	0	24	5	0	0	10
Rename Method	19	15	71	6	16	21	1	2	16
Rename Field	31	22	137	0	2	5	1	1	10

effects of refactoring which aren't covered by the refactoring according to Fowler.

Extract subclass also requires use of the rename method refactoring, which may explain the high numbers for that refactoring. To try and explain the high numbers of rename field refactoring, one theory may be that developers automatically change the name of fields when methods are "pulled up" (in keeping with the corresponding change of method name). A conclusion that we can draw is that there may well be relationships between some of the fifteen refactorings in line with the mechanics specified by (Fowler, 1999). However, we suggest that most of the simple refactorings were not as part of any larger refactoring, based on the very low number of "larger" refactorings. When considering refactoring, we have to understand the implications of carrying out what may appear to be a straightforward refactoring. In the next section, we summarize and distill the heuristics that the previous two sections have presented.

Summary of Heuristics

In the third and fourth sections, we identified a number of experiments and empirical studies as a means of demonstrating firstly, what should be refactored and secondly, when refactoring should be undertaken. A number of key indicators were identified as a result, most based on data from those studies. In this section, we summarize and distill the heuristics and metrics identified in the third and fourth sections. We begin by proposing six heuristics which we feel could be applied in a refactoring sense.

Heuristics

The first heuristic that we propose is *Look at the trends in class features and class dependencies of your system before you attempt any refactoring.* Many systems have evolved to contain very few of the features that lend themselves to refactoring. For example, the relatively low number of attributes, severely restricting the possibility of refactorings related to attributes. The same can be said of key classes, that is, those classes which have many dependencies. Care should be exercised in any refactoring because of the potential for mistakes.

The second heuristic that we propose is *Accept that automation is realistic for a relatively small subset of refactorings. Many of the more complex refactorings can only be achieved manually with tool support.* The example which we used was

that of the Substitute Algorithm refactoring. Identifying what code has been changed and how is best undertaken manually. Tools can help, but only as support.

The third heuristic that we propose is *Within an inheritance hierarchy, dependencies of descendent class should be a prime consideration in making any refactoring decision.* Many of the relatively simple refactorings proposed by Fowler are complicated by the need to account for affected classes in the inheritance hierarchy.

The fourth heuristic that we propose is *Coupling (rather than cohesion) should be the feature of a class we aim to optimise.* Cohesion is a subjective concept and for any refactoring, we should try to eliminate where possible any subjectivity.

The fifth heuristic that we propose is *Consistent effort should be applied to the refactoring process whenever possible; growth of the system should also be monitored.* Despite the fact that empirical evidence suggests a surge in refactorings at version 3-4 of a system, we would encourage a smooth and consistent use of refactoring techniques.

Finally, we propose that: *When considering any refactoring, we need to appreciate that other refactorings may also be necessary due to a dependency between refactorings.* There is some empirical evidence of a nesting of refactorings; this may have implications for the cost both in time and financially of making a refactoring change.

Metrics

From the analysis of the different empirical studies, and in the same sense that we proposed heuristics for refactoring, we can propose six metrics which would provide the refactorer with an indication of "what" to refactor and "when" to refactor. These can be summarized as:

1. The number of attributes (public, private and protected)
2. The number of methods (public, private and protected)
3. Number of descendents of a class in the inheritance hierarchy
4. Number of classes to which a particular class is coupled
5. Changes in LOC to classes
6. Changes in "the number of changes" applied to a class

Interestingly, the set of six metrics include both product metrics, aimed at the static program code (metrics 1-4) and process metrics, aimed at what happens to the program over its lifetime (metrics 5-6). We note also that the metrics should be used in combination and not in isolation. For example, metrics 1 and 2 are very often related in terms of refactoring mechanics. Metric 4 includes inheritance coupling (metric 3), and as we suggested in the fourth section, metrics 5 and 6 should both be used to target classes growing at a relatively higher rate than other classes. Finally, the existence of key classes (the third section) embraces and requires the monitoring of all six metrics. (It is noteworthy that metrics 2-4 have corresponding equivalents in the C&K set of metrics and metric 1 is used in the computation of the LCOM metric, also of C&K.) In the next section, we point to future directions in the refactoring sense.

FUTURE DIRECTIONS

Some of the issues outlined in previous sections have tended to cast doubt on the viability of certain refactorings. Some have shown how quantitative and qualitative benefits can accrue from undertaking refactorings. Some of the issues have shown that we should focus on the coupling levels of the classes as a mechanism for deciding whether to refactor or not. The first area which the refactoring area could benefit from is a series of tools to guide the refactoring process. These tools should

indicate the quantitative and qualitative effects of carrying out that refactoring in terms of other refactorings also applicable; simulating the effect and mechanics would provide the developer with valuable information about the structure and state of the application being considered. Software metrics could be used at each stage of the refactoring mechanics to inform any such decision. This may help in the quest for "what" to refactor. The metrics which guide this process would need to be chosen carefully, however.

In terms of when to refactor, we would envisage that useful future research would be to investigate the key indicators which would help the development staff to know that refactoring is overdue. For example, if a subset of classes appears to require a disproportionate amount of maintenance effort then this should be a warning signal to the development staff.

In terms of *whether* to refactor (are the costs outweighed by the benefits?), a significant piece of research, already started by the authors, and a relatively short-term future direction would be to identify the relationships between the different refactorings (including those herein) and the occurrence of faults. In other words, is there a correlation between, let us say, the changes made to method signatures and consequent occurrence of faults directly related to that change? This research could lead to a refactoring order which states the relative possibility of faults arising should a particular refactoring be made. On the other hand, it may also indicate typical areas for refactoring effort to be directed and invested.

A further future direction would be use of appropriate intelligent data analysis techniques for simplifying computationally difficult problems. Identification of many of the more complex refactorings, for example, the Substitute Algorithm refactoring (third section) are very difficult to automate; they would require some form of heuristic search to be tackled effectively. Future research could investigate the potential for applying the different algorithms in a refactoring sense. Such techniques may also be able to provide predictive features for estimating the likely impact of undertaking a single or combination of refactorings. Use of simulation techniques may also be a fruitful research topic in this context for demonstrating the benefits of refactoring. Software metrics could play a key role in this sense.

This chapter has used a series of ongoing experiments and empirical studies as a basis of many of its claims. Finally, an important direction which the empirical research community should take in the future is thus to build up a body of experimental knowledge from which we can learn about refactoring (in general), the possibilities for applying new refactorings and the dissemination of information about refactoring. This knowledge should form a freely-available repository of data and other resources to inform the process of what and when to refactor.

CONCLUSION

In this chapter, we have tried to show how empirical studies have informed our understanding of refactoring. More empirical studies of various types need to be undertaken to build up a body of knowledge about refactoring before any conclusions can be drawn. We have also not included in this chapter any discussion about the role and relationship that refactoring has with the occurrence of faults. In other words, does *not* undertaking certain types of refactoring cause faults to arise? Equally, does refactoring uncover faults through the extra testing necessary as part of the refactoring mechanics?

In this chapter, we have also hypothesized on a number of occasions that developer habits may cause systems to deteriorate such that refactoring is then necessary. Future research directions may also include an analysis of developer habits as a good indication of where systems are beginning to decay. We have also described some of the current open issues in the field of refactoring. We

have investigated the features of refactoring and looked at the area from two perspectives. Firstly, we attempted to answer the question of "what" to refactor and looked at a number of issues from an empirical viewpoint which either lend themselves or do not lend themselves to refactoring. We have also investigated the question of "when" to refactor. Secondly, we have shown that empirical evidence suggests that refactoring is done in bursts towards the start of the system's lifetime, rather than as Fowler suggests that refactoring needs constant and consistent effort.

Finally, the question which we haven't been able to answer in this chapter is the relationship between refactorings as we've described them and the wide range of other changes made to software as part of the run-of-the-mill maintenance process. This could be an interesting area of potential research, not least because of the discussion on the link between certain refactorings in the previous section.

The key conclusions from this chapter are that we need a good understanding of the features and trends in systems at different levels of detail before we should attempt refactoring. The decision on which refactorings to carry out also needs to be planned carefully since they will require significant effort both in their mechanics and subsequent testing effort. We also feel that development staff should "listen" to the system and use metrics to provide information on what is happening to a system and hence inform the refactoring process. Ultimately, we would want to minimize the amount of time developers spend carrying out maintenance. Although refactoring takes time and effort, the general consensus is that effort expended in the short-term will provide real benefits in the long-term.

Chapter 8.16
Model-Driven Software Refactoring

Chemnitz University of Technology, Germany

ABSTRACT

In this chapter, we explore the emerging research domain of model-driven software refactoring. Program refactoring is a proven technique that aims at improving the quality of source code. Applying refactoring in a model-driven software engineering context raises many new challenges such as how to define, detect and improve model quality, how to preserve model behavior, and so on. Based on a concrete case study with a state-of-the-art model-driven software development tool, AndroMDA, we explore some of these challenges in more detail. We propose to resolve some of the encountered problems by relying on well-understood techniques of meta-modeling, model transformation and graph transformation.

INTRODUCTION

In the current research and practice on software engineering, there are two very important lines of research for which tool support is becoming widely available. The first line of research is *program refactoring*, the second one is *model-driven software engineering*. To this date, however, the links and potential synergies between these two lines of research have not been sufficiently explored. This will be the main contribution of this chapter.

Model-Driven Software Engineering

In the realm of software engineering, we are witnessing an increasing momentum towards the

use of models for developing software systems. This trend commonly referred to as model-driven software engineering, emphasizes on models as the primary artifacts in all phases of software development, from requirements analysis over system design to implementation, deployment, verification and validation. This uniform use of models promises to cope with the intrinsic complexity of software-intensive systems by raising the level of abstraction, and by hiding the *accidental complexity* of the underlying technology as much as possible (Brooks, 1995). The use of models thus opens up new possibilities for creating, analyzing, manipulating and formally reasoning about systems at a high level of abstraction.

To reap all the benefits of model-driven engineering, it is essential to install a sophisticated mechanism of *model transformation*, that enables a wide range of different automated activities such as translation of models (expressed in different modeling languages), generating code from models, model refinement, model synthesis or model extraction, model restructuring etc. To achieve this, languages, formalisms, techniques and tools that support model transformation are needed. More importantly, their impact on the quality and semantics of models needs to be better understood.

Program Refactoring

Refactoring is a well-known technique to improve the quality of software. Martin Fowler (1999) defines it as "A change made to the internal structure of software to make it easier to understand and cheaper to modify without changing its observable behavior".

The research topic of refactoring has been studied extensively at the level of programs (i.e., source code). As a result, all major integrated software development environments provide some kind of automated support for program refactoring.

As a simple example of a program refactoring, consider the refactoring *Extract Method*, one of the more than 60 refactorings proposed by Fowler. Essentially, it is applied to a method in which part of the method body needs to be extracted into a new method that will be called by the original one. The situation before this program refactoring on a piece of Java source code is shown in Figure

```
     protected LectureVO[] handleFindLecture
          (java.lang.String title, domain.Weekday day, domain.Time
time)
        throws java.lang.Exception
    *  { SearchCriteria c = this.initialise(title,day,time);
       Collection coll =
            getLectureDao().findLecture(LectureDao.TRANSFORM_
LECTUREVO,c);
       LectureVO[] lectures = new LectureVO[coll.size()];
       return (LectureVO[])coll.toArray(lectures); }
    * protected SearchCriteria initialise
    *      (java.lang.String title, domain.Weekday day, domain.Time
time)
    *   throws java.lang.Exception
    * { SearchCriteria c = new SearchCriteria();
    *   c.setDay(day);
```

1, the situation after is shown in Figure 2. The code lines that differ between both versions are marked with an asterisk.

For program refactoring, a wide variety of formalisms has been proposed to gain a deeper understanding, and to allow formal analysis. One of these formalisms is graph transformation theory (Mens *et al*., 2005). We mention it here explicitly, as we will show later in this chapter how this formalism can be applied to support model refactoring as well. It is, however, not our goal to provide a detailed overview of existing work on program refactoring here. For the interested reader, we refer to a detailed survey of the state-of-the-art in this domain (Mens & Tourwé, 2004).

Model-Driven Software Refactoring

A natural next step seems to explore how the idea of refactoring may be applied in a model-driven software development context. We will refer to this combination as *model-driven software refactoring* and we will explore the ramifications of this synergy in the current chapter.

One of the straightforward ways to address refactoring in a model-driven context is by raising refactorings to the level of models, thereby introducing the notion of *model refactoring*, which is a specific kind of model transformation that allows us to improve the structure of the model while preserving its quality characteristics. To the best of our knowledge, Sunyé *et al*. (2001) were the first to apply the idea of refactoring to models expressed in the Unified Modeling Language (UML).

A simple yet illustrative example of a UML model refactoring is shown in Figure 3. It depicts a class model in which two classes having attributes of the same type have been identified. The model refactoring consists of removing the redundancy

Figure 3. Example of a model refactoring on UML class diagrams (©2007 Tom Mens, UMH. Used with permission)

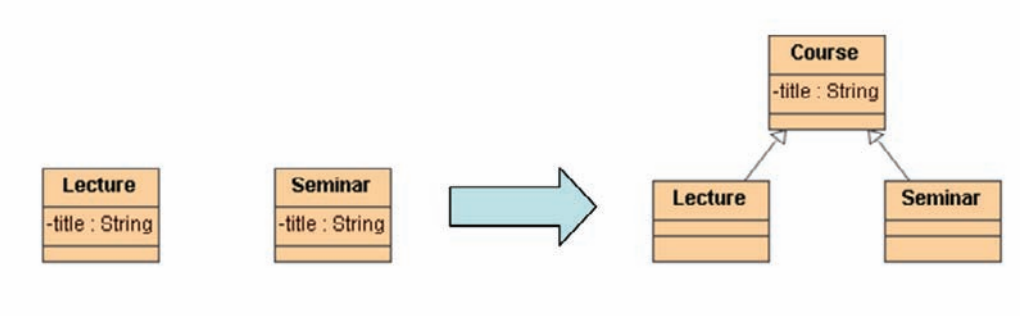

Figure 4. A scenario for model-driven software refactoring (©2007 Tom Mens, UMH. Used with permission)

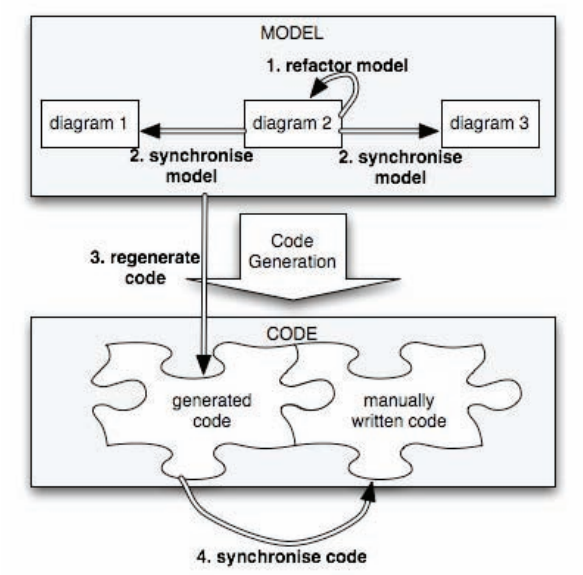


by introducing an abstract super class of both classes, and moving up the attribute to this new super class.

The above example may look simple, but it should be seen in a more general context, which makes dealing with model refactorings considerable less trivial. Consider the scenario depicted in Figure 4. It clearly illustrates the potentially high impact a simple refactoring may have on the software system. We assume that a

model is built up from many different views, typically using a variety of different diagrammatic notations (e.g., class diagrams, state diagrams, use case diagrams, interaction diagrams, activity diagrams, and many more). We also assume that the model is used to generate code, while certain fragments of the code still need to be implemented manually. Whenever we make a change (in this case, a refactoring) to a single view or diagram in the model (step 1 in Figure 4), it is likely that we need to synchronize all related views, in order to avoid them becoming inconsistent (step 2 in Figure 4) (Grundy *et al.*, 1998). Next, since the model has been changed, part of the code will need to be regenerated (step 3 in Figure 4). Finally, the manually written code that depends on this generated code will need to be adapted as well (step 4 in Figure 4).

STATE-OF-THE-ART IN MODEL REFACTORING

At the level of models, research on refactoring is still in its infancy. Little research has been performed on model refactoring, and many open questions remain that are worthy of further investigation. For example, the relation between model refactoring and its effect on the model quality remains a largely unanswered question. From a practical point of view, only very few tools provide integrated support for model refactoring. Also, the types of models for which refactoring is supported is very limited.

In research literature, mainly UML models are considered as suitable candidates for model refactoring (Sunyé *et al.*, 2001; Astels, 2002; Boger *et al.*, 2002). In particular, refactoring of class models (e.g., UML class diagrams) has been investigated by various researchers. The advantage of such models is that they provide a representation that is relatively close to the way object-oriented programs are structured. As such, many of the refactorings known from object-oriented programming (Fowler, 1999) can be ported to UML class diagrams as well. For example, the refactoring shown in Figure 1 can also be considered as a class diagram refactoring, since a new method is created that will be visible in a class diagram. Of course, additional techniques are needed in order to ensure traceability and consistency between class diagrams and their corresponding source code when applying class diagram refactorings (Bouden, 2006).

When it comes to reasoning about the behavior preservation properties of class diagram refactorings, however, things become more difficult for various reasons. The main problem is that class diagrams provide an essentially structural description of the software architecture. Hence, behavioral information has to be expressed in a different way, either by resorting to OCL constraints, behavioral models (e.g., state diagrams or interaction diagrams), or by program code.

With respect to refactoring of behavioral models, not much work is available. We are only aware of a few approaches that address the problem of refactoring state diagrams, and try to prove their behavior preservation properties in a formal way. Van Kempen *et al.* (2005) use a formalism based on CSP to describe statechart refactorings, and show how this formalism can be used to verify that a refactoring effectively preserves behavior. Pretschner and Prenninger (2006) provide a formal approach for refactoring state machines based on logical predicates and tables. Integrating these ideas into tool support is left for future work. Apart from some limitations imposed by the formalisms used, a more general problem is that there is still no generally accepted formal semantics for (UML) state diagrams. Many different interpretations exist and, obviously, this has an important effect on how the behavior is formally defined.

Though research on model refactoring is still in its infancy, a number of formalisms have already been proposed to understand and explore model

refactoring. Most of these approaches suggest expressing model refactoring in a declarative way. Van Der Straeten *et al.* (2004) propose to use description logics; Van Der Straeten & D'Hondt (2006) suggest the use of a forward-chaining logic reasoning engine to support composite model refactorings. Gheyi *et al.* (2005) specify model refactorings using Alloy, a formal object-oriented modeling language. They use its formal verification system to specify and prove the soundness of the transformations. Biermann *et al.* (2006) and Mens *et al.* (2007) use graph transformation theory as an underlying foundation for specifying model refactoring, and rely on the formal properties to reason about and analyze these refactorings.

An important aspect of refactoring in a model-driven software development context that is typically neglected in research literature is how it interferes with code generation. Most contemporary tools for model-driven software development allow generating a substantial part of the source code automatically from the model, while other parts still need to be specified manually (see Figure 4). This introduces the need to synchronize between models and source code when either one of them changes. How such synchronization can be achieved in presence of automated refactoring support is a question that has not been addressed in detail in research literature. If a model is being refactored, how should the corresponding source code be modified accordingly? Vice versa, if source code is being refactored, how will the models be affected? These are the kind of questions that will be addressed in this chapter. To this extent, we will report on our experience with AndroMDA, a state-of-the-art tool for model-driven software development based on UML.

MOTIVATING EXAMPLE: MODEL-DRIVEN DEVELOPMENT WITH ANDROMDA

This section presents the model-driven development of a small web application for a simple university calendar. We will develop this calendar in two iteration steps using AndroMDA[1]. First the underlying data model is designed and a web application with a default web presentation is generated. Second, application-specific services and the web presentation are developed with AndroMDA. This means that use cases are defined and refined by activity diagrams that can use controllers and services. The development is not hundred percent model-driven, since service and controller bodies have to be coded by hand.

For both iteration steps, we first present the UML model using the AndroMDA profile and then discuss a refactoring step useful in that context.

Getting Started with Developing a University Calendar Using AndroMDA

One of the main tools for model-driven software development is AndroMDA. Its transformation engine is structured by cartridges. A number of pre-defined cartridges is already available realizing the generation of web applications from UML models. We illustrate model-driven software development based on AndroMDA by the example of a very simple university calendar.

In principle, the model-driven development process of AndroMDA is based on use cases. But in this initial example, we start with an even simpler way of using AndroMDA. We just design the underlying data model and AndroMDA generates a complete web application with a default web presentation from that.

A web application generated by AndroMDA has a three-tier architecture consisting of a service

layer building up on a data base, controllers using the services defined, and a web presentation. The underlying data model, services and controllers are defined by an UML class diagram. Additionally, visual object classes are modeled, which are used for presenting data to the user, decoupled from the internal data model.

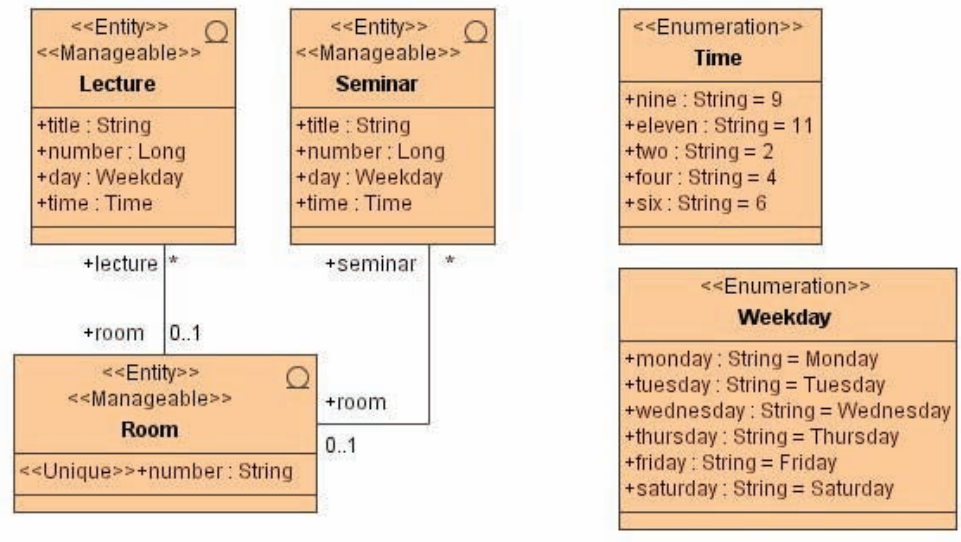
An example of an AndroMDA class diagram is shown in Figure 5. It depicts a simple data model for a university calendar. We can observe that the basic entities are `Rooms` that can be occupied for giving a Lecture or a Seminar. Based on this class diagram, AndroMDA can generate a default web interface for managing lectures, seminars and rooms. Users can add and delete instances, change attribute values and perform searches. The webpage for managing lectures is shown in Figure 6.

The UML profiles used in connection with AndroMDA can be considered as a domain-specific language, dedicated to the generation of web applications. This is achieved by giving a specific semantics to UML models by relying on that dedicated UML profiles. They extend the semantics of the UML by introducing specific stereotypes, to which additional constraints and tagged values are attached. For example, the stereotype «Entity» attached to a class is used to represent a data entity to be stored in a database. If, additionally, the «Manageable» stereotype is used, it causes AndroMDA to generate a default web presentation for managing the corresponding entities. The use of such manageable entities has been illustrated in Figure 5.

First Refactoring of the University Calendar

Due to their compactness, large parts of AndroMDA UML models are used for generating user interfaces. Thus, model refactorings in this context are likely to cause changes in user inter-

Figure 5. Data model for a simple university calendar (©2007 Tom Mens, UMH. Used with permission)



faces as well. Following Fowler (1999) in a strict sense, refactorings should not change the user interface of software, since they are supposed to "preserve the observable behavior". This strict interpretation of refactoring, however, makes little sense if applied in a model-driven software development context, due to the side-effects that model refactorings may cause on the generated code, especially user interfaces. Thus, Fowler's definition of refactoring should be interpreted in a more liberal way, in the sense that it should not change the functionality offered by software. Modifications to the *usability* of the software or to other non-functional properties (such as interoperability, portability, reusability, adaptability and the like) should be allowed, if the goal of these modifications is to improve the software quality.

In the remainder of this section we will show a concrete refactoring on our university calendar case study to clarify what refactoring can mean in the context of model-driven development.

Since «Entity» classes Lecture and Seminar contain several attributes in common (see Figure 5), it would make sense to refactor this data model by adding a new abstract superclass, called Course, and pulling up all common attributes to this new class. The result of this refactoring is shown in Figure 7.

Note that tagged value @andromda.hibernate.inheritance has to be set to interface for restricting the management facilities for courses to searching functionalities only.

When regenerating a web application from the refactored data model in Figure 7, most of the user interface remains unaltered. But a new webpage

Figure 6. Webpage for managing lectures (©2007 Tom Mens, UMH. Used with permission)

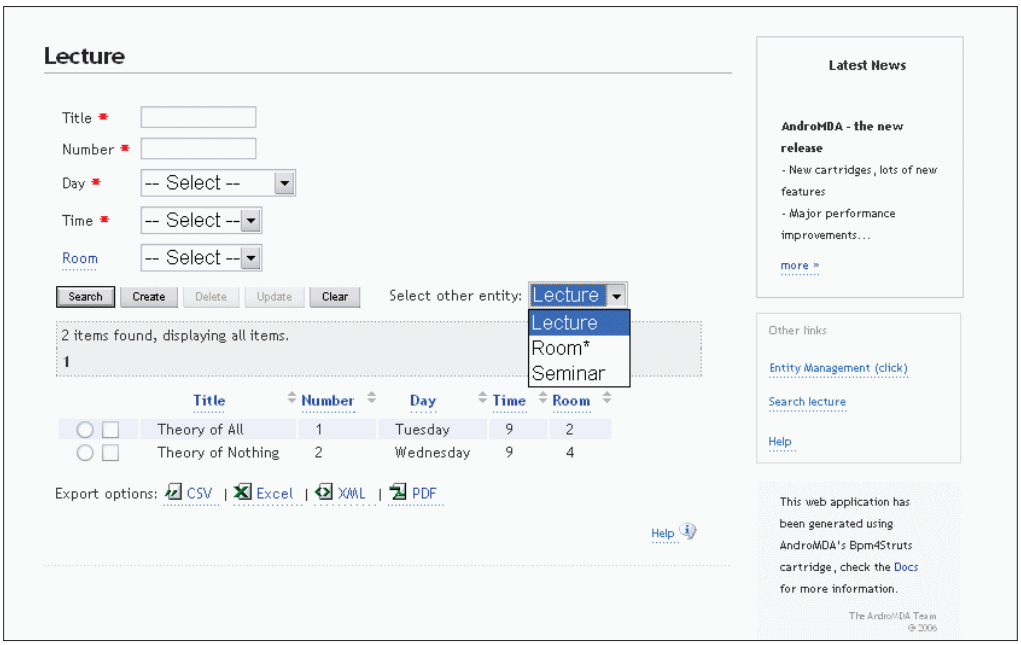


Figure 7. Data model for a simple university calendar after having applied the Pull Up Attribute refactoring (©2007 Tom Mens, UMH. Used with permission)

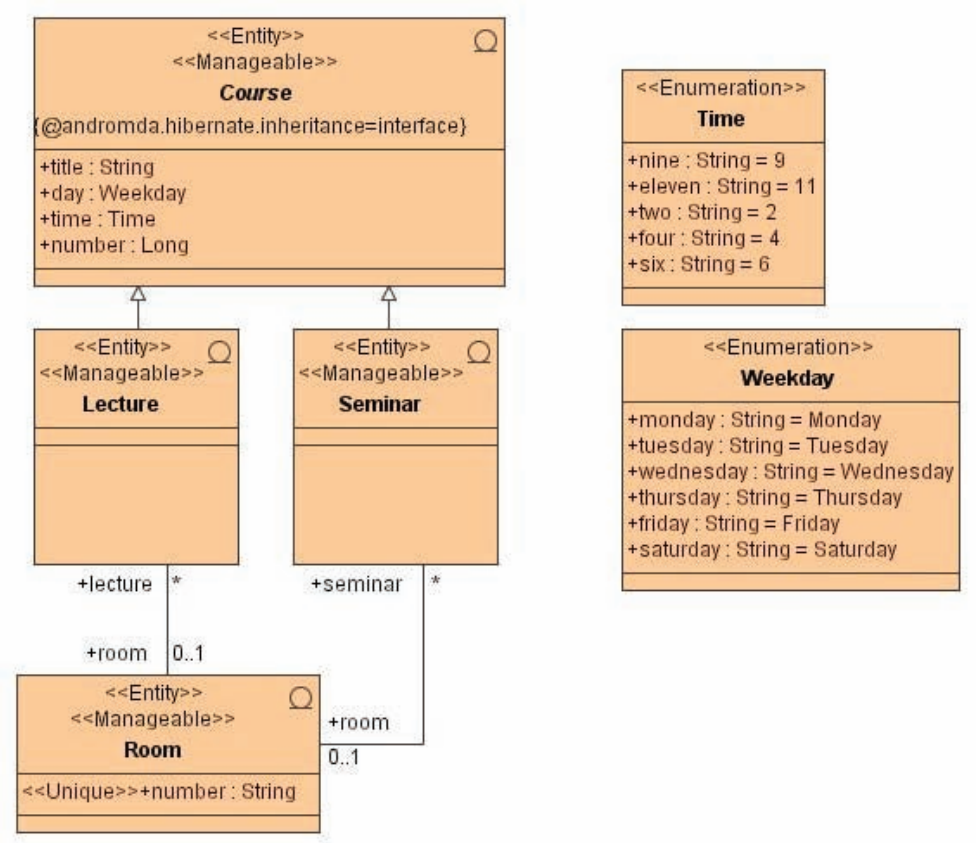


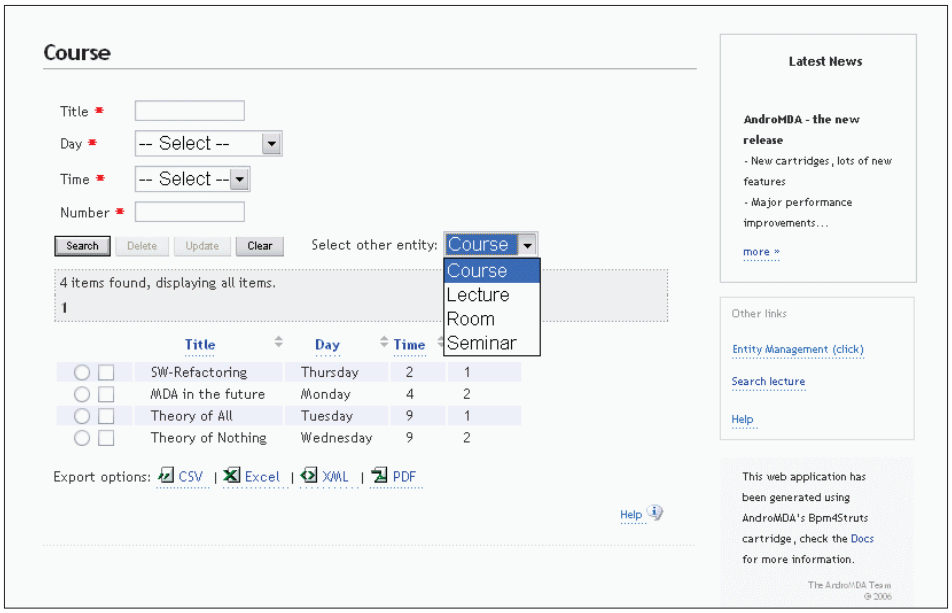
will appear for managing courses, as shown in Figure 8. Because of the tagged value attached to Course, this webpage only offers search functionality, but does not allow the addition or deletion of course instances.

In the example explained in section 3.1, all application code is generated from the model. Thus, refactoring the model alone appears to be sufficient to refactor the whole software application. However, it should be noted that, due to the refactoring applied to the model, the behavior has been changed slightly, since AndroMDA has generated a new kind of webpage.

Developing Application-Specific Use Cases with AndroMDA

In this section, we will consider additional stereotypes and tagged values in the AndroMDA UML profile, but only as far as we need them to

Figure 8. Webpage for managing courses (©2007 Tom Mens, UMH. Used with permission)



develop our example. For a complete overview of all available stereotypes and how to use them we refer to the AndroMDA website.

«Service» is a class stereotype used to specify application-specific services. These services typically use one or more entities that store the data used by the services. For the model-driven development of a web presentation, we extend the model by use cases that are refined by activity diagrams. This model part describes the web presentation and its usage of controllers based on services. The development is not hundred percent model-driven, since service and controller bodies have to be coded by hand.

To illustrate the development of specific web applications we reconsider the university calendar and develop a specific use case diagram for lectures (see Figure 9). Use case Search lectures has two stereotypes being «FrontEndUseCase», which determines the use case to be visible to the user in form of a webpage, and «FrontEndApplication», which defines this use case to be the starting one.

Use case Search lectures is refined by an activity diagram that supports a search activity and the presentation of filtered lectures (see Figure 10). Activity Search lectures is an internal activity that calls the controller method showLectures(). Activity Present lectures has stereotype «FrontEndView» implying that this activity models a webpage. Both activities are connected by two transitions arranged in a cyclic way. After calling method showLectures() the result is transferred to the webpage by signal show, which has the resulting value object array as parameter. Signal search and its parameters

Figure 9. Example of a use case model in AndroMDA (©2007 Tom Mens, UMH. Used with permission)

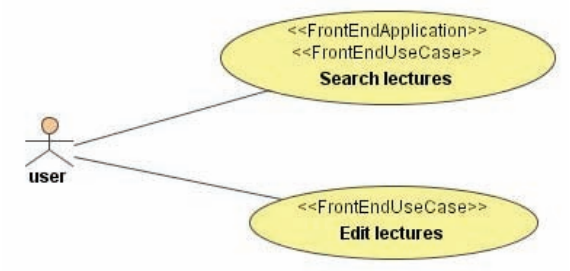


Figure 10. Example of an activity diagram specifying the Search lectures use case (©2007 Tom Mens, UMH. Used with permission)

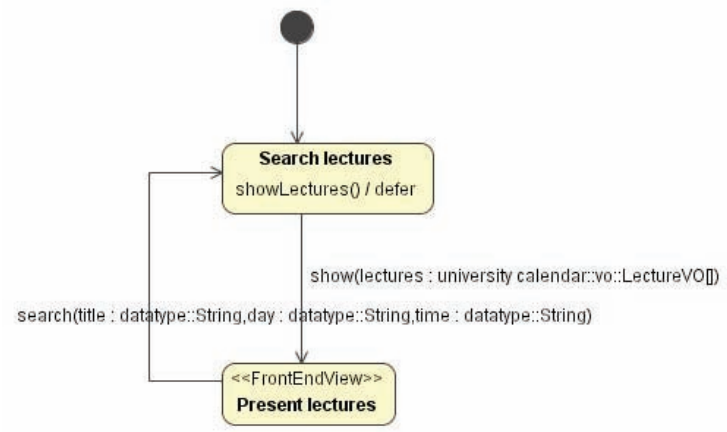

are used to model the web form for filtering the lectures.

The class model in Figure 5 is again used as data model. To show lectures, a special value object class for lectures is used, which is specified by stereotype «ValueObject» (see Figure 11). This makes sense in terms of encapsulation (think of security, extensibility, etc.) and corresponds to the layered model-view-controller approach. Necessary information of the business layer is packaged into so-called "value objects", which are used for the transfer to the presentation layer.

Figure 11. Value Object and Criteria classes (©2007 Tom Mens, UMH. Used with permission)

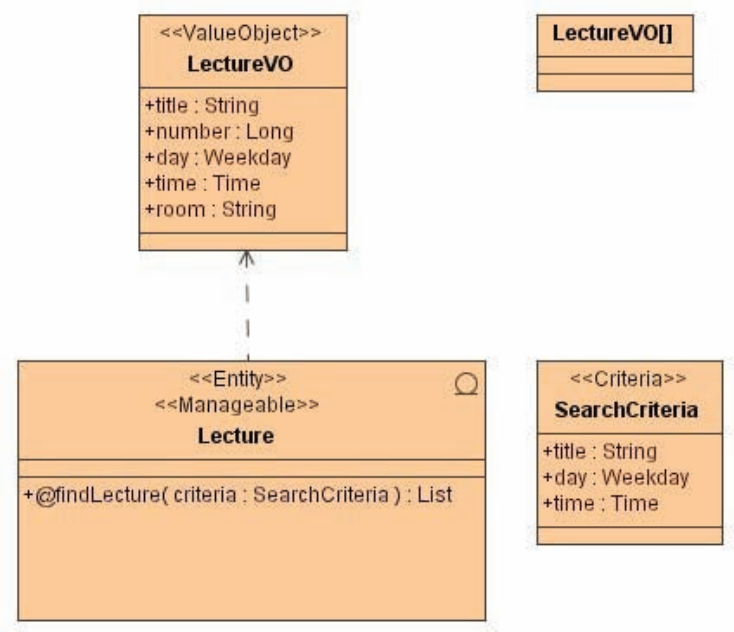

Figure 12. Service and controller classes (©2007 Tom Mens, UMH. Used with permission)

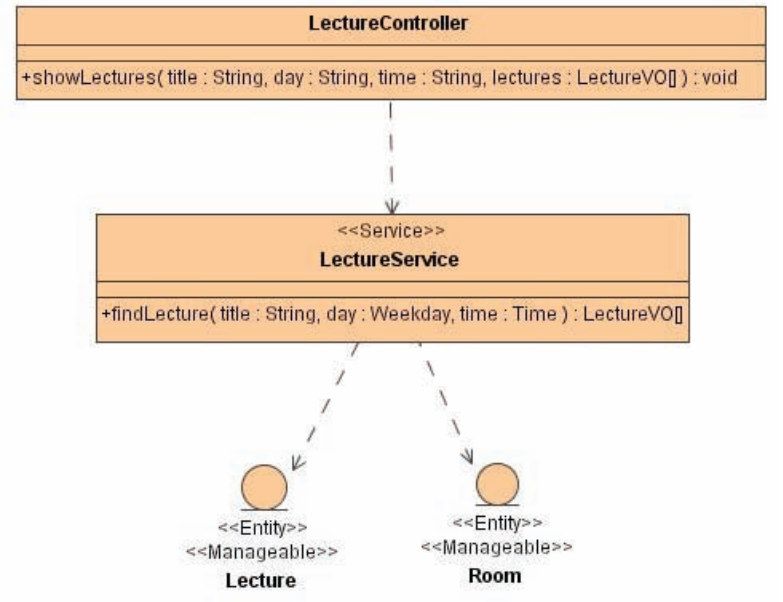

Passing real entity objects to the client may pose a security risk. Do you want the client application to have access to the salary information inside the Lecturer entity?

An attribute room of type String was added to LectureVO in order to allow a connection to the unique number of the Room class. Since value objects are used at the presentation layer, the types used are primitive ones; entity types are not used in that layer. A dependency relation between an entity and a value object is used to generate translation methods from the entity to its corresponding value object. Moreover, search criteria can be defined by a class of stereotype «Criteria».

Method showLectures() that is called from activity Search lectures in Figure 10, is defined in LectureController, a class that relies on class LectureService. This class is stereotyped as «Service» and relies on entities Lecture and Room (see Figure 12). However, the bodies of service and controller methods cannot be modeled, but have to be coded directly by hand. For example, the implementation of service method findLecture()is shown in Figure 1. Because of special naming conventions of AndroMDA it has to be named handleFindLecture().

The web application generated by AndroMDA from the complete model given in the previous figures (together with manually written code parts) produces the webpage shown in Figure 13. Please note that the names used as page title, in the search form and for the buttons are generated from the model.

Further Refactoring of the University Calendar

As a second model refactoring[2], we will discuss the renaming of attribute time to startime based on the model given in Section 3.3. We will argue that this refactoring affects the usability of the generated software. The refactoring is primarily performed on entity class Lecture, but since there is a value object class LectureVO for that entity, the corresponding value class attribute time has to be renamed into starttime, too (see Figure 14). The same is true in SearchCriteria. Thus, the standard refactoring method *Rename Attribute* becomes domain-specific and affects several classes in this domain-specific context.

Since the value object attribute is not used directly in other parts of the model, the model does not have to be updated any further. But the hand-written code (given in Figure 1) is affected, since accessor method setTime() is no longer available after regenerating the code. Thus, it has to be renamed as well, by calling method setStarttime() instead. After having performed this refactoring, the webpage for searching lectures has been changed slightly. As a result, the usability is affected, though not dramatically, since the column named "Time" of the presented table presented has changed into "Starttime" (see Figure 15).

Based on the analysis of both model refactorings carried out in this section, we can derive the following important preliminary conclusions:

- Generic model refactorings need to be adapted and refined in order to work properly in a domain-specific modeling language.
- Model refactorings may also affect, and require changes to the hand-written source code.
- Model refactorings may change external qualities as perceived by the user, such as usability aspects.

CHALLENGES IN MODEL-DRIVEN SOFTWARE REFACTORING

In this section, we will discuss some important challenges in model refactoring that have to do with the relation between model refactoring and model quality. It is not our ambition to solve all these challenges in the current chapter. In Sections 5 and 6 we will therefore only focus on those challenges that we consider being most urgent and most important and we will exemplify our proposed solution using the case study introduced in the previous section.

Model Quality

A first challenge is to provide a precise definition of model quality. A model can have many different non-functional properties or quality characteristics that may be desirable (some examples are: usability, readability, performance and adaptability). It remains an open challenge to identify which qualities are necessary and sufficient for which type of stakeholder, as well as how to specify these qualities formally, and how to relate them to one another.

Since the main goal of refactoring is to improve certain aspects of the software quality, we need means to assess this quality at the model level in an objective way. On the one hand, this will allow software modelers to identify which parts of the model contain symptoms of poor quality, and are hence potential candidates for model refactoring. On the other hand, quality assessment techniques can be used to verify to which extent model refactorings actually improve the model quality.

One of the ways to assess model quality is by resorting to what we will call *model smells*. These are the model-level equivalent of *bad smells*, a term originally coined by Kent Beck in (Fowler, 1999) to refer to structures in the code that suggest opportunities for refactoring. Typical model

smells have to do with redundancies, ambiguities, inconsistencies, incompleteness, non-adherence to design conventions or standards, abuse of the modeling notation, and so on. A challenge here is to come up with a comprehensive and commonly accepted list of model smells, as well as tool support to detect such smells in an automated way. What is also needed is a good understanding of the relation between model smells and model refactoring, in order to be able to suggest, for any given model smell, appropriate model refactorings that can remove this smell.

A second way to assess and control model quality is by resorting to *model metrics*. In analogy with software metrics (Fenton & Pfleeger, 1997) they are used to measure and quantify desirable aspects of models. It remains an open question, however, how to define model metrics in such a way that they correlate well with external model quality characteristics. Another important issue is to explore the relation between model metrics and model refactoring, and in particular to assess to which extent model refactorings affect metric values. These issues have been addressed by (Demeyer *et al.*, 2000; Du Bois, 2006; Tahvildari & Kontogiannis, 2004) though mainly at code level.

A final way to improve model quality is by introducing design patterns, which are proven solutions to recurring problems (Gamma *et al.*, 1994). At code level, Kerievsky (2004) explored the relation between refactorings and design patterns. It remains to be seen how similar results may be achieved at the level of models.

Kamthan (2004) provided a quality framework for UML models. It systematically studies the quality goals, how to assess them, as well as techniques for improving the quality, similar to the ones discussed above.

Model Synchronization

With respect to model refactoring, one of the key questions is how it actually differs from program refactoring. Can the same ideas, techniques and even tools used for program refactoring be ported to the level of models? If not, what is it precisely that makes them different?

One answer to this question is that models are typically built up from different views, using different types of diagrams, that all need to be kept consistent. This in contrast to programs, that are often (though not always) expressed within a single programming language.[3]

Perhaps a more important difference is that models are abstract artifacts whose main purpose is to facilitate software development by generating a large portion of the source code that would otherwise need to be written manually. However, full code generation is unfeasible in practice for most application domains. The additional challenge therefore consists in the need to synchronize and maintain consistency between models and their corresponding program code, especially when part of this program code has been specified or modified manually. In the context of model transformation, this implies that automated model refactorings (or other transformations) may need to be supplemented with code-level transformations in order to ensure overall consistency. Vice versa, program refactorings may need to be supplemented with model-level transformations to ensure their consistency.

Though no general solutions exist yet, the problem of model synchronization and model consistency maintenance is well known in literature. For example, (Van Gorp *et al.*, 2003) discuss the problem of keeping the UML models consistent with their corresponding program code. (Correa & Werner, 2004) explain how OCL constraints need to be kept in sync when the class diagrams are refactored and vice versa. Egyed (2006) proposes an incremental approach to model consistency checking that scales up to large industrial models. Liu *et al.* (2002) and Van Der Straeten & D'Hondt (2006) rely on a rule-based approach for detecting and resolving UML model inconsistencies, respectively. Van Der Straeten *et*

al. (2003) bear on the formalism of description logics to achieve the same goal. Mens *et al.* (2006) propose to resolve inconsistencies in an incremental fashion by relying on the formalism of graph transformation. Grundy *et al.* (1998) report on how tool support can be provided for managing inconsistencies in a software system composed of multiple views. Goedicke *et al.* (1999) address the same problem by relying on the formalism of distributed graph transformation.

Behavior Preservation

Another important challenge of model refactoring has to do with *behavior preservation*. By definition, a model refactoring is supposed to preserve the observable behavior of the model it is transforming. In order to achieve this, we need a precise definition of "behavior" in general, and for models in particular. In addition, we need formalisms that allow us to specify behavioral invariants, i.e., properties that need to be preserved by the refactoring. The formalism should then verify which of these invariants are preserved by the model refactoring. Although formal research on behavior preservation is still in its infancy, in Section 2 we already pointed to a few approaches that carried out initial research in this direction. Another approach that is worthwhile mentioning is the work by Gheyi *et al.* (2005). They suggest specifying model refactorings in *Alloy*, an object-oriented modeling language used for formal specification. It can be used to prove semantics-preserving properties of model refactorings.

A more pragmatic way to ensure that the behavior remains preserved by a refactoring is by resorting to *testing* techniques. Many researchers have looked at how to combine the ideas of testing with model-driven engineering (Brottier *et al.*, 2006; Mottu *et al.*, 2006). Test-driven development is suggested by the agile methods community as good practice for writing high-quality software. In combination with refactoring, it implies that before and after each refactoring step, tests are executed to ensure that the behavior remains unaltered.

Domain-Specific Modeling

A final challenge is the need to define model refactorings in domain-specific extensions of the UML (such as AndroMDA), or even in dedicated domain-specific modeling languages. These refactorings should be expressible in a generic yet customizable way. Indeed, given the large number of very diverse domain-specific languages, it is not feasible, nor desirable, to develop dedicated tools for all of them from scratch.

Zhang *et al.* (2004) therefore proposed a generic model transformation engine and used it to specify refactorings for domain-specific models. Their tool is implemented in the Generic Modeling Environment (GME), a UML-based meta-modeling environment. A model refactoring browser has been implemented as a GME plug-in. Their tool enables the automation and user-defined customization of model refactorings using ECL (Embedded Constraint Language), an extension of the declarative OCL language with imperative constructs to support model transformation. As an example of the expressiveness of their approach, they illustrated how it can be applied to class diagrams, state diagrams and Petri nets. The solution that we will explore later in this chapter is related, in the sense that we will propose a generic approach for UML-based model refactoring based on graph transformation concepts.

In general, the main challenge remains to determine, for a given domain-specific modeling language, which transformations can be considered as meaningful refactorings. On the one hand, they will need to preserve some notion of "behavior" and, on the other hand, they need to improve some quality aspect. These notions of behavior and quality can differ widely depending on the domain under study. For domains that do not refer to software (e.g., business domains, technical domains, etc.) it is much harder to come

to a meaningful definition of behavior, implying that the notion of refactoring would become much harder to define in that context.

Analyzing Model Refactorings

Even more advanced support for model refactorings can be envisaged if we have a precise means to analyze and understand the relationships between refactorings. This will enable us to build up complex refactorings from simpler ones; to detect whether refactorings are mutually exclusive, in the sense that they are not jointly applicable and to analyze causal dependencies between refactorings. These techniques have been explored in detail by Mens *et al.* (2007), and promise to offer more guidance to the developer on what is the most appropriate refactoring to apply in which context. A short introduction to this line of research will be given in Section 6.

MOTIVATING EXAMPLE REVISITED

In Section 3 two concrete model refactorings have been applied to AndroMDA models: pulling up an attribute into a new superclass and renaming an entity. In this section, we explore some more refactorings for AndroMDA models.[4] We start by considering a set of "standard" model refactorings widely used to restructure class diagrams. As it will turn out, most of these refactorings have side-effects due to constraints imposed by AndroMDA's code generator. Therefore, these model refactorings need to be customized to take into account more domain-specific information. Next to these "standard" refactorings, we will also discuss entirely new "domain-specific" refactorings for AndroMDA models.

In the following, we will take a slightly broader view, and we discuss three categories of model transformations as follows:

(1) model refactorings that do not affect the user interface at all;
(2) model refactorings that do affect the user interface with respect to the usability, but that do not affect what the user can do with the application;
(3) model transformations that also affect the actual behavior/functionality of the application.

The latter category does not contain refactorings in the strict sense of the word, but it is nevertheless useful and necessary to deal with them. For example, it could be the case that what is perceived as a normal refactoring will actually *extend* the behavior as a side effect of the code generation process.

Pull Up Attribute

When pulling up an attribute to a super class, as explained in Section 3.2, the code generator will generate a new webpage corresponding to this super class, with search functionality for each manageable entity. Thus, this model transformation belongs to category (3).

Rename

The refactoring example in Section 3.4 is concerned with renaming an attribute of an entity class. This refactoring affects the user interface, if the entity is manageable. In this case, one of the columns in the table of the webpage has been renamed. Furthermore, in case that the entity class comes along with a value object class that is derived from the entity class, a renaming of an entity attribute has to be accompanied by a renaming of the corresponding attribute in its value object class. If, in addition, this value object attribute is used in some activity diagram, the name has to be adapted there as well. Furthermore, this value object attribute can occur in hand-written code,

which implies that renaming has to be performed also in that part of the code.

A similar situation would arise if we renamed the entity class itself, as it would be reflected by a change in the title of the corresponding webpage for manageable entities. In case that the renamed entity class comes along with a value object class whose name is derived from the entity class name (e.g., in Figure 14, "LectureVO" is derived from "Lecture" by suffixing "VO"), renaming has to be accompanied by a renaming of its corresponding value object class. Furthermore, the renaming has to be propagated as discussed for attributes. In all cases presented, although the user interface changes slightly, the functionality of the application is not affected. Hence, these refactorings belong to category (2).

Similar to entities, use cases can be renamed as well. This might have an effect on activity diagrams, since AndroMDA supports the connection of several activity diagrams via use case names. For example, an end activity of one activity diagram may be named as a use case, which means that the control flow would continue at the start activity of the corresponding activity diagram. In the generated web applications, use cases are listed on the right-hand side of each webpage. Again, a renamed use case would change the usability of the web application, but not its functionality, so the refactoring belongs to category (2).

In summary, we see that renaming in AndroMDA may have a high impact. Due to the fact that the code generator automatically produces new types of elements based on the names of existing elements, a seemingly simple change (in casu renaming) will propagate to many different places. A tool that would implement this model refactoring would therefore need to take these issues into account to ensure that the renaming does not lead to an inconsistent model or code. Furthermore, because the changes affect hand-written code, the refactoring may require a certain amount of user interaction.

Create Value Object

A domain-specific refactoring for AndroMDA models is the creation of value objects for entities. An example is visually represented in Figure 16. Given a class with stereotype «Entity» (for example, class Lecture), a new class with stereotype «Value Object» is created and the entity class becomes dependent on this new class. The value object class is named after its entity class followed by suffix "VO" (for example, value object class LectureVO). The entity attributes are copied to the value object class, keeping names and types, by default. If internal information should be hidden from the client, the corresponding attribute would not be copied. This refactoring belongs to category (1) and does not affect any other part of the model, since the value object class is only created without being used yet.

Merge Services

Another domain-specific model refactoring is *Merge Services*. It takes two «Service» classes and merges them as well as all their incoming and outgoing dependencies. Consider the following example where both a LecturService and RoomService exist (see Figure 17). If we do not consider remote services and have only one controller class, it does not make sense to have two service classes. Therefore, both should be merged into LectureService. After refactoring, the controller class will have only one outgoing dependency. As a result, the hand-written code for the controller method will be affected. Nevertheless, this restructuring will not modify the external behavior, so users of the generated web application will not notice any change. Hence, this refactoring falls into category (1).

Split Activity

The front-end of a web application is modeled by use cases and activity diagrams. A refactoring

Figure 16. Example of the domain-specific model refactoring CreateValueObject (©2007 Tom Mens, UMH. Used with permission)

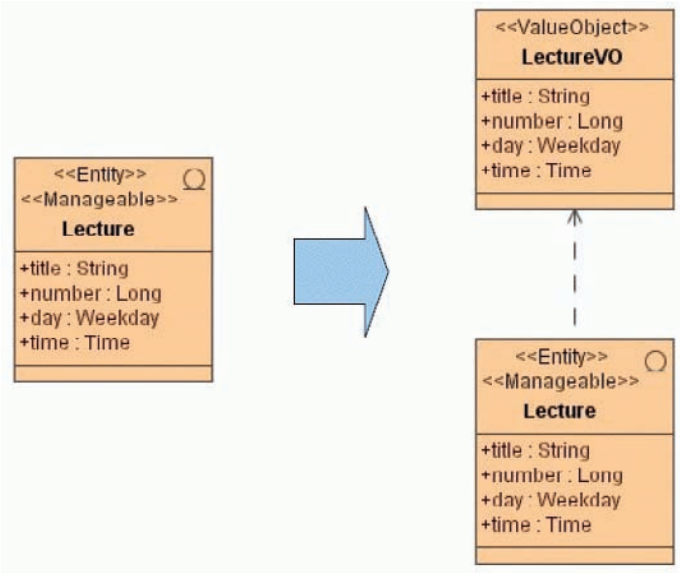

Figure 17. Service classes LectureService and RoomService with dependencies (©2007 Tom Mens, UMH. Used with permission)

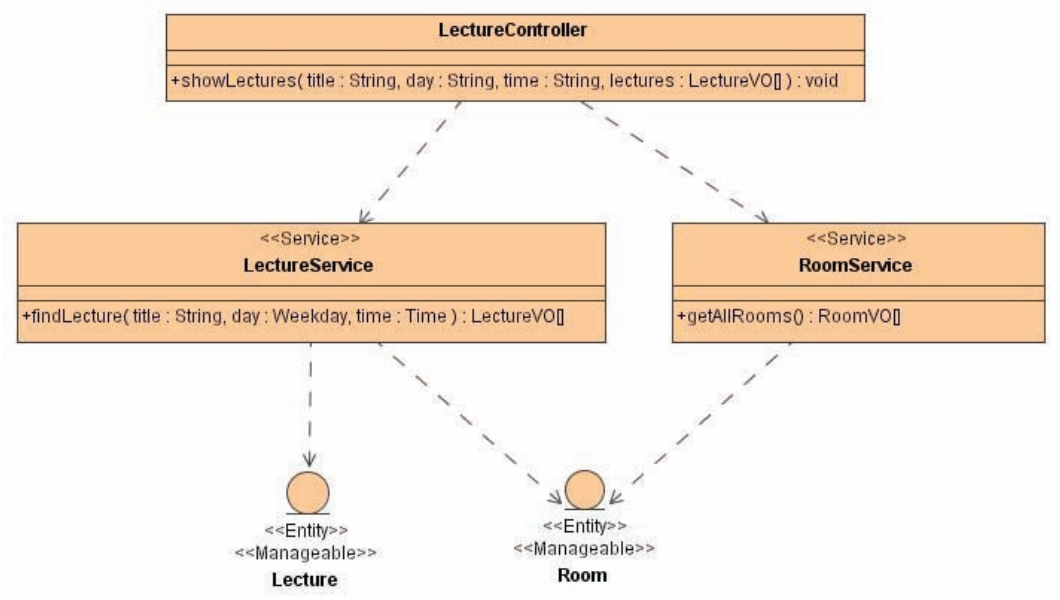

like the splitting of activities into two consecutive ones, linked by a transition, can directly affect the web presentation. If the original activity was a «FrontEndView», the corresponding webpage is split into two pages. If an internal activity was split, this refactoring has to be accompanied by a splitting of the corresponding controller method called. In the first case, the refactoring belongs to category (2), in the second case it belongs to category (1).

Extract Method

Extract Method is a refactoring from the standard catalogue established by Fowler. In the context of model-driven development, and AndroMDA in particular, it can have new effects. Consider the scenario in Figure 19. First, we perform the extract method refactoring to the hand-written code, as illustrated in Figure 2 where a method, called initialise(), is extracted from a given service method handleFindLecture. To reflect this change at model level, we modify the class diagram by adding the extracted method to the class LectureService as well (see Figure 18). Consequently, the code generator will generate extra code for this method, which requires the manually written code to be adapted to make it consistent again. In particular, method initialise()needs to be renamed into handleInitialise(), because this is the convention used by the code generator: all service methods need to be prefixed with "handle" at source code level. We can use this knowledge to constrain the Extract Method refactoring to make it domain-specific: When extracting a method, the name that the user needs to provide for the extracted method needs to follow the naming conventions imposed by the code generator. Not doing so will cause the precondition of the refactoring to fail.

The above scenario is generalized and visualized in Figure 19. It shows how a refactoring at source code level (step 1) may require

Figure 18. Changes to the class diagram as a result of applying the Extract Method program refactoring (see Figure 2) (©2007 Tom Mens, UMH. Used with permission)

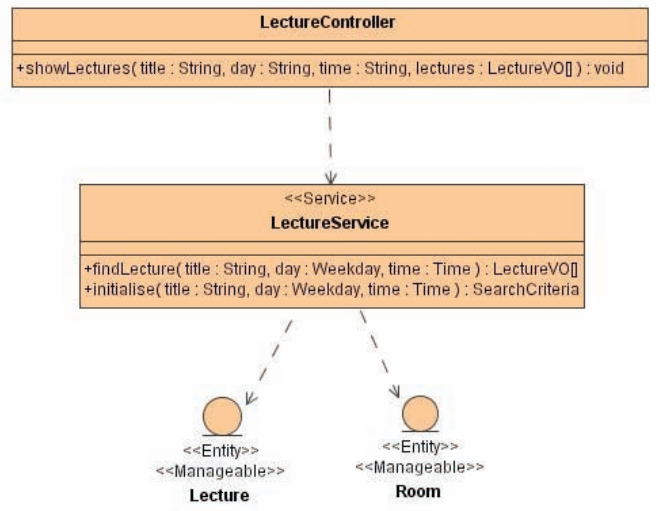

Figure 19. Another scenario of model-driven software refactoring, initiated by a refactoring of the hand-written source code (©2007 Tom Mens, UMH. Used with permission)

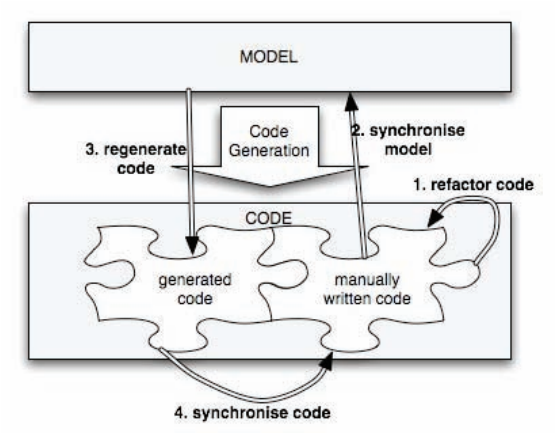

synchronization of the corresponding model (step 2) which, after regenerating the code (step 3) involves another modification to the hand-written part of the code (step 4). The last step is not needed, if the user obeys the naming convention for the new method as discussed above.

SPECIFYING AND ANALYZING MODEL REFACTORINGS

In Section 5, the important challenge of domain-independent support for model refactoring was discussed. A possible formalism that can be used to specify and also analyze refactorings is the theory of *graph transformation* (Ehrig *et al.* 2006). Compared to other approaches it has a number of advantages: it allows one to specify program refactorings and model refactorings for various languages in a uniform and generic way, by representing the software artifact under consideration as a graph, and by specifying the refactorings as graph transformation rules. In addition, one can benefit from the formal properties of graph transformation theory to reason about refactoring in a formal way. For example, properties such as termination, composition, parallel dependencies, and sequential dependencies can be analyzed.

Since the Eclipse Modeling Framework (EMF) has become a key reference for model specification in the world of model-driven development, we rely our approach to model refactoring on EMF model transformation. This approach is presented in Section 6.1. To perform a formal analysis of EMF transformations we translate them to graph transformations, which is possible under certain circumstances. In Section 6.2, a conflict and dependency analysis of model refactorings is presented, assuming that the model refactorings are defined by graph transformation rules.

Technical Solution

From a technical point of view, we will discuss how to implement and execute model refactorings.

In particular, we will consider how to realize model refactoring within the Eclipse Modeling Framework (EMF). As a prerequisite, a specification of the underlying modeling language is needed, which will be given by a meta-model. Figure 20 shows an EMF model that represents a simplified extract of the AndroMDA meta-model. Figure 21 shows an instance of this EMF model for the entity class Lecture of the simple university calendar.

Biermann *et al.* (2006) explain in detail how EMF model refactoring can be expressed by EMF model transformation. This kind of model transformation is specified by rules and is performed in-place, i.e., the current model is directly changed and not copied. Each transformation rule consists of a left-hand side (LHS), indicating the preconditions of the transformation, a right-hand side (RHS), formulating the post conditions of the transformations, and optional negative application conditions (NAC), defining forbidden structures that prevent application of the transformation rule. Objects that are checked as precondition preserved during a transformation are indicated by colors. Object nodes of the same color present one and the same object in different parts of a rule. While attributes in the LHS may have constant values or rule variables only, they are allowed to carry Java expressions in the RHS, too. The same variable at different places in the rules means the same value at all places. In the following, we use this approach to EMF model transformation for specifying UML model refactorings.

In Figure 22 and Figure 23, two model transformation rules are shown, which both are needed to perform refactoring *Create Value Object* explained in Figure 16 of Section 5. Rule *CreateValueObjectClass* is applied once, creating a new value object class and a dependency of the entity class on this new class. A class model with an entity class is needed to create a value object class and a dependency in between. The name of

Figure 20. Extract of AndroMDA meta-model as EMF model (©2007 Tom Mens, UMH. Used with permission)

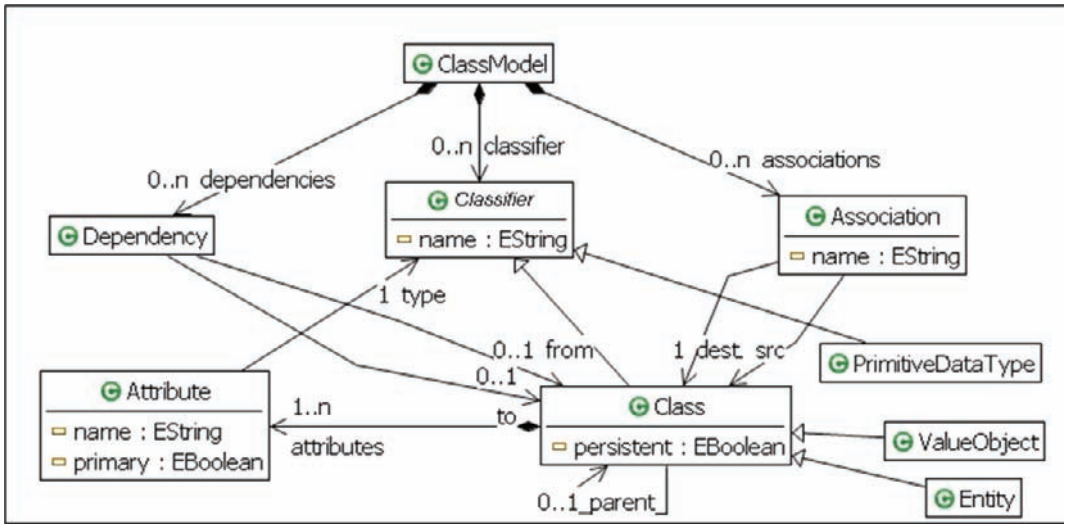

Figure 21. Entity class Lecture *with attributes in abstract syntax as EMF model instance (©2007 Tom Mens, UMH. Used with permission)*

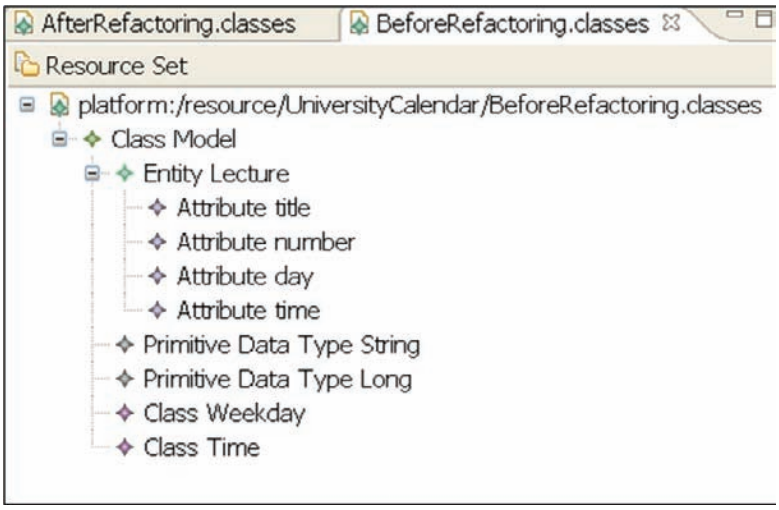

Figure 22. EMF model transformation rule CreateValueObjectClass for refactoring method Create Value Object (©2007 Tom Mens, UMH. Used with permission)

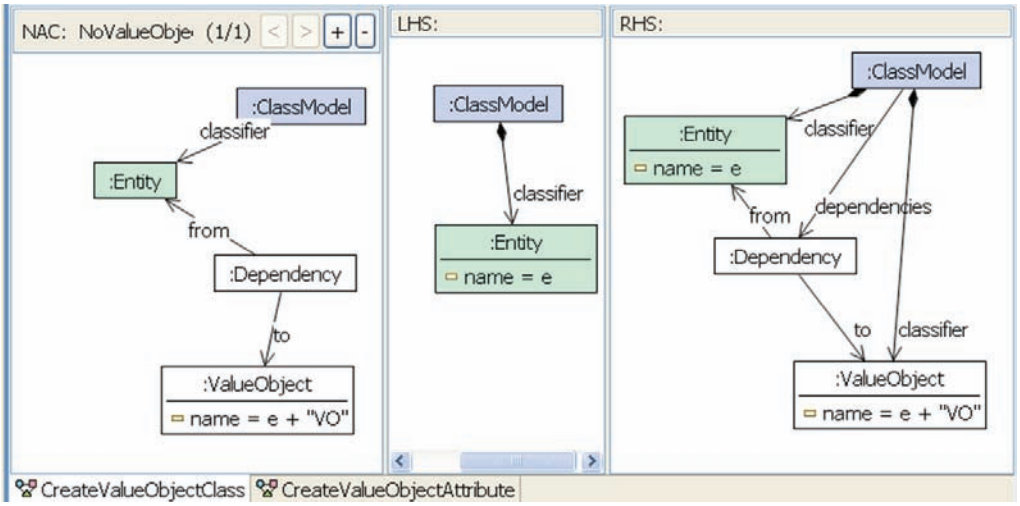

Figure 23. EMF model transformation rule CreateValueObjectAttribute for refactoring method Create Value Object (©2007 Tom Mens, UMH. Used with permission)

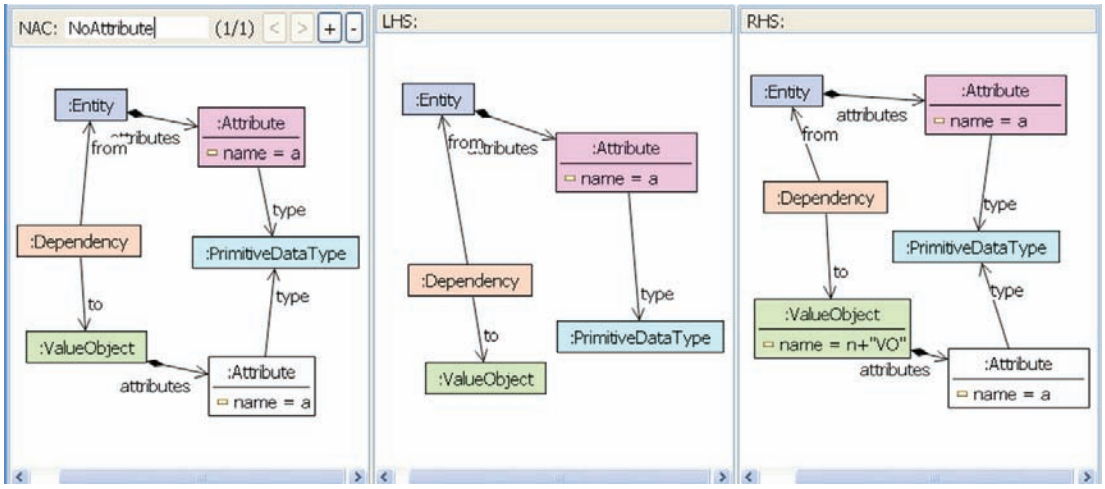

Figure 24. Entity class Lecture with value object class LectureVO in abstract syntax as EMF model instance (©2007 Tom Mens, UMH. Used with permission)

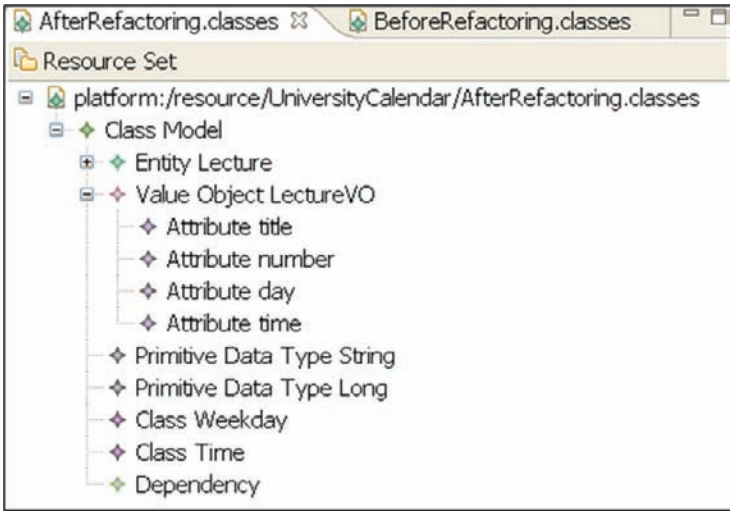


this new value object class is constructed by taking the entity class name e and adding suffix "VO". This rule is applied only if a value object class of this name has not already been created.

Thereafter, rule *CreateValueObjectAttribute* is applied for each of the attributes of the entity class that should occur also in the value object class. Each time it is applied, it copies an attribute that has not yet been copied into the value object.

Applying rule *CreateValueObjectClass* once and rule *CreateValueObjectAttribute* as often as entity class Lecture has attributes (i.e., four times in this case) to the EMF model instance in Figure 21, we obtain the EMF model instance in Figure 24.

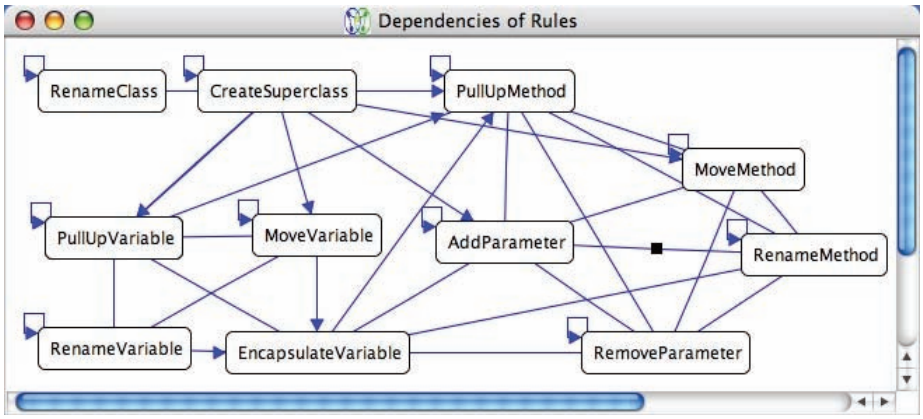
To open up the possibility for analyzing EMF model refactorings, we translate them to graph transformations. In this way, the formal analysis for graph transformation becomes available for EMF model refactoring. Although EMF models show a graph-like structure and can be transformed similarly to graphs, there is an important difference between both. In contrast to graphs, EMF models have a distinguished tree structure that is defined by the containment relation between their classes. Each class can be contained in at most one other class. Since an EMF model may have non-containment references in addition, the following question arises: What if a class, which is transitively contained in a root class, has non-containment references to other classes not transitively contained in some root class? In this case we consider the EMF model to be inconsistent.

A transformation can invalidate an EMF model, if its rule deletes one or more objects. To ensure consistent transformations only, rules that delete objects or containment links or redirect them, have to be equipped with additional NACs.

Formal Solution

As an illustration of how refactoring dependency analysis may increase the understanding of refactoring, consider the following scenario. Assume that a software developer wants to know which refactoring rules need to be applied in order to restructure a software system. Typically, many different refactoring rules may be applicable, and it is not easy to find out what would be the most

Figure 25. Sequential dependencies computed by AGG for a representative set of refactorings implemented as graph transformations (©2007 Tom Mens, UMH. Used with permission)



optimal way to apply these rules. Joint application of some refactoring rules may not be possible due to parallel dependencies between them, and some refactoring rules may sequentially depend on other ones. Graph transformation theory allows us to compute such dependencies by relying on the idea of *critical pair analysis.* The general-purpose graph transformation tool AGG[5] provides an algorithm implementing this analysis.

Figure 25 gives an example of all sequential dependencies that have been computed between a representative, yet simplified, subset of refactorings expressed as graph transformation rules. For example, we see that there is a sequential dependency between the *CreateSuperclass* refactoring and the *PullUpVariable* refactoring. *CreateSuperclass* inserts a new intermediate superclass (identified by node number 2) in between a class (node 1) and its old superclass (node 3). *PullUpVariable* moves a variable contained in a class up to its superclass. The dependency between both transformation rules, as computed by AGG, is visualized in Figure 26. The effect of applying *CreateSuperclass* before *PullUpVariable* will be that the variable will be pulled up to the newly introduced intermediate superclass instead of the old one. As such, there is a sequential dependency between both refactoring rules. It is even the case, in this example, that the application of both refactorings in a different order will produce a different result.

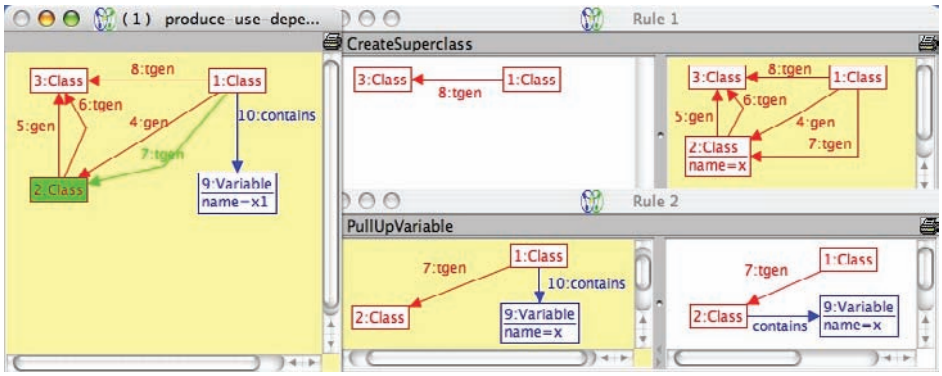
For a more detailed discussion of how critical pair analysis can be used to reason about refactoring dependencies, we refer to (Mens *et al.*, 2007) that provides a detailed account on these issues.

Related Work

Various authors have proposed to use some kind of rule-based approach to specify model refactorings, so it appears to be a natural choice:

Grunske *et al.* (2005) show an example in Fujaba[6] of how model refactoring may be achieved using graph transformation based on story-driven modeling. Bottoni *et al.* (2005) use distributed graph transformation concepts to specify coherent refactorings of several software artifacts, especially UML models and Java programs. Both kinds of artifacts are represented by their abstract syntax structures. Synchronized rules are defined to specify not only refactoring

Figure 26. Example of a sequential dependency between the CreateSuperclass and the PullUpVariable refactoring (©2007 Tom Mens, UMH. Used with permission)



on models and programs separately, but to update also the correlation between different model parts and program. Synchronized rules are applied in parallel to keep coherence between model and program. Considering the special case where exactly two parts (one model diagram and the program or two model diagrams) are related, the triple graph grammar (TGG) approach could also be used (Schürr 1994; Königs & Schürr 2006). Originally formulated for graphs, TGGs are also defined and performed on the basis of MOF models by the modeling environment MOFLON[7].

(Porres, 2003) uses the transformation language SMW to specify model refactorings. This script language is also rule-based and resembles the Object Constraint Language (OCL). SMW is oriented at OCL for querying patterns, but also provides basic operations to realize transformations. A prototypical refactoring tool for UML models has been implemented based on SMW.

Van Der Straeten & D'Hondt (2006) suggest using a rule-based approach to apply model refactorings, based on an underlying inconsistency detection and resolution mechanism implemented in the description logics engine RACER[8].

We decided to specify model refactorings based on EMF model transformation, since EMF is developing to a standard format for models and to be compatible with upcoming UML CASE tools based on EMF. Moreover, our approach opens up the possibility for analyzing model refactorings, since EMF model transformations can be translated to algebraic graph transformations.

SUMMARY

Software complexity is constantly increasing, and can only be tamed by raising the level of abstraction from code to models. With the model-driven software engineering paradigm, automated code generation techniques can be used to hide the accidental complexity of the underlying technology (Brooks, 1995). This enables one to deal with complex software in a systematic way.

To guarantee high-quality software, it is also important to address concerns such as readability, extensibility, reusability and usability of software. Software refactoring is a proven technique to reach these goals in a structured, semi-automated manner.

By integrating the process of refactoring into model-driven software development, we arrive at what we call *model-driven software refactoring.* Analogously to program refactoring, the first phase is to determine potential candidates for model refactorings, which can be obtained using "model smells" and "model metrics". The second phase consists of applying the selected refactorings. This would be a relatively straightforward issue, if hundred-percent code generation were achievable. In practice, for large and complex software systems, this is not the case. Full code generation is not even desirable in many situations since – at least for describing algorithms or data conversions – source code seems to be more adequate than behavioral models. An additional difficulty is the lack of a general accepted semantics of UML. This makes it very difficult to determine whether a given model transformation is behavior preserving, which is the main criterion to decide whether something can be called refactoring or not, according to Fowler (1999).

As a feasibility study, we have chosen AndroMDA to illustrate the model-driven development of web applications. We illustrated and discussed a number of standard and domain-specific restructurings. Since they often change the observable behavior of the software in some sense, we explored to what extent they can be considered as refactorings. All restructurings were categorized into three groups, ordered by the fulfillment degree of Fowler's criterion. The obtained results show that we should address the notion of model refactoring with care, and may serve as suggestions for better tool support:

- We may want to support refactorings that do not fully preserve behavior, as long as they improve other important software quality aspects. This also implies that we need techniques to assess the effect of a model transformation on the software quality.
- We need to find a balance between, and provide user support for the ability to specify generic model refactorings, and the ability to adapt and refine these refactorings to work properly in a domain-specific modeling language;
- We need to provide an interactive round-trip engineering approach to refactoring. When performing model refactorings, it turns out that manual intervention is frequently required in order to keep the abstraction levels of *source code* and *model* consistent. Model refactorings may also affect and require changes to the hand-written source code.

From a theoretical point of view, we have suggested to use graph transformation to provide a formal specification of model refactorings. It has the advantage of defining refactorings in a generic way, while still being able to provide tool support in commonly accepted modeling environments such as EMF. In addition, the theory of graph transformation allows us to formally reason about dependencies between different types of refactorings. Such a static analysis of potential conflicts and dependencies between refactorings can be helpful for the user during the interactive process of trying to improve the software quality by means of disciplined model transformations.

FUTURE RESEARCH DIRECTIONS

In Section 4, we identified many important challenges in model-driven software refactoring. We only worked out some of these challenges in more detail: the need for a formal specification of model refactorings, the need to reason about behavior preservation, the need to synchronize models and source code whilst applying refactorings, the need to relate and integrate the aspects of model refactoring and model quality. There are still many other challenges that remain largely unaddressed:

When developing large software systems in a model-driven manner, several development teams might be involved. In this case, it would be advantageous if the model could be subdivided into several parts that could be developed in a distributed way. Considering refactoring in this setting, model elements from different submodels might be involved. Thus, several distributed refactoring steps have to be performed and potentially synchronized if they involve common model parts. Distributed refactoring steps could be considered as distributed model transformations (Goedicke *et al.*, 1999; Bottoni *et al.*, 2005).

The usual way to test refactorings is by testing the code before and after refactoring steps. Clearly, the code has to satisfy the same test cases before and after refactoring it. Considering refactoring within model-driven development, the same testing procedure should be possible, i.e., test cases for the generated code before and after refactoring should produce the same results. As we discussed within this chapter, model-driven software refactoring often does not fulfill Fowler's criterion in a stringent way. Future investigations should clarify the impact of this kind of restructuring on test suites (Van Deursen *et al.*, 2002).

An important pragmatic challenge that has not been addressed in this chapter has to do with performance and scalability. Is it possible to come up with solutions that scale up to industrial software? Egyed (2006) provided initial evidence that this is actually the case, by providing an instant model synchronization approach that scales up to large industrial software models.

Another interesting research direction is to

apply refactorings at the meta-model level. This raises the additional difficulty of needing to convert all models that conform to this meta-model accordingly, preferably in an automated way.

Chapter 8.17
Benchmarking in the Semantic Web

Raúl García-Castro
Universidad Politécnica de Madrid, Spain

Asunción Gómez-Pérez
Universidad Politécnica de Madrid, Spain

ABSTRACT

The Semantic Web technology needs to be thoroughly evaluated for providing objective results and obtaining massive improvement in its quality; thus, the transfer of this technology from research to industry will speed up. This chapter presents software benchmarking, a process that aims to improve the Semantic Web technology and to find the best practices. The chapter also describes a specific software benchmarking methodology and shows how this methodology has been used to benchmark the interoperability of ontology development tools, employing RDF(S) as the interchange language.

INTRODUCTION

The Semantic Web technology has considerably improved since the 1990's, when the first tools were developed; although it has mainly been applied in research laboratories, in recent years companies have started to be interested in this technology and its application.

To transfer the Semantic Web technology from the academia, its current niche, to the industrial world it is necessary that this technology reaches a maturity level that enables it to comply with the quality requirements of the industry. Therefore, the Semantic Web technology needs to be thoroughly evaluated both for providing objective results and for attaining a massive improvement in its quality.

Until recently, the Semantic Web technology was seldom evaluated; now, however, this technology is widely used and numerous studies concerning its evaluation have appeared in the last few years. So now it seems quite necessary that researchers increase the quality of their evaluations and improve the technology collec-

tively by benchmarking it, employing for this a methodological process.

Evaluating and benchmarking this technology within the Semantic Web can be quite costly because most of the people involved do not know how to carry out these processes and also because no standard nor agreed methods to follow now exist. On the other hand, since it is quite difficult to reuse the results and put into practice the lessons learnt in previous activities, it is necessary to develop new methods and tools every time this technology has to be evaluated or benchmarked.

Software benchmarking is presented in this chapter as a continuous process whose aim is to improve software products, services, and processes by evaluating and comparing them with those considered the best. Although software evaluations are performed inside the benchmarking activities, benchmarking provides some benefits that cannot be obtained from evaluations, as for example, the continuous improvement of software, or the extraction of the best practices used to develop the software.

Within the Knowledge Web[a] European Network of Excellence a new methodology for benchmarking Semantic Web technology has been developed; this methodology is now being adopted in different benchmarking studies and applied to the different types of Semantic Web technologies (ontology development tools, ontology alignment tools, ontology-based annotation tools, and reasoners). The methodology focuses on the special interests of the industry and research fields and on their different needs. At the end of the chapter, we describe how we have followed this methodology during one of the activities performed to benchmark the interoperability of ontology development tools, employing RDF(S) as the interchange language.

EVALUATION AND BENCHMARKING IN THE LITERATURE

Software Evaluation

Software evaluation plays an important role in different areas of Software Engineering, such as Software Measurement, Software Experimentation or Software Testing. In this section, we present a general view of these areas.

According to the ISO 14598 standard (ISO/IEC, 1999), software evaluation is *the systematic examination of to which extent an entity is capable of fulfilling specified requirements*; this standard considers software not just as a set of computer programs but also as a set of procedures, documentation and data.

Software evaluation can take place all along the software life cycle. It can be performed during the software development process by evaluating intermediate software products or when the development has finished.

Although evaluations are usually carried out inside the organisation that develops the software, other independent groups such as users or auditors can also make them. When independent third parties evaluate software, they are usually very effective, though their evaluations can become very expensive (Rakitin, 1997).

The goals of evaluating software vary since they depend on each specific case, but in general, they can be summarised (Basili et al., 1986; Park et al., 1996; Gediga et al., 2002) as follows:

- To **describe** the software in order to understand it and establish baselines for comparisons.
- To **assess** the software with respect to some quality requirements or criteria and determine the degree of quality required from the software product and its weaknesses.

- To **improve** the software by identifying opportunities and, thus, improving its quality. This improvement is measured by comparing the software with the baselines.
- To **compare** alternative software products or different versions of a same product.
- To **control** software quality by ensuring that it meets the required level of quality.
- To **predict** new trends in order to take decisions and establish new goals and plans for accomplishing them.

It is understood that the methods to follow to evaluate software vary from one author to another and from one Software Engineering area to another. However, from the methods proposed in the areas of a) Software Evaluation (ISO/IEC, 1999; Basili, 1985), b) Software Experimentation (Basili & Selby, 1991; Perry et al., 2000; Freimut et al., 2002), c) Software Measurement (Park et al., 1996; IEEE, 1998), and d) Software Testing (Abran et al., 2004) we can extract a common set of tasks that must be carried out in software evaluations. These tasks are the following:

1. To establish the evaluation requirements by setting its goals, the entities to evaluate, and their relevant attributes.
2. To define the evaluation by explaining the data to collect, the evaluation criteria to follow, and the mechanisms to collect data and implement these mechanisms.
3. To produce the evaluation plan.
4. To execute the evaluation and to collect data.
5. To analyse the collected data.

Benchmarking in the Literature

In the last decades, the word benchmarking has become relevant within the business management community. The most well-known definitions of the term are those by Camp (1989) and Spendolini (1992). Camp defines benchmarking as *the search for industry best practices that lead to superior performance*; on the other hand, Spendolini has expanded Camp's definition by adding that benchmarking is *a continuous, systematic process for evaluating the products, services, and work processes of organisations that are recognised as representing best practices for the purpose of organisational improvement.* In this context, best practices are good practices that have worked well elsewhere, are proven and have produced successful results (Wireman, 2003).

These definitions highlight the two main benchmarking characteristics:

- Continuous improvement.
- Search for best practices.

The Software Engineering community does not share a common benchmarking definition but several. Here we present some of the most representative:

- Both Kitchenham (1996) and Weiss (2002) define benchmarking as a software evaluation method suitable for system comparisons. Whereas for Kitchenham benchmarking is *the process of running a number of standard tests using a number of alternative tools/methods and assessing the relative performance of the tools in those tests*, for Weiss benchmarking is *a method of measuring performance against a standard, or a given set of standards.*
- Wohlin et al. (2002) have adopted the benchmarking definition from the business world, that is, they consider benchmarking as a continuous improvement process that strives to be the best of the best through the comparison of similar processes in different contexts.

Software Benchmarking

In this section, we have followed the notions that support continuous improvement and search for best practices within business management benchmarking; these notions have led us to consider software benchmarking as a continuous improvement process instead of as a punctual activity. Equally important for us are the concept of comparing software through evaluations and that of carrying out the benchmarking activity through a systematic procedure.

All these concepts permit us to define **software benchmarking** as a continuous process whose aim is to improve software products, services, and processes by systematically evaluating and comparing them with those considered to be the best.

This definition, however, does not specify the type of the entities considered in benchmarking (software products, services or processes), nor does it determine the software life-cycle phase when benchmarking is performed, and nor does it explain who is responsible for benchmarking. However, software benchmarking is usually performed on software products already developed and is executed by their developers.

The reason for benchmarking software products instead of just evaluating them is to gain those benefits that cannot be obtained from software evaluations. When we evaluate software we can observe its weaknesses and its compliance to quality requirements. If, on the other hand, several software products are involved in the evaluation, then we can have a comparative analysis of these products and provide some recommendations. But when we benchmark several software products, in addition to all the benefits commented, we obtain products that are continuously improved, recommendations for developers on the practices used and, from these practices, those that can be considered the best.

Software Evaluation in Benchmarking Activities

To evaluate software is not a straightforward task; however, as this is an issue that has been thoroughly examined both in theory and practice, several authors have proposed different recommendations to consider (Basili et al., 1986; Perry et al., 2000; Freimut et al., 2002; Juristo & Moreno, 2001; Kitchenham et al., 2002).

These recommendations are also applicable to the software evaluations made during the benchmarking activities. However, when we have to define this kind of software evaluations, we must take into account some additional recommendations.

And the most important recommendation is that the evaluation of the benchmarking procedure must be an **improvement-oriented activity**. Its intended results will not only be used for comparing the different software products, but for learning how to improve such products. This requires that the evaluation yield not only some comparative results but also that it show the practices that produced these results.

Another recommendation is that benchmarking evaluations should be as **general** as possible since they will be performed by different groups of people in different locations and on different software.

Benchmarking is a process driven by a community; therefore, to gain credibility, effectiveness and impact, its evaluations should also be **community-driven**.

Additionally, benchmarking evaluations should be **reproducible** since they are intended to be used not only by the people participating in the benchmarking, but by the whole community. This requires that the evaluation be thoroughly detailed, providing public data and procedures.

To perform the evaluations consumes significant resources; these evaluations, on the other

hand, must be made by several groups of people. Therefore, evaluations should be as **economical** as possible, employing for this activity common evaluation frameworks and, when this is not possible, limiting the scope of the evaluation.

Furthermore, as benchmarking is a continuous process, benchmarking evaluations should have a **limited scope**, leaving other objectives for the next benchmarking iterations and incrementing progressively the complexity of the evaluations. We must add here that a broader evaluation scope does not entail better results but more resources.

As the next section shows, most of these recommendations should also be adopted in the benchmark suites. Therefore, it is advisable to **use benchmark suites** in the evaluations.

Benchmark Suites

A benchmark suite is a collection of benchmarks, being a benchmark *a test or set of tests used to compare the performance of alternative tools or techniques* (Sim et al., 2003).

A benchmark definition must include the following:

- The **context** of the benchmark, namely, which tools and which of their characteristics are measured with it (efficiency, interoperability, portability, usability, etc.).
- The **requirements** for running the benchmark, namely, the tools (hardware or software), data, or people needed.
- The **input variables** that affect the execution of the benchmark and the values that the variables will take.
- The **procedure** to execute the benchmark and obtain its results.
- The **evaluation criteria** followed to interpret these results.

A benchmark suite definition must include the definitions of all its benchmarks. Generally, all these benchmarks share some of their characteristics, such as context or requirements. These characteristics, therefore, must be specified at the benchmark suite level, and not individually for each benchmark.

Desirable Properties of a Benchmark Suite

The properties below, which are extracted from the works of different authors (Bull et al., 1999; Shirazi et al., 1999; Sim et al., 2003; Stefani et al., 2003), can help both to develop new benchmark suites and to assess the quality of the existing ones before being used.

Although a good benchmark suite should have most of these properties, each evaluation will require considering some of them previously. However, we must not forget that achieving these properties completely is not possible since the increment of some properties has a negative effect on the others.

- **Accessibility.** A benchmark suite must be accessible to anyone interested. This involves providing (a) the necessary software to execute the benchmark suite, (b) the software documentation, and (c) the software source code to increase transparency. Then the results obtained from executing the benchmark suite should be made public so that anybody can execute it and then compare his/her results with those available.
- **Affordability.** Using a benchmark suite normally entails a number of costs regarding human, software, and hardware resources. Thus, the costs of using a benchmark suite must be lower than those of defining, implementing, and carrying out any other experiments that fulfil the same goal. On the other hand, the resources consumed in the execution of a benchmark suite can be reduced by (a) automating the execution of

the benchmark suite, (b) providing components for data collection and analysis, and (c) facilitating its use in different heterogeneous systems.

- **Simplicity.** The benchmark suite must be simple and interpretable and should be well documented; therefore, whoever wants to use it must be able to understand how it works and the results that it yields. If the benchmark suite is not transparent enough, its results will be questioned and may be interpreted incorrectly. To avoid this, the elements of the benchmark suite should have a common structure and use, and common inputs and outputs. Measurements, on the other hand, should have the same meanings across the benchmark suite.
- **Representativity.** The actions that perform the benchmarks composing the benchmark suite must be representative of the actions normally performed on the system.
- **Portability.** The benchmark suite should be executed on a wide range of environments and should be applicable to as many systems as possible. Besides, it should be specified at a high enough level of abstraction to ensure that it can be transferred to different tools and techniques and that is not biased against other technologies.
- **Scalability.** The benchmark suite should be parameterised to allow scaling the benchmarks with varying input rates. In addition, it should work with tools or techniques of different levels of maturity and should be applicable to research prototypes and commercial products.
- **Robustness.** The benchmark suite must allow for unpredictable environment behaviours and should not be sensitive to factors irrelevant to the study. When running the same benchmark suite on a given system and under the same conditions several times, the results obtained should not vary considerably.
- **Consensus.** The benchmark suite must be developed by experts capable of applying their knowledge of the domain and of identifying the key problems. Additionally, it should be assessed and agreed on by the whole community.

EVALUATION AND BENCHMARKING WITHIN THE SEMANTIC WEB

This section provides an overview of the evaluation and benchmarking trends now occurring in the Semantic Web area; it also describes to what extent the evaluation and benchmarking activities performed on the Semantic Web technology can be partially or totally reused in different tools, and the facilities provided for doing so.

To this end, we have performed a survey of the main conferences on the Semantic Web field and of the workshops whose main topic is Semantic Web technology evaluation. We have examined the proceedings of five conferences: International Semantic Web Conference (ISWC), European Semantic Web Conference (ESWC), Asian Semantic Web Conference (ASWC), International Conference on Knowledge Capture (K-CAP), and International Conference on Knowledge Engineering and Knowledge Management (EKAW); and we have studied five workshops: Workshop on Evaluation of Ontology-based Tools (EON), Workshop on Scalable Semantic Web Knowledge Base Systems (SSWS), Workshop on Practical and Scalable Semantic Systems (PSSS), International Workshop on Ontology Matching (OM), and Workshop on Integrating Ontologies (IntOnt). The survey includes all the papers accepted in these conferences and workshops from 2000 to 2006.

It is clear that the papers examined, which were presented in the conferences and workshops above commented, do not provide exhaustive information, but they can provide an overview of the current trends.

We consider that fulfilling the desirable properties of a benchmark suite and the recommendations for defining evaluations in benchmarking activities, both defined in the previous section, is an indication of evaluation reusability. And thus, with these desirable properties and recommendations in mind we have produced a questionnaire that should be filled in for each of the selected papers. As an example, the questions asked for assessing the portability of an evaluation approach are the following:

- *In which type of tools can the evaluation be performed?*
- *Can the evaluation approach be transferred to other tools?*
- *On which of the operating systems/platforms can the evaluation be performed?*

Although software evaluations are frequent in research papers, we focused on those papers where the evaluation approaches followed are reusable to a certain extent. However, we did not distinguish between evaluations that are performed within the benchmarking activities and evaluations that are not, nor did we distinguish between these benchmarking activities that use benchmark suites and those that do not. Thus, the criteria we followed to select the papers are:

- The paper describes how to evaluate several tools, or it shows the results of the evaluation over several tools, or both.
- The evaluation described in the paper involves more than one tool or is intended to be applied to more than one tool.
- The evaluation described in the paper is targeted to software tools or to methods implemented by some software.

With these criteria we selected 61 papers and filled in the questionnaire. Of these papers, 21 deal with the description and application of an evaluation, 7 simply describe an evaluation, and 33 show how an evaluation is made. Among the papers selected, we included those workshop papers that present proposals for performing a common evaluation and the papers written on this evaluation by the participants together with the results of their findings.

Figure 1 and Figure 2 show the trend concerning papers related to evaluation that were published in the last few years. As for the 17 papers presented in the conferences, they have led us to conclude, first, that the number of papers increases every year and, second, that no evaluation-related papers were submitted to the EKAW and K-CAP conferences; this may occur because these conferences are more oriented to knowledge management than to the Semantic Web. With regard to the 44 papers presented in workshops, we have noticed that only 7 of them are regular papers and that the other papers are either evaluation proposals or evaluation results. There is a call for participation in evaluations every year; we have observed that in these evaluations the number of evaluation contributions varies, whereas the number of regular papers is more or less constant.

Our survey shows the results of the reusability of the evaluation approaches in which it can be observed that some of them are positive and some, negative.

The positive results confirm that, in general, the evaluation approaches are easy to understand because they clearly establish both the input data, according to a common structure, and the evaluation criteria for analysing the results. In addition, in most cases, performing the evaluations is not expensive since the evaluation approaches provide common evaluation frameworks and, quite often, the whole evaluation or part of it can be automated. In other cases, however, some software supports the evaluation, being this software and its source code usually accessible. Scalability and robustness have also been taken into account throughout the evaluations.

Figure 1. Evaluation-related papers in conferences

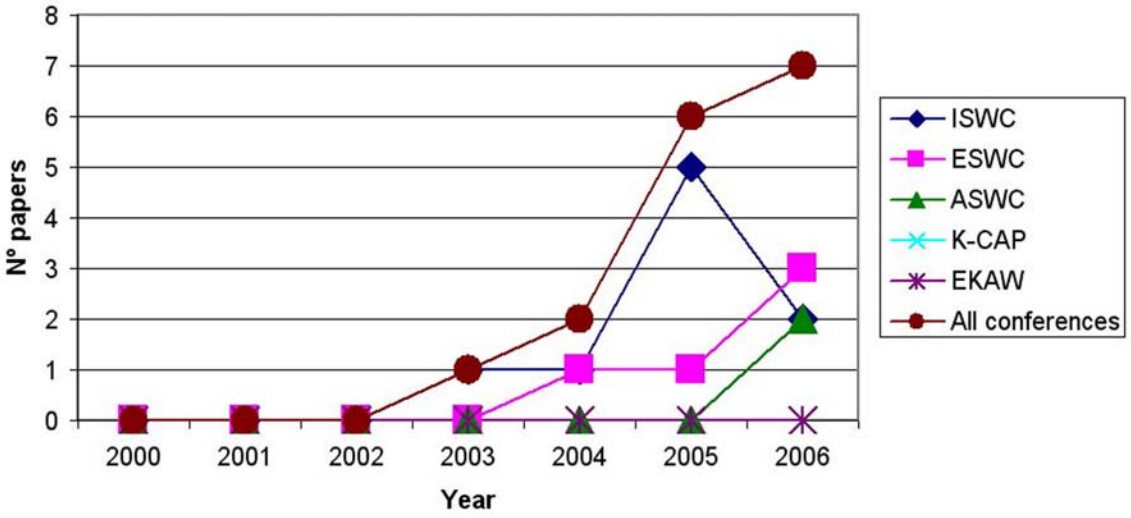

Figure 2. Evaluation-related papers in workshops

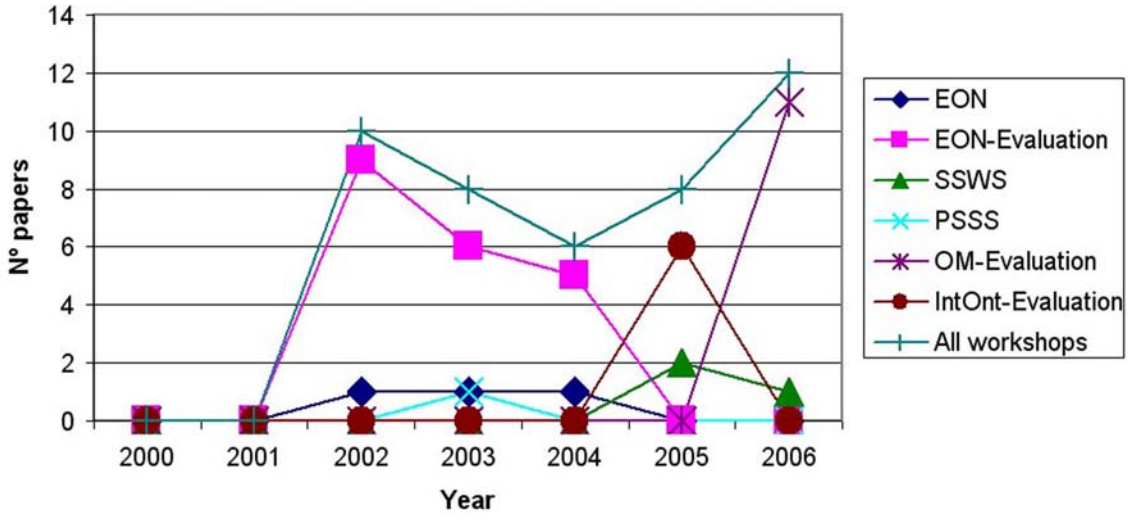


The negative results show that most of the papers deal with a small group of Semantic Web tools (ontology alignment tools, ontology development tools and ontology repositories) and that, in general, evaluations are not applicable to other types of tools. Besides, the accessibility of these evaluations is not high, the procedure to perform the evaluation is not always clearly defined, and

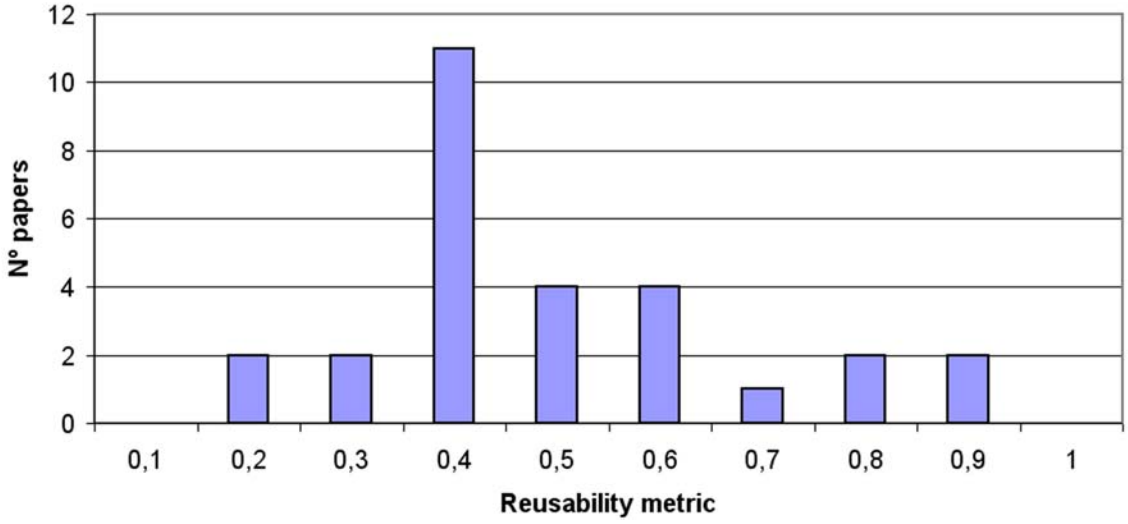
the input data is not always accessible. We can add that only in a few cases the papers provide a web page with information on the evaluation. The input data is not representative of the actions performed on the system and, occasionally, the evaluation has been developed and agreed on by a community. Furthermore, the existing evaluation approaches are not transferrable and the cost of performing the evaluation is never considered; most of the evaluations are defined as one-time activities. Only in a few cases improvement is a goal and, quite often, the practices that lead to the results or improvement recommendations cannot be obtained directly from these results.

As we mentioned before, each of the questions of the questionnaire is related to one of the desirable properties of a benchmark suite. Therefore, we have described the reusability of the evaluation presented in each paper taking into account the number of questions answered positively for each of these properties. For each paper, we have calculated the percentage of positive answers for each dimension and the mean of all these percentages. The resulting value ranges from 0 (not reusable at all) to 1 (totally reusable). Even though this is not a robust metric, it gives us a hint of the reusability of the evaluations.

Figure 3 presents the histogram of the reusability metric used with the 28 papers that describe how to perform an evaluation over several tools. The horizontal axis represents the different ranges of the reusability metric, whereas the vertical axis represents the number of papers in each range. We can clearly observe that most of the papers have low values and are far from the ideal situation.

As a summary of this section we can conclude that although the number of evaluation and benchmarking activities is continuously increasing in the Semantic Web area, such number is still not good enough to ensure a high quality technology, and that the activities carried out involved just a few types of Semantic Web technologies. Consequently, the reusability of the evaluation approaches is not high enough, which is a hindrance for their use.

Figure 3. Histogram of the reusability metric



THE BENCHMARKING METHODOLOGY FOR SEMANTIC WEB TECHNOLOGY

This section summarises the benchmarking methodology for Semantic Web technology developed by the authors in the Knowledge Web European Network of Excellence. A detailed description of this methodology can be found in (García-Castro et al., 2004).

The methodology has been inspired by works of quality improvement from different fields. The main inputs for this methodology were the benchmarking methodologies of the business management community and their notions of continuous improvement and best practices. We have also taken into account the evaluation and improvement processes proposed in the Software Engineering area such as those cited in Section 2.1.

Benchmarking Actors

The tasks of the benchmarking process are carried out by different actors according to the kind of roles to be performed in each task. The different types of actors involved are the following:

- **Benchmarking initiator.** The benchmarking initiator is the member (or members) of an organisation who makes the first tasks of the benchmarking process. His/her work consists in preparing a proposal for carrying out the benchmarking activity in the organisation and in obtaining the management approval to perform it.
- **Organisation management.** The organisation management plays a key role in the benchmarking process: this actor must approve the benchmarking activity and the changes that result from it. The organization management must also assign resources to the benchmarking and integrate the benchmarking planning into the organisation planning.
- **Benchmarking team.** Once the organisation management approves the benchmarking proposal, the benchmarking team is composed. Their members have to belong to the organisation and are responsible for performing most of the remaining benchmarking processes.
- **Benchmarking partners.** The benchmarking partners are the organisations participating in the benchmarking activity. All the partners must agree on the steps to follow during the benchmarking, and their needs must be considered.
- **Tool developers.** The developers of the tool must implement the necessary changes in the tool to improve it. Some of the developers may also be part of the benchmarking team and, if so, care must be taken to minimise bias.

Benchmarking Process

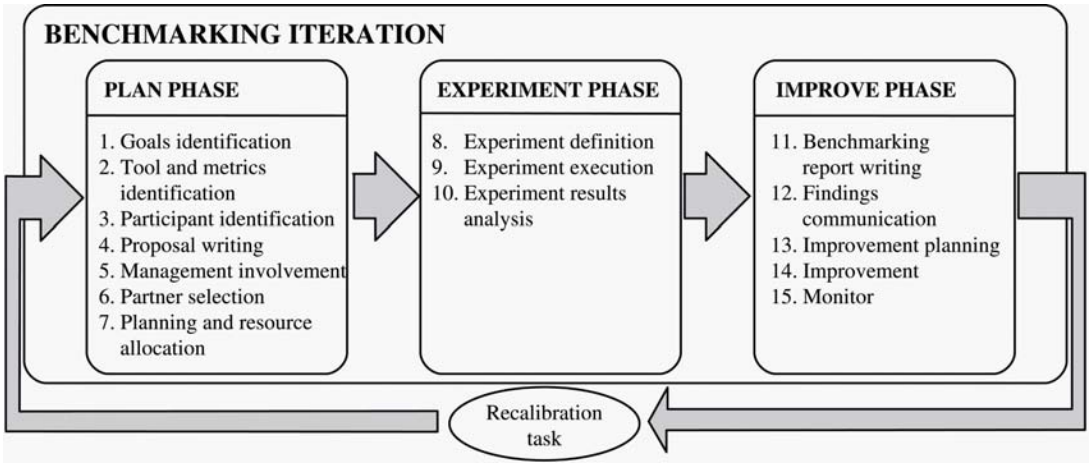
The benchmarking methodology for Semantic Web technology describes a benchmarking process together with the main phases to follow when benchmarking this technology and it also provides a set of guidelines. Therefore, this methodology has a twofold use: to help carry out software benchmarking activities, and to know, at a specific time, which is the actual progress of a benchmarking activity.

The benchmarking process defined in this methodology is composed of a benchmarking iteration that is repeated forever. Each iteration, as shown in Figure 4, is composed of three phases (*Plan*, *Experiment* and *Improve*) and ends with a *Recalibration* task.

Plan Phase

The *Plan* phase is composed of the different tasks that must be performed (1) to prepare the benchmarking proposal, (2) to obtain support from the organisation management, (3) to find

Figure 4. The software benchmarking methodology



other organisations willing to participate in benchmarking, and 4) to plan benchmarking. These tasks are the following:

P1. Goals identification. In this task, the *benchmarking initiator* (the member or members of the organisation who are aware of the need for benchmarking) must identify the benchmarking goals according to the goals and strategies of the organization as well as the benefits and costs involved in carrying out benchmarking. However, every organization may have its own goals and these can be quite different. For example, some may be interested in assessing the performance and improving the quality of the software over its lifetime, others, in comparing their software with the software that is considered the best, whereas some others are interested in establishing or creating standards by analysing the different existing software.

P2. Software and metrics identification. In this task, the *benchmarking initiator* should make an analysis of the software products developed in the organisation in order to understand and document them, identifying the weaknesses and functionalities that require improvement. Then, he/she must select the products to be benchmarked, the functionalities relevant to the study and the evaluation criteria to follow to assess these functionalities; these criteria must take into account the organisation's software, the benchmarking goals, the benefits and costs identified in the previous task as well as other factors considered critical by the organisation, such as quality requirements, end-user needs, etc.

P3. Participant identification. In this task, the *benchmarking initiator* must identify and contact the members concerned with the software and the functionalities selected (managers, developers, end users, etc.) and other relevant participants that do not belong to the organisation (customers or consultants). The benchmarking initiator is responsible for organizing the benchmarking team and, quite often, he is a member of the team. The team should be small and include those organisation members whose work and interest are related to the software, who have a thorough

understanding of the software and have gained valuable experience with it. They must be aware of the time they will spend in the benchmarking activity and of their responsibilities, and they should be trained in the tasks they will have to perform.

P4. Proposal writing. In this task, the *benchmarking team* (and the *benchmarking initiator*, if he does not belong to the team) must write a document with the benchmarking proposal. The proposal will be used as a reference along the benchmarking process and must include all the relevant information on the process: the information identified in the previous benchmarking tasks (goals, benefits, costs, software, metrics, members involved, and benchmarking team), a description of the benchmarking process, and a full detailed description of the benchmarking costs along with the resources needed. To do this, the benchmarking team should take into consideration the different intended readers of the benchmarking proposal, namely, the organisation managers, the organisation developers, the members of partner organisations, and the members of the benchmarking team.

P5. Management involvement. In this task, the *benchmarking initiator* must bring the benchmarking proposal to the *organisation management.* This task is of great significance because the management approval is required if we want to continue with the benchmarking process. Management support will also be requested in the future, when the changes required for benchmarking will have to be implemented, either in the software or in the organisation processes that affect the software.

P6. Partner selection. In this task, the *benchmarking team* must collect and analyse information on the software products that are to be compared with the software selected, and on the organisations that develop the products. The benchmarking team must also select the software employed in the benchmarking study taking into account its relevance and use in the community or in the industry, its public availability, how the software has adopted the latest technological tendencies, etc. In order to obtain better results with benchmarking, the software selected should be the software considered the best. Then, the benchmarking team must contact the people from the organisations that develop these software products to find out whether they are interested in becoming *benchmarking partners.* These partners will also have to establish a team and to take the proposal to their own organisation management for approval. During this task, the benchmarking proposal will be modified by incorporating the partners' opinions and requirements. This will result in an updated proposal that, depending on the magnitude of the modifications, should be presented again to each organisation management for approval.

P7. Planning and resource allocation. In this task, the *organisation managements* and the *benchmarking teams* must specify the planning of the remainder of the process, considering the different resources that will be devoted to it, and finally they must reach a consensus. This planning must be given careful consideration and should be integrated into each organisation planning.

Experiment Phase

The *Experiment* phase is composed of the tasks in which the experimentation on the software products is performed. These tasks are the following:

E1. Experiment definition. In this task, the *benchmarking teams* of each organization must establish the experiment that will be performed on each of the software products, and then the members must agree on it. The experiment must be defined according to the benchmarking goals, the software functionalities selected, and their corresponding criteria, as stated in the benchmarking proposal. The experiment must also provide objective and reliable software data not just of its performance, but also of the reasons of

its performance; in addition, its future reusability must be also be considered. The benchmarking teams must determine and agree on the planning to follow during the experimentation; this new planning must be decided according to the benchmarking planning established previously.

E2. Experiment execution. As indicated in the experimentation planning, explained in the previous task, the *benchmarking teams* must perform the established experiments on their software products. Then the data obtained from all the experiments must be compiled, documented, and written in a common format to facilitate its future analysis.

E3. Experiment results analysis. In this task, the *benchmarking teams* must analyse the results, detect and document any significant differences found in them, and determine the practices leading to these different results in order to identify whether, among the practices found, some of them can be considered the best practices. Then, the benchmarking teams should write a report with all the findings of the experimentation, that is, the experimentation results, the differences in the results, the practices and the best practices found, etc.

Improve Phase

The *Improve* phase comprises the tasks where the results of the benchmarking process are produced and then communicated to the benchmarking partners; it also comprises the tasks where, in several cycles, the improvement of the different software products takes place. The tasks are the following:

I1. Benchmarking report writing. In this task, the *benchmarking teams* must write the benchmarking report. This report is intended to provide an understandable summary of the benchmarking carried out, and it should be written bearing in mind its different audiences: managers, benchmarking teams, developers, etc. The benchmarking report must include a) an explanation of the process followed, together with all the relevant information of the updated version of the benchmarking proposal; and b) the results and conclusions of the experiments presented in the experiment report, including the practices found and highlighting the best practices. The report should also contain the recommendations provided by the benchmarking teams for improving the software products according to the experiment results, the practices found, and the best practices implemented by the community.

I2. Findings communication. Here, the *benchmarking teams* must communicate, in successive meetings, the results of the benchmarking to their organisations and, particularly, to all the members concerned and identified when planning benchmarking. The goals of these meetings are:

- To obtain feedback from the members concerned on the benchmarking process, the results, and the improvement recommendations.
- To obtain support and commitment from the organisation members for implementing the improvement recommendations on the software.

Any feedback received during these communications must be collected, documented and analysed. This analysis may finally involve having to review the work done and to update the benchmarking report.

I3. Improvement planning. The last three tasks of the *Improve* phase (*Improvement planning, Improvement* and *Monitor*) form a cycle that must be carried out separately in each organisation. The *benchmarking teams* and the *organisation managements* must identify, from the benchmarking report and the monitoring reports, which are the changes needed to improve their software products. Besides, they must forecast the improvements to be achieved after performing these changes. Both the organisation management and the benchmarking team must provide

mechanisms for ensuring improvements in their organisation and for measuring the software functionalities. These last mechanisms can be obtained from the *Experiment* phase. Then, the organisation management and the benchmarking team must establish a planning for improving the software benchmarked, taking into account the different resources devoted to the improvement. This planning must be then integrated into the organisation planning.

I4. Improvement. It is in this task where the *developers* of each of the software product must implement the necessary changes to achieve the desired results. For this, they must measure the state of the software before and after implementing any changes, using for that purpose the measurement mechanisms provided by the benchmarking team in the previous task. Then, the developers must compare the resulting measurements with those that were obtained before implementing the changes and with the improvement forecasted.

I5. Monitor. In each organisation, the *benchmarking team* must provide *software developers* with means for monitoring the organisation's software. Software developers must periodically monitor the software and write a report with the results of this process. These results may show the need for new improvements in software and may also mean the beginning of a new improvement cycle which involves having to perform again the two tasks previously mentioned: *Improvement Planning* and *Improvement.*

Recalibration Task

The recalibration task is performed at the end of each iteration. Here the *benchmarking teams* must recalibrate the process by applying the lessons learnt while performing it. Thus, the organisation (and the whole community) achieves improvement not just in the software, but also in the benchmarking process. This recalibration is needed because both the software and the organisations evolve and innovate over time.

BENCHMARKING THE INTEROPERABILITY OF ONTOLOGY DEVELOPMENT TOOLS USING RDF(S) AS THE INTERCHANGE LANGUAGE

This section presents how we have applied the software benchmarking methodology, presented in the previous section, to one important problem of the Semantic Web: technology interoperability.

Ontologies permit interoperability among heterogeneous Semantic Web technologies, and ideally, one could use all the existing technologies seamlessly. The technologies appear in different forms (ontology development tools, ontology repositories, ontology alignment tools, reasoners, etc.), but although all these tools use different kinds of ontologies, not all of them share a common knowledge representation model.

This diversity in the representation formalisms of the tools causes problems when the tools try to interoperate. This is so because the tools require translating their ontologies from their own knowledge models to a common model and vice versa, and these problems occur even when we employ standard APIs for managing ontologies in the common knowledge model.

As we have observed in previous workshops on Evaluation of Ontology-based Tools (EON) (Sure & Corcho, 2003), interoperability among different ontology tools is not straightforward. Finding out why interoperability fails is cumbersome and not at all trivial because any assumption made for translating ontologies within one tool may easily prevent the successful interoperability with other tools.

To solve this problem, the Knowledge Web European Network of Excellence organized a benchmarking of interoperability of ontology development tools using RDF(S) as the interchange language. Its goal was to assess and improve the interoperability of the tools.

The section that follows describes such benchmarking activity. The methodology presented in

the previous section provides the general guidelines that can be adapted to this case. So we present here how this new benchmarking was organized, the experiments conducted on the participating tools, and its results.

Organising the Benchmarking

The goals of benchmarking the interoperability of ontology development tools are related to the benefits pursued through it, and these are:

- To *evaluate and improve* their interoperability.
- To acquire a *deep understanding* of the practices used to develop the importers and exporters of these tools, and to extract from these practices those that can be considered the *best practices.*
- To produce *recommendations* on their interoperability for users.
- To create *consensual processes* for evaluating their interoperability.

These goals concern different communities that somehow are related to the ontology development tools, namely, the research community, the industrial community, and the tool developers.

Participation in the benchmarking was open to any organisation irrespective of being a Knowledge Web partner or not. To involve other organisations in the process with the aim of having the best-in-class tools participating, several actions were taken:

- The benchmarking proposal, the document being used as a reference along the benchmarking, was published as a public web page[b] and included all the relevant information about the benchmarking: motivation, goals, benefits and costs, tools and people involved, planning, related events, and a complete description of the experimentation and the benchmark suites.
- Research was carried out on the existing ontology development tools, both the freely available and the commercial versions, which could export and import to and from RDF(S); In addition, their developers were contacted. Any tool capable of importing and exporting RDF could participate in the benchmarking or will benefit from the created benchmarks in a near future.
- The interoperability benchmarking was announced with a call for participation through the main mailing lists of the Semantic Web area and through lists specific to ontology development tools.

Six tools took part in the benchmarking, three of which are ontology development tools: KAON[c], Protégé[d] (using its RDF backend), and

Table 1. Ontology tools participating in the benchmarking

Tool	Knowledge model	Version	Developer	Experimenter
Corese	RDF(S)	2.1.2	INRIA	INRIA
Jena	RDF(S)	2.3	HP	U. P. Madrid
KAON	RDF(S) extension	1.2.9	U. Karlsruhe	U. Karlsruhe
Sesame	RDF(S)	2.0 alpha 3	Aduna	U. P. Madrid
Protégé	Frames	3.2 beta build 230	Stanford U.	U. P. Madrid
WebODE	Frames	2.0 build 109	U. P. Madrid	U. P. Madrid

WebODE[e]; the other three are RDF repositories: Corese[f], Jena[g] and Sesame[h]. As Table 1 shows, the tools do not share a common knowledge model and benchmarking was not always performed by the tool developers.

The experimentation conducted on the tools aimed to obtain results for interoperability improvement. Therefore, other quality attributes such as performance, scalability, interoperability, robustness, etc. were not considered. However, an approach for benchmarking the performance and scalability of ontology development tools can be found in (García-Castro & Gómez-Pérez, 2005).

The experimentation was carried out taking into account the most common ways of interchanging ontologies that ontology tools provide, such as the following:

- Interchanging ontologies by exporting them from a tool into an interchange language and then importing them into the other tool.
- Using RDF(S) as the interchange language, and serializing the ontologies into the RDF/XML syntax. A future benchmarking activity inside Knowledge Web will cover the case of using OWL as the interchange language.

The interoperability of ontology tools using an interchange language depends on the capabilities of the tools to import and export ontologies from/to this language. Therefore, the experimentation included not only the evaluation of the interoperability but also of the RDF(S) import and export functionalities.

The evaluation criteria must describe in depth the import, export and interoperability capabilities of the tools, whereas the experiments to be performed in the benchmarking must provide data explaining how the tools comply with these criteria. Therefore, to obtain detailed information about these capabilities, we need to know:

- The elements of the *internal knowledge model* of an ontology development tool that can be imported from RDF(S), exported to RDF(S) and interchanged with other tool, using RDF(S) as the interchange language.
- The *secondary effects* of importing, exporting, and interchanging these components, such as insertion or loss of information.
- The *subset of elements* of the internal knowledge models that these tools may use to interoperate correctly.

To obtain these experimentation data, we defined three benchmark suites that evaluate the capabilities of the tools (García-Castro et al., 2006), which were common for all the tools. Since the quality of the benchmark suites to be used is essential for the results, the first step was to agree on the definition of the suites. Then, we decided to make the import and export experiments before the interoperability one because the results of the first experiments affected those of the second.

A benchmark execution comprises (a) the definition of the expected ontology that results from importing, exporting or interchanging the ontology described in the benchmark, (b) the import, export, or interchange of the ontology defined in the benchmark, and (c) the comparison of the expected ontology with the imported, exported or interchanged ontology, checking whether there is some addition or loss of information. The steps to follow to execute the three benchmark suites are similar.

The benchmark suites were intended to be executed manually but, as they contained many benchmarks, it was highly recommended to execute them (or part of them) automatically. In the cases of Corese, Jena, Sesame, and WebODE, most of the experiment was automated. In the other cases, it was performed manually.

The benchmarking web page[i] contains the results of the experiments and a complete and

detailed description of (a) the benchmark suites, (b) all the files to be used in the experiments, and (c) the templates for collecting the results.

Benchmark Suites

The benchmark suites check the correct import, export and interchange of ontologies that model a simple combination of ontology components (classes, properties, instances, etc.). Because one of the goals of benchmarking is to improve the tools, the benchmark ontologies are kept simple on purpose in order to isolate the causes of the problems and to identify possible problems.

As the ontology tools that participated in benchmarking had different internal knowledge models, both the experimentation and the analysis of the results were based on a common group of ontology modelling primitives, available both in RDF(S) and in these tools. On the other hand, covering this common group exhaustively would yield a huge number of benchmarks; so we only considered the components most widely used for modelling ontologies in ontology development tools: classes, instances, properties with domain and range, literals, and class and property hierarchies. The remainder of the components has not been dealt with so far.

The **RDF(S) Import Benchmark Suite** contains 82 benchmarks[j], which define a simple RDF(S) ontology serialized in a RDF/XML file, which must be loaded into the ontology development tool.

In order to isolate the factors that affect the correct import of an ontology, we defined two types of import benchmarks: one that evaluates the import of the different combinations of components of the RDF(S) knowledge model, and the other type that evaluates the import of the different variants of the RDF/XML syntax, as stated in the RDF/XML specification.

Table 2 shows the categories of the RDF(S) Import Benchmark Suite, the number of benchmarks, and the components used. All the RDF(S) files to be imported can be downloaded from a single file; besides, templates are provided for collecting the execution results.

Table 2. Categories of the import benchmarks

Category	No.	Components used
Class	2	*rdfs:Class*
Metaclass	5	*rdfs:Class*, *rdf:type*
Subclass	5	*rdfs:Class*, *rdfs:subClassOf*
Class and property	6	*rdfs:Class*, *rdf:Property*, *rdfs:Literal*
Property	2	*rdf:Property*
Subproperty	5	*rdf:Property*, *rdfs:subPropertyOf*
Property with domain and range	24	*rdfs:Class*, *rdf:Property*, *rdfs:Literal*, *rdfs:domain*, *rdfs:range*
Instance	4	*rdfs:Class*, *rdf:type*
Instance and property	14	*rdfs:Class*, *rdf:type*, *rdf:Property*, *rdfs:Literal*
Syntax and abbreviation	15	*rdfs:Class*, *rdf:type*, *rdf:Property*, *rdfs:Literal*

The **RDF(S) Export Benchmark Suite** comprises 66 benchmarks[k], which describe an ontology that must be modelled in the tool and saved to a RDF(S) file.

We have defined two types of benchmarks for isolating the two factors that affect the correct export of an ontology: one type evaluates the correct export of the combinations of components of the ontology development tool knowledge model, and the other evaluates the export of ontologies using concepts and properties whose names have characters restricted by RDF(S), such as those characters that are forbidden when representing RDF(S) or XML URIs.

Table 3 shows the categories of the benchmark suite. The table contains the number of benchmarks and the components used in each category. Templates are also provided for collecting the execution results.

Since the factors that affect both the correct interchange of an ontology (besides the correct functioning of the importers and exporters) and the knowledge model (used for defining the ontologies) are the same as those that affect the RDF(S) Export Benchmark Suite, the ontologies described in the RDF(S) Interoperability Benchmark Suite are identical to those of the RDF(S) Export Benchmark Suite.

The evaluation criteria are common for the three benchmark suites, and are defined as follows:

- **Modelling** (*YES*/*NO*). The ontology tool can model the ontology components described in the benchmark.
- **Execution** (*OK*/*FAIL*). The execution of the benchmark is normally carried out seamlessly, and the tool always produces the expected result. However, when an execution fails, the following information is required:
  - The causes of the failure.
  - The changes performed if the tool had been previously corrected to pass a benchmark correctly.
- **Information added or lost.** The information added to or lost in the ontology interchange when executing the benchmark.

Table 3. Categories of the export benchmarks

Category	No.	Components used
Class	2	*class*
Metaclass	5	*class, instanceOf*
Subclass	5	*class, subClassOf*
Class and object property	4	*class, object property*
Class and datatype property	2	*class, datatype property, literal*
Object property	14	*object property*
Datatype property	12	*datatype property*
Instance	4	*class, instanceOf*
Instance and object property	9	*class, instanceOf, object property*
Instance and datatype property	5	*class, instanceOf, datatype property, literal*
URI character restrictions	4	*class, instanceOf, object property, datatype property, literal*

In the export and interoperability benchmark suites, if a benchmark describes an ontology that cannot be modelled in a certain tool, such benchmark cannot be executed in the tool, being the *Execution* result *N.E.* (Non Executed). However, in the import benchmark suites, even if a tool cannot model some components of the ontology, it should be able to import the rest of the components correctly.

Import and Export Results

The results obtained when importing from and exporting to RDF(S) depend mainly on the knowledge model of the tool that executes the benchmark suite. The tools that natively support the RDF(S) knowledge model (Corese, Jena and Sesame, essentially the RDF repositories) do not need to perform any translation in the ontologies when importing/exporting them from/to RDF(S). The RDF repositories import and export correctly all the combinations of components from/to RDF(S) because these operations do not require any translation.

In the case of tools with non-RDF knowledge models (KAON, Protégé and WebODE, the ontology development tools), some of their knowledge model components can also be represented in RDF(S), but some others cannot, and these tools do need to translate ontologies between their knowledge models and RDF(S). Finally, we must add that not all the combinations of components of the RDF(S) knowledge model that have been considered can be modelled into all the tools, as Table 4 shows.

Next, we present an analysis of the results of importing and exporting in the ontology development tools that participated in the benchmarking.

Table 4. Combinations of components modelled by the tools

Combination of components	RDF repos.	KAON	Protégé	WebODE
Classes	Y	Y	Y	Y
...instance of metaclasses	Y	Y	Y	N
Class hierarchies without cycles	Y	Y	Y	Y
...with cycles	Y	N	N	N
Datatype properties without domain or range	Y	Y	Y	N
...with multiple domains	Y	Y	N	N
...whose range is String	Y	Y	Y	Y
...whose range is a XML Schema datatype	Y	Y	N	Y
Object properties without domain or range	Y	Y	Y	N
...with multiple domains or ranges	Y	Y	N	N
...with a domain and range	Y	Y	Y	Y
Instances of a single class	Y	Y	Y	Y
...of multiple classes	Y	Y	Y	N
...related via object or datatype properties	Y	Y	Y	Y
...related via datatype properties whose range is a XML Schema datatype	Y	N	N	Y

Import Results

In general, the ontology development tools import correctly from RDF(S) all or most of the combinations of components that they model; they seldom add or lose information. The only exceptions are:

- Protégé, which presents problems, but only when it imports classes or instances that are instances of multiple classes.
- WebODE, which presents problems, but only when it imports properties with a XML Schema datatype as range.

When the tools import ontologies with combinations of components that they cannot model, they lose the information about these components. Nevertheless, these tools usually try to represent such components partially using for this other components from their knowledge models. In most cases, the importing is performed correctly. The only exceptions are:

- KAON, which causes problems when it imports class hierarchies with cycles.
- Protégé, which causes problems when it imports class and property hierarchies with cycles and properties with multiple domains.
- WebODE, which causes problems when it imports properties with multiple domains or ranges.

When dealing with the different variants of the RDF/XML syntax, we can observe that the ontology development tools

- Import correctly resources with the different URI reference syntaxes.
- Import correctly resources with different syntaxes (shortened and unshortened) of empty nodes, of multiple properties, of typed nodes, of string literals, and of blank nodes. The only exceptions are: KAON when it imports resources with multiple properties in the unshortened syntax; and Protégé when it imports resources with empty and blank nodes in the unshortened syntax. Do not import language identification attributes (*xml:lang*) in tags.

Export Results

In general, the ontology development tools export correctly to RDF(S) all or most of the combinations of components that they model with no loss of information. In particular:

- KAON causes problems only when it exports to RDF(S) datatype properties without range and datatype properties with multiple domains plus a XML Schema datatype as range.
- Protégé causes problems only when it exports to RDF(S) classes or instances that are instances of multiple classes and template slots with multiple domains.

When ontology development tools export components present in their knowledge model that cannot be represented in RDF(S), such as their own datatypes, they usually insert new information in the ontology, but they also lose some.

When dealing with concepts and properties whose names do not fulfil URI character restrictions, each ontology development tool behaves differently:

- When names do not start with a letter or "_", some tools leave the name unchanged, whereas others replace the first character with "_".
- Spaces in names are replaced by "-" or "_", depending on the tool.
- URI reserved characters and XML delimiter characters are left unchanged, replaced by "_", or encoded, depending on the tool.

Interoperability Results

The RDF repositories (Corese, Jena and Sesame) interoperate correctly between themselves, because they always import and export from/to RDF(S) correctly. This produces that the interoperability between the ontology development tools and the RDF repositories depends only on the capabilities of the former to import and export from/to RDF(S); therefore, the results of this interoperability are identical to those presented in the previous section.

The import and export results presented in previous sections indicate that some problems arise in the process of importing and exporting ontologies, whereas the interoperability results, on the other hand, show more problems.

As a general comment we can say that interoperability between the tools depends on

a. the correct functioning of their RDF(S) importers and exporters and
b. the way chosen for serializing the exported ontologies in the RDF/XML syntax.

Furthermore, we have observed that the problems affecting any of these factors also affect the results of not just one but several benchmarks. This means that, in some cases, to correct a single import or export problem, or to change the way of serializing ontologies can produce significant interoperability improvements.

Below we list the components that can be interchanged between the tools. These components are summarized in Table 5; each column of the table shows whether the combination of components can be interchanged between a group of tools[l]. The "-" character means that the component cannot

Table 5. Components interchanged between the tools

Combination of components	K-K	P-P	W-W	K-P	K-W	P-W	K-P-W
Classes	Y	Y	Y	Y	Y	Y	Y
...instance of a single metaclass	Y	Y	-	N	-	-	-
...instance of a multiple metaclasses	Y	N	-	N	-	-	-
Class hierarchies without cycles	Y	Y	Y	Y	Y	Y	Y
Datatype properties without domain or range	Y	Y	-	N	-	-	-
...with multiple domains	Y	-	-	-	-	-	-
...whose range is String	Y	Y	Y	N	N	Y	N
...whose range is a XML Schema datatype	Y	-	Y	-	Y	-	-
Object properties without domain or range	Y	Y	-	Y	-	-	-
...with multiple domains or ranges	Y	-	-	-	-	-	-
...with a domain and range	Y	Y	Y	Y	Y	Y	Y
Instances of a single class	Y	Y	Y	Y	Y	Y	Y
...of multiple classes	Y	N	-	N	-	-	-
...related via object properties	Y	Y	Y	Y	Y	Y	Y
...related via datatype properties	Y	Y	Y	N	Y	Y	N
...related via datatype properties whose range is a XML Schema datatype	-	-	Y	-	-	-	-

be modelled in some of the tools and, therefore, cannot be interchanged between them.

Interoperability Using the Same Tool

Ontology development tools seem to pose no problems when the source and the destination of an ontology interchange are the same tool. The only exception is Protégé when it interchanges classes that are instances of multiple metaclasses and instances of multiple classes; this is so because Protégé does not import resources that are instances of multiple metaclasses.

Interoperability between Each Pair of Tools

The interoperability between different tools varies depending on the tools. As the detailed interoperability results show, in some cases, the tools are able to interchange certain components from one tool to another, but not the other way round.

When **KAON** interoperates with **Protégé**, they can interchange correctly some of the common components that these tools are able to model. However, with components such as classes that are instances of a single metaclass or of multiple metaclasses, datatype properties without domain or range, datatype properties whose range is *String*, instances of multiple classes, and instances related through datatype properties, we have encountered some problems.

When **KAON** interoperates with **WebODE**, they can interchange correctly most of the common components that these tools can model, but when they interchange datatype properties with domain and whose range is *String*, the results are not the same.

When **Protégé** interoperates with **WebODE**, they can interchange correctly all the common components that these tools can model.

Interoperability between All the Tools

Interoperability between **KAON**, **Protégé** and **WebODE** can be achieved by most of the common components that these tools can model. The only components that these tools cannot use are datatype properties with domain and whose range is *String*, and instances related through datatype properties.

Therefore, interoperability was achieved among the tools that participated in the benchmarking by using classes, class hierarchies without cycles, object properties with domain and with range, instances of a single class, and instances related through object properties.

Interoperability Regarding URI Character Restrictions

Interoperability is low when tools interchange ontologies containing URI character restrictions in class and property names. This is so because tools usually encode some or all the characters that do not comply with these restrictions, which provokes changes in class and property names.

Recommendations

Recommendations for Ontology Engineers

This section offers recommendations for ontology engineers which use more than one ontology tool to build ontologies. Depending on the tools used, the level of interoperability may be higher or lower, as can be seen in Section 5.4.

If the ontology is being developed bearing in mind interoperability, ontology engineers should be aware of the components that can be represented in the ontology development tools and in RDF(S). And they should try to use the common knowledge

components that these tools have so as to avoid the knowledge losses commented above.

Ontology engineers should also be aware of the semantic equivalences and differences between the knowledge models of the tools and the interchange language. For example, in Protégé, multiple domains in template slots are considered the union of all the domains, whereas in RDF(S) multiple domains in properties are considered the intersection of all the domains; in WebODE, on the other hand, instance attributes are local to a single concept, whereas in RDF(S) properties are global and can be used in any class.

It is not recommended to name resources using spaces or any character that is restricted in the RDF(S), URI, or XML specifications.

When the RDF repositories interoperate, even though these repositories export and import correctly to RDF(S), ontology engineers should consider the limitations that other tools have when they export their ontologies to RDF(S).

Recommendations for Tool Developers

This section includes general recommendations for improving the interoperability of the tools while developing them. In (García-Castro et al., 2006), we offer full detailed recommendations regarding the results and practices gathered to improve each of the participant tools. Although it is not compulsory to follow these recommendations, they help correct interoperability problems as we could observe when we analysed the results.

The interoperability between ontology tools (using RDF(S) as the interchange language) depends on how the importers and exporters of these tools work; on the other hand, how these importers and exporters work depends on the development decisions made by the tool developers, and these are different people with different needs. Therefore, to provide general recommendations for developers is not straightforward, though some comments can be extracted from the analysis of the benchmarking results.

In some occasions, a development decision will produce interoperability improvement with some tools and interoperability loss with others. For example, when exporting classes that are instances of a metaclass, some tools require that the class be defined as instance of *rdfs:Class*, whereas other tools require the opposite.

Tool developers, therefore, should analyze the collateral consequences of the development decisions. Thus, if a datatype is imported as a class in the ontology, then the literal values of this datatype should be imported as instances in the ontology, which would complicate the management of these values.

They also should be aware of the semantic equivalences and differences between the knowledge models of their tool and the interchange language; on the other hand, the tools should notify the user when the semantics is changed.

The first requirement for achieving interoperability is that the importers and exporters of the tools be robust and work correctly when dealing with unexpected inputs. Although this is an obvious comment, the results show that this requirement is not achieved by the tools and that some tools even crash when importing some combinations of components.

Above all, tools should deal correctly with the combinations of components that are present in the interchange language but cannot be modelled in them. For example, although cycles in class and property hierarchies cannot be modelled in some ontology development tools, these tools should be able to import these hierarchies by eliminating the cycles.

If developers want to export components that are commonly used by ontology development tools, the components should be completely defined in the file. This means that metaclasses and classes in class hierarchies should be defined as instances of *rdfs:Class*, properties should be defined as instances of *rdf:Property*, etc.

Exporting complete definitions of other components can cause problems if these are imported

by other tools. And not every tool deals with datatypes defined as instances of *rdfs:Datatype* in the file, or with *rdf:datatype* attributes in properties.

If the document does not define a default namespace, every exported resource should have a namespace.

CONCLUSION

This chapter states the need to evaluate and benchmark the Semantic Web technology and provides some references that can be helpful in these activities. It also presents the authors' approach to software benchmarking and compares it with other existing evaluation and benchmarking approaches.

We have tried to explain how the benchmarking methodology can help assess and improve software, whereas the use of benchmark suites is advisable when performing evaluations in benchmarking.

One of the strong points we make on benchmarking is its community-driven approach. Benchmarking should be performed by the experts of the community since the benefits obtained after performing it affect the whole community.

Benchmarking does not imply comparing the results of the tools but comparing the practices that lead to these results. Therefore, experimentation should be designed to obtain these practices as well as the results.

However, as we have seen, benchmarking is not the solution to every case. In a preliminary step, developers would have to asses whether benchmarking is the correct approach; as benchmarking is useful when the goals are to improve the software and to extract the practices performed by others.

Benchmarking is an activity that takes long time to perform because it requires tasks that are not immediate: announcements, agreements, etc. Therefore, benchmarking activities should start early in time, and the benchmarking planning should consider a realistic duration of the benchmarking and the resources needed for carrying them out.

We have also shown how we have applied the benchmarking methodology to a concrete case in the Semantic Web area: interoperability of ontology development tools using RDF(S) as interchange language.

Providing benchmark suites in the benchmarking allows evaluating other tools with RDF(S) import and export capabilities without their having to participate in the benchmarking; this can be useful both while the tools are being developed and afterwards, when their development has finished. In addition, the benchmarking results can be used by ontology development tool users that may find problems when interchanging ontologies or may want to foresee the results of a future interchange.

Although it is not required that the tool developers participate in the benchmarking and perform the experiments over their tool, their involvement facilitates the execution and analysis of the experimentation results to a large extent. In all the cases where tool developers carried out the experimentation over their own tools, a great improvement occurred before the *Improve* phase of the methodology because developers were able to detect problems and correct their tools while executing the benchmark suites.

We have observed that the manual execution of the experiments and the analysis of the results cause the benchmark suite to be costly. Consequently, tool developers often automate the execution of the benchmark suites, but not always. Another drawback of the manual execution of experiments is that the results obtained depend on the people performing these experiments, on their expertise with the tools, and on their ability to extract the practices performed.

FUTURE RESEARCH DIRECTIONS

As shown in Section 3, current evaluation and benchmarking activities over the Semantic Web technology are scarce and a hindrance to the full development and maturity of this technology. The Semantic Web needs to produce methods and tools for evaluating the technology at great scale and in an easy and economical way. This requires defining technology evaluations focusing on their reusability.

In the last few years, evaluation and benchmarking efforts have mainly focused on some types of technologies and on some of their metrics, namely, the interoperability of ontology development tools, the precision and recall of ontology alignment tools, and the efficiency and scalability of ontology repositories. But now we think that new efforts are required, first, to involve other Semantic Web technologies (ontology learning tools, ontology annotation tools, ontology population tools, etc.) and, second, to broaden the scope of these evaluations by considering a wider range of evaluation metrics for the technology (latency, robustness, security, usability, etc.).

The role of the research community when defining and performing benchmarking activities is crucial. Community-driven benchmarking connects experts and allows obtaining high quality results and increasing the credibility of the benchmarking and its results.

However, future research must focus on performing evaluations centred on the user of the Semantic Web technology. And it would be advisable to consider audiences from beyond the research community itself as recipients of the evaluation results.

APPENDIX: QUESTIONS FOR DISCUSSION

Beginner:

1. Which are the main characteristics of benchmarking?
2. Which is the goal of the *Recalibration* task in the benchmarking methodology?
3. Which are the factors that influence the correct interchange of an ontology between two Semantic Web tools?
4. When exporting one ontology from an ontology development tool to RDF(S) having interoperability in mind, is it advisable to export the complete definition of all its components?

Intermediate:

1. Which are the differences between evaluation and benchmarking?
2. Are the users of the software involved in the benchmarking?
3. Is management support needed in the *Improve* phase of the methodology?
4. Which RDF(S) components can be represented in KAON, Protégé and WebODE?

Advanced:

1. Which resources are needed for performing a benchmarking activity?
2. Why are there three different evaluation criteria to define the results of the RDF(S) Import, Export and Interoperability benchmark suites?
3. Why is it not enough to have a single ontology representation language to achieve interoperability between the Semantic Web technologies?

Practical Exercises:

1. Select one conference paper that presents some evaluation or benchmarking approach and then evaluate its reusability according to the desirable properties of a benchmark suite and the recommendations given for software evaluation in benchmarking activities.
2. Create a mid-size ontology using one ontology development tool. Can you anticipate the consequences of exporting that ontology to RDF(S)? And of importing it into another ontology development tool?
3. Then, export the ontology to RDF(S). Was your prediction correct? Has it had information addition or loss?
4. Finally, import the exported ontology into the other ontology development tool. Was your prediction correct? Has it had information addition or loss?

ANSWERS TO THE QUESTIONS FOR DISCUSSION

Beginner:

1. The main characteristics of benchmarking are continuous improvement and the search for best practices.
2. The goal of the *Recalibration* task is to improve the benchmarking process by recalibrating it and applying the lessons learnt while performing it.
3. The factors that influence the correct interchange of an ontology between two tools are the combinations of components of the knowledge model of the ontology development tool and the naming of the components present in the ontology.
4. It is advisable to export the complete definition of all its components only for

components commonly used by ontology development tools.

Intermediate:

1. Benchmarking is a continuous process, whereas an evaluation is a punctual activity. In addition, benchmarking involves evaluating software but its goals are to obtain a continuous improvement on the software and the practices used when developing the tools.
2. Yes, the users of the software are identified in the *Participant identification* task and in the *Findings communication* task.
3. Yes, it is needed to implement the necessary changes in the software and in the organisation processes affecting the software.
4. Classes, class hierarchies without cycles, datatype properties with a class as a domain and a string range, object properties with a domain and a range, instances of a single class, instances related by object properties, and instances related by datatype properties with a string range.

Advanced:

1. The resources needed are human resources though some equipment and travel resources are also required, and these are mainly used in three tasks: benchmarking organisation, experimentation definition and execution, and result analysis.
2. Because these three evaluation criteria are necessary to represent the different situations and behaviours that can occur when two tools interchange one ontology.
3. Because different types of users need different tools; existing tools have different knowledge representation models; and tools need to translate their ontologies from their knowledge models to the common ontology representation language.

ABSTRACT

To exploit the unprecedented opportunities offered by the E-Service Applications, businesses and users alike would need a highly-available, reliable, and efficient telecommunication infrastructure. This chapter provides an insight into building the next-generation network infrastructure, that is, the All-Optical Internet. It also reveals the factors driving the convergence of the Internet Protocol (IP) and the Wavelength-Division Multiplexing (WDM) technology. The chapter discusses the dominant optical networks architectures in an attempt to show the evolution towards the ultimate all-optical packet-switching network. A special focus is given to the Optical Burst Switching (OBS) as a new emerging switching paradigm and a highly promising technology. OBS network architecture, burst assembly, signaling and reservation protocols, QoS support, and contention resolution techniques are presented. Furthermore, realistic suggestions and strategies to efficiently deploy OBS are given.

INTRODUCTION

The Internet is a technology with many properties that has the potential to influence, and even transform established ways of conducting business, especially Electronic Services, while at the same time creating entirely new industries and businesses. The Internet has a profound impact on the competitive landscape, since it is affecting the way that firms' activities are coordinated, how commerce is conducted, how business communities are created, and how communications are defined and performed.

As we are moving towards the Web-dependent era, the 99 percent or even the 99.99 percent network reliability would be inadequate for the mission-critical applications that have genuine requirements that exceed the typical application needs.

The e-service applications are typically reliant on IP data networks that construct the Internet, which has become a ubiquitous success. Furthermore, the capacity of optical fibers is doubling annually toward a terabit per second per fiber, providing strong incentives to exploit the huge bandwidth of fiber-optic networks, which has increased considerably with the introduction of Wavelength-Division Multiplexing (WDM) technology.

The rapid advancement of optical technologies and the growing effort to enhance the Internet Protocol (IP) makes it possible to move from the current network architecture to an all-optical Internet, where the network traffic is optically transmitted, buffered, amplified, and switched through high performance Internet switches and routers directly connected using WDM optical links.

ALL-OPTICAL INTERNET

The Internet is an interconnection of computer networks that are a combination of hardware and software, controlled by a set of protocols to transmit and communicate data. The Internet uses the TCP/IP protocol suite, where the Transmission Control Protocol (TCP) is a connection-oriented end-to-end protocol. TCP is used to create logical connections between various applications running on different hosts, prior to executing protocols that exchange information. TCP relies on the Internet Protocol (IP) to route the packets (data units that are routed between an origin and a destination) through the network. Therefore, the Internet is simply a massive network of networks.

Depending on the deployed physical technology, three network generations can be distinguished. The first-generation networks are based on copper wire or radio; subsequently; the copper wire (around 10 gigabits per second) was replaced by a more sophisticated transmission medium, the optical fiber, which offers an immense bandwidth (theoretically, 50 terabits per second), low error rate, high reliability, availability, and maintainability. Additionally, optical fibers feature many other advantages, for example, lightweight and small space requirements, resistance to corrosive materials, less signal attenuation, and high immunity to tapping. Having optical fiber as the transmission medium in the second-generation networks enhanced the network performance and throughput; however, this improvement was restricted by the so-called Electronic Bottleneck. Electronic bottleneck phenomenon is caused by the limited processing speed of electronic components (a few gigabits per second) deployed in switches/routers, multiplexers, and end-nodes in the network. As the electronic processing speed is at its peak, the solution is to transfer the switching and routing functions from the electronic domain to the optical domain. Therefore, the third-generation networks will be designed as all-optical networks, where the data are transmitted all-optically through the network from source to destination.

IP and WDM Convergence

The success of the Internet and its omnipresence has made the Internet Protocol (IP) a de facto standard, and the demand for IP network solutions has increased exponentially. With the Internet protocol, voice and video as well as real-time multimedia traffic could be integrated and transmitted with the data traffic over a single network infrastructure, providing unprecedented opportunity for businesses to improve their services, reduce expenses, and increase their revenues. With the technological evolution, IP diminished the boundaries between the computing, entertainment, and the telecom industries, which led to more customer centric business models. Being an intermediate layer between an immense variety of IP-based services and almost all the layer-2 technologies, IP is more than a revenue-generating integration layer. IP convergence is not merely an option; it is inevitably becoming a business necessity in the Internet-dependent era and the new customer-centric economy. Such convergence is best supported by the WDM technology. WDM, which is conceptually similar to Frequency Division Multiplexing (FDM), is a method of transmitting many light beams of different wavelengths simultaneously down the core of a single optical fiber. Therefore, with WDM the available bandwidth can be increased without deploying additional optical fibers. Furthermore, WDM relieves the effect of electronic bottleneck by dividing the optical transmission spectrum into a number of non-overlapping channels; thus, the electronic components would only work at their own speed (few gigabits per second) and not at the aggregated transmission rate. IP/WDM convergence will eventually be translated to an efficient, robust, reliable, and feasible all-optical Internet.

Optical Switching Paradigms

Several different switching paradigms have been devised to transfer data over WDM, such as Optical Circuit Switching (OCS), a wavelength-routed network (Mukherjee, 1997), Optical Packet Switching (OPS) (Xu, Perros, & Rouskas, 2001; Yao, Dixit, & Mukherjee, 2000), and Optical Burst Switching (OBS) (Qiao & Yoo, 1999). Wavelength-routed optical networks (currently deployed) represent a promising technology for optical networks. However, wavelength-routed optical networks, which employ circuit switching, may not be the optimal choice and the most appropriate switching paradigm to support the various requirements of the Internet traffic. Alternatively, optical packet switching paradigm appears to be the optimum option. Unfortunately, OPS is not mature enough to provide a viable solution. Therefore, a switching technique that provides granularity in between wavelengths and packets was shaped, thus occupying the middle of the spectrum between circuit switching and packet switching paradigms. Optical burst switching is a switching technique where the benefits of both packet-switching networks and circuit-switching networks are combined; OBS borrows ideas from both to deliver a completely new functionality.

Optical Circuit Switching

In circuit switching, each sender and receiver are connected with a dedicated communication path (circuit), established through one or more intermediate switching nodes. The communication path must be set up between the two end-nodes before they could communicate. Although circuit switching is the most familiar technique used to build communication networks, and even though wavelength-routed optical networks have already been deployed, circuit switching may not be the most appropriate switching technique for the emerging

optical Internet. Circuit-switched networks lack flexibility and convergence capabilities, which lead to poor wavelength utilization, especially if the connection holding time (i.e., the time of data exchange) is very short; the situation is worsened by the bursty nature of the data traffic. Therefore, in order to fully utilize the WDM wavelengths, a sophisticated traffic grooming mechanism is needed to statistically multiplex the data coming from different sources.

Optical Packet Switching

Optical packet switching is an alternative optical switching paradigm that appears to be the optimum choice. However, with the immature current optical technology, it is impossible (at least in short-medium term) to deploy OPS networks viably. Packet switches usually work synchronously, where the arriving packets at different input ports must be aligned before being switched using the switching fabrics. This process is difficult and expensive to be implemented fully in the optical domain. Another operation concern is the relatively long time in which the optical-switching fabrics are configured compared to the data transmission speed. This is clearly demonstrated using the following example based on the current developments in the optical technology, considering an optical packet switch, with a switching fabric that takes 1 *ms* to be configured (i.e., set up a connection from an input port to an output port). At a data rate of 2.5 Gbps, it takes about 5 μs to transmit a 12,500-bit packet. Therefore, if a switch operates at the packet level, then less than 0.5% of the time is used for switching data, while the rest is wasted in setting up the switching fabric.

A more prevailing OPS's deployment issue, is the realization of the "Store and Forward" concept that is the requisite idea in packet switching networks. To store packets in switches, a buffering strategy is needed to resolve contentions in the output ports. Optical switches currently use optical fibers as Fiber Delay Lines (FDL) to emulate buffers by delaying packets for a fixed time (Xu et al., 2001). The FDLs are far away behind the random access electronic buffers, in term of cost, performance, and deployment simplicity.

Optical Burst Switching

The concept of burst switching first emerged in the context of voice communications. OBS is an adaptation of a stander known as ATM Block Transfer (ABT) developed by the telecommunication standardization sector of the International Telecommunication Union (ITU-T) for burst switching in Asynchronous Transfer Mode (ATM) networks. OBS consists of core nodes, built from optical and electronic components, and edge (Ingress/ Egress) nodes connected by WDM links. OBS differs from optical packet switching and the original burst-switching concept introduced in the 1980's (Amstutz, 1989; Kulzer & Montgomery, 1984) in a main aspect, that is, the separation of the control and the data payloads, both in time (i.e., the control information is transmitted at an offset time prior to its corresponding data payload) and physical space (i.e., the control packets and the data propagate on different designated channels). In conventional OBS, there is no need for buffering and electronic processing of data. Furthermore, OBS insures efficient bandwidth utilization, since the bandwidth is reserved only when the data is to be transferred through the link.

Optical Components

In order to build an all-optical Internet, different functional optical elements are required. These elements could be classified either as "switching" or "non-switching" components; "switching" components enable networking, while "non-switching" components are primarily used on optical links. However, a simple classification could be determined by the placement of the optical elements in the system. They can be placed

either on the transmitting-end, on the link, or on the receiving-end. In this section, the key optical communications elements are briefly described.

- **Optical fibers:** Optical fibers are made of glass or plastic, and they transmit signals in the form of light at about two-thirds the speed of light in a vacuum. In the optical fibers, the lightwaves (signals) are guided with a minimum attenuation.
- **Light sources and light detectors:** At both ends of an optical transmission system, light sources and light detectors are found. At the transmitting-end, the light source (light emitter) modulates electrical signals into light pulses. The opposite process, that is, to modulate light pulses into electrical signals, is performed by the light detectors at the receiving-end.
- **Optical Amplifiers:** To amplify an attenuated optical signal, unlike the conventional repeaters that perform respectively optical-electrical conversion, electrical amplification, and then electrical-optical conversion, the optical amplifiers operate completely in the optical domain. The optical amplifiers can boost the power levels of the optical signals. Amplifiers can be classified to two fundamental amplifier types: Semiconductor Optical Amplifiers (SOAs) and Doped-Fiber Amplifiers (DFAs).
- **Multiplexers and De-multiplexers:** Multiplexers and De-multiplexers are essential components in the optical transmission systems. Multiplexers converge and combine multiple incoming signals into one beam. The de-multiplexers have the ability to separate out the combined components of the beam and discreetly detect the different signals.
- **Optical Add/Drop Multiplexers:** Optical Add/Drop Multiplexers (OADMs) are key elements on the progress toward the ultimate goal of all-optical networks. Unlike the multiplexers and de-multiplexers, the OADMs are capable of adding or removing one or more wavelengths without the need for combining or separating all wavelengths.
- **Wavelength converters:** An optical wavelength converter is a device capable of directly translating (converting) data contained on an incoming wavelength to another wavelength without optical-electrical-optical conversion. Therefore, wavelength converters are very important elements in the deployment of all-optical networks. Two classes of wavelength converters can be identified: Optical-Gating Wavelength Converters and Wave-Mixing Wavelength Converters.

OPTICAL BURST SWITCHING

In this chapter, a comprehensive discussion of Optical Burst Switching (OBS) is presented. The OBS networks variants, reservation protocols, node architecture and switching technology, Quality of Service provisioning, and contention resolution techniques are discussed.

OBS Network Functionality

Optical Burst Switching is a relatively new switching technique and is still at the definition phase, which is clearly indicated by the number of research groups and their publications, specifically, on new OBS architectures (Callegate, Cankaya, Xiong, & Vandenhoute, 1999; Dolzer, 2002; Verma, Chaskar, & Ravikanth, 2000; Xu et al., 2001; Yoo, Qiao, & Dixit, 2001), prototypes (Baldine, Rouskas, Perros, & Stevenson, 2002), reservation mechanisms (Detti & Listanti, 2001; Dolzer, Gauger, Spath, & Bodamer, 2001; Qiao & Yoo, 2000; Tancevski, Yegnanarayanam, Castanon, Tamil, Masetti, & McDermott, 2000; Turner, 1999; Wei, Pastor, Ramamurthy, & Tsal, 1999; Xiong, Vanderhoute, & Cankaya, 2000;

Yoo, Jeong, & Qiao, 1997) and assembly mechanisms (Ge, Callegati, & Tamil, 2000; Hu, Dolzer, & Gauger, 2003; Vokkarane, Haridoss, & Jue, 2002). However, despite the fact that there is no standard architecture or a universal definition of optical burst switching, OBS networks assume the following general characteristics:

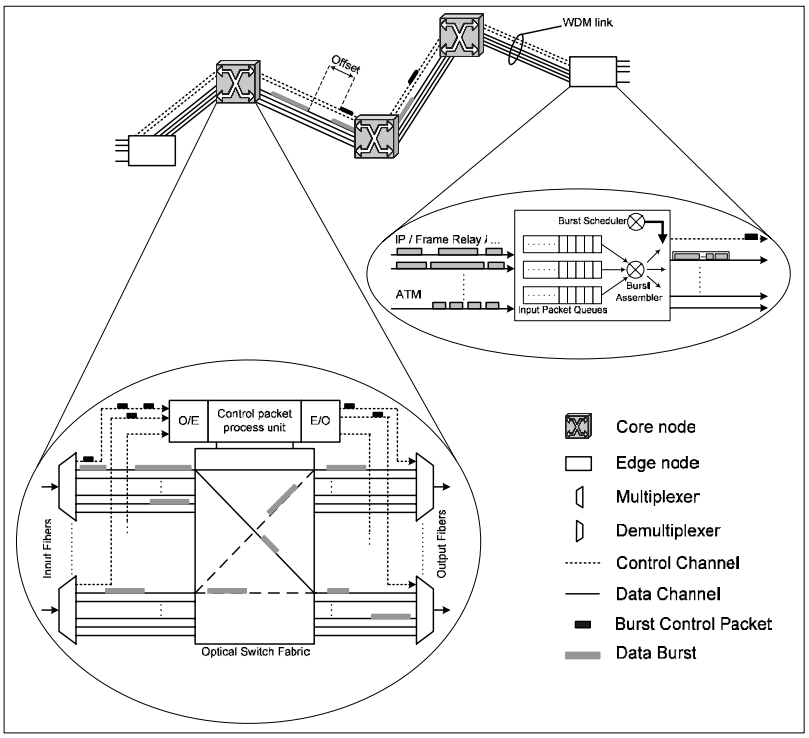
- **Granularity:** The transmission units (called bursts) are macro-packets, each of which should have a duration that is as short as possible, as it does not require a dedicated channel, but long enough to be efficiently switched optically; that is, between the optical circuit switching and optical packet switching granularity.
- **Separation of control and data:** Control information and data payload propagate on separate channels (wavelengths).
- **One-way reservation:** Network resources are generally allocated in one-way reservation fashion. That is, bursts (data) are transmitted at an offset time after their control information without receiving or waiting for any acknowledgements, to confirm the switching resources reservation, back from the destination nodes.
- **Variable burst length:** The duration (size) of the data burst may be variable. However, the burst duration should be long enough to be efficiently switched in the optical domain, and short enough to be statistically multiplexed.
- **Optical Buffering/Wavelength conversion:** In the conventional implementation of OBS networks, optical buffers/wavelength converters are not mandatory in the intermediate nodes. Thus, the data bursts would be switched optically from source to destination, without any delay (buffering), and using the same wavelength.

Not all of these characteristics need be satisfied at once and without variation in all OBS implementations, thus, allowing for design flexibility and a possible smooth evolution towards the packet switching technique, when the development on the optical switching technology matures.

As mentioned before, the model of burst switching is not new as a concept. Burst-switching has been already known since the 1980's. However, the concept has never been implemented widely and successfully in conventional electrical networks. Due to its complexity and high cost, burst switching could not compete with established, flexible, and relatively cheap electronic packet switching techniques (e.g., Asynchronous Transfer Mode (ATM)). However, with the introduction of very high-speed optical transmission techniques, this has changed. It has been agreed that it is more advantageous, cost effective, and efficient to keep data in the optical domain and to avoid optical-electrical-optical conversions. In view of the fact that all-optical packet switching techniques are still too complex to be widely deployed, a hybrid approach is desirable. In this approach, the data payload (that does not need to be processed at the core nodes) is kept in the optical domain, whereas the control information can go through optical-electrical-optical conversions to be efficiently processed in the electrical domain. OBS offers exactly that, by separating the control and the data in the physical space, that is, the control information and the data propagate discretely in different designated channels, and maybe with different data rates. OBS also separates the control and the data in time, that is, the control packet is transmitted at an offset time prior to its corresponding data. In the buffer-less core nodes, the offset time is to compensate for both processing and configuration time, needed respectively by the control unit to process the control information and the switching-fabric to be configured.

Figure 1 shows some of the main components of an OBS network. There are two types of nodes, edge (ingress/egress) nodes and core nodes. In the edge nodes, network traffic is collected from

Figure 1. Illustration of optical burst-switched network components



access networks and assembled into macro data units called data bursts (DBs). Core nodes serve as transit nodes at the core network. Their main task is to switch bursts (data) all-optically without any conversion or processing. The switching fabrics are configured according to the control information contained in the Burst Control Packets (BCPs), which are transmitted as reservation requests at an offset time ahead of their corresponding data bursts.

In the literature, various OBS switching protocols with different tradeoffs can be found. The OBS switching protocols differ in the choice of the offset time that can be zero or more, and the bandwidth reservation and release techniques (bandwidth holding time).

Three main OBS implementations can be identified, based on the offset time which is defined as the interval of time between the transmission of the first bit of the BCP and the transmission of the first bit of the data burst. The offset time can be nil, round-trip dependent, or source-routing dependent.

- **Nil offset time:** This OBS implementation is the closest to optical packet switching, and it is similar to ATM Block Transfer and Immediate Transmission (ABT-IT). The DBs and their corresponding BCPs are transmitted on different wavelengths and separated by a zero or a negligible offset time. The BCPs reserve the network resources

(wavelength and buffer) upon arrival to the core nodes. The DBs are buffered until the BCPs are processed and the switching fabrics are configured. Currently the buffers are hard-to-implement expensive FDLs that can buffer the data optically only for a short fixed time. Therefore, this implementation is feasible only when the switch configuration time (including the BCPs processing time) is very short.

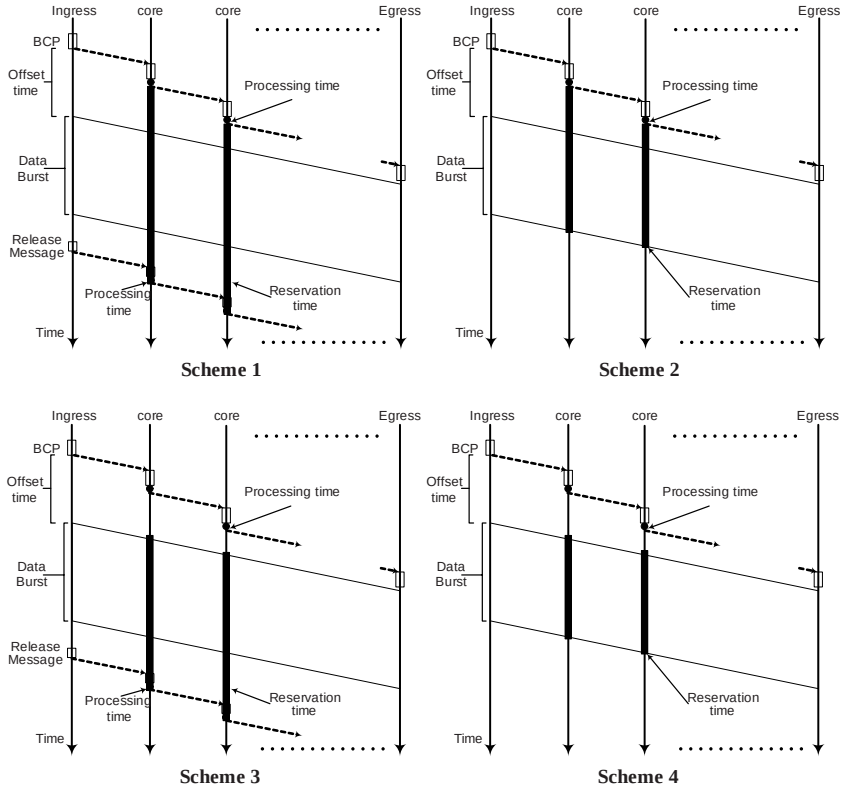
- **Round-trip-dependent offset time:** The offset time is equivalent to the round-trip time, that is, the time between the sending of a BCP and the receiving of its corresponding acknowledgment. In this implementation, a DB is transmitted only after receiving a positive response (acknowledgment) to its resource reservation request sent via the BCP, therefore, guaranteeing an uninterrupted all-optical transmission path for the DB from source to destination. Suffering from lengthy offset time due to the two-way propagation delay needed to set up an end-to-end lightpath before transmitting the user data, this scheme is the closest to optical circuit switching.
- **Source-routing-dependent offset time:** This implementation is similar to the ATM Block Transfer and Delayed Transmission (ABT-DT). The ingress node sends each control packet, followed by its corresponding data burst after an offset time. Thus, data bursts are sent without waiting for any acknowledgment or feedback on the reservation requests. This one-way reservation scheme avoids the two-way-reservation propagation delay in order to reduce the data waiting time at the ingress nodes. In this scheme, to efficiently calculate the offset time, some sort of source routing is used to determine the number of intermediate nodes from source to destination.

Channel Reservation Schemes

Under the s*ource-routing-dependent offset time* implementation, four channel reservation schemes can be identified. Depending on when the channel reservation starts and ends, the reservation schemes differ in their burst-dropping performance and their complexity. Accompanied by the illustration in Figure 2, the schemes are briefly explained as follows:

- **Scheme 1:** Each BCP contains the offset time that separates it from its corresponding DB, but not the duration of the DB. Thus, the core nodes reserve a channel as soon as they receive the BCP (reservation request). The channel remains reserved until the core nodes receive a release message that follows the transmitted DB. Therefore, for each channel, only an on/off ($1_2/0_2$) flag should be kept in each core node to indicate whether the channel is busy (reserved) or free (available). This scheme is usually referred to as Explicit Setup and Explicit Release scheme.
- **Scheme 2:** Each BCP contains the offset time that separates it from its corresponding DB and the duration of that DB. Thus, the core nodes reserve the channels as soon as they receive the BCP. Since the end of each DB is known (calculated using the duration of the DB), the channels are reserved only until the end of the DB. This scheme is more complex than the previous scheme, as each channel should be associated with a timer, which indicates when the channel will become available. This scheme is referred to as Explicit Setup and Estimated Release scheme.
- **Scheme 3:** Similarly to “scheme 1”, each BCP contains the offset time that separates it from its corresponding DB, but not the

Figure 2. One-way-based channel reservation schemes



duration of the DB, and the reserved channels are released only when the core nodes receive the corresponding release messages. However, the reservation of the channels starts approximately at the time of the DBs arrivals. This scheme is referred to as Estimated Setup and Explicit Release scheme.

- **Scheme 4:** Similarly to "scheme 2", each BCP contains both the offset time that separates it from its corresponding DB and the duration of that DB as well. Since both the beginning and the end of each DB is known (calculated respectively using the offset and the duration of the data burst), the reservation starts at the beginning of the burst and ends at its end. The reservation process is controlled using a two-element array that its elements correspondingly refer to the arrival and departure time of the burst to/from the core node. This scheme is referred to as Estimated Setup and Estimated Release scheme.

Several signaling protocols were developed for OBS networks, with different tradeoffs. For example, Just-In-Time (JIT) was developed by Wei and McFarland (2000) under Scheme 1. The Horizon protocol was proposed by Turner (1999)

under Scheme 2; under Scheme 4, Just-Enough-Time (JET) was developed by Qiao and Yoo (1999). JET was further extended by Gauger, Dolzer, and Scharf (2002) to be deployed in switches with optical buffers. For the complete operation of these signaling protocols, a variety of Channel Scheduling algorithms were proposed in the literature. Channel scheduling algorithms are used by the schedulers in the core nodes to determine the status of each channel (or possibly the optical buffer), on which the channel reservation decision is based. A channel is said to be scheduled, if it is occupied/reserved by a data burst. The time that a channel is unscheduled is known as "void", that is, the time that the channel is not occupied between two successive bursts. Schedulers use the information associated with the BCPs, for example, offset time (burst arrival time), and burst length (burst exit time). In certain Scheduling algorithms, the schedulers need to keep track of the voids between scheduled burst. Three main channel scheduling algorithms can be found in the literature: (1) First Fit Unscheduled Channel (FFUC) algorithm, (2) Latest Available Unscheduled Channel (LAUC) algorithm, and (3) Latest Available Void Filling (LAVF) algorithm. The implementation and the working of these algorithms are beyond the scope of this chapter.

Node Architecture and Switching Technology

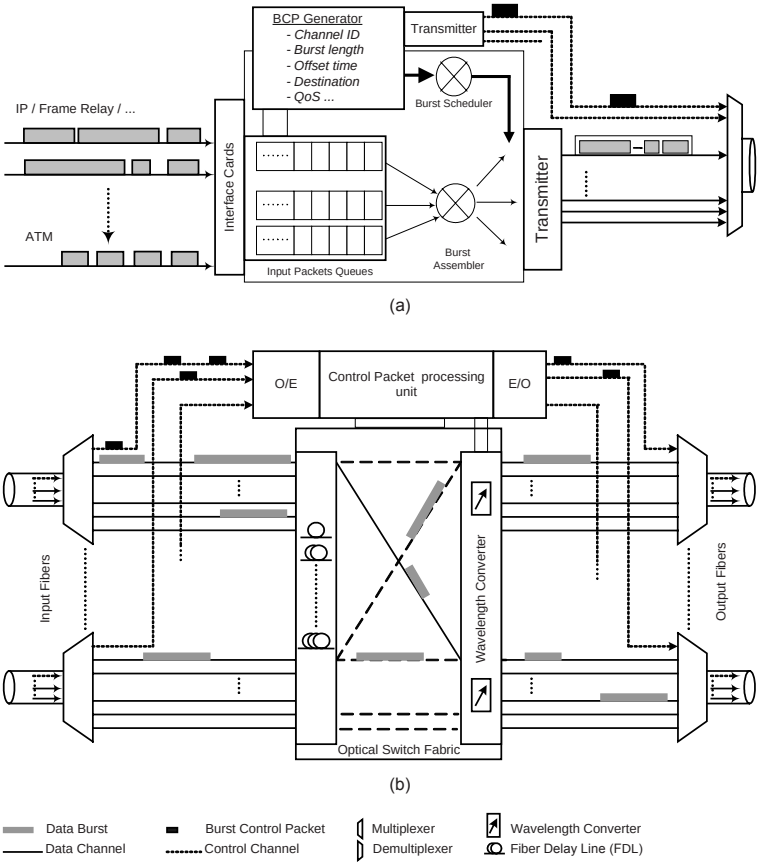
The switching technology is a very critical architectural aspect in the design of OBS networks. In order to effectively operate an OBS network with efficient bandwidth utilization, the switching time should be negligible compared to the mean transmission time of the data bursts. Therefore, both the deployed switching technology and the mean burst length have to be chosen appropriately. For example, an OBS network using fiber links at the rate of 10 Gbps to transmit a burst of about 1 Mbyte cannot adopt Micro Electro-Mechanical Systems (MEMS) (Suzuki, Otani, & Hayashi, 2003), since they require switching times between 1-10 ms, which is greater than the transmission time of an entire burst. However, if the mean burst duration is selected properly, both the Acousto-Optic Tunable Filters (AOTFs) (Sadot & Boimovich, 1998) and Semiconductor Optical Amplifiers (SOAs) (Renaud, Bachmann, & Erman, 1998) could be used as switching technology for OBS networks, as their switching time is respectively below 10 μs and 10 ns.

The OBS nodes are classified as edge nodes or core nodes. Edge nodes (Ingress/Egress) provide an interface between the OBS network (optical domain) and legacy access networks. Besides serving as an interface point between access networks and OBS, an ingress node should be capable of performing bursts assembly, BCPs generation, burst/channel scheduling, and routing. The ingress architecture is illustrated in Figure 3(a). Generally an ingress node will contain input interface cards to legacy networks, BCPs generator, bursts assembler, scheduler, and optical transmitters. In addition to the output interface cards, the Egress node contains bursts disassembler, BCPs processor/terminator, and optical receivers. Note that a generic edge node should have the functionalities of both the ingress and the egress nodes. As intermediate nodes between the edge nodes, the core nodes are located inside the OBS network. A general architecture of OBS core node is shown in Figure 3(b). The OBS core node (switch) should be equipped with the capabilities of routing, bursts switching (optically), and BCPs processing (electronically). The capabilities of a core node may be farther extended to provide optical data buffering and wavelengths conversion.

A generic core node contains the following:

- **Optical receivers/transmitters:** Reception/Transmission of the control information and data bursts; *Optical multiplexer and de-multiplexers:* Responsible for optical channels multiplexing and de-multiplexing;

Figure 3. (a) Architecture of OBS egress node, (b) Architecture of OBS core node



- **Input/Output interface for BCP:** Control reception/transmission and O/E/O conversions;
- **Control packet processing unit:** For BCPs interpretation, channels scheduling, collision resolution, routing, and optical switching-fabric control;
- **Optical switching fabric:** To optically switch data bursts; And possibly *Wavelength converters* and *fiber delay lines (FDLs).*

Data Burst Assembly

At the edge node, the burst assembly/disassembly process is implemented. A very important design parameter in OBS networks, the assembly process takes place at the ingress nodes. Burst assembly (burstification) is the process of aggregating a number of smaller transport units, for example, IP packets or ATM cells, into larger transport units called data bursts. Motivated by the need

of optimizing the switching performance in the optical domain, larger transport units allow the switches to switch the same amount of data by handling less requests, since the ratio between the control information and transmitted data gets smaller. Furthermore, the efficiency of optical switching is improved due to the reduction in the mean inter-arrival time between the switched data units (bursts).

Generally, the assembly algorithms are based on a threshold that could be time, burst-length, or hybrid time-length threshold. In a single data burst, the assembled data units may belong to various upper layer traffic flows, and ultimately destined to different final destinations; however, the destination OBS egress node of all the data units must be the same. The arriving upper layer packets are stored in appropriate queues (according to their egress destination, QoS requirement, Class of Service (CoS)) in the burst assembler. A new burst is constructed and its control packet is generated when the threshold is reached. Obviously, the generated traffic will have variable burst length and constant inter-arrival time, if the algorithm operates only based on time as threshold; however, this may produce excessively large data bursts if the upper layer traffic streams are experiencing high loads. Conversely, if the algorithm operates based on the burst-length threshold, the inter-arrival time will vary, while the burst length is maintained constant. Optimally, a hybrid approach is used, that is, a combination of the time and length thresholds. In all cases, a minimum burst-length should be imposed to avoid too small bursts, which may cause the generation of too many control packets that may lead to traffic congestion on the control channels. A data burst is constructed when its length gets bigger than a pre-defined value, or when the maximum assembly time is reached; in the later case, data padding may be applied to bring the data burst to an appropriate length. Furthermore, a minimum burst-length should be imposed to avoid too small bursts, which may cause the generation of too many control packets that may lead to traffic congestion in the control channels.

More sophisticated assembly algorithms that trade-in the simplicity with the flexibility were proposed in the literature. For example The Adaptive-Assembly-Period (AAP) Algorithm, proposed by Cao, Li, Chen, and Qiao (2002). AAP analyzes current IP traffic statistics and change the values of thresholds accordingly, which can reduce the queuing delay in the edge nodes.

The data bursts disassembly (de-burstification) process is performed by disassemblers at the egress nodes upon the bursts' arrival. In the egress-nodes, the BCPs are processed and terminated, and the data bursts are disassembled to the initial data units. The data units are then forwarded to their final destinations.

QoS Support and Contention Resolution

The number of users (with different needs) and electronic applications (with different requirements) is growing exponentially on the Internet, causing the Internet to start suffering from its own success, in terms of bandwidth and service differentiation. Using optical infrastructure, the available capacity limits could be solved by bandwidth over-provisioning. However, because IP is a best-effort protocol, there is a need to incorporate QoS mechanisms and flow control capabilities.

OBS-QoS Mechanisms

A great effort has been directed to the QoS provisioning in the Internet, where many QoS mechanisms were introduced. However, the mechanisms that worked for electronic packet switched networks did not find the same success in optical networks, because of the lack of efficient optical buffers, which reduces the switches'

scheduling capabilities. In this section, we will present an overview of the main QoS provisioning strategies proposed for OBS networks.

- **Offset-Based QoS Scheme:** Offset-based QoS (Fan, Feng, Wang, & Ge, 2002) scheme adds an extra offset time to the basic offset between the BCP and its corresponding DB. The additional offset time, called QoS offset, is to compensate for the processing time of the BCP. The duration of such a QoS offset is varied, depending on the priority of the service class. This scheme is proposed for JET, whereby higher priority classes have larger offsets. With this scheme, if a low priority DB with no additional QoS offset time and a higher priority DB with a QoS offset try to make network resources reservation, the DB with the larger offset will be able to reserve resources in advance, before the low priority DB. In general, this will result in a lower burst loss probability of high priority classes compared to the lower priority classes.

Although the offset-based QoS scheme does provide an acceptable service differentiation, it is faced with some challenges that cannot be ignored. For example, DBs of high priority classes suffer longer waiting time (delay) than the data bursts of low priority classes. Furthermore, the scheme is non-preemptive that is, as long as low priority DBs can block optical paths, no complete isolation is achieved. Yet, starvation of low priority classes is possible if the offered traffic load of high priority bursts is high and not controlled.

- **Active dropping-based QoS scheme:** In this scheme, a burst dropper (hardware) is implemented in front of every core node (Chen, Hamdi, & Tsang, 2001). Dependent on a dropping policy, some BCPs and their corresponding DBs are dropped before reaching the reservation unit. Therefore, the admission to the outgoing wavelengths is controlled, enabling the core nodes to locally control the offered load of certain service classes to maintain network resources for other service classes. Active Dropping-based QoS scheme intervene before congestion occurs, as the selective dropping of DBs is initiated according to the data traffic profile to guarantee that the higher priority classes have higher chances to make successful reservations. However, this scheme suffers from a major disadvantage which is the absence of feedback from the core nodes to the edge nodes, and thus traffic volume of different classes cannot be controlled. Furthermore, isolation between different traffic classes is not guaranteed. If the offered traffic load of a low priority class is significantly augmented, which increases the overall burst loss probability; burst loss probabilities of all classes are increased. Therefore, an additional traffic control mechanism is required.
- **Segmentation-based QoS scheme:** In segmentation-based QoS scheme (Vokkarane & Jue, 2002), each data burst is subdivided into several independent segments. If DBs contend for the same network resources, the contention is resolved by discarding or deflecting some segments of one of the contending data bursts. The remaining part of the burst (truncated DB) will be then forwarded to the downstream nodes where it will experience either more shortening, be dropped, or be delivered to the egress node. Unfortunately, this scheme is implemented at the cost of increasing the size of the control packets, since the BCP should at least contain the segments number, the burst length, and the routing information.

Furthermore, the implementation of burst segmentation strategies is faced by some challenges and practical issues summarized as follows:

- **Switching time (ST):** ST is the time needed to reconfigure the switching fabric. ST depends on the design and implementation of the core node and on the used switching technology. ST may differ from one core node to another.
- **Data burst size:** Since the transmission of DBs depends on the transmission of their BCPs, the DB length should agree with minimum and maximum length requirements, to avoid congestion in the control channels. The same is true for the truncated burst (i.e., DB that lost some of its packets).
- **Segment Delineation:** Since the data bursts are transmitted all-optically, the segments' boundaries are transparent to the core nodes, and their sizes are not reflected in the BCP.
- **Fiber Delay Lines (FDLs):** As in Optical Composite Burst Switching (OCBS) (Detti, Eramo, & Listanti, 2002), FDLs are needed to delay the data bursts while their control packets are being electronically updated with the new burst size, which increases the electronic processing time needed before forwarding the control packet to the next node.
- **Trail-control messages:** Generated by the node where the DB has been truncated, the trailing control message is needed to indicate the data burst's new size to the downstream nodes, to avoid unnecessary resource reservation, and needless contention resolution actions.

Contention Resolution

In OCS, each traffic flow is supplied with the appropriate network resources, precisely with the necessary bandwidth. Therefore, flows would not contend for the same network resources in the core nodes of an OCS network. However, contention is a major problem in both OPS and OBS, which are based on multiplexing gain between the traffic flows. Typically, in electronic packet switching, this problem is solved using random access electronic buffers; however, this solution is far from being feasible in all-optical networks where optical buffering is yet to be a viable technology. In OBS, contention occurs when two or more bursts are destined to use the same channel from the same fiber (i.e., output port) at the same time. The contention can be resolved in one of three techniques. The contending burst can be optically delayed/buffered (time domain), converted to another channel in the same fiber (optical domain), or deflected to another output port (space domain).

- **Buffering:** One of the most prevailing factors that have motivated the development of OBS network is the immaturity of the optical buffering technology. Therefore, the use of optical buffers as a contention resolution technique in the OBS networks is less than feasible. Nevertheless, several proposals, and many research activities, were dedicated to the study of buffering techniques in OBS networks. Buffering is to delay or to queue contending bursts instead of dropping them. If optical-electrical-optical conversion is allowed (i.e., not an all-optical network) then random access electronic buffers can be used to buffer the burst for a long time. However, to implement an all-optical network (i.e., the data is maintained in the optical domain end-to-end), an optical buffering technique is needed. Optical buffering currently can only be implemented using Fiber Delay Lines (FDLs). The time that the bursts can be delayed is directly proportional to the length of the FDL. More efficient optical buffers can be realized through multiple delay lines of the same or different lengths, deployed in stages (Chlamtac, Fumagalli, Kazovsky, Melman, et al., 1996) or in parallel (Haas, 1993). Such buffers can hold DBs for variable amounts of time. Recently, designs

of large optical buffers (Hunter, Cornwell, Gilfedder, et al., 1998; Tancevski, Castanon, Callegati, & Tamil, 1999) were proposed without large delay lines. However, in any optical buffer architecture, the size of the buffers and their flexibility is severely constrained by physical space and the effects of fiber dispersion. Therefore, fiber delay lines could be suitable for prototype switches in experimental environments, but not for real and commercial deployments.

- **Wavelength conversion:** WDM systems are multiple channel systems. Optical switches are connected with fiber links that are expected to carry hundreds of channels in the near future. This can be exploited to resolve traffic flow contentions. If two traffic flows contend for the same channel, one of the flows can be wavelength-converted to a free channel, and transmitted on the same link. It is clear that with this technique the contentions between data bursts in an OBS network can be minimized. However, using wavelength converters will increase the overall hardware cost of the WDM network, in addition to the complexity and technical issues associated with the wavelength conversion technology itself. Wavelength-conversion-enabled optical networks can be categorized to either: (1) networks with full wavelength conversion (any channel can be converted/shifted to any other channel); (2) networks with limited/fixed wavelength conversion (only limited/fixed channels can be converted); or (3) networks with sparse wavelength conversion (not all the network's nodes have wavelength conversion capabilities)
- **Deflection:** To delay (hold) data bursts, an alternative to the use of FDLs is the use of fiber links connecting the core nodes. When two bursts contend for the same output port, one will be switched to the correct output port, and the other will be switched (deflected) to any other available output port. Therefore, both bursts are given a chance to be switched instead of dropping one of them to resolve the contention. Because the correct output port leads usually to the shortest path (networking context) toward the destination, the bursts that are not switched to the correct output ports may end up following longer paths to their destinations. This technique is referred to as "hot-potato" routing. A drawback of this technique is the complexity associated with the calculation of the offset time of the deflected burst since it will travel on a different path with different hop count. Furthermore, the end-to-end high delays experienced by the deflected DBs may cause the DBs to be out-of-order at the destination, or trigger upper layers retransmission mechanisms. Additionally, deflecting data bursts because of local congestion may instigate global congestion. In the literature, deflection routing is studied on various network topologies, with and without FDLs.

In all the three aforementioned techniques, the data bursts are treated as single fused data units. However, there is another interesting OBS approach that suggests that the bursts should be dealt with as a combination of basic transport units called segments. Each of these segments may consist of a single packet or multiple packets. The segments indicate the possible partitioning points of a burst while the burst is traveling in the optical domain. With this approach, when a contention occurs, only the overlapping (time aspect) segments of the contending bursts are dropped, buffered, deflected, or converted to a different channel. It has been demonstrated in literature (Detti et al., 2002; Vokkarane, Jue, & Sitaraman, 2002) that the contention resolution techniques based on burst segmentation are efficient, and outperformed the traditional OBS with the "entire-burst-dropping" policy. Unfortunately the

implementation of burst segmentation strategies is faced by some technical challenges, besides the complexity added to the algorithms and protocols on both edge and core nodes.

Flavors of OBS Networks

Besides the traditional definition presented at the beginning of this chapter, the following implementations of OBS can be found in literature; each implementation has its advantages and disadvantages.

- **OBS with fixed data burst length:** In this implementation of OBS, all data bursts have the same length. Its major advantage is the simplification of the switching technique. However, its disadvantage is the long queuing time of the upper layer packets if there is no adequate traffic load. An ineffectual solution to this disadvantage is data padding. This concept is closely related to the cell-switching paradigm where the transport unit is fixed in size.
- **OBS with two-way setup:** In this implementation of OBS, a burst will be transmitted only after having received a positive acknowledgement of its resource reservation request. Its advantage is the burst-blocking avoidance in the network's core nodes. However, the additional waiting time may cause buffers to overflow at the network ingress.
- **Mandatory FDL/Wavelength Converters in all nodes:** With the disadvantage of increasing dramatically the cost of the network, OBS could be implemented with core nodes that are capable to buffer the data bursts and/or convert them to any other wavelength. In this implementation some sort of store-and-forward routing for optical bursts is deployed, where each burst is delayed for a certain time until its corresponding control information is processed and an appropriate switching decision is determined, that is, the burst could be forwarded to an output port, converted to another wavelength, or simply dropped.
- **OBS networks for Ethernet:** Extending Ethernet services over OBS was proposed in Sheeshia, Qiao, and Liu (2002) as a more scalable and bandwidth-efficient implementation compared to the Ethernet over Synchronous Optical Network (SONET). The possible role that OBS will play in the development of 10-Gbit Ethernet (10GbE) metropolitan networks was investigated. OBS was demonstrated as an improved network resource-sharing platform and efficient transport for Ethernet traffic, particularly if it is coupled with the Generalized Multiprotocol Label Switching (GMPLS).

It is clear that OBS is a technology-driven paradigm; consequently, the architecture and the operational policies of the future OBS networks will be shaped by the upcoming developments in the multiplexing and switching technologies. The technology needed to generate and transmit more than 1,000 high-quality WDM channels with fixed wavelength spacing is already available. Furthermore, the Waveband Switching (i.e., switching multiple wavelengths as a single entity) is being researched. Therefore, the future OBS would be based on waveband-selective switching or other more advanced switching technologies. In the rest of the chapter, an attempt to streamline the OBS networks that are using burst segmentation techniques is presented.

STAGED RESERVATION SCHEME (SRS)

The Staged Reservation Scheme (SRS) (Abid, Abbou, & Ewe, 2005) is introduced to streamline previous reservation protocols that are based on burst segmentation strategy, to increase the throughput of the core nodes, and to overcome

some of the limitations associated with the burst segmentation concept (shown earlier). In SRS the data burst is divided into equal Data Segments (DSs). This is an indication to where the DB might be partitioned, while traveling in the optical-domain. The DSs have the same attributes and characteristics as any DB (i.e., each segment may range from one to several packets, and its length is reflected in the BCP). The control packets format was designed to be scalable to high transmission speeds, and to reflect the DSs' length in addition to the DBs' length.

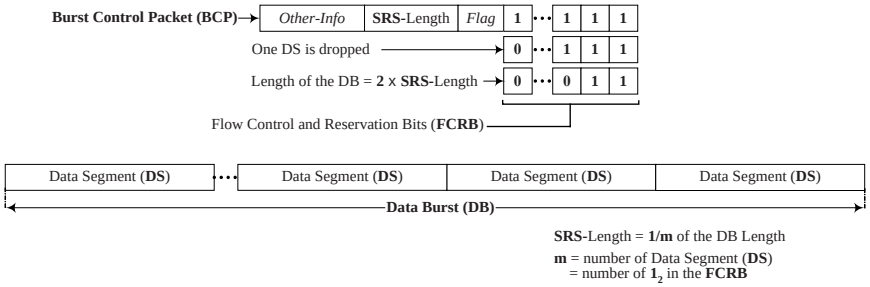
BCPs Format in SRS

The burst control packet format in SRS is redesigned and changed from the traditional format to provide a constant transmission overhead and to make the BCP scalable to higher speeds, as it uses the *Flow Control and Reservation Bits* (FCRB) as the segments' length indicator instead of flags (Detti et al., 2002). The illustration shown in Figure 4 of the format of the BCP is briefly presented here.

- **FCRB field:** *Flow Control and Reservation Bits* field is created by the ingress-node to reflect the permitted segmentations. In the core-nodes, the SRS-length is multiplied by the number of 1_2 in FCRB to obtain the actual size of the corresponding DB. For example 0111_2 is an indication that the length of the DB (or truncated DB) is (3 * SRS-length), and it might be segmented into three segments. The size of FCRB is dynamic in that it may vary from one DB to another, and the burst assembly algorithm controls it.
- **Flag field:** The field is a sequence of bits with a recognizable pattern that identifies the end of the FCRB field (as its size is not fixed), and identifies the beginning of the SRE-length field.
- **SRS-length field:** The field contains the length of one DS. However, SRS-length combined with FCRB provides sufficient information about the DB's length and segmentation. To avoid congestion in OBS control-channel, SRS-length should comply with a minimum length (Detti et al., 2002), which is the minimum permitted data burst length transmitted over the optical links. The SRS-length may vary from one DB to another.
- **Other-Info fields:** The rest of the fields may contain routing information (e.g., burst destination address), offset time, and so forth.

By adopting SRS dropping policy, which will be described in the following subsection, if a contention is anticipated in the core-nodes, the

Figure 4. Data burst structure and burst control packet format in SRS scheme



resources allocation process will not be aborted (i.e., BCP is dropped and subsequently the corresponding DB is entirely discarded). Conversely, the FCRB field in the corresponding BCP is updated according to the resources that the core-node can provide (or free up). Hence, only the overlapping segments are dropped at the arrival time, allowing part of the DB to be transmitted (i.e., the data length that can be handled by the node at the arrival time) as shown in Figure 5. Since the BCPs are updated before forwarding them to the downstream nodes, to reflect the new DBs' length, the need for trailing messages is eliminated, and the contention is resolved at the BCPs level rather than at the DBs level.

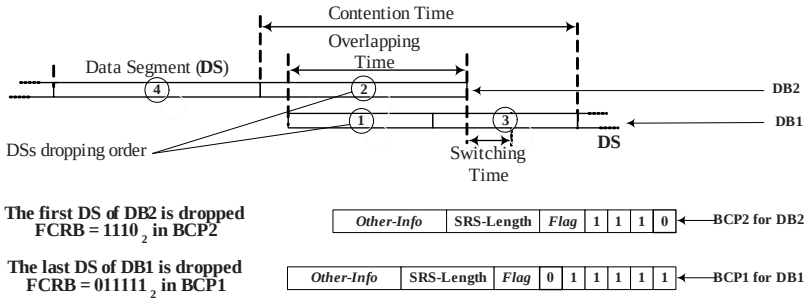
SRS Dropping Policy

Beside the *Switching-Time* (ST), the dropping policy is based on the *Overlapping-Time* (OT), and the *Contention-Time* (CT) (i.e., the aggregated length (duration) of all the DSs that are entirely or partly overlapping minus the OT), as illustrated in Figure 5. The OT may span many DSs from the contending DBs. Therefore; the overlapping DSs are dropped alternately one-by-one from the contending DSs until the CT is reached. This guarantees a reasonable level of fairness between the data bursts (i.e., the number of discarded DSs is distributed among the contending DBs). The dropping policy rules are formulated in an algorithm that will be presented when the fairness in network resources allocation in the core nodes is discussed.

The contention, therefore, is resolved by performing the following three steps:

- Firstly, if ***(OT + ST) > CT***, then a DS is added to the CT to efficiently contain the ST in the dropped DSs. The added DS is selected from the DB with the smallest SRS-length, or randomly if the contending DSs are equal in length. The ST is assumed to be much smaller than the duration of one DS.
- Secondly, if the "***SRS-length***" is the same for both contending DBs (i.e., the DSs are equal in length), then the dropping process starts from the DS at the tail of the first DB, not at the head of the contending DB. This gives fair chance to the packets to arrive to the destination in the correct sequence (assuming the retransmission of the lost packets).
- Thirdly, if the "***SRS-length***" is not the same for the contending DBs, then the dropping process starts at the DS of the shorter DB. The DS may be at the tail of the first DB or at the head of the contending DB (as it is

Figure 5. SRS dropping policy with relation to CT, OT, and ST



deemed that the amount of transmitted data has higher priority than its order).

Fairness in Resources Allocation in SRS Core Node

A key parameter in the design of an OBS network is the maximum and minimum burst size, which is managed by the edge nodes using the assembly algorithms. This key parameter is entirely overlooked by the resource allocation schemes based on the burst segmentation concept, since no policies related to the size of the truncated burst (i.e., shortened data burst) are implemented, during the burst segmentation process in the core nodes. Furthermore, there is no fairness in allocating the network resources to the contending data bursts (usually form different sources), as all the segments are simply discarded from only one burst to resolve the contention.

A better solution would be selecting evenly (fairly) the segments to be dropped from both contending data bursts. Likewise, the truncated burst size should be monitored at the core nodes, and guaranteed to be larger than the Minimum Burst Length (MBL), which is the minimum length allowed into the network to avoid congestion in the control channels.

Besides fairness, data burst size, and implementation simplicity, any proposed technique should be designed to deal with the switching time, which is the time needed to configure the switching fabric (i.e., to switch an output port from one DB to another). To understand what follows, the following definitions are provided and illustrated in Figure 6.

- DB_O: Original Data Burst with Arrival time T_{OA} and Leaving time T_{OL},
- DB_C : Contending Data Burst with Arrival time T_{CA} and Leaving time T_{CL},
- *TDB*: Truncated Data Burst (i.e., a DB with dropped segments),
- *N*, *M*: Respectively, the number of segments in DB_O, DB_C,
- *DS*: Data Segment with Length *DSL*,
- *R*: the expected number of segments to be dropped from each data burst\

$$R = \left\lceil \frac{|T_{CA} - T_{OL}|}{2DSL} \right\rceil^{*}$$

When data bursts arrive to a core node, the technique performs three functions arranged in three main events. After an initialization (Table 1), the *Contention_Detection* (Table 2) event is

Figure 6. Illustrations: (a) Segments dropping process, (b) DB structure in SRS-based QoS scheme

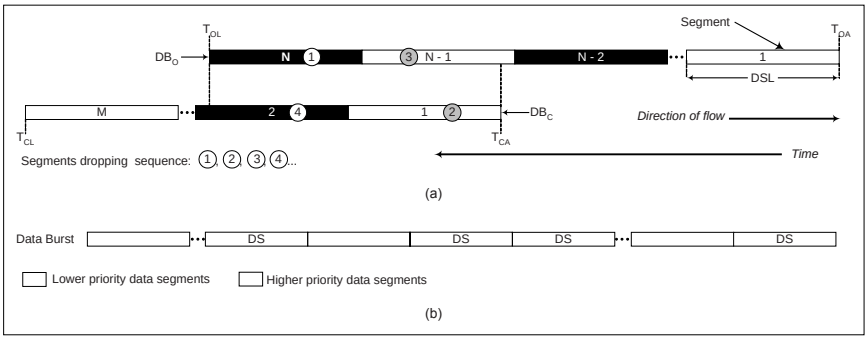


Table 1. Initialization

```
Initialization
 /* Original data burst length. */
 DBL_o = T_OL – T_OA = N * DSL
 /* Contending data burst length.  */
 DBL_c = T_CL – T_CA = M * DSL
 /* Length to be dropped from each data burst. */
 LTD = R * DSL
```

Table 2. Contention detection

```
Event :: Contention_Detection
/* There is a contention if the condition is true */
   IF ((T_CA – T_OL) < ST) THEN
      R = ⌈ |T_CA – T_OL| / 2DSL ⌉  /* calculate R. */
      Execute: Length _of _Truncated_Burst
   END IF
End of Event
```

Table 3. Length of truncated burst

```
Event :: Length _of _Truncated_Burst
/* The truncated burst will be less than the allowed
burst length if the condition is true */
   IF ((DBL_o – LTD < MBL) || (DBL_c – LTD < MBL)) THEN
      IF (DBL_c < DBL_o) THEN
        /* DB_C is the smallest, therefore, dropped */
        Drop DB_c
      ELSE
        /* DB_O is the smallest, therefore, dropped */
        Drop DB_o
      END IF
   ELSE
       Execute: Even_Resource_Allocation
   END IF
End of Event
```

performed; if a contention is detected, then *R* (number of segments to be dropped from the contending data bursts) is calculated, and the second event is executed. The second event named *Length_of _Truncated_Burst* (Table 3) is executed to guarantee that whatever is left from the data bursts after dropping some of their segments is good for transmission over the OBS network. In this event, if one of the truncated data bursts does not meet the MBL requirements, then the conten-

Table 4. Even resource allocation

```
Event :: Even_Resource_Allocation
/* Initialize counter */
i = 1
   DO
   {
   IF (i % 2 = 0) THEN
   /* DB_C is reduced by one DS from the burst head*/
      T_CA = T_CA + DSL
   ELSE
   /* DB_O is reduced by one DS from the burst tail*/
      T_OL = T_OL – DSL
   END IF
   /* Increase the counter i by 1 */
i++
   }
   WHILE ((T_CA – T_OL) < ST)
End of Event
```

tion is simply resolved by dropping the shortest data burst in its entirety. However, the third event is executed if the truncated data bursts are larger than MBL. The *Even_Resource_Allocation* (Table 4) is used to resolve the burst contention by discarding the overlapping segments *alternatively*, starting from the tail of the original burst, and then the head of the contending burst as shown in Figure 6(a).

SRS-Based QoS Scheme

Motivated by the SRS design, its dropping policy, and the use of the FCRB field, the SRS-based QoS mechanism is introduced. In this mechanism, the QoS requirements of the upper layer packets are defined based on their traffic class. Packets of the same class and destination are assembled into the same data segment, which will be labeled with a priority number accordingly. A data burst may contain data segments of the same or different priorities. Using an appropriate assembly algorithm, the data segments are assembled into data bursts in such a way that the lower priority data segments envelop the higher priority data segments as shown in Figure 6(b). To realize the SRS-based QoS scheme, both the edge nodes and core nodes must cooperate, using an assembly algorithm in the edge nodes and the SRS dropping policy in core nodes.

Assembly Algorithm

Although either timer-based or burstlength-based assembly algorithm could be used, it is preferred to use hybrid assembly algorithms. In the hybrid approach, first a burst length threshold is used in assembling the data segments; this allows the control of the data segments size, which must be fixed and restricted to a maximum length. (In some cases, data padding may be needed.) Second, in constructing the data bursts (from data segments) and to control the packets delay at the edge nodes, a timer threshold is used; that is, after a fixed time, all the data segments (could be of different priorities) destined to the same egress are assembled into a data burst. The data bursts are then transmitted to their destinations

through the core nodes to undergo the SRS dropping policy.

FCRB for Congestion Control

In the course of discussing the QoS, congestion in networks appears to cause real problems by reducing the availability and the throughput of the network. Congestion is a complex phenomenon, and it occurs when the traffic load (number of bursts) on the network begins to approach the network capacity. Therefore, a congestion control mechanism is needed to maintain the number of the bursts being transmitted through the network within the limits at which the network performance is acceptable.

By using an explicit congestion avoidance technique, the edge nodes can use as much of the network capacity as possible, while reacting to the congestion in a controlled manner. In the proposed SRS-based QoS, an explicit signaling technique is used. In this signaling technique, the bits of FCRB are used to indicate explicitly the amount of data (i.e., the number of data segments in the DB) sent and the arrived amount. This signaling approach can work in one of two directions: forward (to notify the Egress), or backward (to notify the Ingress).

- **Forward signaling:** notifies the egress node that congestion procedures should be initiated where applicable for traffic in the opposite direction of the received bursts. It indicates the number of the dropped data segments, and that the received burst has encountered congested resources. This information could be sent back to the source node, and the end system will exercise flow control on the traffic sources at the higher layers (e.g., TCP).
- **Backward signaling:** notifies the ingress node that congestion procedures should be initiated where applicable for traffic in the same direction as the sent bursts. It indicates the number of data segments dropped, and that the sent burst has encountered congested resources. The ingress node will then lower the number of data segments sent in each DB to be equal to the number of data segments that could get through the network to the destination. Then the number of data segments is augmented progressively until the maximum size of the data burst is reached, or until the FCRB field reports congestion.

SUMMARY

The network infrastructure has a decisive role in the success of any e-services provider. The next-generation network infrastructure is expected to be reliable, efficient, and supported by robust QoS schemes. The success of IP, with its flexibility, and the advent of WDM technology, with its advantages, are behind the widespread interest in selecting the IP/WDM internetworking model to build an All-optical Internet. Eventually, the next-generation network will be an all-optical Internet where the traffic flows are optically transmitted, switched/routed, tuned/amplified, and buffered.

The OBS is a major candidate to be deployed as the switching paradigm for the Next-Generation Optical Internet. OBS is flexible, manageable, and offers a good balance between OPS and OCS. Furthermore, OBS is amenable for improvement and expansion whenever the developments in optical technology permit.

In this chapter, a broad discussion on optical switching is presented. Many architectural and design aspects of OBS were reviewed, including burst assembly, signaling and reservation protocols, and QoS provisioning. At the end of the chapter, the recent work in OBS schemes is covered; however, the OBS paradigm remains an open field for more research and improvement.
